MQL5 Language REFERENCE

for the MetaTrader 5 client terminal

STUDY MQL5 and SOLVE any tasks:

- Create your own technical indicators of any complexity level
- Use algorithmic trading — automate strategies to work on various financial markets
- Develop your own analytical tools based on mathematical achievements and traditional methods
- Write automated trading systems for solving a wide range of tasks (trading, monitoring, alerting, etc.)

Content

MQL5 Reference

MetaQuotes Language 5 (MQL5) is a high-level language designed for developing technical indicators, trading robots and utility applications, which automate financial trading. MQL5 has been developed by MetaQuotes for their trading platform. The language syntax is very close to C++ enabling programmers to develop applications in the object-oriented programming (OOP) style.

In addition to the MQL5 language, the trading platform package also includes the MetaEditor IDE with highly advanced code writing tools, such as templates, snippets, debugging, profiling and auto completion tools, as well as built-in MQL5 Storage enabling file versioning.

The language support is available on the MQL5.community website, which contains a huge free CodeBase and a plethora of articles. These articles cover all the aspects of the modern trading, including neural networks, statistics and analysis, high-frequency trading, arbitrage, testing and optimization of trading strategies, use of trading automation robots, and more.

Traders and MQL5 program developers can communicate on the forum, order and develop applications using the Freelance service, as well as buy and sell protected programs in the Market of automated trading applications.

The MQL5 language provides specialized trading functions and predefined event handlers to help programmers develop Expert Advisors (EAs), which automatically control trading processes following specific trading rules. In addition to EAs, MQL5 allows developing custom technical indicators, scripts and libraries.

This MQL5 language reference contains functions, operations, reserved words and other language constructions divided into categories. The reference also provides descriptions of Standard Library classes used for developing trading strategies, control panels, custom graphics and enabling file access.

Additionally, the CodeBase contains the ALGLIB numerical analysis library, which can be used for solving various mathematical problems.

Types of MQL5 Applications

MQL5 programs are divided into five specialized types based on the trading automation tasks that they implement:

- **Expert Advisor** is an automated trading system linked to a chart. An Expert Advisor contains event handlers to manage predefined events which activate execution of appropriate trading strategy elements. For example, an event of program initialization and deinitializtion, new ticks, timer events, changes in the Depth of Market, chart and custom events.
  In addition to calculating trading signals based on the implemented rules, Expert Advisors can also automatically execute trades and send them directly to a trading server. Expert Advisors are stored in <*Terminal_Directory*>*MQL5**Experts*.
- **Custom Indicator**s is a technical indicator developed by a user in addition to standard indicators integrated into the trading platform. Custom indicators, as well as standard ones, cannot trade automatically, but only implement analytical functions. Custom indicators can utilize values of other indicators for calculations, and can be called from Expert Advisors.
  Custom indicators are stored in <*Terminal_Directory*>*MQL5**Indicators*.

- **Script** is a program for a single execution of an action. Unlike Expert Advisors, scripts do not handle any event except for trigger. A script code must contain the OnStart handler function.
  Scripts are stored in <*Terminal_DIrectory*>*MQL5**Scripts*.
- **Service** is a program that, unlike indicators, Expert Advisors and scripts, does not require to be bound to a chart to work. Like scripts, services do not handle any event except for trigger. To launch a service, its code should contain the OnStart handler function. Services do not accept any other events except Start, but they are able to send custom events to charts using EventChartCustom. Services are stored in <terminal_directory>\MQL5\Services.
- **Library** is a set of custom functions. Libraries are intended to store and distribute commonly used algorithms of custom programs.
  Libraries are stored in <*Terminal_Directory*>*MQL5**Libraries*.
- **Include File** is a source text of the most frequently used blocks of custom programs. Such files can be included into the source texts of Expert Advisors, scripts, custom indicators, and libraries at the compiling stage. The use of included files is more preferable than the use of libraries because of additional burden occurring at calling library functions.
  Include files can be stored in the same directory where the original file is located. In this case the #include directive with double quotes is used. Another option is to store include files in <*Terminal_Directory*>*MQL5**Include*. In this case #include with angle brackets should be used.

Language Basics

The MetaQuotes Language 5 (MQL5) is an object-oriented high-level programming language intended for writing automated trading strategies, custom technical indicators for the analysis of various financial markets. It allows not only to write a variety of expert systems, designed to operate in real time, but also create their own graphical tools to help you make trade decisions.

MQL5 is based on the concept of the popular programming language C++. As compared to MQL4, the new language now has enumerations, structures, classes and event handling. By increasing the number of embedded main types, the interaction of executable programs in MQL5 with other applications through dll is now as easy as possible. MQL5 syntax is similar to the syntax of C++, and this makes it easy to translate into it programs from modern programming languages.

To help you study the MQL5 language, all topics are grouped into the following sections:

- Syntax
- Data Types
- Operations and Expressions
- Operators
- Functions
- Variables
- Preprocessor
- Object-Oriented Programming
- Namespaces

Syntax

As to the syntax, THE MQL5 language for programming trading strategies is very much similar to the C++ programming language, except for some features:

- no address arithmetic;
- no goto operator;
- an anonymous enumeration can't be declared;
- no multiple inheritance.

Enumerations, Structures and Classes, Inheritance

Comments

Multi-line comments start with the /* pair of symbols and end with the */ one. Such kind of comments cannot be nested. Single-line comments begin with the // pair of symbols and end with the newline character, they can be nested in other multi-line comments. Comments are allowed everywhere where the spaces are allowed, they can have any number of spaces in them.

Examples:

```
//--- Single-line comment
/*  Multi-
    line         // Nested single-line comment
    comment
*/
```

Identifiers

Identifiers are used as names of variables and functions. The length of the identifier can not exceed 63 characters.

Characters allowed to be written in an identifier: figures 0-9, the Latin uppercase and lowercase letters a-z and A-Z, recognized as different characters, the underscore character (_).The first character can not be a digit.

The identifier must not coincide with reserved word.

Examples:

```
NAME1 name1 Total_5 Paper
```

Variables, Functions

Reserved Words

The following identifiers are recorded as reserved words, each of them corresponds to a certain action, and cannot be used in another meaning:

Data Types

bool	float	uint
char	int	ulong
class	long	union
color	short	ushort
datetime	string	void
double	struct	
enum	uchar	

Access Specificators

const	private	virtual
delete	protected	
override	public	

Memory Classes

extern	input	static

Operators

break	dynamic_cast	operator
case	else	pack
continue	for	return
default	if	sizeof
delete	new	switch
do	offsetof	while

Other

this	#define	#import
true	#ifdef	#include

this	#define	#import
false	#ifndef	#property
template	#else	group
typename	#endif	namespace

Data Types

Any program operates with data. Data can be of different types depending on their purposes. For example, integer data are used to access to array components. Price data belong to those of double precision with floating point. This is related to the fact that no special data type for price data is provided in MQL5.

Data of different types are processed with different rates. Integer data are processed at the fastest. To process the double precision data, a special co-processor is used. However, because of complexity of internal representation of data with floating point, they are processed slower than the integer ones.

String data are processed at the longest because of dynamic computer memory allocation/reallocation.

The basic data types are:

- integers (char, short, int, long, uchar, ushort, uint, ulong);
- logical (bool);
- literals (ushort);
- strings (string);
- floating-point numbers (double, float);
- color (color);
- date and time (datetime);
- enumerations (enum).

Complex data types are:

- structures;
- classes.

In terms of OOP complex data types are called abstract data types.

The *color* and *datetime* types make sense only to facilitate visualization and input of parameters defined from outside - from the table of Expert Advisor or custom indicator properties (the Inputs tab). Data of *color* and *datetime* types are represented as integers. Integer types and floating-point types are called arithmetic (numeric) types.

Only implicit type casting is used in expressions, unless the explicit casting is specified.

See also

Typecasting

Integer Types

In MQL5 integers are represented by eleven types. Some types can be used together with other ones, if required by the program logic, but in this case it's necessary to remember the rules of typecasting.

The table below lists the characteristics of each type. Besides, the last column features a type in C++ corresponding to each type.

Type	Size in Bytes	Minimum Value	Maximum Value	C++ Analog
char	1	-128	127	char
uchar	1	0	255	unsigned char, BYTE
bool	1	0(false)	1(true)	bool
short	2	-32 768	32 767	short, wchar_t
ushort	2	0	65 535	unsigned short, WORD
int	4	- 2 147 483 648	2 147 483 647	int
uint	4	0	4 294 967 295	unsigned int, DWORD
color	4	-1	16 777 215	int, COLORREF
long	8	-9 223 372 036 854 775 808	9 223 372 036 854 775 807	__int64
ulong	8	0	18 446 744 073 709 551 615	unsigned __int64
datetime	8	0 (1970.01.01 0:00:00)	32 535 244 799 (3000.12.31 23:59:59)	__time64_t

Integer type values can also be presented as numeric constants, color literals, date-time literals, character constants and enumerations.

Conversion Functions, Numerical Type Constants

Char, Short, Int and Long Types

char

The *char* type takes 1 byte of memory (8 bits) and allows expressing in the binary notation 2^8=256 values. The *char* type can contain both positive and negative values. The range of values is from -128 to 127.

uchar

The *uchar* integer type also occupies 1 byte of memory, as well as the *char* type, but unlike it *uchar* is intended only for positive values. The minimum value is zero, the maximum value is 255. The first letter u in the name of the *uchar* type is the abbreviation for *unsigned*.

short

The size of the *short* type is 2 bytes (16 bits) and, accordingly, it allows expressing the range of values equal to 2 to the power 16: 2^16 = 65 536.Since the *short* type is a signed one, and contains both positive and negative values, the range of values is between -32 768 and 32 767.

ushort

The unsigned *short* type is the type *ushort*, which also has a size of 2 bytes. The minimum value is 0, the maximum value is 65 535.

int

The size of the *int* type is 4 bytes (32 bits). The minimal value is -2 147 483 648, the maximal one is 2 147 483 647.

uint

The unsigned integer type is *uint*. It takes 4 bytes of memory and allows expressing integers from 0 to 4 294 967 295.

long

The size of the *long* type is 8 bytes (64 bits). The minimum value is -9 223 372 036 854 775 808, the maximum value is 9 223 372 036 854 775 807.

ulong

The *ulong* type also occupies 8 bytes and can store values from 0 to 18 446 744 073 709 551 615.

Examples:

```
char  ch=12;
short sh=-5000;
int   in=2445777;
```

Since the unsigned integer types are not designed for storing negative values, the attempt to set a negative value can lead to unexpected consequences. Such a simple script will lead to an infinite loop:

```
//--- Infinite loop
void OnStart()
  {
   uchar  u_ch;

   for(char ch=-128;ch<128;ch++)
     {
      u_ch=ch;
      Print("ch = ",ch," u_ch = ",u_ch);
     }
  }
```

The correct variant is:

```
//--- Correct variant
void OnStart()
  {
   uchar  u_ch;

   for(char ch=-128;ch<=127;ch++)
     {
      u_ch=ch;
      Print("ch = ",ch," u_ch = ",u_ch);
      if(ch==127) break;
     }
  }
```

Result:

```
   ch= -128  u_ch= 128
   ch= -127  u_ch= 129
   ch= -126  u_ch= 130
   ch= -125  u_ch= 131
   ch= -124  u_ch= 132
   ch= -123  u_ch= 133
   ch= -122  u_ch= 134
   ch= -121  u_ch= 135
   ch= -120  u_ch= 136
   ch= -119  u_ch= 137
   ch= -118  u_ch= 138
   ch= -117  u_ch= 139
   ch= -116  u_ch= 140
   ch= -115  u_ch= 141
   ch= -114  u_ch= 142
   ch= -113  u_ch= 143
   ch= -112  u_ch= 144
   ch= -111  u_ch= 145
```

```
    ...
```

Examples:

```
//--- Negative values can not be stored in unsigned types
uchar  u_ch=-120;
ushort u_sh=-5000;
uint   u_in=-401280;
```

Hexadecimal: numbers 0-9, the letters a-f or A-F for the values of 10-15; start with 0x or 0X.

Examples:

```
0x0A, 0x12, 0X12, 0x2f, 0xA3, 0Xa3, 0X7C7
```

For integer variables, the values can be set in binary form using B prefix. For example, you can encode the working hours of a trading session into int type variable and use information about them according to the required algorithm:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set 1 for working hours and 0 for nonworking ones
   int AsianSession   =B'111111111'; // Asian session from 0:00 to 9:00
   int EuropeanSession=B'111111111000000000'; // European session 9:00 - 18:00
   int AmericanSession =B'111111110000000000000011'; // American session 16:00 - 02:00
//--- derive numerical values of the sessions
   PrintFormat("Asian session hours as value =%d",AsianSession);
   PrintFormat("European session hours as value is %d",EuropeanSession);
   PrintFormat("American session hours as value is %d",AmericanSession);
//--- and now let's display string representations of the sessions' working hours
   Print("Asian session ",GetHoursForSession(AsianSession));
   Print("European session ",GetHoursForSession(EuropeanSession));
   Print("American session ",GetHoursForSession(AmericanSession));
//---
  }
//+------------------------------------------------------------------+
//| return the session's working hours as a string                   |
//+------------------------------------------------------------------+
string GetHoursForSession(int session)
  {
//--- in order to check, use AND bit operations and left shift by 1 bit <<=1
//--- start checking from the lowest bit
   int bit=1;
   string out="working hours: ";
//--- check all 24 bits starting from the zero and up to 23 inclusively
   for(int i=0;i<24;i++)
     {
      //--- receive bit state in number
```

```
      bool workinghour=(session&bit)==bit;
      //--- add the hour's number to the message
      if(workinghour )out=out+StringFormat("%d ",i);
      //--- shift by one bit to the left to check the value of the next one
      bit<<=1;
     }
//--- result string
   return out;
  }
```

Typecasting

Character Constants

Characters as elements of a string in MQL5 are indexes in the Unicode character set. They are hexadecimal values that can be cast into integers, and that can be manipulated by integer operations like addition and subtraction.

Any single character in quotation marks or a hexadecimal ASCII code of a character as '\x10' is a character constant and is of ushort type. For example, a record of '0' type is a numerical value 30, that corresponds to the index of zero in the table of characters.

Example:

```
void OnStart()
  {
//--- define character constants
   int symbol_0='0';
   int symbol_9=symbol_0+9; // get symbol '9'
//--- output values of constants
   printf("In a decimal form: symbol_0 = %d,  symbol_9 = %d",symbol_0,symbol_9);
   printf("In a hexadecimal form: symbol_0 = 0x%x,  symbol_9 = 0x%x",symbol_0,symbol_9
//--- enter constants into a string
   string test="";
   StringSetCharacter(test,0,symbol_0);
   StringSetCharacter(test,1,symbol_9);
//--- this is what they look like in a string
   Print(test);
  }
```

A backslash is a control character for a compiler when dealing with constant strings and character constants in a source text of a program. Some symbols, for example a single quote ('), double quotes ("), backslash (\) and control characters can be represented as a combination of symbols that start with a backslash (\), according to the below table:

Character name	Mnemonic code or image	Record in MQL5	Numeric value
new line (line feed)	LF	'\n'	10
horizontal tab	HT	'\t'	9
carriage return	CR	'\r'	13
backslash	\	'\\'	92
single quote	'	'\''	39
double quote	"	'\"'	34
hexadecimal code	hhhh	'\xhhhh'	1 to 4 hexadecimal characters
decimal code	d	'\d'	decimal number from 0 to 65535

If a backslash is followed by a character other than those described above, result is undefined.

Example

```
void OnStart()
  {
//--- declare character constants
   int a='A';
   int b='$';
   int c='©';       // code 0xA9
   int d='\xAE';    // code of the symbol ®
//--- output print constants
   Print(a,b,c,d);
//--- add a character to the string
   string test="";
   StringSetCharacter(test,0,a);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,b);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,c);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,d);
   Print(test);
//--- represent characters as a number
   int a1=65;
   int b1=36;
   int c1=169;
   int d1=174;
//--- add a character to the string
   StringSetCharacter(test,1,a1);
   Print(test);
//--- add a character to the string
   StringSetCharacter(test,1,b1);
   Print(test);
//--- add a character to the string
   StringSetCharacter(test,1,c1);
   Print(test);
//--- add a character to the string
   StringSetCharacter(test,1,d1);
   Print(test);
  }
```

As it was mentioned above, the value of a character constant (or variable) is an index in the table of characters. Index being an integer, it can be written in different ways.

```
void OnStart()
  {
```

```
//---
   int a=0xAE;     // the code of ® corresponds to the '\xAE' literal
   int b=0x24;     // the code of $ corresponds to the '\x24' literal
   int c=0xA9;     // the code of © corresponds to the '\xA9' literal
   int d=0x263A;   // the code of ☺ corresponds to the '\x263A' literal
//--- show values
   Print(a,b,c,d);
//--- add a character to the string
   string test="";
   StringSetCharacter(test,0,a);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,b);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,c);
   Print(test);
//--- replace a character in a string
   StringSetCharacter(test,0,d);
   Print(test);
//--- codes of suits
   int a1=0x2660;
   int b1=0x2661;
   int c1=0x2662;
   int d1=0x2663;
//--- add a character of spades
   StringSetCharacter(test,1,a1);
   Print(test);
//--- add a character of hearts
   StringSetCharacter(test,2,b1);
   Print(test);
//--- add a character of diamonds
   StringSetCharacter(test,3,c1);
   Print(test);
//--- add a character of clubs
   StringSetCharacter(test,4,d1);
   Print(test);
//--- Example of character literals in a string
   test="Queen\x2660Ace\x2662";
   printf("%s",test);
  }
```

The internal representation of a character literal is the ushort type. Character constants can accept values from 0 to 65535.

StringSetCharacter(), StringGetCharacter(), ShortToString(), ShortArrayToString(), StringToShortArray()

Datetime Type

The datetime type is intended for storing the date and time as the number of seconds elapsed since January 01, 1970. This type occupies 8 bytes of memory.

Constants of the date and time can be represented as a literal string, which consists of 6 parts showing the numerical value of the year, month, day (or day, month, year), hours, minutes and seconds. The constant is enclosed in single quotation marks and starts with the D character.

Values range from 1 January, 1970 to 31 December, 3000. Either date (year , month, day) or time (hours, minutes, seconds), or all together can be omitted.

With literal date specification, it is desirable that you specify year, month and day. Otherwise the compiler returns a warning about an incomplete entry.

Examples:

```
datetime NY=D'2015.01.01 00:00';      // Time of beginning of year 2015
datetime d1=D'1980.07.19 12:30:27';   // Year Month Day Hours Minutes Seconds
datetime d2=D'19.07.1980 12:30:27';   // Equal to D'1980.07.19 12:30:27';
datetime d3=D'19.07.1980 12';         // Equal to D'1980.07.19 12:00:00'
datetime d4=D'01.01.2004';            // Equal to D'01.01.2004 00:00:00'
datetime compilation_date=__DATE__;              // Compilation date
datetime compilation_date_time=__DATETIME__;     // Compilation date and time
datetime compilation_time=__DATETIME__-__DATE__;// Compilation time
//--- Examples of declarations after which compiler warnings will be returned
datetime warning1=D'12:30:27';        // Equal to D'[date of compilation] 12:30:27'
datetime warning2=D'';                // Equal to __DATETIME__
```

See also

Structure of the Date Type, Date and Time, TimeToString, StringToTime

Color Type

The color type is intended for storing information about color and occupies 4 bytes in memory. The first byte is ignored, the remaining 3 bytes contain the RGB-components.

Color constants can be represented in three ways: literally, by integers, or by name (for named Web-colors only).

Literal representation consists of three parts representing numerical rate values of the three main color components: red, green, blue. The constant starts with C and is enclosed in single quotes. Numerical rate values of a color component lie in the range from 0 to 255.

Integer-valued representation is written in a form of hexadecimal or a decimal number. A hexadecimal number looks like 0x00BBGGRR, where RR is the rate of the red color component, GG - of the green one, and BB - of the blue one. Decimal constants are not directly reflected in the RGB. They represent a decimal value of the hexadecimal integer representation.

Specific colors reflect the so-called Web-colors set.

Examples:

```
//--- Literals
C'128,128,128'    // Gray
C'0x00,0x00,0xFF' // Blue
//color names
clrRed               // Red
clrYellow            // Yellow
clrBlack             // Black
//--- Integral representations
0xFFFFFF          // White
16777215          // White
0x008000          // Green
32768             // Green
```

See also

Web Colors, ColorToString, StringToColor, Typecasting

Bool Type

The bool type is intended to store the logical values of true or false, numeric representation of them is 1 or 0, respectively.

Examples:

```
bool a = true;
bool b = false;
bool c = 1;
```

The internal representation is a whole number 1 byte large. It should be noted that in logical expressions you can use other integer or real types or expressions of these types - the compiler will not generate any error. In this case, the zero value will be interpreted as false, and all other values - as true.

Examples:

```
   int i=5;
   double d=-2.5;
   if(i) Print("i = ",i," and is set to true");
   else Print("i = ",i," and is set to false");

   if(d) Print("d = ",d," and has the true value");
   else Print("d = ",d," and has the false value");

   i=0;
   if(i) Print("i = ",i," and has the true value");
   else Print("i = ",i," and has the false value");

   d=0.0;
   if(d) Print("d = ",d," and has the true value");
   else Print("d = ",d," and has the false value");

//--- Execution results
//   i= 5 and has the true value
//   d= -2.5 and has the true value
//   i= 0 and has the false value
//   d= 0 and has the false value
```

See also

Boolean Operations, Precedence Rules

Enumerations

Data of the enum type belong to a certain limited set of data. Defining the enumeration type:

```
enum name of enumerable type
  {
   list of values
  };
```

The list of values is a list of identifiers of named constants separated by commas.

Example:

```
enum months  // enumeration of named constants
   {
    January,
    February,
    March,
    April,
    May,
    June,
    July,
    August,
    September,
    October,
    November,
    December
   };
```

After the enumeration is declared, a new integer-valued 4-byte data type appears. Declaration of the new data type allows the compiler to strictly control types of passed parameters, because enumeration introduces new named constants. In the above example, the January named constant has the value of 0, February - 1, December - 11.

Rule: If a certain value is not assigned to a named constant that is a member of the enumeration, its new value will be formed automatically. If it is the first member of the enumeration, the 0 value will be assigned to it. For all subsequent members, values will be calculated based on the value of the previous members by adding one.

Example:

```
enum intervals  // Enumeration of named constants
   {
    month=1,     // Interval of one month
    two_months,  // Two months
    quarter,     // Three months - quarter
    halfyear=6,  // Half a year
    year=12,     // Year - 12 months
   };
```

Notes

- Unlike C++, the size of the internal representation of the enumerated type in MQL5 is always equal to 4 bytes. That is, sizeof (months) returns the value 4.
- Unlike C++, an anonymous enumeration can't be declared in MQL5. That is, a unique name must be always specified after the enum keyword.

Typecasting

Real Types (double, float)

Real types (or floating-point types) represent values with a fractional part. In the MQL5 language there are two types for floating point numbers.The method of representation of real numbers in the computer memory is defined by the IEEE 754 standard and is independent of platforms, operating systems or programming languages.

Type	Size in bytes	Minimal Positive Value	Maximum Value	C++ Analog
float	4	1.175494351e-38	3.402823466e+38	float
double	8	2.2250738585072014e-308	1.7976931348623158e+308	double

double

double real number type occupies 64 bits (1 sign bit, 11 exponent bits and 52 mantissa bits).

float

float real number type occupies 32 bits (1 sign bit, 8 exponent bits and 23 mantissa bits).

vector

One-dimensional array of double type numbers. Memory for data is allocated dynamically. Vector properties can be obtained using the methods, while the vector size can be changed. The vector<double> entry can be used in template functions.

vectorf

One-dimensional array of float type numbers can be used instead of vector if the loss of precision does not matter. The vector<float> entry can be used in template functions.

vectorc

One-dimensional array of complex type numbers is meant to handle complex numbers. The vector<complex> entry can be used in template functions. Operations on vectorc type vectors are not implemented yet.

matrix

Matrix is a two-dimensional array of double type numbers. Memory for matrix elements is distributed dynamically. Matrix properties can be obtained using the methods, while the matrix shape can be changed. The matrix<double> entry can be used in template functions.

matrixf

Two-dimensional array of float type numbers can be used instead of matrix if the loss of precision does not matter. The matrix<float> entry can be used in template functions.

matrixc

Two-dimensional array of complex type numbers is meant to handle complex numbers. The matrix<complex> entry can be used in template functions. Operations on matrixc type matrices are not implemented yet.

The double name means that the accuracy of these numbers is twice the accuracy of the float type numbers. In most cases, the double type is the most convenient one. In many cases the limited precision of float numbers is not enough. The reason why the float type is still used is saving the memory (this is important for large arrays of real numbers).

Floating-point constants consist of an integer part, a point (.) and the fractional part. The integer and fractional parts are sequences of decimal digits.

Examples:

```
double a=12.111;
double b=-956.1007;
float  c =0.0001;
float  d =16;
```

There is a scientific way of writing real constants, often this method of recording is more compact than the traditional one.

Example:

```
double c1=1.12123515e-25;
double c2=0.000000000000000000000000112123515; // 24 zero after the decimal point

Print("1. c1 =",DoubleToString(c1,16));
// Result: 1. c1 = 0.0000000000000000

Print("2. c1 =",DoubleToString(c1,-16));
// Result: 2. c1 = 1.1212351499999999e-025

Print("3. c2 =",DoubleToString(c2,-16));
// Result: 3. c2 = 1.1212351499999999e-025
```

It should be remembered that real numbers are stored in memory with some limited accuracy in the binary system, while generally the decimal notation is used. That's why many numbers that are precisely represented in the decimal system can be written only as an infinite fraction in the binary system.

For example, numbers 0.3 and 0.7 are represented in the computer as infinite fractions, while the number of 0.25 is stored exactly, because it represents the power of two.

In this regard, it is strongly recommended not to compare two real numbers for equality, because such a comparison is not correct.

Example:

```
void OnStart()
  {
//---
   double three=3.0;
   double x,y,z;
   x=1/three;
   y=4/three;
   z=5/three;
   if(x+y==z)
      Print("1/3 + 4/3 == 5/3");
   else
      Print("1/3 + 4/3 != 5/3");
// Result: 1/3 + 4/3 != 5/3
  }
```

If you still need to compare the equality of two real numbers, then you can do this in two different ways. The first way is to compare the difference between two numbers with some small quantity that specifies the accuracy of comparison.

Example:

```
bool EqualDoubles(double d1,double d2,double epsilon)
  {
   if(epsilon<0)
      epsilon=-epsilon;
//---
   if(d1-d2>epsilon)
      return false;
   if(d1-d2<-epsilon)
      return false;
//---
   return true;
  }
void OnStart()
  {
   double d_val=0.7;
   float  f_val=0.7;
   if(EqualDoubles(d_val,f_val,0.000000000000001))
      Print(d_val," equals ",f_val);
   else
      Print("Different: d_val = ",DoubleToString(d_val,16),"  f_val = ",DoubleToStrin
// Result: Different: d_val= 0.7000000000000000   f_val= 0.6999999880790710
  }
```

Note that the value of epsilon in the above example can not be less than the predefined constant DBL_EPSILON. The value of this constant is 2.2204460492503131e-016. The constant corresponding to

the float type is FLT_EPSILON = 1.192092896e-07. The meaning of these values is the following: it is the lowest value that satisfies the condition 1.0 + DBL_EPSILON! = 1.0 (for numbers of float type 1.0 + FLT_EPSILON! = 1.0).

The second way offers comparing the normalized difference of two real numbers with zero. It's meaningless to compare the difference of normalized numbers with a zero, because any mathematical operation with normalized numbers gives a non-normalized result.

Example:

```
bool CompareDoubles(double number1,double number2)
  {
   if(NormalizeDouble(number1-number2,8)==0)
      return(true);
   else
      return(false);
  }
void OnStart()
  {
   double d_val=0.3;
   float  f_val=0.3;
   if(CompareDoubles(d_val,f_val))
      Print(d_val," equals ",f_val);
   else
      Print("Different: d_val = ",DoubleToString(d_val,16),"  f_val = ",DoubleToStrinq
// Result: Different: d_val= 0.3000000000000000   f_val= 0.3000000119209290
  }
```

Some operations of the mathematical co-processor can result in the invalid real number, which can't be used in mathematical operations and operations of comparison, because the result of operations with invalid real numbers is undefined. For example, when trying to calculate the arcsine of 2, the result is the negative infinity.

Example:

```
   double abnormal = MathArcsin(2.0);
   Print("MathArcsin(2.0) =",abnormal);
// Result:  MathArcsin(2.0) = -1.#IND
```

Besides the minus infinity there is the plus infinity and NaN (not a number). To determine that this number is invalid, you can use MathIsValidNumber(). According to the IEEE standard, they have a special machine representation. For example, plus infinity for the double type has the bit representation of 0x7FF0 0000 0000 0000.

Examples:

```
struct str1
  {
   double d;
  };
struct str2
  {
```

```
   long l;
  };

//--- Start
   str1 s1;
   str2 s2;
//---
   s1.d=MathArcsin(2.0);         // Get the invalid number -1.#IND
   s2=s1;
   printf("1.  %f %I64X",s1.d,s2.l);
//---
   s2.l=0xFFFF000000000000;      // invalid number -1.#QNAN
   s1=s2;
   printf("2.  %f %I64X",s1.d,s2.l);
//---
   s2.l=0x7FF7000000000000;      // greatest non-number SNaN
   s1=s2;
   printf("3.   %f %I64X",s1.d,s2.l);
//---
   s2.l=0x7FF8000000000000;      // smallest non-number QNaN
   s1=s2;
   printf("4.   %f %I64X",s1.d,s2.l);
//---
   s2.l=0x7FFF000000000000;      // greatest non-number QNaN
   s1=s2;
   printf("5.   %f %I64X",s1.d,s2.l);
//---
   s2.l=0x7FF0000000000000;      // Positive infinity 1.#INF and smallest non-number SN
   s1=s2;
   printf("6.   %f %I64X",s1.d,s2.l);
//---
   s2.l=0xFFF0000000000000;      // Negative infinity -1.#INF
   s1=s2;
   printf("7.  %f %I64X",s1.d,s2.l);
//---
   s2.l=0x8000000000000000;      // Negative zero -0.0
   s1=s2;
   printf("8.  %f %I64X",s1.d,s2.l);
//---
   s2.l=0x3FE0000000000000;      // 0.5
   s1=s2;
   printf("9.   %f %I64X",s1.d,s2.l);
//---
   s2.l=0x3FF0000000000000;      // 1.0
   s1=s2;
   printf("10.  %f %I64X",s1.d,s2.l);
//---
   s2.l=0x7FEFFFFFFFFFFFFF;      // Greatest normalized number (MAX_DBL)
   s1=s2;
```

```
   printf("11.  %.16e %I64X",s1.d,s2.l);
//---
   s2.l=0x0010000000000000;     // Smallest positive normalized (MIN_DBL)
   s1=s2;
   printf("12.  %.16e %.16I64X",s1.d,s2.l);
//---
   s1.d=0.7;                    // Show that the number of 0.7 - endless fraction
   s2=s1;
   printf("13.  %.16e %.16I64X",s1.d,s2.l);
/*
1.  -1.#IND00 FFF8000000000000
2.  -1.#QNAN0 FFFF000000000000
3.   1.#SNAN0 7FF7000000000000
4.   1.#QNAN0 7FF8000000000000
5.   1.#QNAN0 7FFF000000000000
6.   1.#INF00 7FF0000000000000
7.  -1.#INF00 FFF0000000000000
8.  -0.000000 8000000000000000
9.   0.500000 3FE0000000000000
10.  1.000000 3FF0000000000000

DoubleToString, NormalizeDouble, Numeric Type Constants

Complex number (complex)

The built-in complex type is a structure with two double fields:

```
struct complex
  {
   double            real;    // Real part
   double            imag;    // Imaginary part
  };
```

The "complex" type can be passed by value as a parameter for MQL5 functions (in contrast to ordinary structures, which are only passed by reference). For functions imported from DLLs, the "complex" type must be passed only by reference.

The 'i' suffix is used to describe complex constants:

```
complex square(complex c)
  {
   return(c*c);
  }
void OnStart()
  {
   Print(square(1+2i));  // A constant is passed as a parameter
  }
// "(-3,4)" will be output, which is a string representation of the complex number
```

Only simple operations are currently available for complex numbers: =, +, -, *, /, +=, -=, *=, /=, ==,!=.

Support for additional mathematical functions will be added later, enabling the calculation of the absolute value, sine, cosine and others.

vectorc

One-dimensional array of complex type numbers is meant to handle complex numbers. The vector<complex> entry can be used in template functions. Operations on vectorc type vectors are not implemented yet.

matrixc

Two-dimensional array of complex type numbers is meant to handle complex numbers. The matrix<complex> entry can be used in template functions. Operations on matrixc type matrices are not implemented yet.

String Type

The string type is used for storing text strings. A text string is a sequence of characters in the Unicode format with the final zero at the end of it. A string constant can be assigned to a string variable. A string constant is a sequence of Unicode characters enclosed in double quotes: "This is a string constant".

If you need to include a double quote (") into a string, the backslash character (\) must be put before it. Any special character constants can be written in a string, if the backslash character (\) is typed before them.

Examples:

```
string svar="This is a character string";
string svar2=StringSubstr(svar,0,4);
Print("Copyright symbol\t\x00A9");
FileWrite(handle,"This string contains a new line symbols \n");
string MT5path="C:\\Program Files\\MetaTrader 5";
```

To make the source code readable, long constant strings can be split into parts without addition operation. During compilation, these parts will be combined into one long string:

```
//--- Declare a long constant string
   string HTML_head="<!DOCTYPE html PUBLIC \"-//W3C//DTD XHTML 1.0 Transitional//EN\""
                    " \"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd\">\n"
                    "<html xmlns=\"http://www.w3.org/1999/xhtml\">\n"
                    "<head>\n"
                    "<meta http-equiv=\"Content-Type\" content=\"text/html; charset=ut
                    "<title>Trade Operations Report</title>\n"
                    "</head>";
//--- Output the constant string into log
   Print(HTML_head);
  }
```

Built-in string type methods

Strings can be handled by string functions, conversion functions and built-in methods of string type provided in the table:

String method	Analog	Description
Constructor string(const int len)		Constructs a string of a specified
string[] length both for reading and writing. The index should be within BufferSize()		Provides access to the string element by a specified index

String method	Analog	Description
static string string.Init(const int len, const ushort character);	StringInit	Initializes a string using specified symbols with a specified size
void string.Fill(const ushort character);	StringFill	Fills in the string with a specified symbol
int string.Len();	StringLen	Returns the number of characters in a string
int string.BufferSize();	StringBufferLen	Returns the size of a buffer distributed for a string
bool string.SetLen(const int new_len);	StringSetLength	Sets a specified length (in characters) for a string
bool string.Reserve(const int buffer_len);	StringReserve	Reserves the buffer of a specified size for a string in memory
bool string.Add(const string substring);	StringAdd	Adds a specified substring to the end
int string.Concatenate(const scalar val1, const scalar val2...);	StringConcatenate	Forms a string consisting of passed parameters
array string.Split(const ushort separator, const bool long_separator);	StringSplit	Returns a string array by a specified separator
int string.Compare(const string str, const bool case_sensivity);	StringCompare	Compares with a specified string and returns 1 if the first string exceeds the second one; 0 - if the strings are equal; -1 (minus one) - if the first string is less than the second one
string string.Substr(const int start_pos, const int len);	StringSubstr	Retrieves a substring from a specified position
int string.Find(const string substr, const int pos);	StringFind	Returns an index of the position the necessary substring starts from
void string.ToLower();	StringToLower	Converts all characters to lower case
void string.ToUpper();	StringToUpper	Converts all characters to upper case
int string.TrimLeft();	StringTrimLeft	Deletes spaces, as well as carriage movement and tabulation characters to the left
int string.TrimRight()	StringTrimRight	Deletes spaces, as well as carriage movement and tabulation characters to the right
void string.Double(const double var, const int digits=8);	DoubleToString	Converts a string to a double type number

String method	Analog	Description
void string.Enum(const enum value);	EnumToString	Converts the enumeration value of any type into a string
void string.Integer(const int value, const int str_len=0, const ushort fill=' ');	IntegerToString	Converts a string to a long type number
void string.CharArray(const uchar array[], const int start_pos=0, const int len=-1, const uint cp=CP_ACP);	CharArrayToString	Converts part of the uchar type array to a string
void string.ShortArray(const ushort array[], const int start_pos=0, const int len=-1);	ShortArrayToString	Copies part of the ushort type array to a string
void string.Time(const datetime dt,const int mode=TIME_DATE|TIME_MINUTES);	TimeToString	Converts datetime to the "yyyy.mm.dd hh:mi" format string.
void string.Format(const string format_str);	StringFormat	Formats the obtained parameters into a string

Structures, Classes and Interfaces

Structures

A structure is a set of elements of any type (except for the void type). Thus, the structure combines logically related data of different types.

Structure Declaration

The structure data type is determined by the following description:

```
struct structure_name
  {
   elements_description
  };
```

The structure name can't be used as an identifier (name of a variable or function). It should be noted that in MQL5 structure elements follow one another directly, without alignment. In C++ such an order is made to the compiler using the following instruction:

```
#pragma pack(1)
```

If you want to do another alignment in the structure, use auxiliary members, "fillers" to the right size.

Example:

```
struct trade_settings
  {
   uchar  slippage;     // value of the permissible slippage-size 1 byte
   char   reserved1;    // skip 1 byte
   short  reserved2;    // skip 2 bytes
   int    reserved4;    // another 4 bytes are skipped. ensure alignment of the bounda
   double take;         // values of the price of profit fixing
   double stop;         // price value of the protective stop
  };
```

Such a description of aligned structures is necessary only for transferring to imported dll-functions.

Attention: This example illustrates incorrectly designed data. It would be better first to declare the *take* and *stop* large data of the double type, and then declare the *slippage* member of the uchar type. In this case, the internal representation of data will always be the same regardless of the value specified in *#pragma pack()*.

If a structure contains variables of the string type and/or object of a dynamic array, the compiler assigns an implicit constructor to such a structure. This constructor resets all the structure members of string type and correctly initializes objects of the dynamic array.

Simple Structures

Structures that do not contain strings, class objects, pointers and objects of dynamic arrays are called simple structures. Variables of simple structures, as well as their arrays can be passed as parameters to functions imported from DLL.

Copying of simple structures is allowed only in two cases:

- If the objects belong to the same structure type
- if the objects are connected by the lineage meaning that one structure is a descendant of another.

To provide an example, let's develop the CustomMqlTick custom structure with its contents identical to the built-in MqlTick one. The compiler does not allow copying the MqlTick object value to the CustomMqlTick type object. Direct typecasting to the necessary type also causes the compilation error:

```
      //--- copying simple structures of different types is forbidden
      my_tick1=last_tick;               // compiler returns an error here

      //--- typecasting structures of different types to each other is forbidden as we
      my_tick1=(CustomMqlTick)last_tick;// compiler returns an error here
```

Therefore, only one option is left - copying the values of the structure elements one by one. It is still allowed to copy the values of the same type of CustomMqlTick.

```
      CustomMqlTick my_tick1,my_tick2;
      //--- it is allowed to copy the objects of the same type of CustomMqlTick the fo
      my_tick2=my_tick1;

      //--- create an array out of the objects of the simple CustomMqlTick structure a
      CustomMqlTick arr[2];
      arr[0]=my_tick1;
      arr[1]=my_tick2;
```

The ArrayPrint() function is called for a check to display the *arr[] array value in the journal*.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- develop the structure similar to the built-in MqlTick
   struct CustomMqlTick
     {
      datetime          time;          // Last price update time
      double            bid;           // Current Bid price
      double            ask;           // Current Ask price
      double            last;          // Current price of the last trade (Last)
      ulong             volume;        // Volume for the current Last price
      long              time_msc;      // Last price update time in milliseconds
      uint              flags;         // Tick flags
     };
   //--- get the last tick value
   MqlTick last_tick;
   CustomMqlTick my_tick1,my_tick2;
//--- attempt to copy data from MqlTick to CustomMqlTick
   if(SymbolInfoTick(Symbol(),last_tick))
     {
```

```
      //--- copying unrelated simple structures is forbidden
      //1. my_tick1=last_tick;               // compiler returns an error here

      //--- typecasting unrelated structures to each other is forbidden as well
      //2. my_tick1=(CustomMqlTick)last_tick;// compiler returns an error here

      //--- therefore, copy the structure members one by one
      my_tick1.time=last_tick.time;
      my_tick1.bid=last_tick.bid;
      my_tick1.ask=last_tick.ask;
      my_tick1.volume=last_tick.volume;
      my_tick1.time_msc=last_tick.time_msc;
      my_tick1.flags=last_tick.flags;

      //--- it is allowed to copy the objects of the same type of CustomMqlTick the fo
      my_tick2=my_tick1;

      //--- create an array out of the objects of the simple CustomMqlTick structure a
      CustomMqlTick arr[2];
      arr[0]=my_tick1;
      arr[1]=my_tick2;
      ArrayPrint(arr);
//--- example of displaying values of the array containing the objects of CustomMqlTic
      /*
                        [time]    [bid]    [ask]    [last] [volume]     [time_msc] [flags]
      [0] 2017.05.29 15:04:37 1.11854 1.11863 +0.00000  1450000 1496070277157       2
      [1] 2017.05.29 15:04:37 1.11854 1.11863 +0.00000  1450000 1496070277157       2
      */
     }
   else
      Print("SymbolInfoTick() failed, error = ",GetLastError());
  }
```

The second example shows the features of copying simple structures by the lineage. Suppose that we have the Animal basic structure, from which the Cat and Dog structures are derived. We can copy the Animal and Cat objects, as well as the Animal and Dog objects to each other but we cannot copy Cat and Dog to each other, although both are descendants of the Animal structure.

```
//--- structure for describing dogs
struct Dog: Animal
  {
   bool              hunting;       // hunting breed
  };
//--- structure for describing cats
struct Cat: Animal
  {
   bool              home;          // home breed
  };
//--- create objects of child structures
```

```
   Dog dog;
   Cat cat;
//--- can be copied from ancestor to descendant (Animal ==> Dog)
   dog=some_animal;
   dog.swim=true;    // dogs can swim
//--- you cannot copy objects of child structures (Dog != Cat)
   cat=dog;        // compiler returns an error
```

Complete example code:

```
//--- basic structure for describing animals
struct Animal
  {
   int               head;          // number of heads
   int               legs;          // number of legs
   int               wings;         // number of wings
   bool              tail;          // tail
   bool              fly;           // flying
   bool              swim;          // swimming
   bool              run;           // running
  };
//--- structure for describing dogs
struct Dog: Animal
  {
   bool              hunting;       // hunting breed
  };
//--- structure for describing cats
struct Cat: Animal
  {
   bool              home;          // home breed
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create and describe an object of the basic Animal type
   Animal some_animal;
   some_animal.head=1;
   some_animal.legs=4;
   some_animal.wings=0;
   some_animal.tail=true;
   some_animal.fly=false;
   some_animal.swim=false;
   some_animal.run=true;
//--- create objects of child types
   Dog dog;
   Cat cat;
//--- can be copied from ancestor to descendant (Animal ==> Dog)
```

```
   dog=some_animal;
   dog.swim=true;    // dogs can swim
//--- you cannot copy objects of child structures (Dog != Cat)
   //cat=dog;        // compiler returns an error here
//--- therefore, it is possible to copy elements one by one only
   cat.head=dog.head;
   cat.legs=dog.legs;
   cat.wings=dog.wings;
   cat.tail=dog.tail;
   cat.fly=dog.fly;
   cat.swim=false;   // cats cannot swim
//--- it is possible to copy the values from descendant to ancestor
   Animal elephant;
   elephant=cat;
   elephant.run=false;// elephants cannot run
   elephant.swim=true;// elephants can swim
//--- create an array
   Animal animals[4];
   animals[0]=some_animal;
   animals[1]=dog;
   animals[2]=cat;
   animals[3]=elephant;
//--- print out
   ArrayPrint(animals);
//--- execution result
/*
        [head] [legs] [wings] [tail] [fly] [swim] [run]
   [0]      1      4        0   true false  false  true
   [1]      1      4        0   true false   true  true
   [2]      1      4        0   true false  false false
   [3]      1      4        0   true false   true false
*/
  }
```

Another way to copy simple types is using a union. The objects of the structures should be members of the same union - see the example in union.

Access to Structure Members

The name of a structure becomes a new data type, so you can declare variables of this type. The structure can be declared only once within a project. The structure members are accessed using the point operation (.).

Example:

```
struct trade_settings
  {
   double take;         // values of the profit fixing price
   double stop;         // value of the protective stop price
   uchar  slippage;     // value of the acceptable slippage
```

```
  };
//--- create up and initialize a variable of the trade_settings type
trade_settings my_set={0.0,0.0,5};
if (input_TP>0) my_set.take=input_TP;
```

'pack' for aligning structure and class fields

The special pack attribute allows setting the alignment of structure or class fields.

```
 pack([n])
```

where n is one of the following values: 1, 2, 4, 8 or 16. It may be absent.

Example:

```
   struct pack(sizeof(long)) MyStruct
     {
      // structure members are to be aligned to the 8-byte boundary
     };
or
   struct MyStruct pack(sizeof(long))
     {
      // structure members are to be aligned to the 8-byte boundary
     };
```

'pack(1)' is applied by default for structures. This means that the structure members are located one after another in memory, and the structure size is equal to the sum of its members' size.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- simple structure with no alignment
   struct Simple_Structure
     {
      char              c; // sizeof(char)=1
      short             s; // sizeof(short)=2
      int               i; // sizeof(int)=4
      double            d; // sizeof(double)=8
     };
   //--- declare a simple structure instance
   Simple_Structure s;
//--- display the size of each structure member
   Print("sizeof(s.c)=",sizeof(s.c));
   Print("sizeof(s.s)=",sizeof(s.s));
   Print("sizeof(s.i)=",sizeof(s.i));
   Print("sizeof(s.d)=",sizeof(s.d));
//--- make sure the size of POD structure is equal to the sum of its members' size
```

```
   Print("sizeof(simple_structure)=",sizeof(simple_structure));
/*
  Result:
   sizeof(s.c)=1
   sizeof(s.s)=2
   sizeof(s.i)=4
   sizeof(s.d)=8
   sizeof(simple_structure)=15
*/
  }
```

Alignment of the structure fields may be needed when exchanging data with third-party libraries (*.DLL) where such alignment is applied.

Let's use some examples to show how alignment works. We will apply a structure consisting of four members with no alignment.

```
//--- simple structure with no alignment
   struct Simple_Structure pack() // no size is specified, alignment to the boundary
     {
      char              c; // sizeof(char)=1
      short             s; // sizeof(short)=2
      int               i; // sizeof(int)=4
      double            d; // sizeof(double)=8
     };
//--- declare a simple structure instance
   Simple_Structure s;
```

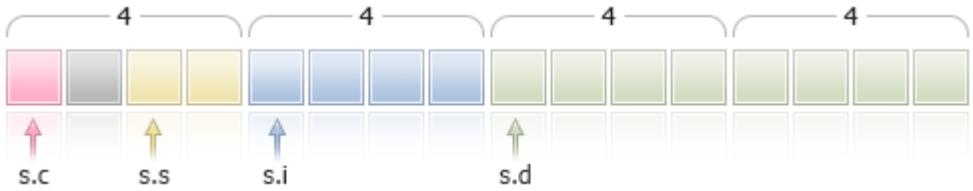
Structure fields are to be located in memory one after another according to the declaration order and type size. The structure size is 15, while an offset to the structure fields in the arrays is undefined.

Now declare the same structure with the alignment of 4 bytes and run the code.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- simple structure with the 4-byte alignment
   struct Simple_Structure pack(4)
     {
      char              c; // sizeof(char)=1
      short             s; // sizeof(short)=2
      int               i; // sizeof(int)=4
      double            d; // sizeof(double)=8
     };
```

```
   //--- declare a simple structure instance
   Simple_Structure s;
//--- display the size of each structure member
   Print("sizeof(s.c)=",sizeof(s.c));
   Print("sizeof(s.s)=",sizeof(s.s));
   Print("sizeof(s.i)=",sizeof(s.i));
   Print("sizeof(s.d)=",sizeof(s.d));
//--- make sure the size of POD structure is now not equal to the sum of its members'
   Print("sizeof(simple_structure)=",sizeof(simple_structure));
/*
  Result:
   sizeof(s.c)=1
   sizeof(s.s)=2
   sizeof(s.i)=4
   sizeof(s.d)=8
   sizeof(simple_structure)=16 // structure size has changed
*/
  }
```

The structure size has changed so that all members of 4 bytes and more has an offset from the beginning of the structure multiple of 4 bytes. Smaller members are to be aligned to their own size boundary (for example, 2 for 'short'). This is how it looks (the added byte is shown in gray).



In this case, 1 byte is added after the **s.c** member, so that the **s.s** (sizeof(short)==2) field has the boundary of 2 bytes (alignment for 'short' type).

The offset to the beginning of the structure in the array is also aligned to the 4-byte boundary, i.e. the addresses of the a[0], a[1] and a[n] elements are to be multiple of 4 bytes for Simple_Structure arr[].

Let's consider two more structures consisting of similar types with 4-bytes alignment but different member order. In the first structure, the members are located in type size ascending order.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- simple structure aligned to the 4-byte boundary
   struct CharShortInt pack(4)
     {
      char              c; // sizeof(char)=1
      short             s; // sizeof(short)=2
      int               i; // sizeof(double)=4
     };
```

```
//--- declare a simple structure instance
   CharShortInt ch_sh_in;
//--- display the size of each structure member
   Print("sizeof(ch_sh_in.c)=",sizeof(ch_sh_in.c));
   Print("sizeof(ch_sh_in.s)=",sizeof(ch_sh_in.s));
   Print("sizeof(ch_sh_in.i)=",sizeof(ch_sh_in.i));

//--- make sure the size of POD structure is equal to the sum of its members' size
   Print("sizeof(CharShortInt)=",sizeof(CharShortInt));
/*
  Result:
   sizeof(ch_sh_in.c)=1
   sizeof(ch_sh_in.s)=2
   sizeof(ch_sh_in.i)=4
   sizeof(CharShortInt)=8
*/
  }
```

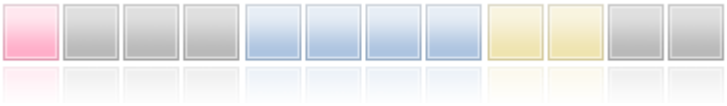
As we can see, the structure size is 8 and consists of the two 4-byte blocks. The first block contains the fields with 'char' and 'short' types, while the second one contains the field with 'int' type.

Now let's turn the first structure into the second one, which differs only in the field order, by moving the 'short' type member to the end.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- simple structure aligned to the 4-byte boundary
   struct CharIntShort pack(4)
     {
      char              c; // sizeof(char)=1
      int               i; // sizeof(double)=4
      short             s; // sizeof(short)=2
     };
//--- declare a simple structure instance
   CharIntShort ch_in_sh;
//--- display the size of each structure member
   Print("sizeof(ch_in_sh.c)=",sizeof(ch_in_sh.c));
   Print("sizeof(ch_in_sh.i)=",sizeof(ch_in_sh.i));
   Print("sizeof(ch_in_sh.s)=",sizeof(ch_in_sh.s));
//--- make sure the size of POD structure is equal to the sum of its members' size
   Print("sizeof(CharIntShort)=",sizeof(CharIntShort));
/*
  Result:
```

```
   sizeof(ch_in_sh.c)=1
   sizeof(ch_in_sh.i)=4
   sizeof(ch_in_sh.s)=2
   sizeof(CharIntShort)=12
*/
  }
```

Although the structure content has not changed, altering the member sequence has increased its size.



Alignment should also be considered when inheriting. Let's demonstrate this using the simple Parent structure having a single 'char' type member. The structure size without alignment is 1.

```
   struct Parent
     {
      char              c;     // sizeof(char)=1
     };
```

Let's create the Children child class featuring the 'short' (sizeof(short)=2) type member.

```
   struct Children pack(2) : Parent
     {
      short             s;    // sizeof(short)=2
     };
```

As a result, when setting alignment to 2 bytes, the structure size is equal to 4, although the size of its members is 3. In this example, 2 bytes are to be allocated to the Parent class, so that the access to the 'short' field of the child class is aligned to 2 bytes.

The knowledge of how memory is allocated for the structure members is necessary if an MQL5 application interacts with third-party data by writing/reading on the files or streams level.

The MQL5\Include\WinAPI directory of the Standard Library contains the functions for working with the WinAPI functions. These functions apply the structures with a specified alignment for the cases when it is required for working with WinAPI.

offsetof is a special command directly related to the pack attribute. It allows us to obtain a member offset from the beginning of the structure.

```
//--- declare the Children type variable
   Children child;
//--- detect offsets from the beginning of the structure
   Print("offsetof(Children,c)=",offsetof(Children,c));
   Print("offsetof(Children,s)=",offsetof(Children,s));
/*
  Result:
   offsetof(Children,c)=0
   offsetof(Children,s)=2
*/
```

Specifier 'final'

The use of the 'final' specifier during structure declaration prohibits further inheritance from this structure. If a structure requires no further modifications, or modifications are not allowed for security reasons, declare this structure with the 'final' modifier. In addition, all the members of the structure will also be implicitly considered final.

```
struct settings final
  {
  //--- Structure body
  };

struct trade_settings : public settings
  {
  //--- Structure body
  };
```

If you try to inherit from a structure with the 'final' modifier as shown in the above example, the compiler will return an error:

```
cannot inherit from 'settings' as it has been declared as 'final'
see declaration of 'settings'
```

Classes

Classes differ from structures in the following:

- the keyword class is used in declaration;
- by default, all class members have access specifier private, unless otherwise indicated. Data-members of the structure have the default type of access as public, unless otherwise indicated;
- class objects always have a table of virtual functions, even if there are no virtual functions declared in the class. Structures cannot have virtual functions;
- the new operator can be applied to class objects; this operator cannot be applied to structures;
- classes can be inherited only from classes, structures can be inherited only from structures.

Classes and structures can have an explicit constructor and destructor. If your constructor is explicitly defined, the initialization of a structure or class variable using the initializing sequence is impossible.

Example:

```
struct trade_settings
  {
   double take;         // values of the profit fixing price
   double stop;         // value of the protective stop price
   uchar  slippage;     // value of the acceptable slippage
   //--- Constructor
          trade_settings() { take=0.0; stop=0.0; slippage=5; }
   //--- Destructor
         ~trade_settings() { Print("This is the end"); }
  };
//--- Compiler will generate an error message that initialization is impossible
trade_settings my_set={0.0,0.0,5};
```

Constructors and Destructors

A constructor is a special function, which is called automatically when creating an object of a structure or class and is usually used to initialize class members. Further we will talk only about classes, while the same applies to structures, unless otherwise indicated. The name of a constructor must match the class name. The constructor has no return type (you can specify the void type).

Defined class members - strings, dynamic arrays and objects that require initialization - will be in any case initialized, regardless of whether there is a constructor.

Each class can have multiple constructors, differing by the number of parameters and the initialization list. A constructor that requires specifying parameters is called a parametric constructor.

A constructor with no parameters is called **a default constructor**. If no constructors are declared in a class, the compiler creates a default constructor during compilation.

```
//+------------------------------------------------------------------+
//| A class for working with a date                                  |
//+------------------------------------------------------------------+
class MyDateClass
  {
private:
   int               m_year;           // Year
   int               m_month;          // Month
   int               m_day;            // Day of the month
   int               m_hour;           // Hour in a day
   int               m_minute;         // Minutes
   int               m_second;         // Seconds
public:
   //--- Default constructor
                     MyDateClass(void);
   //--- Parametric constructor
                     MyDateClass(int h,int m,int s);
  };
```

A constructor can be declared in the class description and then its body can be defined. For example, two constructors of MyDateClass can be defined the following way:

```
//+------------------------------------------------------------------+
//| Default constructor                                              |
//+------------------------------------------------------------------+
MyDateClass::MyDateClass(void)
  {
//---
   MqlDateTime mdt;
   datetime t=TimeCurrent(mdt);
   m_year=mdt.year;
   m_month=mdt.mon;
   m_day=mdt.day;
```

```
   m_hour=mdt.hour;
   m_minute=mdt.min;
   m_second=mdt.sec;
   Print(__FUNCTION__);
  }
//+------------------------------------------------------------------+
//| Parametric constructor                                           |
//+------------------------------------------------------------------+
MyDateClass::MyDateClass(int h,int m,int s)
  {
   MqlDateTime mdt;
   datetime t=TimeCurrent(mdt);
   m_year=mdt.year;
   m_month=mdt.mon;
   m_day=mdt.day;
   m_hour=h;
   m_minute=m;
   m_second=s;
   Print(__FUNCTION__);
  }
```

In the default constructor, all members of the class are filled using the TimeCurrent() function. In the parametric constructor only hour values are filled in. Other members of the class (m_year, m_month and m_day) will be automatically initialized with the current date.

The default constructor has a special purpose when initializing an array of objects of its class. The constructor, all parameters of which have default values, **is not** a default constructor. Here is an example:

```
//+------------------------------------------------------------------+
//| A class with a default constructor                               |
//+------------------------------------------------------------------+
class CFoo
  {
   datetime          m_call_time;     // Time of the last object call
public:
   //--- Constructor with a parameter that has a default value is not a default consti
                     CFoo(const datetime t=0){m_call_time=t;};
   //--- Copy constructor
                     CFoo(const CFoo &foo){m_call_time=foo.m_call_time;};

   string ToString(){return(TimeToString(m_call_time,TIME_DATE|TIME_SECONDS));};
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
// CFoo foo; // This variant cannot be used - a default constructor is not set
//--- Possible options to create the CFoo object
```

```
   CFoo foo1(TimeCurrent());      // An explicit call of a parametric constructor
   CFoo foo2();                   // An explicit call of a parametric constructor with
   CFoo foo3=D'2009.09.09';       // An implicit call of a parametric constructor
   CFoo foo40(foo1);              // An explicit call of a copy constructor
   CFoo foo41=foo1;               // An implicit call of a copy constructor
   CFoo foo5;                     // An explicit call of a default constructor (if ther
                                  // then a parametric constructor with a default value
//--- Possible options to receive CFoo pointers
   CFoo *pfoo6=new CFoo();        // Dynamic creation of an object and receiving of a p
   CFoo *pfoo7=new CFoo(TimeCurrent());// Another option of dynamic object creation
   CFoo *pfoo8=GetPointer(foo1); // Now pfoo8 points to object foo1
   CFoo *pfoo9=pfoo7;             // pfoo9 and pfoo7 point to one and the same object
   // CFoo foo_array[3];          // This option cannot be used - a default constructor
//--- Show the value of m_call_time
   Print("foo1.m_call_time=",foo1.ToString());
   Print("foo2.m_call_time=",foo2.ToString());
   Print("foo3.m_call_time=",foo3.ToString());
   Print("foo4.m_call_time=",foo4.ToString());
   Print("foo5.m_call_time=",foo5.ToString());
   Print("pfoo6.m_call_time=",pfoo6.ToString());
   Print("pfoo7.m_call_time=",pfoo7.ToString());
   Print("pfoo8.m_call_time=",pfoo8.ToString());
   Print("pfoo9.m_call_time=",pfoo9.ToString());
//--- Delete dynamically created arrays
   delete pfoo6;
   delete pfoo7;
   //delete pfoo8;  // You do not need to delete pfoo8 explicitly, since it points to
   //delete pfoo9;  // You do not need to delete pfoo9 explicitly. since it points to
  }
```

If you uncomment these strings

```
   //CFoo foo_array[3];     // This variant cannot be used - a default constructor is r
```

or

```
   //CFoo foo_dyn_array[];  // This variant cannot be used - a default constructor is r
```

then the compiler will return an error for them "default constructor is not defined".

If a class has a user-defined constructor, the default constructor is not generated by the compiler. This means that if a parametric constructor is declared in a class, but a default constructor is not declared, you can not declare the arrays of objects of this class. The compiler will return an error for this script:

```
//+------------------------------------------------------------------+
//| A class without a default constructor                            |
//+------------------------------------------------------------------+
class CFoo
  {
   string            m_name;
public:
```

```
                     CFoo(string name) { m_name=name;}
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Get the "default constructor is not defined" error during compilation
   CFoo badFoo[5];
  }
```

In this example, the CFoo class has a declared parametric constructor - in such cases, the compiler does not create a default constructor automatically during compilation. At the same time when you declare an array of objects, it is assumed that all objects should be created and initialized automatically. During auto-initialization of an object, it is necessary to call a default constructor, but since the default constructor is not explicitly declared and not automatically generated by the compiler, it is impossible to create such an object. For this reason, the compiler generates an error at the compilation stage.

There is a special syntax to initialize an object using a constructor. Constructor initializers (special constructions for initialization) for the members of a struct or class can be specified in the initialization list.

An initialization list is a list of initializers separated by commas, which comes after the colon after the list of parameters of a constructor and precedes the body (goes before an opening brace). There are several requirements:

- Initialization lists can be used only in constructors;
- Parent members cannot be initialized in the initialization list;
- The initialization list must be followed by a definition (implementation) of a function.

Here is an example of several constructors for initializing class members.

```
//+------------------------------------------------------------------+
//| A class for storing the name of a character                      |
//+------------------------------------------------------------------+
class CPerson
  {
   string            m_first_name;     // First name
   string            m_second_name;    // Second name
public:
   //--- An empty default constructor
                     CPerson() {Print(__FUNCTION__);};
   //--- A parametric constructor
                     CPerson(string full_name);
   //--- A constructor with an initialization list
                     CPerson(string surname,string name): m_second_name(surname), m_fi
   void PrintName(){PrintFormat("Name=%s Surname=%s",m_first_name,m_second_name);};
  };
//+------------------------------------------------------------------+
//|                                                                  |
```

```
//+------------------------------------------------------------------+
CPerson::CPerson(string full_name)
  {
   int pos=StringFind(full_name," ");
   if(pos>=0)
     {
      m_first_name=StringSubstr(full_name,0,pos);
      m_second_name=StringSubstr(full_name,pos+1);
     }
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Get an error "default constructor is not defined"
   CPerson people[5];
   CPerson Tom="Tom Sawyer";                        // Tom Sawyer
   CPerson Huck("Huckleberry","Finn");              // Huckleberry Finn
   CPerson *Pooh = new CPerson("Winnie","Pooh");  // Winnie the Pooh
   //--- Output values
   Tom.PrintName();
   Huck.PrintName();
   Pooh.PrintName();

   //--- Delete a dynamically created object
   delete Pooh;
  }
```

In this case, the CPerson class has three constructors:

1. An explicit default constructor, which allows creating an array of objects of this class;
2. A constructor with one parameter, which gets a full name as a parameter and divides it to the name and second name according to the found space;
3. A constructor with two parameters that contains an initialization list. Initializers - m_second_name(surname) and m_first_name(name).

Note that the initialization using a list has replaced an assignment. Individual members must be initialized as:

```
class_member (a list of expressions)
```

In the initialization list, members can go in any order, but all members of the class will be initialized according to the order of their announcement. This means that in the third constructor, first the m_first_name member will be initialized, as it is announced first, and only after it m_second_name is initialized. This should be taken into account in cases where the initialization of some members of the class depends on the values in other class members.

If a default constructor is not declared in the base class, and at the same time one or more constructors with parameters are declared, you should always call one of the base class constructors in

the initialization list. It goes through the comma as ordinary members of the list and will be called first during object initialization, no matter where in the initialization list it is located.

```
//+------------------------------------------------------------------+
//| Base class                                                       |
//+------------------------------------------------------------------+
class CFoo
  {
   string            m_name;
public:
   //--- A constructor with an initialization list
                     CFoo(string name) : m_name(name) { Print(m_name);}
  };
//+------------------------------------------------------------------+
//| Class derived from CFoo                                          |
//+------------------------------------------------------------------+
class CBar : CFoo
  {
   CFoo              m_member;      // A class member is an object of the parent
public:
   //--- A default constructor in the initialization list calls the constructor of a p
                     CBar(): m_member(_Symbol), CFoo("CBAR") {Print(__FUNCTION__);}
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   CBar bar;
  }
```

In this example, when creating the bar object, a default constructor CBar() will be called, in which first a constructor for the parent CFoo is called, and then comes a constructor for the m_member class member.

A destructor is a special function that is called automatically when a class object is destroyed. The name of the destructor is written as a class name with a tilde (~). Strings, dynamic arrays and objects, requiring deinitialization, will be de-initialized anyway, regardless of the destructor presence or absence. If there is a destructor, these actions will be performed after calling the destructor.

Destructors are always virtual, regardless of whether they are declared with the virtual keyword or not.

Defining Class Methods

Class function-methods can be defined both inside the class and outside the class declaration. If the method is defined within a class, then its body comes right after the method declaration.

Example:

```
class CTetrisShape
  {
```

```
protected:
   int               m_type;
   int               m_xpos;
   int               m_ypos;
   int               m_xsize;
   int               m_ysize;
   int               m_prev_turn;
   int               m_turn;
   int               m_right_border;
public:
   void              CTetrisShape();
   void              SetRightBorder(int border) { m_right_border=border; }
   void              SetYPos(int ypos)          { m_ypos=ypos;           }
   void              SetXPos(int xpos)          { m_xpos=xpos;           }
   int               GetYPos()                  { return(m_ypos);        }
   int               GetXPos()                  { return(m_xpos);        }
   int               GetYSize()                 { return(m_ysize);       }
   int               GetXSize()                 { return(m_xsize);       }
   int               GetType()                  { return(m_type);        }
   void              Left()                     { m_xpos-=SHAPE_SIZE;    }
   void              Right()                    { m_xpos+=SHAPE_SIZE;    }
   void              Rotate()                   { m_prev_turn=m_turn; if(++m_turn>3) r
   virtual void      Draw()                     { return;                }
   virtual bool      CheckDown(int& pad_array[]);
   virtual bool      CheckLeft(int& side_row[]);
   virtual bool      CheckRight(int& side_row[]);
  };
```

Functions from SetRightBorder(int border) to Draw() are declared and defined directly inside the CTetrisShape class.

The CTetrisShape() constructor and methods CheckDown(int& pad_array[]), CheckLeft(int& side_row[]) and CheckRight(int& side_row[]) are only declared inside the class, but not defined yet. Definitions of these functions will be further in the code. In order to define the method outside the class, the scope resolution operator is used, the class name is used as the scope.

Example:

```
//+------------------------------------------------------------------+
//| Constructor of the basic class                                   |
//+------------------------------------------------------------------+
void CTetrisShape::CTetrisShape()
  {
   m_type=0;
   m_ypos=0;
   m_xpos=0;
   m_xsize=SHAPE_SIZE;
   m_ysize=SHAPE_SIZE;
   m_prev_turn=0;
   m_turn=0;
```

```
   m_right_border=0;
  }
//+------------------------------------------------------------------+
//| Checking ability to move down (for the stick and cube)           |
//+------------------------------------------------------------------+
bool CTetrisShape::CheckDown(int& pad_array[])
  {
   int i,xsize=m_xsize/SHAPE_SIZE;
//---
   for(i=0; i<xsize; i++)
     {
      if(m_ypos+m_ysize>=pad_array[i]) return(false);
     }
//---
   return(true);
  }
```

Public, Protected and Private Access Specifiers

When developing a new class, it is recommended to restrict access to the members from the outside. For this purpose keywords private or protected are used. In this case, hidden data can be accessed only from function-methods of the same class. If the *protected* keyword is used, hidden data can be accessed also from methods of classes - inheritors of this class. The same method can be used to restrict the access to functions-methods of a class.

If you need to completely open access to members and/or methods of a class, use the keyword public.

Example:

```
class CTetrisField
  {
private:
   int               m_score;                           // Score
   int               m_ypos;                            // Current position of the fi
   int               m_field[FIELD_HEIGHT][FIELD_WIDTH]; // Matrix of the well
   int               m_rows[FIELD_HEIGHT];              // Numbering of the well rows
   int               m_last_row;                        // Last free row
   CTetrisShape     *m_shape;                           // Tetris figure
   bool              m_bover;                           // Game over
public:
   void              CTetrisField() { m_shape=NULL; m_bover=false; }
   void              Init();
   void              Deinit();
   void              Down();
   void              Left();
   void              Right();
   void              Rotate();
   void              Drop();
private:
   void              NewShape();
```

```
   void              CheckAndDeleteRows();
   void              LabelOver();
  };
```

Any class members and methods declared after the specifier **public:** (and before the next access specifier) are available in any reference to the class object by the program. In this example these are the following members: functions CTetrisField(), Init(), Deinit(), Down(), Left(), Right(), Rotate() and Drop().

Any members that are declared after the access specifier to the elements **private:** (and before the next access specifier) are available only to members-functions of this class. Specifiers of access to elements always end with a colon (:) and can appear in the class definition many times.

Any class members declared after the **protected:** access specifier (and up to the next access specifier) are available only to members-functions of this class and members-functions of the class descendants. When attempting to refer to the members featuring the private and protected specifiers from the outside, we get the compilation stage error. Example:

```
class A
  {
protected:
   //--- the copy operator is available only inside class A and its descendants
   void operator=(const A &)
     {
     }
  };
class B
  {
   //--- class A object declared
   A                 a;
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   //--- declare two B type variables
   B b1, b2;
   //--- attempt to copy one object into another
   b2=b1;
  }
```

When compiling the code, the error message is received — an attempt to call the remote copy operator:

```
attempting to reference deleted function 'void B::operator=(const B&)'   trash3.mq5
```

The second string below provides a more detailed description — the copy operator in class B was explicitly deleted, since the unavailable copy operator of class A is called:

```
   function 'void B::operator=(const B&)' was implicitly deleted because it invokes in
```

Access to the members of the basis class can be redefined during inheritance in derived classes.

'delete' specifier

The delete specifier marks the class members-functions that cannot be used. This means if the program refers to such a function explicitly or implicitly, the error is received at the compilation stage already. For example, this specifier allows you to make parent methods unavailable in a child class. The same result can be achieved if we declare the function in the private area of the parent class (declarations in the private section). Here, using delete makes the code more readable and manageable at the level of descendants.

```
class A
  {
public:
                     A(void) {value=5;};
   double            GetValue(void) {return(value);}
private:
   double            value;
  };
class B: public A
  {
   double            GetValue(void)=delete;
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the A type variable
   A a;
   Print("a.GetValue()=", a.GetValue());
//--- attempt to get value from the B type variable
   B b;
   Print("b.GetValue()=", b.GetValue()); // the compiler displays an error at this str
  }
```

The compiler message:

```
attempting to reference deleted function 'double B::GetValue()'
   function 'double B::GetValue()' was explicitly deleted here
```

The 'delete' specifier allows disabling auto casting or the copy constructor, which otherwise would have to be hidden in the private section as well. Example:

```
class A
  {
public:
   void              SetValue(double v) {value=v;}
   //--- disable int type call
   void              SetValue(int) = delete;
   //--- disable the copy operator
```

```
   void              operator=(const A&) = delete;
private:
   double            value;
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare two A type variables
   A a1, a2;
   a1.SetValue(3);      // error!
   a1.SetValue(3.14);   // OK
   a2=a1;               // error!
  }
```

During the compilation, we get the error messages:

```
attempting to reference deleted function 'void A::SetValue(int)'
   function 'void A::SetValue(int)' was explicitly deleted here
attempting to reference deleted function 'void A::operator=(const A&)'
   function 'void A::operator=(const A&)' was explicitly deleted here
```

Specifier 'final'

The use of the 'final' specifier during class declaration prohibits further inheritance from this class. If the class interface requires no further modifications, or modifications are not allowed for security reasons, declare this class with the 'final' modifier. In addition, all the members of the class will also be implicitly considered final.

```
class CFoo final
  {
  //--- Class body
  };

class CBar : public CFoo
  {
  //--- Class body
  };
```

If you try to inherit form a class with the 'final' specifier as shown in the above example, the compiler will return an error:

```
cannot inherit from 'CFoo' as it has been declared as 'final'
see declaration of 'CFoo'
```

Unions (union)

Union is a special data type consisting of several variables sharing the same memory area. Therefore, the union provides the ability to interpret the same bit sequence in two (or more) different ways. Union declaration is similar to structure declaration and starts with the union keyword.

```
union LongDouble
```

```
{
  long   long_value;
  double double_value;
};
```

Unlike the structure, various union members belong to the same memory area. In this example, the union of LongDouble is declared with long and double type values sharing the same memory area. Please note that it is impossible to make the union store a *long* integer value and a *double* real value simultaneously (unlike a structure), since long_value and double_value variables overlap (in memory). On the other hand, an MQL5 program is able to process data containing in the union as an integer (long) or real (double) value at any time. Therefore, the union allows receiving two (or more) options for representing the same data sequence.

During the union declaration, the compiler automatically allocates the memory area sufficient to store the largest type (by volume) in the variable union. The same syntax is used for accessing the union element as for the structures - point operator.

```
union LongDouble
{
  long   long_value;
  double double_value;
};
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   LongDouble lb;
//--- get and display the invalid -nan(ind) number
   lb.double_value=MathArcsin(2.0);
   printf("1.  double=%f                integer=%I64X",lb.double_value,lb.long_value);
//--- largest normalized value (DBL_MAX)
   lb.long_value=0x7FEFFFFFFFFFFFFF;
   printf("2.  double=%.16e  integer=%I64X",lb.double_value,lb.long_value);
//--- smallest positive normalized (DBL_MIN)
   lb.long_value=0x0010000000000000;
   printf("3.  double=%.16e  integer=%.16I64X",lb.double_value,lb.long_value);
  }
/*  Execution result
    1.  double=-nan(ind)                integer=FFF8000000000000
    2.  double=1.7976931348623157e+308  integer=7FEFFFFFFFFFFFFF
    3.  double=2.2250738585072014e-308  integer=0010000000000000
*/
```

Since the unions allow the program to interpret the same memory data in different ways, they are often used when an unusual type conversion is required.

The unions cannot be involved in the inheritance, and they also cannot have static members due to their very nature. In all other aspects, the *union* behaves like a structure with all its members having a zero offset. The following types cannot be the union members:

- dynamic arrays
- strings
- pointers to objects and functions
- class objects
- structure objects having constructors or destructors
- structure objects having members from the points 1-5

Similar to classes, the union is capable of having constructors and destructors, as well as methods. By default, the union members are of public access type. In order to create private elements, use the private keyword. All these possibilities are displayed in the example illustrating how to convert a color of the color type to ARGB as does the ColorToARGB() function.

```
//+------------------------------------------------------------------+
//| Union for color(BGR) conversion to ARGB                          |
//+------------------------------------------------------------------+
union ARGB
  {
   uchar             argb[4];
   color             clr;
   //--- constructors
                     ARGB(color col,uchar a=0){Color(col,a);};
                    ~ARGB(){};
   //--- public methods
public:
   uchar   Alpha(){return(argb[3]);};
   void    Alpha(const uchar alpha){argb[3]=alpha;};
   color   Color(){ return(color(clr));};
   //--- private methods
private:
   //+------------------------------------------------------------------+
   //| set the alpha channel value and color                            |
   //+------------------------------------------------------------------+
   void    Color(color col,uchar alpha)
     {
      //--- set color to clr member
      clr=col;
      //--- set the Alpha component value - opacity level
      argb[3]=alpha;
      //--- interchange the bytes of R and B components (Red and Blue)
      uchar t=argb[0];argb[0]=argb[2];argb[2]=t;
     };
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- 0x55 means 55/255=21.6 % (0% - fully transparent)
```

```
   uchar alpha=0x55;
//--- color type is represented as 0x00BBGGRR
   color test_color=clrDarkOrange;
//--- values of bytes from the ARGB union are accepted here
   uchar argb[];
   PrintFormat("0x%.8X - here is how the 'color' type look like for %s, BGR=(%s)",
               test_color,ColorToString(test_color,true),ColorToString(test_color));
//--- ARGB type is represented as 0x00RRGGBB, RR and BB components are swapped
   ARGB argb_color(test_color);
//--- copy the bytes array
   ArrayCopy(argb,argb_color.argb);
//--- here is how it looks in ARGB representation
   PrintFormat("0x%.8X - ARGB representation with the alpha channel=0x%.2x, ARGB=(%d,%
               argb_color.clr,argb_color.Alpha(),argb[3],argb[2],argb[1],argb[0]);
//--- add opacity level
   argb_color.Alpha(alpha);
//--- try defining ARGB as 'color' type
   Print("ARGB as color=(",argb_color.clr,")  alpha channel=",argb_color.Alpha());
//--- copy the bytes array
   ArrayCopy(argb,argb_color.argb);
//--- here is how it looks in ARGB representation
   PrintFormat("0x%.8X - ARGB representation with the alpha channel=0x%.2x, ARGB=(%d,%
               argb_color.clr,argb_color.Alpha(),argb[3],argb[2],argb[1],argb[0]);
//--- check with the ColorToARGB() function results
   PrintFormat("0x%.8X - result of ColorToARGB(%s,0x%.2x)",ColorToARGB(test_color,alph
               ColorToString(test_color,true),alpha);
  }
/* Execution result
   0x00008CFF - here is how the color type looks for clrDarkOrange, BGR=(255,140,0)
   0x00FF8C00 - ARGB representation with the alpha channel=0x00, ARGB=(0,255,140,0)
   ARGB as color=(0,140,255)  alpha channel=85
   0x55FF8C00 - ARGB representation with the alpha channel=0x55, ARGB=(85,255,140,0)
   0x55FF8C00 - result of ColorToARGB(clrDarkOrange,0x55)
*/
```

Interfaces

An interface allows determining specific functionality, which a class can then implement. In fact, an interface is a class that cannot contain any members, and may not have a constructor and/or a destructor. All methods declared in an interface are purely virtual, even without an explicit definition.

An interface is defined using the "interface" keyword. Example:

```
//--- Basic interface for describing animals
interface IAnimal
  {
//--- The methods of the interface have public access by default
   void Sound();  // The sound produced by the animal
  };
```

```
//+------------------------------------------------------------------+
//|  The CCat class is inherited from the IAnimal interface          |
//+------------------------------------------------------------------+
class CCat : public IAnimal
  {
public:
                     CCat() { Print("Cat was born"); }
                    ~CCat() { Print("Cat is dead");  }
   //--- Implementing the Sound method of the IAnimal interface
   void Sound(){ Print("meou"); }
  };
//+------------------------------------------------------------------+
//|  The CDog class is inherited from the IAnimal interface          |
//+------------------------------------------------------------------+
class CDog : public IAnimal
  {
public:
                     CDog() { Print("Dog was born"); }
                    ~CDog() { Print("Dog is dead");  }
   //--- Implementing the Sound method of the IAnimal interface
   void Sound(){ Print("guaf"); }
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- An array of pointers to objects of the IAnimal type
   IAnimal *animals[2];
//--- Creating child classes of IAnimal and saving pointers to them into an array
   animals[0]=new CCat;
   animals[1]=new CDog;
//--- Calling the Sound() method of the basic IAnimal interface for each child
   for(int i=0;i<ArraySize(animals);++i)
      animals[i].Sound();
//--- Deleting objects
   for(int i=0;i<ArraySize(animals);++i)
      delete animals[i];
//--- Execution result
/*
   Cat was born
   Dog was born
   meou
   guaf
   Cat is dead
   Dog is dead
*/
  }
```

Like with abstract classes, an interface object cannot be created without inheritance. An interface can only be inherited from other interfaces and can be a parent for a class. An interface is always publicly visible.

An interface cannot be declared within a class or structure declaration, but a pointer to the interface can be saved in a variable of type void *. Generally speaking, a pointer to an object of any class can be saved into a variable of type void *. In order to convert a void * pointer to a pointer to an object of a particular class, use the dynamic_cast operator. If conversion is not possible, the result of the dynamic_cast operation will be NULL.

Dynamic Array Object

Dynamic Arrays

Maximum 4-dimension array can be declared. When declaring a dynamic array (an array of unspecified value in the first pair of square brackets), the compiler automatically creates a variable of the above structure (a dynamic array object) and provides a code for the correct initialization.

Dynamic arrays are automatically freed when going beyond the visibility area of the block they are declared in.

Example:

```
double matrix[][10][20]; // 3-dimensional dynamic array
ArrayResize(matrix,5);   // Set the size of the first dimension
```

Static Arrays

When all significant array dimensions are explicitly specified, the compiler pre-allocates the necessary memory size. Such an array is called static. Nevertheless, the compiler allocates additional memory for the object of a dynamic array, which (object) is associated with the pre-allocated static buffer (memory part for storing the array).

Creating a dynamic array object is due to the possible need to pass this static array as a parameter to some function.

Examples:

```
double stat_array[5]; // 1-dimensional static array
some_function(stat_array);
...
bool some_function(double& array[])
  {
   if(ArrayResize(array,100)<0) return(false);
   ...
   return(true);
  }
```

Arrays in Structures

When a static array is declared as a member of a structure, a dynamic array object is not created. This is done to ensure compatibility of data structures used in the Windows API.

However, static arrays that are declared as members of structures can also be passed to MQL5 functions. In this case, when passing the parameter, a temporary object of a dynamic array will be created. Such an object is linked with the static array - member of structure.

Matrices and vectors

Type vector is a special data type in MQL5, which enables operations with vectors. A vector is a one-dimensional array of type double. It is one of the fundamental concepts of linear algebra, which is used in many fields of science, including physics, geometry, and others. Vectors are used to solve systems of linear equations, in 3D graphics and in other application areas. Vectors can be added and multiplied. The length or distance between vectors can be obtained through the Norm. In programming, vectors are usually represented by arrays of homogeneous elements, which may have no regular vector operations, i.e. when arrays cannot be added or multiply, and they have no norm.

Vectors can be represented as row vectors and string vectors when working with matrices. Also, vectors in linear algebra use the concepts of covariance and contravariance. These concepts do not make any difference when writing an MQL5 code, as only the programmer decides what each object of the vector type is. For example, it can be rotation, displacement or compression vector in 3D graphics.

Generally speaking, from the point of view of linear algebra, a number is also a vector, but in a one-dimensional vector space. A vector itself can be considered as a special case of a matrix.

Type matrix is another special data type in MQL5 to represent matrices. A matrix is actually a two-dimensional array of type double. Vectors and matrices have been introduced into MQL5 for easier operations with certain types of data sets. With them, developers can benefit from the linear algebra possibilities in a simple and math-like form. Matrices can be used to compactly write systems of linear or differential equations. The number of matrix rows corresponds to the number of equations, while the the number of columns is equal to the number of unknowns. As a result, systems of linear equations can be solved through matrix operations.

The following data types exist:

- matrix — a matrix containing double elements.
- matrixf — a matrix containing float elements.
- matrixc — a matrix containing complex elements.
- vector — a vector containing double elements.
- vectorf — a vector containing float elements.
- vectorc — a vector containing complex elements.

Template functions support notations like matrix<double>, matrix<float>, vector<double>, vector<float> instead of the corresponding types.

The following algebraic operations are defined for the matrices:

- Addition of same-size matrices
- Multiplication of suitable-size matrices: the number of columns in the left matrix must equal the number of rows in the right matrix
- Matrix multiplication by a column vector; multiplication of a row vector by a matrix according to the matrix multiplication rule. In this sense the vector is a special case of a matrix
- Matrix multiplication by a number, that is, by a scalar

Mathematics considers many different matrix types. For example, identity matrix, symmetric, skew-symmetric, upper and lower triangular matrices, and other types. Various Normal forms play an important role in the matrix theory. They represent a certain canonical form of a matrix, which can be

obtained by means of certain transformations. In practice, normal forms that have additional properties, such as for example stability, are used.

The use of vectors and matrices, or rather, of special methods of the relevant types, enables the creation of simpler, briefer and clearer code, which is close to mathematical notation. With these methods, you can avoid the need to create nested loops or to mind correct indexing of arrays in calculations. Therefore, the use of these methods increases reliability and speed in developing complex programs.

List of matrix and vector methods

Types matrix and vector include methods that correspond to the relevant NumPy library methods. Using these methods, you can translate algorithms and codes from Python to MQL5 with minimum efforts. A lot of data processing tasks, mathematical equations, neural networks and machine learning tasks can be solved using ready-made Python methods and libraries.

Method matrix/vector	Analogous method in NumPy	Description
void matrix.Eye(const int rows, const int cols, const int ndiag=0)	eye	Construct a matrix with ones on the diagonal and zeros elsewhere
void matrix.Identity(const int rows)	identity	Construct a square matrix with ones on the main diagonal
void matrix.Ones(const int rows, const int cols)	ones	Construct a new matrix of given rows and columns, filled with ones
void matrix.Zeros(const int rows, const int cols)	zeros	Construct a new matrix of given rows and columns, filled with zeros
void matrix.Full(const int rows, const int cols, const scalar value)	full	Construct a new matrix of given rows and columns, filled with scalar value
void matrix.Copy(const matrix a)	copy	Construct a copy of the given matrix
void matrix.FromBuffer(const int rows, const int cols, const scalar array[], const int count=-1, const int offset=0)	frombuffer	Construct a matrix created from a 1-dimensional array
void matrix.FromFile(const int rows, condt int cols, const int file_handle, const int count=-1, const int offset=0)	fromfile	Construct a matrix from data in a text or binary file
void vector.FromString(const string source, const string sep=" ")	fromstring	Construct a vector initialized from text data in a string
void vector.Arange(const scalar start, const scalar stop, const scalar step=1)	arange	Construct evenly spaced values within a given interval

Method matrix/vector	Analogous method in NumPy	Description
void matrix.Diag(const vector v, const int ndiag=0)	diag	Extract a diagonal or construct a diagonal matrix
void matrix.Tri(const int rows, const int cols, const int ndiag=0)	tri	Construct a matrix with ones at and below the given diagonal and zeros elsewhere
void matrix.Tril(const int rows, const int cols, const scalar array[], const int ndiag=0)	tril	Return a copy of a matrix with elements above the k-th diagonal zeroed
void matrix.Triu(const int rows, const int cols, const scalar array[], const int ndiag=0)	triu	Return a copy of a matrix with the elements below the k-th diagonal zeroed
void matrix.Vander(const vector v, const int cols=-1, const bool increasing=false)	vander	Generate a Vandermonde matrix
vector matrix.Row(const unsigned nrow)		Return a row vector
vector matrix.Col(const unsigned ncol)		Return a column vector
unsigned matrix.Rows()		Return the number of rows in a matrix
unsigned matrix.Cols()		Return the number of columns in a matrix
void matrix.Init()		Initialize a matrix
matrix matrix.Transpose()	transpose	Reverse or permute the axes of a matrix; returns the modified matrix
matrix matrix.Dot(const matrix b)	dot	Dot product of two matrices
matrix matrix.Inner(const matrix b)	inner	Inner product of two matrices
matrix matrix.Outer(const matrix b)	outer	Compute the outer product of two matrices
matrix matrix.MatMul(const matrix b)	matmul	Matrix product of two matrices
matrix matrix.MatrixPower(const int power)	matrix_power	Raise a square matrix to the (integer) power n
matrix matrix.Kron(const matrix b)	kron	Return Kronecker product of two matrices
bool matrix.Cholesky(matrix& L)	cholesky	Return the Cholesky decomposition

Method matrix/vector	Analogous method in NumPy	Description
bool matrix.QR(matrix& Q, matrix& R)	qr	Compute the qr factorization of a matrix
bool matrix.SVD(matrix& U, matrix& V, vector& singular_values)	svd	Singular value decomposition
bool matrix.Eig(matrix& eigen_vectors, vector& eigen_values)	eig	Compute the eigenvalues and right eigenvectors of a square matrix
bool matrix.EigH(matrix& eigen_vectors, vector& eigen_values)	eigh	Return the eigenvalues and eigenvectors of a Hermitian matrix
bool matrix.EigVals(vector& eigen_values)	eigvals	Compute the eigenvalues of a general matrix
bool matrix.EigValsH(vector& eigen_values)	eigvalsh	Compute the eigenvalues of a Hermitian matrix
bool matrix.LU(matrix& L, matrix& U)		LU decomposition of a matrix as the product of a lower triangular matrix and an upper triangular matrix
bool matrix.LUP(matrix& L, matrix& U, matrix& P)		LUP decomposition with partial pivoting, which refers to LU decomposition with row permutations only: PA=LU
double matrix.Norm(const norm)	norm	Return matrix or vector norm
double matrix.Cond(const norm)	cond	Compute the condition number of a matrix
vector matrix.Spectrum()		Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A
double matrix.Det()	det	Compute the determinant of an array
int matrix.Rank()	matrix_rank	Return matrix rank of array using the Gaussian method
int matrix.SLogDet(int& sign)	slogdet	Compute the sign and logarithm of the determinant of an array
double matrix.Trace()	trace	Return the sum along diagonals of the matrix
vector matrix.Solve(const vector b)	solve	Solve a linear matrix equation, or system of linear algebraic equations

Method matrix/vector	Analogous method in NumPy	Description
vector matrix.LstSq(const vector b)	lstsq	Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices)
matrix matrix.Inv()	inv	Compute the (multiplicative) inverse of a matrix
matrix matrix.PInv()	pinv	Compute the pseudo-inverse of a matrix by the Moore-Penrose method
int matrix.Compare(const matrix matrix_c, const double epsilon) int matrix.Compare(const matrix matrix_c, const int digits) int vector.Compare(const vector vector_c, const double epsilon) int vector.Compare(const vector vector_c, const int digits)		Compare the elements of two matrices/vectors with the specified precision
double matrix.Flat(const ulong index) bool matrix.Flat(const ulong index,const double value)	flat	Allows addressing a matrix element through one index instead of two
double vector.ArgMax() double matrix.ArgMax() vector matrix.ArgMax(const int axis)	argmax	Return the index of the maximum value
double vector.ArgMin() double matrix.ArgMin() vector matrix.ArgMin(const int axis)	argmin	Return the index of the minimum value
double vector.Max() double matrix.Max() vector matrix.Max(const int axis)	max	Return the maximum value in a matrix/vector
double vector.Mean() double matrix.Mean() vector matrix.Mean(const int axis)	mean	Compute the arithmetic mean of element values
double vector.Min() double matrix.Min() vector matrix.Min(const int axis)	min	Return the minimum value in a matrix/vector
double vector.Sum() double matrix.Sum() vector matrix.Sum(const int axis)	sum	Return the sum of the matrix/vector elements which can also be performed for the given axis (axes).
void vector.Clip(const double min_value,const double max_value)	clip	Limit the elements of a matrix/vector to a specified range

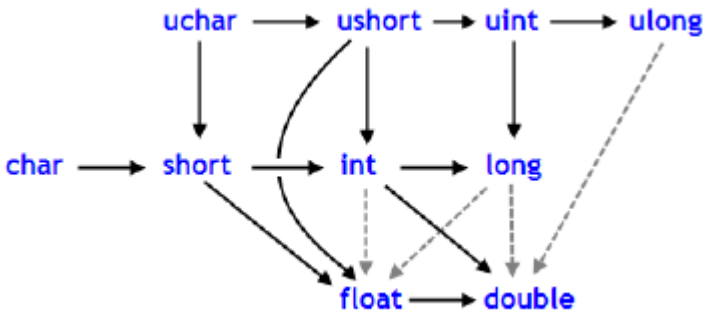
Method matrix/vector	Analogous method in NumPy	Description
void matrix.Clip(const double min_value,const double max_value)		of valid values
vector vector.CumProd() vector matrix.CumProd() matrix matrix.CumProd(const int axis)	cumprod	Return the cumulative product of matrix/vector elements, including those along the given axis
vector vector.CumSum() vector matrix.CumSum() matrix matrix.CumSum(const int axis)	cumsum	Return the cumulative sum of matrix/vector elements, including those along the given axis
double vector.Prod(const double initial=1) double matrix.Prod(const double initial=1) vector matrix.Prod(const int axis,const double initial=1)	prod	Return the product of the matrix/vector elements which can also be performed for the given axis
void matrix.Reshape(const ulong rows, const ulong cols)	reshape	Change the shape of a matrix without changing its data
void matrix.Resize(const ulong rows,const ulong cols)	resize	Return a new matrix with a changed shape and size
bool matrix.SwapRows(const ulong row1, const ulong row2)		Swap rows in a matrix
bool matrix.SwapCols(const ulong col1, const ulong col2)		Swap columns in a matrix
double vector.Ptp() double matrix.Ptp() vector matrix.Ptp(const int axis)	ptp	Return the range of values of a matrix/vector or of the given matrix axis, equivalent to Max() - Min()
double vector.Percentile(const int percent) double matrix.Percentile(const int percent) vector matrix.Percentile(const int percent,const int axis)	percentile	Return the specified percentile of values of matrix/vector elements or elements along the specified axis. Valid values of the 'percent' parameter are in the range [0, 100]
double vector.Quantile(const int percent) double matrix.Quantile(const int percent) vector matrix.Quantile(const int percent,const int axis)	quantile	Return the specified quantile of values of matrix/vector elements or elements along the specified axis. The 'percent' parameter takes values in the range [0, 1]
double vector.Median() double matrix.Median()	median	Compute the median of the matrix/vector elements. The

Method matrix/vector	Analogous method in NumPy	Description
vector matrix.Median(const int axis)		median is the middle value that separates the highest half of the array/vector elements from the lowest half of elements.
double vector.Average() double matrix.Average() vector matrix.Average(const int axis)	average	Compute the arithmetic mean of matrix/vector values. The sum of the weights in the denominator cannot be equal to 0, but some weights can be 0
double vector.Std() double matrix.Std() vector matrix.Std(const int axis)	std	Return the standard deviation of values of matrix/vector elements or of elements along the given axis
double vector.Var() double matrix.Var() vector matrix.Var(const int axis)	var	Compute the variance of values of matrix/vector elements
double vector.CorrCoef(const vector& v) matrix matrix.CorrCoef()	corrcoef	Compute the Pearson correlation coefficient (linear correlation coefficient). The correlation coefficient is in the range [-1, 1]
vector vector.Correlate(const vector& v,enum mode)	correlate	Compute the cross-correlation of two vectors. The 'mode' parameter determines the linear convolution calculation mode
vector vector.Convolve(const vector& v, enum mode)	convolve	Return the discrete, linear convolution of two vectors The 'mode' parameter determines the linear convolution calculation mode
matrix matrix.Cov() matrix vector.Cov(const vector& v); (resulting matrix 2 x 2)	cov	Compute the covariance matrix. The covariance of two samples (two random variables) is a measure of their linear dependence

Typecasting

Casting Numeric Types

Often a necessity occurs to convert one numeric type into another. Not all numeric types can be converted into another. Here is the scheme of allowed casting:



Solid lines with arrows indicate changes that are performed almost without any loss of information. Instead of the char type, the bool type can be used (both take 1 byte of memory), instead of type int, the color type can be used (4 bytes), instead of the long type, datetime can be used (take 8 bytes). The four dashed grey lines, also arrowed, denote conversions, when the loss of precision can occur. For example, the number of digits in an integer equal to 123456789 (int) is higher than the number of digits that can be represented by float.

```
   int n=123456789;
   float f=n;     // the content of f is equal to 1.234567892E8
   Print("n = ",n,"   f = ",f);
   // result n= 123456789    f= 123456792.00000
```

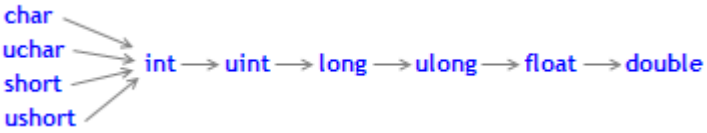
A number converted into float has the same order, but is less accurate. Conversions, contrary to black arrows, can be performed with possible data loss. Conversions between char and uchar, short and ushort, int and uint, long and ulong (conversions to both sides), may lead to the loss of data.

As a result of converting floating point values to integer type, the fractional part is always deleted. If you want to round off a float to the nearest whole number (which in many cases is more useful), you should use MathRound().

Example:

```
//--- Gravitational acceleration
   double g=9.8;
   double round_g=(int)g;
   double math_round_g=MathRound(g);
   Print("round_g = ",round_g);
   Print("math_round_g = ",math_round_g);
/*
   Result:
   round_g = 9
   math_round_g = 10
*/
```

If two values are combined by a binary operator, before the operation execution the operand of a lower type is converted to the higher type in accordance with the priority given in the below scheme:



The data types char, uchar, short, and ushort unconditionally are converted to the int type.

Examples:

```
   char   c1=3;
//--- First example
   double d2=c1/2+0.3;
   Print("c1/2 + 0.3 = ",d2);
// Result:   c1/2+0.3 = 1.3

//--- Second example
   d2=c1/2.0+0.3;
   Print("c1/2.0 + 0.3 = ",d2);
// Result:   c1/2.0+0.3 = 1.8
```

The calculated expression consists of two operations. In the first example, the variable c1 of the char type is converted to a temporary variable of the int type, because the second operand in the division operation, the constant 2, is of the higher type int. As a result of the integer division 3/2 we get the value 1, which is of the int type.

In the second operation of the first example, the second operand is the constant 0.3, which is of the double type, so the result of the first operation is converted into a temporary variable of the double type with a value of 1.0.

In the second example the variable of the char type c1 is converted to a temporary variable of the double type, because the second operand in the division operation, the constant 2.0, is of the double type; no further conversions are made.

Typecasting of Numeric Types

In the expressions of the MQL5 language both explicit and implicit typecasting can be used. The explicit typecasting is written as follows:

```
var_1 = (type)var_2;
```

An expression or function execution result can be used as the var_2 variable. The function style notation of the explicit typecasting is also possible:

```
var_1 = type(var_2);
```

Let's consider an explicit typecasting on the basis of the first example.

```
//--- Third example
   double d2=(double)c1/2+0.3;
```

```
   Print("(double)c1/2 + 0.3 = ",d2);
// Result:   (double)c1/2+0.3 = 1.80000000
```

Before the division operation is performed, the c1 variable is explicitly cast to the double type. Now the integer constant 2 is cast to the value 2.0 of the double type, because as a result of converting the first operand has taken the double type. In fact, the explicit typecasting is a unary operation.

Besides, when trying to cast types, the result may go beyond the permissible range. In this case, the truncation occurs. For example:

```
   char c;
   uchar u;
   c=400;
   u=400;
   Print("c = ",c); // Result c=-112
   Print("u = ",u); // Result u=144
```

Before operations (except for the assignment ones) are performed, the data are converted into the maximum priority type. Before assignment operations are performed, the data are cast into the target type.

Examples:

```
   int    i=1/2;         // no types casting, the result is 0
   Print("i = 1/2  ",i);

   int k=1/2.0;          // the expression is cast to the double type,
   Print("k = 1/2  ",k);  // then is to the target type of int, the result is 0

   double d=1.0/2.0;     // no types casting, the result is 0.5
   Print("d = 1/2.0; ",d);

   double e=1/2.0;       // the expression is cast to the double type,
   Print("e = 1/2.0; ",e);// that is the same as the target type, the result is 0.5

   double x=1/2;         // the expression of the int type is cast to the double target
   Print("x = 1/2; ",x);  // the result is 0.0
```

When converting long/ulong type into double, precision may be lost in case the integer value is greater than 9223372036854774784 or less than -9223372036854774784.

```
void OnStart()
  {
   long l_max=LONG_MAX;
   long l_min=LONG_MIN+1;
//--- define the highest integer value, which does not lose accuracy when being cast t
   while(l_max!=long((double)l_max))
      l_max--;
//--- define the lowest integer value, which does not lose accuracy when being cast to
   while(l_min!=long((double)l_min))
      l_min++;
//--- derive the found interval for integer values
```

```
   PrintFormat("When casting an integer value to double, it must be "
               "within [%I64d, %I64d] interval",l_min,l_max);
//--- now, let's see what happens if the value falls out of this interval
   PrintFormat("l_max+1=%I64d, double(l_max+1)=%.f, ulong(double(l_max+1))=%I64d",
               l_max+1,double(l_max+1),long(double(l_max+1)));
   PrintFormat("l_min-1=%I64d, double(l_min-1)=%.f, ulong(double(l_min-1))=%I64d",
               l_min-1,double(l_min-1),long(double(l_min-1)));
//--- receive the following result
// When casting an integer value to double, it should be within [-9223372036854774784,
// l_max+1=9223372036854774785, double(l_max+1)=9223372036854774800, ulong(double(l_ma
// l_min-1=-9223372036854774785, double(l_min-1)=-9223372036854774800, ulong(double(l_
  }
```

Typecasting for the String Type

The string type has the highest priority among simple types. Therefore, if one of operands of an operation is of the string type, the second operand will be cast to a string automatically. Note that for a string, a single dyadic two-place operation of addition is possible. The explicit casting of string to any numeric type is allowed.

Examples:

```
   string s1=1.0/8;            // the expression is cast to the double type,
   Print("s1 = 1.0/8; ",s1);     //  then is to the target type of string,
// result is "0.12500000" (a string containing 10 characters)

   string s2=NULL;             // string deinitialization
   Print("s2 = NULL; ",s2);      // the result is an empty string
   string s3="Ticket N"+12345; // the expression is cast to the string type
   Print("s3 = \"Ticket N\"+12345",s3);

   string str1="true";
   string str2="0,255,0";
   string str3="2009.06.01";
   string str4="1.2345e2";
   Print(bool(str1));
   Print(color(str2));
   Print(datetime(str3));
   Print(double(str4));
```

Typecasting of Base Class Pointers to Pointers of Derivative Classes

Objects of the open generated class can also be viewed as objects of the corresponding base class. This leads to some interesting consequences. For example, despite the fact that objects of different classes, generated by a single base class, may differ significantly from each other, we can create a

linked list (List) of them, as we view them as objects of the base type. But the converse is not true: the base class objects are not automatically objects of a derived class.

You can use the explicit casting to convert the base class pointers to the pointers of a derived class. But you must be fully confident in the admissibility of such a transformation, because otherwise a critical runtime error will occur and the mql5 program will be stopped.

Dynamic typecasting using dynamic_cast operator

Dynamic typecasting is performed using dynamic_cast operator that can be applied only to pointers to classes. Type validation is performed at runtime. This means that the compiler does not check the data type applied for typecasting when dynamic_cast operator is used. If a pointer is converted to a data type which is not the actual type of an object, the result is NULL.

```
dynamic_cast <type-id> ( expression )
```

The *type-id* parameter in angle brackets should point to a previously defined class type. Unlike C++, *expression* operand type can be of any value except for void.

Example:

```
class CBar { };
class CFoo : public CBar { };

void OnStart()
  {
   CBar bar;
//--- dynamic casting of *bar pointer type to *foo pointer is allowed
   CFoo *foo = dynamic_cast<CFoo *>(&bar); // no critical error
   Print(foo);                             // foo=NULL
//--- an attempt to explicitly cast a Bar type object reference to a Foo type object
   foo=(CFoo *)&bar;                       // critical runtime error
   Print(foo);                             // this string is not executed
  }
```

Data Types

Void Type and NULL Constant

Syntactically the void type is a fundamental type along with types of char, uchar, bool, short, ushort, int, uint, color, long, ulong, datetime, float, double and string. This type is used either to indicate that the function does not return any value, or as a function parameter it denotes the absence of parameters.

The predefined constant variable **NULL** is of the *void* type. It can be assigned to variables of any other fundamental types without conversion. The comparison of fundamental type variables with the **NULL** value is allowed.

Example:

```
//--- If the string is not initialized, then assign our predefined value to it
if(some_string==NULL) some_string="empty";
```

Also **NULL** can be compared to pointers to objects created with the new operator.

Variables, Functions

User-defined types

The typedef keyword in C++ allows creating user-defined data types. To do this, simply specify a new data type name for an already existing data type. The new data type is not created. A new name for the existing type is defined instead. User-defined types make applications more flexible: sometimes, it is enough to change typedef instructions using substitution macros (#define). User-defined types also improve code readability since it is possible to apply custom names to standard data types using typedef. The general format of the entry for creating a user-defined type:

```
   typedef type new_name;
```

Here, *type* means any acceptable data type, while *new_name* is a new name of the type. A new name is set only as an addition (not as a replacement) to an existing type name. MQL5 allows creating pointers to functions using typedef.

Pointer to the function

A pointer to a function is generally defined in the following format

```
   typedef function_result_type (*Function_name_type)(list_of_input_parameters_types);
```

where after typedef, the function signature (number and type of input parameters, as well as a type of a result returned by the function) is set. Below is a simple example of creating and applying a pointer to a function:

```
//--- declare a pointer to a function that accepts two int parameters
   typedef int (*TFunc)(int,int);
//--- TFunc is a type, and it is possible to declare the variable pointer to the funct
   TFunc func_ptr; // pointer to the function
//--- declare the functions corresponding to the TFunc description
   int sub(int x,int y) { return(x-y); }  // subtract one number from another
   int add(int x,int y) { return(x+y); }  // addition of two numbers
   int neg(int x)       { return(~x);  }  // invert bits in the variable
//--- the func_ptr variable may store the function address to declare it later
   func_ptr=sub;
   Print(func_ptr(10,5));
   func_ptr=add;
   Print(func_ptr(10,5));
   func_ptr=neg;           // error: neg does not have int (int,int) type
   Print(func_ptr(10));    // error: two parameters needed
```

In this example, the *func_ptr* variable may receive the *sub* and *add* functions since they have two inputs each of int type as defined in the *TFunc* pointer to the function. On the contrary, the *neg* function cannot be assigned to the func_ptr pointer since its signature is different.

Arranging event models in the user interface

Pointers to functions allow you to easily create processing of events when creating a user interface. Let's use an example from the CButton section to show how to create buttons and add the functions for handling pressing to them. First, define a pointer to the *TAction* function to be called by pressing the button and create three functions according to the *TAction description*.

```
//--- create a custom function type
typedef int(*TAction)(string,int);
//+------------------------------------------------------------------+
//|  Open the file                                                   |
//+------------------------------------------------------------------+
int Open(string name,int id)
  {
   PrintFormat("%s function called (name=%s id=%d)",__FUNCTION__,name,id);
   return(1);
  }
//+------------------------------------------------------------------+
//|  Save the file                                                   |
//+------------------------------------------------------------------+
int Save(string name,int id)
  {
   PrintFormat("%s function called (name=%s id=%d)",__FUNCTION__,name,id);
   return(2);
  }
//+------------------------------------------------------------------+
//|  Close the file                                                  |
//+------------------------------------------------------------------+
int Close(string name,int id)
  {
   PrintFormat("%s function called (name=%s id=%d)",__FUNCTION__,name,id);
   return(3);
  }
```

Then, create the MyButton class from CButton, where we should add the *TAction* pointer to the function.

```
//+------------------------------------------------------------------+
//| Create the button class with the events processing function      |
//+------------------------------------------------------------------+
class MyButton: public CButton
  {
private:
   TAction           m_action;                    // chart events handler
public:
                     MyButton(void){}
                    ~MyButton(void){}
   //--- constructor specifying the button text and the pointer to the events handlin
                     MyButton(string text, TAction act)
     {
      Text(text);
      m_action=act;
     }
   //--- set the custom function called from the OnEvent() events handler
   void              SetAction(TAction act){m_action=act;}
```

```
   //--- standard chart events handler
   virtual bool      OnEvent(const int id,const long &lparam,const double &dparam,cons
     {
      if(m_action!=NULL && lparam==Id())
        {
         //--- call the custom m_action() handler
         m_action(sparam,(int)lparam);
         return(true);
        }
      else
      //--- return the result of calling the handler from the CButton parent class
         return(CButton::OnEvent(id,lparam,dparam,sparam));
     }
  };
```

Create the CControlsDialog derivative class from CAppDialog, add the *m_buttons* array to it for storing the buttons of the *MyButton* type, as well as the *AddButton(MyButton &button)* and *CreateButtons()* methods.

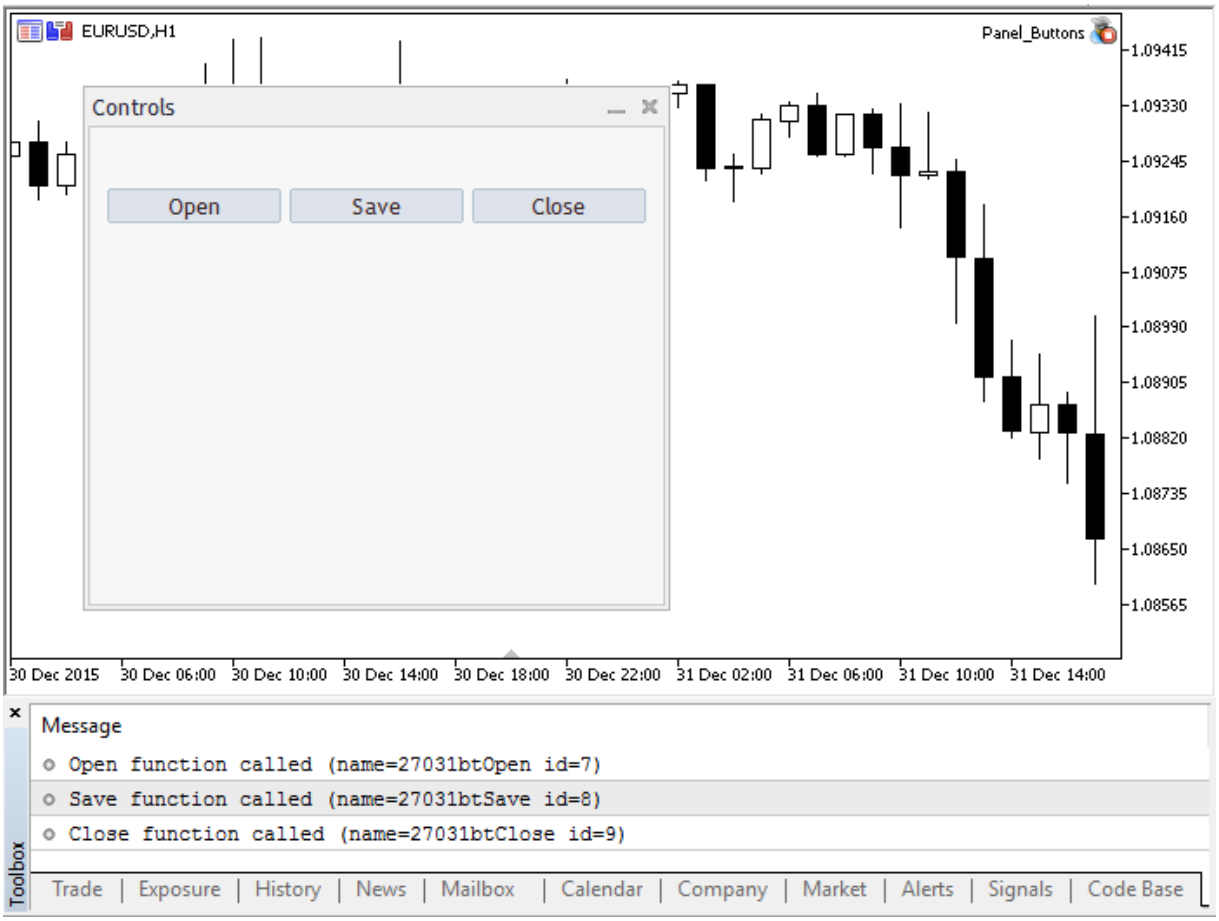
```
//+------------------------------------------------------------------+
//| CControlsDialog class                                            |
//| Objective: graphical panel for managing the application          |
//+------------------------------------------------------------------+
class CControlsDialog : public CAppDialog
  {
private:
   CArrayObj         m_buttons;                    // button array
public:
                     CControlsDialog(void){};
                    ~CControlsDialog(void){};
   //--- create
   virtual bool      Create(const long chart,const string name,const int subwin,const
   //--- add the button
   bool              AddButton(MyButton &button){return(m_buttons.Add(GetPointer(butto
protected:
   //--- create the buttons
   bool              CreateButtons(void);
  };
//+------------------------------------------------------------------+
//| Create the CControlsDialog object on the chart                   |
//+------------------------------------------------------------------+
bool CControlsDialog::Create(const long chart,const string name,const int subwin,const
  {
   if(!CAppDialog::Create(chart,name,subwin,x1,y1,x2,y2))
      return(false);
   return(CreateButtons());
//---
  }
//+------------------------------------------------------------------+
```

```
//| defines                                                          |
//+------------------------------------------------------------------+
//--- indents and gaps
#define INDENT_LEFT                         (11)      // indent from left (with allowa
#define INDENT_TOP                          (11)      // indent from top (with allowar
#define CONTROLS_GAP_X                      (5)       // gap by X coordinate
#define CONTROLS_GAP_Y                      (5)       // gap by Y coordinate
//--- for buttons
#define BUTTON_WIDTH                        (100)     // size by X coordinate
#define BUTTON_HEIGHT                       (20)      // size by Y coordinate
//--- for the indication area
#define EDIT_HEIGHT                         (20)      // size by Y coordinate
//+------------------------------------------------------------------+
//| Create and add buttons to the CControlsDialog panel              |
//+------------------------------------------------------------------+
bool CControlsDialog::CreateButtons(void)
  {
//--- calculate buttons coordinates
   int x1=INDENT_LEFT;
   int y1=INDENT_TOP+(EDIT_HEIGHT+CONTROLS_GAP_Y);
   int x2;
   int y2=y1+BUTTON_HEIGHT;
//--- add buttons objects together with pointers to functions
   AddButton(new MyButton("Open",Open));
   AddButton(new MyButton("Save",Save));
   AddButton(new MyButton("Close",Close));
//--- create the buttons graphically
   for(int i=0;i<m_buttons.Total();i++)
     {
      MyButton *b=(MyButton*)m_buttons.At(i);
      x1=INDENT_LEFT+i*(BUTTON_WIDTH+CONTROLS_GAP_X);
      x2=x1+BUTTON_WIDTH;
      if(!b.Create(m_chart_id,m_name+"bt"+b.Text(),m_subwin,x1,y1,x2,y2))
        {
         PrintFormat("Failed to create button %s %d",b.Text(),i);
         return(false);
        }
      //--- add each button to the CControlsDialog container
      if(!Add(b))
         return(false);
     }
//--- succeed
   return(true);
  }
```

Now, we can develop the program using the CControlsDialog control panel having 3 buttons: Open, Save and Close. When clicking a button, the appropriate function in the form of the *TAction* pointer is called.

```
//--- declare the object on the global level to automatically create it when launchinc
CControlsDialog MyDialog;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- now, create the object on the chart
   if(!MyDialog.Create(0,"Controls",0,40,40,380,344))
      return(INIT_FAILED);
//--- launch the application
   MyDialog.Run();
//--- application successfully initialized
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- destroy dialog
   MyDialog.Destroy(reason);
  }
//+------------------------------------------------------------------+
//| Expert chart event function                                      |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,         // event ID
                  const long& lparam,   // event parameter of the long type
                  const double& dparam, // event parameter of the double type
                  const string& sparam) // event parameter of the string type
  {
//--- call the handler from the parent class (here it is CAppDialog) for the chart eve
   MyDialog.ChartEvent(id,lparam,dparam,sparam);
  }
```

The launched application's appearance and button clicking results are provided on the screenshot.



The full source code of the program

Variables, Functions

Object Pointers

MQL5 enables the dynamic creation of complex type objects. This is done by using the 'new' operatorwhich returns a descriptor of the created object. The descriptor size is 8 bytes. Syntactically, object descriptors in MQL5 are similar to C++ pointers.

Example:

```
MyObject* hobject= new MyObject();
```

Unlike C++, the 'hobject' variable from the example above is not a pointer to memory, but is an object descriptor. Furthermore, in MQL5, all objects in function parameters must be passed by reference. The examples below show the passing of objects as function parameters:

```
class Foo
  {
public:
   string            m_name;
   int               m_id;
   static int        s_counter;
   //--- constructors and destructors
                     Foo(void){Setup("noname");};
                     Foo(string name){Setup(name);};
                    ~Foo(void){};
   //--- initialize the Foo object
   void              Setup(string name)
     {
      m_name=name;
      s_counter++;
      m_id=s_counter;
     }
  };
int Foo::s_counter=0;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the object as a variable, with automatic creation
   Foo foo1;
//--- variant of passing an object by reference
   PrintObject(foo1);

//--- declare a pointer to an object and create it using the 'new' operator
   Foo *foo2=new Foo("foo2");
//--- variant of passing a pointer to an object by reference
   PrintObject(foo2); // the pointer to the object is converted by the compiler automa

//--- declare an array of Foo objects
   Foo foo_objects[5];
```

```
//--- variant of passing an array of objects
   PrintObjectsArray(foo_objects); // a separate function for passing an array of obje

//--- declare an array of pointers to objects of type Foo
   Foo *foo_pointers[5];
   for(int i=0;i<5;i++)
      foo_pointers[i]=new Foo("foo_pointer");
//--- variant of passing an array of pointers
   PrintPointersArray(foo_pointers); // a separate function for passing an array of po

//--- before finishing, be sure to delete the objects created as pointers
   delete(foo2);
//--- remove the array of pointers
   int size=ArraySize(foo_pointers);
   for(int i=0;i<5;i++)
      delete(foo_pointers[i]);
//---
  }
//+------------------------------------------------------------------+
//|  Objects are always passed by reference                          |
//+------------------------------------------------------------------+
void PrintObject(Foo &object)
  {
   Print(__FUNCTION__,": ",object.m_id," Object name=",object.m_name);
  }
//+------------------------------------------------------------------+
//| Pass an array of objects                                         |
//+------------------------------------------------------------------+
void PrintObjectsArray(Foo &objects[])
  {
   int size=ArraySize(objects);
   for(int i=0;i<size;i++)
      PrintObject(objects[i]);
  }
//+------------------------------------------------------------------+
//| Pass an array of object pointers                                 |
//+------------------------------------------------------------------+
void PrintPointersArray(Foo* &objects[])
  {
   int size=ArraySize(objects);
   for(int i=0;i<size;i++)
      PrintObject(objects[i]);
  }
//+------------------------------------------------------------------+
```

Check the pointer before use

An attempt to access an invalid pointer causes the critical shutdown of the program. The CheckPointer function is utilized to check a pointer before use. The pointer can be invalid in the following cases:

- the pointer is equal to NULL;
- the object was destroyed using the delete operator.

This function can be used to validate of a pointer. A non-zero value indicates that data can be accessed at this pointer.

```
class CMyObject
 {
protected:
  double             m_value;
public:
                     CMyObject(void);
                     CMyObject(double value) {m_value=value;};
                    ~CMyObject(void){};
  //---
  double             Value(void) {return(m_value);}
 };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- create a non-initialized object
  CMyObject *pointer;
  if(CheckPointer(pointer)==POINTER_INVALID)
    Print("1. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("1. pointer.Value()=", pointer.Value());

//--- initialize the pointer
  pointer=new CMyObject(M_PI);
  if(CheckPointer(pointer)==POINTER_INVALID)
    Print("2. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("2. pointer.Value()=", pointer.Value());

//--- delete the object
  delete(pointer);
  if(CheckPointer(pointer)==POINTER_INVALID)
    Print("3. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("3. pointer.Value()=", pointer.Value());
 }
/*
   1. pointer is POINTER_INVALID
   2. pointer.Value()=3.141592653589793
   3. pointer is POINTER_INVALID
```

```
*/
```

To quickly validate the pointer, you can also use operator "!" (LNOT) which checks it via an implicit call of the CheckPointer function. This allows a more concise and clear code writing. Below are the checks from the previous example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- create a non-initialized object
  CMyObject *pointer;
  if(!pointer)
    Print("1. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("1. pointer.Value()=", pointer.Value());

//--- initialize the pointer
  pointer=new CMyObject(M_PI);
  if(!pointer)
    Print("2. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("2. pointer.Value()=", pointer.Value());

//--- delete the object
  delete(pointer);
  if(!pointer)
    Print("3. pointer is ", EnumToString(CheckPointer(pointer)));
  else
    Print("3. pointer.Value()=", pointer.Value());
 }
/*
   1. pointer is POINTER_INVALID
   2. pointer.Value()=3.141592653589793
   3. pointer is POINTER_INVALID
*/
```

Operator "==" is used for a quick check for NULL. For example: ptr==NULL or ptr!=NULL.

Passing Parameters by Reference

In MQL5 parameters of simple types can be passed both by value and by reference, while parameters of compound types are always passed by reference. To inform the compiler that a parameter must be passed by reference, the ampersand character **&** is added before the parameter name.

Passing a parameter by reference means passing the address of the variable, that's why all changes in the parameter that is passed by reference will be immediately reflected in the source variable. Using parameter passing by reference, you can implement return of several results of a function at the same time. In order to prevent changing of a parameter passed by reference, use the const modifier.

Thus, if the input parameter of a function is an array, a structure or class object, symbol '&' is placed in the function header after the variable type and before its name.

Example

```
class CDemoClass
  {
private:
   double            m_array[];

public:
   void              setArray(double &array[]);
  };
//+------------------------------------------------------------------+
//| filling the array                                                |
//+------------------------------------------------------------------+
void  CDemoClass::setArray(double &array[])
  {
   if(ArraySize(array)>0)
     {
     ArrayResize(m_array,ArraySize(array));
     ArrayCopy(m_array, array);
     }
  }
```

In the above example class CDemoClass is declared, which contains the private member - array m_array[] of double type. Function setArray() is declared, to which array[] is passed by reference. If the function header doesn't contain the indication about passing by reference, i.e. doesn't contain the ampersand character, an error message will be generated at the attempt to compile such a code.

Despite the fact that the array is passed by reference, we can't assign one array to another. We need to perform the element-wise copying of contents of the source array to the recipient array. The presence of & in the function description is the obligatory condition for arrays and structures when passed as the function parameter.

Keyword this

A variable of class type (object) can be passed both by reference and by pointer. As well as reference, the pointer allows having access to an object. After the object pointer is declared, the new operator should be applied to it to create and initialize it.

The reserved word **this** is intended for obtaining the reference of the object to itself, which is available inside class or structure methods. **this** always references to the object, in the method of which it is used, and the expression GetPointer(this) gives the pointer of the object, whose member is the function, in which call of GetPointer() is performed. In MQL5 functions can't return objects, but they can return the object pointer.

Thus, if we need a function to return an object, we can return the pointer of this object in the form of GetPointer(this). Let's add function getDemoClass() that returns pointer of the object of this class, into the description of CDemoClass.

```
class CDemoClass
  {
private:
   double            m_array[];

public:
   void              setArray(double &array[]);
   CDemoClass       *getDemoClass();
  };
//+------------------------------------------------------------------+
//| filling the array                                                |
//+------------------------------------------------------------------+
void  CDemoClass::setArray(double &array[])
  {
   if(ArraySize(array)>0)
     {
      ArrayResize(m_array,ArraySize(array));
      ArrayCopy(m_array,array);
     }
  }
//+------------------------------------------------------------------+
//| returns its own pointer                                          |
//+------------------------------------------------------------------+
CDemoClass *CDemoClass::getDemoClass(void)
  {
   return(GetPointer(this));
  }
```

Structures don't have pointers, operators *new* and *delete* can't be applied to them, GetPointer(this) can't be used.

Operations and Expressions

Some characters and character sequences are of a special importance. These are so-called operation symbols, for example:

```
+ - * / %      Symbols of arithmetic operations
&& ||          Symbols of logical operations
= += *=        Characters assignment operators
```

Operation symbols are used in expressions and have sense when appropriate operands are given to them. Punctuation marks are emphasized, as well. These are parentheses, braces, comma, colon, and semicolon.

Operation symbols, punctuation marks, and spaces are used to separate language elements from each other.

This section contains the description of the following topics:

- Expressions
- Arithmetic Operations
- Assignment Operations
- Operations of Relation
- Boolean Operations
- Bitwise Operations
- Other Operations
- Priorities and Operations Order

Expressions

An expression consists of one or more operands and operation symbols. An expression can be written in several lines.

Examples:

```
a++; b = 10;          // several expressions are located in one line
//---  one expression is divided into several lines
x = (y * z) /
    (w + 2) + 127;
```

An expression that ends with a semicolon (;) is an operator.

See also

Precedence Rules

Arithmetic Operations

Arithmetic operations include additive and multiplicative operations:

```
Sum of variables                          i = j + 2;
Difference of variables                   i = j - 3;
Changing the sign                         x = - x;
Product of variables                      z = 3 * x;
Division quotient                         i = j / 5;
Remainder of division                     minutes = time % 60;
Adding 1 to the variable value            i++;
Adding 1 to the variable value            ++i;
Subtracting 1 from the variable value     k--;
Subtracting 1 from the variable value     --k;
```

Increment and decrement operations are applied only to variables, they can't be applied to constants. The prefix increment (++i) and decrement (--k) are applied to the variable right before this variable is used in an expression.

Post-increment (i++) and post-decrement (k--) are applied to the variable right after this variable is used in an expression.

Important Notice

```
int i=5;
int k = i++ + ++i;
```

Computational problems may occur while moving the above expression from one programming environment to another one (for example, from Borland C++ to MQL5). In general, the order of computations depends on the compiler implementation. In practice, there are two ways to implement the post-decrement (post-increment):

1. The post-decrement (post-increment) is applied to the variable after calculating the whole expression.
2. The post-decrement (post-increment) is applied to the variable immediately at the operation.

Currently the first way of post-decrement (post-increment) calculation is implemented in MQL5. But even knowing this peculiarity, it is not recommended to experiment with its use.

Examples:

```
int a=3;
a++;             // valid expression
int b=(a++)*3;   // invalid expression
```

See also

Precedence Rules

Assignment Operations

The value of the expression that includes the given operation is the value of the left operand after assignment:

```
Assigning the value of x to the y variable                    y = x;
```

The following operations unite arithmetic or bitwise operations with operation of assignment:

```
Adding x to the y variable                                    y += x;
Subtracting x from the y variable                             y -= x;
Multiplying the y variable by x                               y *= x;
Dividing the y variable by x                                  y /= x;
Reminder of division of the y variable by x                   y %= x;
Shift of the binary representation of y to the right by x bits    y >>= x;
Shift of the binary representation of y to the left by x bits     y <<= x;
AND bitwise operation of binary representations of y and x     y &= x;
OR bitwise operation of binary representations of y and x      y |= x;
Excluding OR bitwise operation of binary representations of y and x    y ^= x;
```

Bitwise operations can be applied to integers only. When performing the operation of the logical shift of the y representation to the right/left by x bits, the 5 smallest binary digits of the x value are used, the highest ones are dropped, i.e. the shift is made to 0-31 bits.

By %= operation (y value by module of x), the result sign is equal to the sign of divided number.

The assignment operator can be used several times in an expression . In this case the processing of the expression is performed from left to right:

```
y=x=3;
```

First, the variable x will be assigned the value 3, then the y variable will be assigned the value of x, i.e. also 3.

See also

Precedence Rules

Operations of Relation

Boolean FALSE is represented with an integer zero value, while the boolean TRUE is represented by any non-zero value.

The value of expressions containing operations of relation or logical operations is FALSE (0) or TRUE (1).

```
True if a is equal to b                    a == b;
True if a is not equal to b                a != b;
True if a is less than b                   a < b;
True if a is greater than b                a > b;
True if a is less than or equal to b       a <= b;
True if a is greater than or equal to b    a >= b;
```

The equality of two real numbers can't be compared. In most cases, two seemingly identical numbers can be unequal because of different values in the 15th decimal place. In order to correctly compare two real numbers, compare the normalized difference of these numbers with zero.

Example:

```
bool CompareDoubles(double number1,double number2)
  {
   if(NormalizeDouble(number1-number2,8)==0) return(true);
   else return(false);
  }
void OnStart()
  {
   double first=0.3;
   double second=3.0;
   double third=second-2.7;
   if(first!=third)
     {
      if(CompareDoubles(first,third))
         printf("%.16f and %.16f are equal",first,third);
     }
  }
// Result: 0.3000000000000000  0.2999999999999998   are equal
```

See also

Precedence Rules

Boolean Operations

Logical Negation NOT (!)

Operand of the logical negation (!) must be of arithmetic type. The result is TRUE (1), if the operand value is FALSE (0); and it is equal to FALSE (0), if the operand differs from FALSE (0).

```
if(!a) Print("not 'a'");
```

Logical Operation OR (||)

Logical OR operation (||) of x and y values. The expression value is TRUE (1), if x or y value is true (not null). Otherwise - FALSE (0).

```
if(x<0 || x>=max_bars) Print("out of range");
```

Logical Operation AND (&&)

Logical operation AND (&&) of x and y values. The expression value is TRUE (1), if the values of x and y are true (not null). Otherwise - FALSE (0).

Brief Estimate of Boolean Operations

The scheme of the so called "brief estimate" is applied to boolean operations, i.e. the calculation of the expression is terminated when the result of the expression can be precisely estimated.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- the first example of the brief estimate
   if(func_false() && func_true())
     {
      Print("Operation &&: You will never see this expression");
     }
   else
     {
      Print("Operation &&: Result of the first expression is false, so the second wasn
     }
//--- the second example of the brief estimate
   if(!func_false() || !func_true())
     {
      Print("Operation ||: Result of the first expression is true, so the second wasn'
     }
   else
     {
      Print("Operation ||: You will never see this expression");
     }
  }
//+------------------------------------------------------------------+
```

```
//| the function always returns false                                |
//+------------------------------------------------------------------+
bool func_false()
  {
   Print("Function func_false()");
   return(false);
  }
//+------------------------------------------------------------------+
//| the function always returns true                                 |
//+------------------------------------------------------------------+
bool func_true()
  {
   Print("Function func_true()");
   return(true);
  }
```

See also

Precedence Rules

Bitwise Operations

Complement to One

Complement of the variable value up to one. The value of the expression contains 1 in all digits where the variable value contains 0, and 0 in all digits where the variable contains 1.

```
b = ~n;
```

Example:

```
   char a='a',b;
   b=~a;
   Print("a = ",a, "  b = ",b);
// The result will be:
// a = 97   b = -98
```

Right Shift

The binary representation of x is shifted to the right by y digits. If the value to shift is of the unsigned type, the logical right shift is made, i.e. the freed left-side bits will be filled with zeroes.

If the value to shift is of a sign type, the arithmetic right shift is made, i.e. the freed left-side digits will be filled with the value of a sign bit (if the number is positive, the value of the sign bit is 0; if the number is negative, the value of the sign bit is 1).

```
x = x >> y;
```

Example:

```
   char a='a',b='b';
   Print("Before:  a = ",a, "  b = ",b);
//--- shift to the right
   b=a>>1;
   Print("After:   a = ",a, "  b = ",b);
// The result will be:
// Before:  a = 97   b = 98
// After:   a = 97   b = 48
```

Left Shift

The binary representation of x is shifted to the left by y digits, the freed right-side digits are filled with zeros.

```
x = x << y;
```

Example:

```
   char a='a',b='b';
   Print("Before:  a = ",a, "  b = ",b);
//--- shift to the left
   b=a<<1;
   Print("After:   a = ",a, "  b = ",b);
```

```
// The result will be:
// Before:  a = 97   b = 98
// After:   a = 97   b = -62
```

It is not recommended to shift by the number of bits larger or equal to the length of the variable shifted, because the result of such an operation is undefined.

Bitwise AND Operation

The bitwise AND operation of binary-coded x and y representations. The value of the expression contains a 1 (TRUE) in all digits where both x and y contain non-zero, and it contains 0 (FALSE) in all other digits.

```
b = ((x & y) != 0);
```

Example:

```
   char a='a',b='b';
//--- AND operation
   char c=a&b;
   Print("a = ",a,"  b = ",b);
   Print("a & b = ",c);
// The result will be:
// a = 97   b = 98
// a & b = 96
```

Bitwise OR Operation

The bitwise OR operation of binary representations of x and y. The value of the expression contains 1 in all digits where x or y does not contain 0, and it contains 0 in all other digits.

```
b = x | y;
```

Example:

```
   char a='a',b='b';
//--- OR operation
   char c=a|b;
   Print("a = ",a,"  b = ",b);
   Print("a | b = ",c);
// The result will be:
// a = 97   b = 98
// a | b = 99
```

Bitwise Exclusive Operation OR

The bitwise exclusive OR (eXclusive OR) operation of binary representations of x and y. The value of the expression contains a 1 in all digits where x and y have different binary values, and it contains 0 in all other digits.

```
b = x ^ y;
```

Example:

```
   char a='a', b='b';
//--- Excluding OR operation
   char c=a^b;
   Print("a = ",a,"  b = ",b);
   Print("a ^ b = ",c);
// The result will be:
// a = 97   b = 98
// a ^ b = 3
```

Bitwise operations are performed with integers only.

See also

Precedence Rules

Other operations

Indexing ([])

When addressing the i-th element of the array, the expression value is the value of a variable with the serial number i.

Example:

```
array[i] = 3; // Assign the value of 3 to i-th element of the array.
```

Only an integer can be index of an array. Four-dimensional and below arrays are allowed. Each dimension is indexed from 0 to **dimension size**-1. In particular case, for a one-dimensional array consisting of 50 elements, the reference to the first element will look like array [0], that to the last element will be array [49].

When addressing beyond the array, the executing subsystem will generate a critical error, and the program will be stopped.

Calling Function with x1, x2 ,..., xn Arguments

Each argument can represent a constant, variable, or expression of the corresponding type. The arguments passed are separated by commas and must be inside of parentheses, the opening parenthesis must follow the name of the called function.

The expression value is the value returned by the function. If the return value is of void type, such function call cannot be placed to the right in the assignment operation. Note that the expressions x1,..., xn are executed exactly in this order.

Example:

```
   int length=1000000;
   string a="a",b="b",c;
//---Other Operations
   int start=GetTickCount(),stop;
   long i;
   for(i=0;i<length;i++)
     {
      c=a+b;
     }
   stop=GetTickCount();
   Print("time for 'c = a + b' = ",(stop-start)," milliseconds, i = ",i);
```

Comma Operation (,)

Expressions separated by commas are executed from left to right. All side effects of the left expression calculation can appear before the right expression is calculated. The result type and value coincide with those of the right expression. The list of parameters to be passed (see above) can be considered as an example.

Example:

```
for(i=0,j=99; i<100; i++,j--) Print(array[i][j]);
```

Dot Operator (.)

For the direct access to the public members of structures and classes the dot operation is used. Syntax:

```
Variable_name_of_structure_type.Member_name
```

Example:

```
   struct SessionTime
     {
      string sessionName;
      int    startHour;
      int    startMinutes;
      int    endHour;
      int    endMinutes;
     } st;
   st.sessionName="Asian";
   st.startHour=0;
   st.startMinutes=0;
   st.endHour=9;
   st.endMinutes=0;
```

Scope Resolution Operation (::)

Each function in a mql5 program has its own execution scope. For example, the Print() system function is performed in a global scope. Imported functions are called in the scope of the corresponding import. Method functions of classes have the scope of the corresponding class. The syntax of the scope resolution operation is as follows:

```
[Scope_name]::Function_name(parameters)
```

If there is no scope name, this is the explicit direction to use the global scope. If there is no scope resolution operation, the function is sought in the nearest scope. If there is no function in the local scope, the search is conducted in the global scope.

The scope resolution operation is also used to define function-class member.

```
type Class_name::Function_name(parameters_description)
   {
// function body
   }
```

Use of several functions of the same name from different execution contexts in a program may cause ambiguity. The priority order of function calls without explicit scope specification is the following:

1. Class methods. If no function with the specified name is set in the class, move to the next level.
2. MQL5 functions. If the language does not have such a function, move to the next level.
3. User defined global functions. If no function with the specified name is found, move to the next level.

4. Imported functions. If no function with the specified name is found, the compiler returns an error.

To avoid the ambiguity of function calls, always explicitly specify the function scope using the scope resolution operation.

Example:

```
#property script_show_inputs
#import "kernel32.dll"
   int GetLastError(void);
#import

class CCheckContext
  {
   int         m_id;
public:
               CCheckContext() { m_id=1234; }
protected:
   int         GetLastError() { return(m_id); }
  };
class CCheckContext2 : public CCheckContext
  {
   int         m_id2;
public:
               CCheckContext2() { m_id2=5678; }
   void        Print();
protected:
   int         GetLastError() { return(m_id2); }
  };
void CCheckContext2::Print()
  {
   ::Print("Terminal GetLastError",::GetLastError());
   ::Print("kernel32 GetLastError",kernel32::GetLastError());
   ::Print("parent GetLastError",CCheckContext::GetLastError());
   ::Print("our GetLastError",GetLastError());
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   CCheckContext2 test;
   test.Print();
  }
//+------------------------------------------------------------------+
```

Operation of Obtaining Data Type Size or Size of Any Data Type Object (sizeof)

Using the sizeof operation, the memory size corresponding to an identifier or type can be defined. The sizeof operation is of the following format:

Example:

```
sizeof(expression)
```

Any identifier, or type name enclosed in brackets can be used as an expression. Note that the void type name can't be used, and the identifier cannot belong to the field of bits, or be a function name.

If the expression is the name of a static array (i.e. the first dimension is given), then the result is the size of the whole array (i.e. the product of the number of elements and the length of the type). If the expression is the name of a dynamic array (the first dimension is not specified), the result will be the size of the object of the dynamic array.

When sizeof is applied to the name of structure or class type, or to the identifier of the structure or class type, the result is the actual size of the structure or class.

Example:

```
struct myStruct
  {
   char   h;
   int    b;
   double f;
  } str;
Print("sizeof(str) = ",sizeof(str));
Print("sizeof(myStruct) = ",sizeof(myStruct));
```

The size is calculated at the compilation stage.

Precedence Rules

Precedence Rules

Each group of operations in the table has the same priority. The higher the priority of operations is, the higher it is position of the group in the table. The precedence rules determine the grouping of operations and operands.

Attention: Precedence of operations in the MQL5 language corresponds to the priority adopted in C++, and differs from the priority given in the MQL4 language.

Operation	Desciption	Execution Order
() [] .	Function Call Referencing to an array element Referencing to a structure element	From left to right
! ~ - ++ -- (type) sizeof	Logical negation Bitwise negation (complement) Sign changing Increment by one Decrement by one Typecasting Determining size in bytes	Right to left
* / %	Multiplication Division Module division	From left to right

%= += -= <<= >>= &= ^= |=	Module with assignment Addition with assignment Subtraction with assignment Left shift with assignment Right shift with assignment Bitwise AND with assignment Exclusive OR with assignment Bitwise OR with assignment	
,	Comma	From left to right

To change the operation execution order, parenthesis that are of higher priority are used.

Operators

Language operators describe some algorithmic operations that must be executed to accomplish a task. The program body is a sequence of such operators. Operators following one by one are separated by semicolons.

Operator	Description
Compound operator {}	One or more operators of any type, enclosed in curly braces {}
Expression operator (;)	Any expression that ends with a semicolon (;)
return operator	Terminates the current function and returns control to the calling program
if-else conditional operator	Is used when it's necessary to make a choice
?: conditional operator	A simple analog of the if-else conditional operator
switch selection operator	Passes control to the operator, which corresponds to the expression value
while loop operator	Performs an operator until the expression checked becomes false. The expression is checked before each iteration
for loop operator	Performs an operator until the expression checked becomes false. The expression is checked before each iteration
do-while loop operator	Performs an operator until the expression checked becomes false. The end condition is checked, after each loop. The loop body is always executed at least once.
break operator	Terminates the execution of the nearest attached external operator switch, while, do-while or for
continue operator	Passes control to the beginning of the nearest external loop operator while, do-while or for
new operator	Creates an object of the appropriate size and returns a descriptor of the created object.
delete operator	Deletes the object created by the new operator

One operator can occupy one or more lines. Two or more operators can be located in the same line. Operators that control over the execution order (if, if-else, switch, while and for), can be nested into each other.

Example:

```
if(Month() == 12)
  if(Day() == 31) Print("Happy New Year!");
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Compound Operator

A compound operator (a block) consists of one or more operators of any type, enclosed in braces {}. The closing brace must not be followed by a semicolon (;).

Example:

```
if(x==0)
  {
   Print("invalid position x = ",x);
   return;
  }
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Expression Operator

Any expression followed by a semicolon (;) is the operator. Here are some examples of expression operators.

Assignment Operator

Identifier = expression;

```
x=3;
y=x=3;
bool equal=(x==y);
```

Assignment operator can be used many times in an expression. In this case, the expression is processed from right to left.

Function Calling Operator

Function_name (argument1,..., argumentN);

```
FileClose(file);
```

Empty Operator

Consists only of a semicolon (;) and is used to denote an empty body of a control operator.

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Return Operator

The return operator terminates the current function execution and returns control to the calling program. The expression calculation result is returned to the calling function. The expression can contain an assignment operator.

Example:

```
int CalcSum(int x, int y)
  {
   return(x+y);
  }
```

In functions with the void return type, the return operator without expression must be used:

```
void SomeFunction()
  {
   Print("Hello!");
   return;     // this operator can be removed
  }
```

The right brace of the function means implicit execution of the return operator without expression.

What can be returned: simple types, simple structures, object pointers. With the *return* operator you can't return any arrays, class objects, variables of compound structure type.

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

If-Else Conditional Operator

The IF - ELSE operator is used when a choice must be made. Formally, the syntax is as follows:

```
if (expression)
     operator1
else
     operator2
```

If the expression is true, operator1 is executed and control is given to the operator that follows operator2 (operator2 is not executed). If the expression is false, operator2 is executed.

The else part of the if operator can be omitted. Thus, a divergence may appear in nested if operators with omitted else part. In this case, else addresses to the nearest previous if operator in the same block that has no else part.

Examples:

```
//--- The else part refers to the second if operator:
if(x>1)
   if(y==2) z=5;
else     z=6;
//--- The else part refers to the first if operator:
if(x>1)
  {
   if(y==2) z=5;
  }
else        z=6;
//--- Nested operators
if(x=='a')
  {
   y=1;
  }
else if(x=='b')
  {
   y=2;
   z=3;
  }
else if(x=='c')
  {
   y=4;
  }
else Print("ERROR");
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Ternary Operator ?:

The general form of the ternary operator is as follows:

```
expression1 ? expression2 : expression3
```

For the first operand - "expression1" - any expression that results in a bool type value can be used. If the result is true, then the operator set by the second operand, i.e. "expression2" is executed.

If the first operand is false, the third operand - "expression3" is performed. The second and third operands, i.e. "expression2" and "expression3" should return values of one type and should not be of void type. The result of the conditional operator execution is the result of expression2 or result of the expression3, depending on the result of expression1.

```
//--- normalize difference between open and close prices for a day range
double true_range = (High==Low)?0:(Close-Open)/(High-Low);
```

This entry is equivalent to the following:

```
   double true_range;
   if(High==Low)true_range=0;                // if High and Low are equal
   else true_range=(Close-Open)/(High-Low); // if the range is not null
```

Operator Use Restrictions

Based on the value of "expression1", the operator must return one of the two values - either "expression2" or "expression3". There are several limitations to these expressions:

1. Do not mix user-defined type with simple type or enumeration. NULL can be used for the pointer.
2. If types of values are simple, the operator will be of the maximum type (see Type casting).
3. If one of the values is an enumeration and the second one is of a numeric type, the enumeration is replaced by int and the second rule is applied.
4. If both values are enumerations, their types must be identical, and the operator will be of type enumeration.

Restrictions for the user-defined types (classes or structures):

a) Types must be identical or one should be derived from the other one.

b) If types are not identical (inheritance), then the child is implicitly cast to the parent, i.e. the operator will be of the parent type.

c) Do not mix object and the pointer - both expressions must be either objects or pointers. NULL can be used for the pointer.

Note

Be careful when using the conditional operator as an argument of an overloaded function, because the type of the result of a conditional operator is defined at the time of program compilation. And this type is determined as the larger of the types "expression2" and "expression3".

Example:

```
void func(double d) { Print("double argument: ",d); }
void func(string s) { Print("string argument: ",s); }

bool   Expression1=true;
double Expression2=M_PI;
string Expression3="3.1415926";

void OnStart()
  {
   func(Expression2);
   func(Expression3);

   func(Expression1?Expression2:Expression3);   // warning on implicit casting to stri
   func(!Expression1?Expression2:Expression3);  // warning on implicit casting to stri
  }

//   Result:
//   double argument: 3.141592653589793
//   string argument: 3.1415926
//   string argument: 3.141592653589793
//   string argument: 3.1415926
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Switch Operator

Compares the expression value with constants in all the *case* variants and passes control to the operator that corresponds to the expression value. Each variant of *case* can be marked with an integer constant, a literal constant or a constant expression. The constant expression can't contain variables or function calls. Expression of the *switch* operator must be of integer type - int or uint.

```
switch(expression)
  {
   case constant: operators
   case constant: operators
      ...
   default: operators
  }
```

Operators marked by the *default* label are executed if none of the constants in *case* operators is equal to the expression value. The *default* variant should not be necessarily declared and should not be necessarily the last one. If none of the constants corresponds to the expression value and the *default* variant is not available, no actions are executed.

The *case* keyword with a constant are just labels, and if operators are executed for some *case* variant, the program will further execute the operators of all subsequent variants until the *break* operator occurs. It allows to bind a sequence of operators with several variants.

A constant expression is calculated during compilation. No two constants in one *switch* operator can have the same value.

Examples:

```
//--- First example
switch(x)
  {
   case 'A':
      Print("CASE A");
      break;
   case 'B':
   case 'C':
      Print("CASE B or C");
      break;
   default:
      Print("NOT A, B or C");
      break;
  }

//---  Second example
   string res="";
   int i=0;
   switch(i)
     {
      case 1:
         res=i;break;
```

```
      default:
         res="default";break;
      case 2:
         res=i;break;
      case 3:
         res=i;break;
     }
   Print(res);
/*
   Result
   default
*/
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

While Loop Operator

The while operator consists of a checked expression and the operator, which must be fulfilled:

```
while(expression)
  operator;
```

If the expression is true, the operator is executed until the expression becomes false. If the expression is false, the control is passed to the next operator. The expression value is defined before the operator is executed. Therefore, if the expression is false from the very beginning, the operator will not be executed at all.

Note

If it is expected that a large number of iterations will be handled in a loop, it is advisable that you check the fact of forced program termination using the IsStopped() function.

Example:

```
while(k<n && !IsStopped())
  {
   y=y*x;
   k++;
  }
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

For Loop Operator

The for operator consists of three expressions and an executable operator:

```
for(expression1; expression2; expression3)
   operator;
```

Expression1 describes the loop initialization. Expression2 checks the conditions of the loop termination. If it is true, the loop body for is executed. The loop repeats expression2 until it becomes false. If it is false, the loop is terminated, and control is given to the next operator. Expression3 is calculated after each iteration.

The for operator is equivalent to the following succession of operators:

```
expression1;
while(expression2)
  {
   operator;
   expression3;
  };
```

Any of the three or all three expressions can be absent in the for operator, but the semicolons (;) that separate them must not be omitted. If expression2 is omitted, it is considered constantly true. The for(;;) operator is a continuous loop, equivalent to the while(1) operator. Each expression 1 or 3 can consist of several expressions combined by a comma operator ','.

Note

If it is expected that a large number of iterations will be handled in a loop, it is advisable that you check the fact of forced program termination using the IsStopped() function.

Examples:

```
for(x=1;x<=7000; x++)
  {
   if(IsStopped())
      break;
   Print(MathPower(x,2));
  }
//--- Another example
for(;!IsStopped();)
  {
   Print(MathPower(x,2));
   x++;
   if(x>10) break;
  }
//--- Third example
for(i=0,j=n-1;i<n && !IsStopped();i++,j--) a[i]=a[j];
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Loop Operator do while

The for and while loops check the termination at the beginning, not at the end of a loop. The third loop operator do - while checks the condition of termination at the end, after each loop iteration. The loop body is always executed at least once.

```
do
   operator;
while(expression);
```

First the operator is executed, then the expression is calculated. If it is true, then the operator is executed again, and so on. If the expression becomes false, the loop terminates.

Note

If it is expected that a large number of iterations will be handled in a loop, it is advisable that you check the fact of forced program termination using the IsStopped() function.

Example:

```
//--- Calculate the Fibonacci series
   int counterFibonacci=15;
   int i=0,first=0,second=1;
   int currentFibonacciNumber;
   do
     {
      currentFibonacciNumber=first+second;
      Print("i = ",i,"  currentFibonacciNumber = ",currentFibonacciNumber);
      first=second;
      second=currentFibonacciNumber;
      i++; // without this operator an infinite loop will appear!
     }
   while(i<counterFibonacci && !IsStopped());
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Break Operator

The break operator terminates the execution of the nearest nested outward switch, while, do-while or for operator. The control is passed to the operator that follows the terminated one. One of the purposes of this operator is to finish the looping execution when a certain value is assigned to a variable.

Example:

```
//--- searching for the first zero element
for(i=0;i<array_size;i++)
  if(array[i]==0)
    break;
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Continue Operator

The continue operator passes control to the beginning of the nearest outward loop while, do-while or for operator, the next iteration being called. The purpose of this operator is opposite to that of break operator.

Example:

```
//--- Sum of all nonzero elements
int func(int array[])
  {
   int array_size=ArraySize(array);
   int sum=0;
   for(int i=0;i<array_size; i++)
     {
      if(a[i]==0) continue;
      sum+=a[i];
     }
   return(sum);
  }
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Object Create Operator new

The new operator automatically creates an object of a corresponding size, calls the object constructor and returns a descriptor of created object. In case of failure, the operator returns a null descriptor that can be compared with the NULL constant.

The new operator can be applied only to class objects. It can't be applied to structures.

The operator shall not be used to create arrays of objects. To do this, use the ArrayResize() function.

Example:

```
//+------------------------------------------------------------------+
//| Figure creation                                                  |
//+------------------------------------------------------------------+
void CTetrisField::NewShape()
  {
   m_ypos=HORZ_BORDER;
//--- randomly create one of the 7 possible shapes
   int nshape=rand()%7;
   switch(nshape)
     {
      case 0: m_shape=new CTetrisShape1; break;
      case 1: m_shape=new CTetrisShape2; break;
      case 2: m_shape=new CTetrisShape3; break;
      case 3: m_shape=new CTetrisShape4; break;
      case 4: m_shape=new CTetrisShape5; break;
      case 5: m_shape=new CTetrisShape6; break;
      case 6: m_shape=new CTetrisShape7; break;
     }
//--- draw
   if(m_shape!=NULL)
     {
      //--- pre-settings
      m_shape.SetRightBorder(WIDTH_IN_PIXELS+VERT_BORDER);
      m_shape.SetYPos(m_ypos);
      m_shape.SetXPos(VERT_BORDER+SHAPE_SIZE*8);
      //--- draw
      m_shape.Draw();
     }
//---
  }
```

It should be noted that object descriptor is not a pointer to memory address.

An object created with the new operator must be explicitly removed using the delete operator.

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Object Delete Operator delete

The delete operator deletes an object created by the new operator, calls the corresponding class destructor and frees up memory occupied by the object. A real descriptor of an existing object is used as an operand. After the delete operation is executed, the object descriptor becomes invalid.

Example:

```
      //--- delete figure
      delete m_shape;
      m_shape=NULL;
      //--- create a new figure
      NewShape();
```

See also

Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Functions

Every task can be divided into subtasks, each of which can either be directly represented in the form of a code, or divided into smaller sub-tasks. This method is called *stepwise refinement*. Functions are used for writing the code of sub-tasks to be solved. The code that describes what a function does is called *function definition:*

```
function_header
  {
   instructions
  }
```

All that is before the first brace is the *header* of the function definition, and what is between braces is the *body* of the function definition. The function header includes a description of the return value type, name (identifier) and formal parameters. The number of parameters passed to the function is limited and cannot exceed 64.

The function can be called from other parts of the program as many times as necessary. In fact, the return type, function identifier and parameter types constitute the *function prototype*.

Function prototype is the function declaration, but not its definition. Due to the explicit declaration of the return type and a list of argument types, the strict type checking and implicit typecasting are possible during function calls. Very often function declarations are used in classes to improve the code readability.

The function definition must exactly match its declaration. Each declared function must be defined.

Example:

```
double                          // return value type
linfunc (double a, double b) // function name and parameter list
  {
                                // composite operator
   return (a + b);              // return value
  }
```

The return operator can return the value of an expression located in this operator. If necessary, the expression value is converted to the function result type. What can be returned: simple types, simple structures, object pointers. With the *return* operator you can't return any arrays, class objects, variables of compound structure type.

A function that returns no value should be described as that of void type.

Example:

```
void errmesg(string s)
  {
   Print("error: "+s);
  }
```

Parameters passed to the function can have default values, which are defined by constants of that type.

Example:

```
int somefunc(double a,
             double d=0.0001,
             int n=5,
             bool b=true,
             string s="passed string")
  {
   Print("Required parameter a = ",a);
   Print("Pass the following parameters: d = ",d," n = ",n," b = ",b," s = ",s);
   return(0);
  }
```

If any of parameters has a default value, all subsequent parameters must also have default values.

Example of incorrect declaration:

```
int somefunc(double a,
             double d=0.0001,    // default value 0.0001 declared
             int n,              // default value is not specified !
             bool b,             // default value is not specified !
             string s="passed string")
  {
  }
```

See also

Overload, Virtual Functions, Polymorphism

Function Call

If a name that has not been described before, appears in the expression and is followed by the left parenthesis, it is contextually considered as the name of a function.

```
function_name (x1, x2,..., xn)
```

Arguments (formal parameters) are passed by value, i.e. each expression x1,..., xn is calculated, and the value is passed to the function. The order of expressions calculation and the order of values loading are not guaranteed. During the execution, the system checks the number and type of arguments passed to the function. Such way of addressing to the function is called a value call.

Function call is an expression, the value of which is the value returned by the function. The function type described above must correspond with the type of the return value. The function can be declared or described in any part of the program on the global scope, i.e., outside other functions. The function cannot be declared or described inside of another function.

Examples:

```
int start()
  {
   double some_array[4]={0.3, 1.4, 2.5, 3.6};
   double a=linfunc(some_array, 10.5, 8);
   //...
  }
double linfunc(double x[], double a, double b)
  {
   return (a*x[0] + b);
  }
```

At calling of a function with default parameters, the list of parameters to be passed can be limited, but not before the first default parameter.

Examples:

```
void somefunc(double init,
              double sec=0.0001, //set default values
              int level=10);
//...
somefunc();                      // Wrong call. The first parameter must be presented
somefunc(3.14);                  // Correct call
somefunc(3.14,0.0002);           // Correct call
somefunc(3.14,0.0002,10);        // Correct call
```

When calling a function, one may not skip parameters, even those having default values:

```
somefunc(3.14, , 10);           // Wrong call -> the second parameter was skipped.
```

See also

Overload, Virtual Functions, Polymorphism

Passing Parameters

There are two methods, by which the machine language can pass arguments to a subprogram (function). The first method is to send a parameter by value. This method copies the argument value into a formal function parameter. Therefore, any changes in this parameter within the function have no influence on the corresponding call argument.

```
//+------------------------------------------------------------------+
//| Passing parameters by value                                      |
//+------------------------------------------------------------------+
double FirstMethod(int i,int j)
  {
   double res;
//---
   i*=2;
   j/=2;
   res=i+j;
//---
   return(res);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int a=14,b=8;
   Print("a and b before call:",a," ",b);
   double d=FirstMethod(a,b);
   Print("a and b after call:",a," ",b);
  }
//--- Result of script execution
//  a and b before call: 14 8
//  a and b after call: 14 8
```

The second method is to pass by reference. In this case, reference to a parameter (not its value) is passed to a function parameter. Inside the function, it is used to refer to the actual parameter specified in the call. This means that the parameter changes will affect the argument used to call the function.

```
//+------------------------------------------------------------------+
//| Passing parameters by reference                                  |
//+------------------------------------------------------------------+
double SecondMethod(int &i,int &j)
  {
   double res;
//---
   i*=2;
   j/=2;
   res=i+j;
```

```
//---
   return(res);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int a=14,b=8;
   Print("a and b before call:",a," ",b);
   double d=SecondMethod(a,b);
   Print("a and b after call:",a," ",b);
  }
//+------------------------------------------------------------------+
//--- result of script execution
//  a and b before call: 14 8
//  a and b after call: 28 4
```

MQL5 uses both methods, with one exception: arrays, structure type variables and class objects are always passed by reference. In order to avoid changes in actual parameters (arguments passed at function call) use the access specifier const. When trying to change the contents of a variable declared with the *const* specifier, the compiler will generate an error.

Note

It should be noted that parameters are passed to a function in reversed order, i.e., first the last parameter is calculated and passed, and then the last but one, etc. The last calculated and passed parameter is the one that stands first after opening parenthesis.

Example:

```
void OnStart()
  {
//---
   int a[]={0,1,2};
   int i=0;

   func(a[i],a[i++],"First call (i = "+string(i)+")");
   func(a[i++],a[i],"Second call (i = "+string(i)+")");
// Result:
// First call (i = 0) : par1 = 1     par2 = 0
// Second call (i = 1) : par1 = 1     par2 = 1

  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
void func(int par1,int par2,string comment)
  {
```

```
   Print(comment,": par1 = ",par1,"    par2 = ",par2);
  }
```

In first call (see example above) the ***i*** variable is first used in strings concatenation:

```
  "First call (i = "+string(i)+")"
```

Here its value doesn't change. Then the ***i*** variable is used in calculation of the ***a[i++]*** array element, i.e. when array element with index i is accessed, the ***i*** variable is incremented. And only after that the first parameter with changed value of ***i*** variable is calculated.

In the second call the same value of i (calculated on the first phase of function calling) is used when calculating all three parameters. Only after the first parameters is calculated the ***i*** variable is changed again.

Visibility Scope and Lifetime of Variables, Overload, Virtual Functions, Polymorphism

Function Overloading

Usually the function name tends to reflect its main purpose. As a rule, readable programs contain various well selected identifiers. Sometimes different functions are used for the same purposes. Let's consider, for example, a function that calculates the average value of an array of double precision numbers and the same function, but operating with an array of integers. Both are convenient to be called AverageFromArray:

```
//+------------------------------------------------------------------+
//| The calculation of average for an array of double type           |
//+------------------------------------------------------------------+
double AverageFromArray(const double & array[],int size)
  {
   if(size<=0) return 0.0;
   double sum=0.0;
   double aver;
//---
   for(int i=0;i<size;i++)
     {
      sum+=array[i];    // Summation for the double
     }
   aver=sum/size;       // Just divide the sum by the number
//---
   Print("Calculation of the average for an array of double type");
   return aver;
  }
//+------------------------------------------------------------------+
//| The calculation of average for an array of int type              |
//+------------------------------------------------------------------+
double AverageFromArray(const int & array[],int size)
  {
   if(size<=0) return 0.0;
   double aver=0.0;
   int sum=0;
//---
   for(int i=0;i<size;i++)
     {
      sum+=array[i];     // Summation for the int
     }
   aver=(double)sum/size;// Give the amount of type double, and divide
//---
   Print("Calculation of the average for an array of int type");
   return aver;
  }
```

Each function contains the message output via the Print() function;

```
   Print("Calculation of the average for an array of int type");
```

The compiler selects a necessary function in accordance with the types of arguments and their quantity. The rule, according to which the choice is made, is called the *signature matching algorithm*. A signature is a list of types used in the function declaration.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int    a[5]={1,2,3,4,5};
   double b[5]={1.1,2.2,3.3,4.4,5.5};
   double int_aver=AverageFromArray(a,5);
   double double_aver=AverageFromArray(b,5);
   Print("int_aver = ",int_aver,"   double_aver = ",double_aver);
  }
//--- Result of the script
// Calculate the average for an array of int type
// Calculate the average for an array of double type
// int_aver= 3.00000000    double_aver= 3.30000000
```

Function overloading is a process of creating several functions with the same name, but different parameters. This means that in overloaded variants of a function, the number of arguments and/or their type must be different. A specific function variant is selected based on the correspondence of the list of arguments when calling the function, to the list of parameters in the function declaration.

When an overloaded function is called, the compiler must have an algorithm to select the appropriate function. The algorithm that performs this choice depends on castings of what types are present. The best correspondence must be unique. An overloaded function must be the best match among all the other variants for at least one argument. At the same time it must match for all other arguments not worse than other variants.

Below is a matching algorithm for each argument.

Algorithm of Choosing an Overloaded Function

1. Use strict matching (if possible).
2. Try standard type increase.
3. Try standard typecasting.

The standard type increase is better than other standard conversions. Increase is the conversion of float to double, of bool, char, short or enum to int. Typecasting of arrays of similar integer types also belongs to typecasting. Similar types are: bool, char, uchar, since all the three types are single-byte integers; double-byte integers short and ushort; 4-byte integers int, uint, and color; long, ulong, and datetime.

Of course, the strict matching is the best. To achieve such a consistency typecasting can be used. The compiler cannot cope with ambiguous situations. Therefore you should not rely on subtle differences of types and implicit conversions that make the overloaded function unclear.

If you doubt, use explicit conversion to ensure strict compliance.

Examples of overloaded functions in MQL5 can be seen in the example of ArrayInitialize() functions.

Function overloading rules apply to overload of class methods.

Overloading of system functions is allowed, but it should be observed that the compiler is able to accurately select the necessary function. For example, we can overload the system function MathMax() in 4 different ways, but only two variants are correct.

Example:

```
// 1. overload is allowed - function differs from built-in MathMax() function in the r
double MathMax(double a,double b,double c);

// 2. overload is not allowed!
// number of parameters is different, but the last has a default value
// this leads to the concealment of the system function when calling, which is unacce
double MathMax(double a,double b,double c=DBL_MIN);

// 3. overload is allowed - normal overload by type of parameters a and b
double MathMax(int a,int b);

// 4. overload is not allowed!
// the number and types of parameters are the same as in original double MathMax(doub
int MathMax(double a,double b);
```

Operation Overloading

For ease of code reading and writing, overloading of some operations is allowed. Overloading operator is written using the keyword operator. The following operators can be overloaded:

- binary +,-,/,*,%,<<,>>,==,!=,<,>,<=,>=,=,+=,-=,/=,*=,%=,&=,|=,^=,<<=,>>=,&&,||,&,|,^
- unary +,-,++,--,!,~
- assignment operator =
- indexing operator []

Operation overloading allows the use of the operating notation (written in the form of simple expressions) for complex objects - structures and classes. Writing expressions using overloaded operations simplifies the view of the source code, because a more complex implementation is hidden.

For example, consider complex numbers, which consist of real and imaginary parts. They are widely used in mathematics. The MQL5 language has no data type to represent complex numbers, but it is possible to create a new data type in the form of a structure or class. Declare the complex structure and define four methods that implement four arithmetic operations:

```
//+------------------------------------------------------------------+
//| A structure for operations with complex numbers                  |
//+------------------------------------------------------------------+
struct complex
  {
   double            re; // Real part
   double            im; // Imaginary part
   //--- Constructors
                     complex():re(0.0),im(0.0) {  }
                     complex(const double r):re(r),im(0.0) {  }
                     complex(const double r,const double i):re(r),im(i) {  }
                     complex(const complex &o):re(o.re),im(o.im) { }
   //--- Arithmetic operations
   complex           Add(const complex &l,const complex &r) const;  // Addition
   complex           Sub(const complex &l,const complex &r) const;  // Subtraction
   complex           Mul(const complex &l,const complex &r) const;  // Multiplication
   complex           Div(const complex &l,const complex &r) const;  // Division
  };
```

Now, in our code we can declare variables representing complex numbers, and work with them.

For example:

```
void OnStart()
  {
//--- Declare and initialize variables of a complex type
   complex a(2,4),b(-4,-2);
   PrintFormat("a=%.2f+i*%.2f,   b=%.2f+i*%.2f",a.re,a.im,b.re,b.im);
//--- Sum up two numbers
   complex z;
```

```
   z=a.Add(a,b);
   PrintFormat("a+b=%.2f+i*%.2f",z.re,z.im);
//--- Multiply two numbers
   z=a.Mul(a,b);
   PrintFormat("a*b=%.2f+i*%.2f",z.re,z.im);
//--- Divide two numbers
   z=a.Div(a,b);
   PrintFormat("a/b=%.2f+i*%.2f",z.re,z.im);
//---
  }
```

But it would be more convenient to use usual operators "+", "-", "*" and "/" for ordinary arithmetic operations with complex numbers.

Keyword operator is used for defining a member function that performs type conversion. Unary and binary operations for class object variables can be overloaded as non-static member functions. They implicitly act on the class object.

Most binary operations can be overloaded like regular functions that take one or both arguments as a class variable or a pointer to an object of this class. For our type complex, overloading in the declaration will look like this:

```
   //--- Operators
   complex operator+(const complex &r) const { return(Add(this,r)); }
   complex operator-(const complex &r) const { return(Sub(this,r)); }
   complex operator*(const complex &r) const { return(Mul(this,r)); }
   complex operator/(const complex &r) const { return(Div(this,r)); }
```

The full example of the script:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Declare and initialize variables of type complex
   complex a(2,4),b(-4,-2);
   PrintFormat("a=%.2f+i*%.2f,   b=%.2f+i*%.2f",a.re,a.im,b.re,b.im);
   //a.re=5;
   //a.im=1;
   //b.re=-1;
   //b.im=-5;
//--- Sum up two numbers
   complex z=a+b;
   PrintFormat("a+b=%.2f+i*%.2f",z.re,z.im);
//--- Multiply two numbers

   z=a*b;
   PrintFormat("a*b=%.2f+i*%.2f",z.re,z.im);
//--- Divide two numbers
   z=a/b;
```

```
   PrintFormat("a/b=%.2f+i*%.2f",z.re,z.im);
//---
  }
//+------------------------------------------------------------------+
//| A structure for operations with complex numbers                  |
//+------------------------------------------------------------------+
struct complex
  {
   double            re; // Real part
   double            im; // Imaginary part
   //--- Constructors
                     complex():re(0.0),im(0.0) {  }
                     complex(const double r):re(r),im(0.0) {  }
                     complex(const double r,const double i):re(r),im(i) {  }
                     complex(const complex &o):re(o.re),im(o.im) { }
   //--- Arithmetic operations
   complex           Add(const complex &l,const complex &r) const;  // Addition
   complex           Sub(const complex &l,const complex &r) const;  // Subtraction
   complex           Mul(const complex &l,const complex &r) const;  // Multiplication
   complex           Div(const complex &l,const complex &r) const;  // Division
   //--- Binary operators
   complex operator+(const complex &r) const { return(Add(this,r)); }
   complex operator-(const complex &r) const { return(Sub(this,r)); }
   complex operator*(const complex &r) const { return(Mul(this,r)); }
   complex operator/(const complex &r) const { return(Div(this,r)); }
  };
//+------------------------------------------------------------------+
//| Addition                                                         |
//+------------------------------------------------------------------+
complex complex::Add(const complex &l,const complex &r) const
  {
   complex res;
//---
   res.re=l.re+r.re;
   res.im=l.im+r.im;
//--- Result
   return res;
  }
//+------------------------------------------------------------------+
//| Subtraction                                                      |
//+------------------------------------------------------------------+
complex complex::Sub(const complex &l,const complex &r) const
  {
   complex res;
//---
   res.re=l.re-r.re;
   res.im=l.im-r.im;
//--- Result
   return res;
```

```
  }
//+------------------------------------------------------------------+
//| Multiplication                                                   |
//+------------------------------------------------------------------+
complex complex::Mul(const complex &l,const complex &r) const
  {
   complex res;
//---
   res.re=l.re*r.re-l.im*r.im;
   res.im=l.re*r.im+l.im*r.re;
//--- Result
   return res;
  }
//+------------------------------------------------------------------+
//| Division                                                         |
//+------------------------------------------------------------------+
complex complex::Div(const complex &l,const complex &r) const
  {
//--- Empty complex number
   complex res(EMPTY_VALUE,EMPTY_VALUE);
//--- Check for zero
   if(r.re==0 && r.im==0)
     {
      Print(__FUNCTION__+": number is zero");
      return(res);
     }
//--- Auxiliary variables
   double e;
   double f;
//--- Selecting calculation variant
   if(MathAbs(r.im)<MathAbs(r.re))
     {
      e = r.im/r.re;
      f = r.re+r.im*e;
      res.re=(l.re+l.im*e)/f;
      res.im=(l.im-l.re*e)/f;
     }
   else
     {
      e = r.re/r.im;
      f = r.im+r.re*e;
      res.re=(l.im+l.re*e)/f;
      res.im=(-l.re+l.im*e)/f;
     }
//--- Result
   return res;
  }
```

Most unary operations for classes can be overloaded as ordinary functions that accept a single class object argument or a pointer to it. Add overloading of unary operations "-" and "!".

```
//+------------------------------------------------------------------+
//| A structure for operations with complex numbers                  |
//+------------------------------------------------------------------+
struct complex
  {
   double            re;       // Real part
   double            im;       // Imaginary part
...
   //--- Unary operators
   complex operator-()  const; // Unary minus
   bool    operator!()  const; // Negation
  };
...
//+------------------------------------------------------------------+
//| Overloading the "unary minus" operator                           |
//+------------------------------------------------------------------+
complex complex::operator-() const
  {
   complex res;
//---
   res.re=-re;
   res.im=-im;
//--- Result
   return res;
  }
//+------------------------------------------------------------------+
//| Overloading the "logical negation" operator                      |
//+------------------------------------------------------------------+
bool complex::operator!() const
  {
//--- Are the real and imaginary parts of the complex number equal to zero?
   return (re!=0 && im!=0);
  }
```

Now we can check the value of a complex number for zero and get a negative value:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Declare and initialize variables of type complex
   complex a(2,4),b(-4,-2);
   PrintFormat("a=%.2f+i*%.2f,   b=%.2f+i*%.2f",a.re,a.im,b.re,b.im);
//--- Divide the two numbers
```

```
   complex z=a/b;
   PrintFormat("a/b=%.2f+i*%.2f",z.re,z.im);
//--- A complex number is equal to zero by default (in the default constructor re==0 a
   complex zero;
   Print("!zero=",!zero);
//--- Assign a negative value
   zero=-z;
   PrintFormat("z=%.2f+i*%.2f,  zero=%.2f+i*%.2f",z.re,z.im, zero.re,zero.im);
   PrintFormat("-zero=%.2f+i*%.2f",-zero.re,-zero.im);
//--- Check for zero once again
   Print("!zero=",!zero);
//---
  }
```

Note that we did not have to overload the assignment operator "=", as structures of simple types can be directly copied one into each other. Thus, we can now write a code for calculations involving complex numbers in the usual manner.

Overloading of the indexing operator allows to obtain the values of the arrays enclosed in an object, in a simple and familiar way, and it also contributes to a better readability of the source code. For example, we need to provide access to a symbol in the string at the specified position. A string in MQL5 is a separate type string, which is not an array of symbols, but with the help of an overloaded indexing operation we can provide a simple and transparent work in the generated CString class:

```
//+------------------------------------------------------------------+
//| Class to access symbols in string as in array of symbols         |
//+------------------------------------------------------------------+
class CString
  {
   string            m_string;

public:
                     CString(string str=NULL):m_string(str) { }
   ushort operator[] (int x) { return(StringGetCharacter(m_string,x)); }
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- An array for receiving symbols from a string
   int     x[]={ 19,4,18,19,27,14,15,4,17,0,19,14,17,27,26,28,27,5,14,
                 17,27,2,11,0,18,18,27,29,30,19,17,8,13,6 };
   CString str("abcdefghijklmnopqrstuvwxyz[ ]CS");
   string  res;
//--- Make up a phrase using symbols from the str variable
   for(int i=0,n=ArraySize(x);i<n;i++)
     {
      res+=ShortToString(str[x[i]]);
     }
```

```
//--- Show the result
   Print(res);
  }
```

Another example of overloading of the indexing operation is operations with matrices. The matrix represents a two-dimensional dynamic array, the array size is not defined in advance. Therefore, you cannot declare an array of form array[][] without specifying the size of the second dimension, and then pass this array as a parameter. A possible solution is a special class CMatrix, which contains an array of CRow class objects.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Operations of addition and multiplication of matrices
   CMatrix A(3),B(3),C();
//--- Prepare an array for rows
   double a1[3]={1,2,3}, a2[3]={2,3,1}, a3[3]={3,1,2};
   double b1[3]={3,2,1}, b2[3]={1,3,2}, b3[3]={2,1,3};
//--- Fill the matrices
   A[0]=a1; A[1]=a2; A[2]=a3;
   B[0]=b1; B[1]=b2; B[2]=b3;
//--- Output the matrices in the Experts log
   Print("---- Elements of matrix A");
   Print(A.String());
   Print("---- Elements of matrix B");
   Print(B.String());

//--- Addition of matrices
   Print("---- Addition of matrices A and B");
   C=A+B;
//--- Output the formatted string representation
   Print(C.String());

//--- Multiplication of matrices
   Print("---- Multiplication of matrices A and B");
   C=A*B;
   Print(C.String());

//--- Now we show how to get values in the style of dynamic arrays matrix[i][j]
   Print("Output the values of matrix C elementwise");
//--- Go through the matrix rows - CRow objects - in a loop
   for(int i=0;i<3;i++)
     {
      string com="| ";
      //--- Form rows from the matrix for the value
      for(int j=0;j<3;j++)
        {
```

```
         //--- Get the matrix element by the number of the row and column
         double element=C[i][j];// [i] - Access to CRow in the array m_rows[] ,
                                // [j] - Overloaded operator of indexing in CRow
         com=com+StringFormat("a(%d,%d)=%G ; ",i,j,element);
        }
      com+="|";
      //--- Output the values of the row
      Print(com);
     }
  }
//+------------------------------------------------------------------+
//| Class "Row"                                                      |
//+------------------------------------------------------------------+
class CRow
  {
private:
   double            m_array[];
public:
   //--- Constructors and a destructor
                     CRow(void)           { ArrayResize(m_array,0);     }
                     CRow(const CRow &r)  { this=r;                     }
                     CRow(const double &array[]);
                    ~CRow(void){};
   //--- Number of elements in the row
   int               Size(void) const     { return(ArraySize(m_array));}
   //--- Returns a string with values
   string            String(void) const;
   //--- Indexing operator
   double            operator[](int i) const  { return(m_array[i]);    }
   //--- Assignment operators
   void              operator=(const double  &array[]); // An array
   void              operator=(const CRow & r);         // Another CRow object
   double            operator*(const CRow &o);          // CRow object for multiplicat
  };
//+------------------------------------------------------------------+
//| Constructor for initializing a row with an array                 |
//+------------------------------------------------------------------+
void  CRow::CRow(const double &array[])
  {
   int size=ArraySize(array);
//--- If the array is not empty
   if(size>0)
     {
      ArrayResize(m_array,size);
      //--- Fill with values
      for(int i=0;i<size;i++)
         m_array[i]=array[i];
     }
//---
```

```
  }
//+------------------------------------------------------------------+
//| Assignment operation for the array                               |
//+------------------------------------------------------------------+
void CRow::operator=(const double &array[])
  {
   int size=ArraySize(array);
   if(size==0) return;
//--- Fill the array with values
   ArrayResize(m_array,size);
   for(int i=0;i<size;i++) m_array[i]=array[i];
//---
  }
//+------------------------------------------------------------------+
//| Assignment operation for CRow                                    |
//+------------------------------------------------------------------+
void CRow::operator=(const CRow  &r)
  {
   int size=r.Size();
   if(size==0) return;
//--- Fill the array with values
   ArrayResize(m_array,size);
   for(int i=0;i<size;i++) m_array[i]=r[i];
//---
  }
//+------------------------------------------------------------------+
//| Operator of multiplication by another row                        |
//+------------------------------------------------------------------+
double CRow::operator*(const CRow &o)
  {
   double res=0;
//--- Verifications
   int size=Size();
   if(size!=o.Size() || size==0)
     {
      Print(__FUNCSIG__,": Failed to multiply two matrices, their sizes are different"
      return(res);
     }
//--- Multiply arrays elementwise and add the products
   for(int i=0;i<size;i++)
      res+=m_array[i]*o[i];
//--- Result
   return(res);
  }
//+------------------------------------------------------------------+
//| Returns a formatted string representation                        |
//+------------------------------------------------------------------+
string CRow::String(void) const
  {
```

```
   string out="";
//--- If the size of the array is greater than zero
   int size=ArraySize(m_array);
//--- We work only with a non-zero number of array elements
   if(size>0)
     {
      out="{";
      for(int i=0;i<size;i++)
        {

Description of External Functions

External functions defined in another module must be explicitly described. The description includes returned type, function name and series of input parameters with their types. The absence of such a description can lead to errors when compiling, building, or executing a program. When describing an external object, use the keyword *#import* indicating the module.

Examples:

```
#import "user32.dll"
  int     MessageBoxW(int hWnd ,string szText,string szCaption,int nType);
  int     SendMessageW(int hWnd,int Msg,int wParam,int lParam);
#import "lib.ex5"
  double  round(double value);
#import
```

With the help of import, it is easy to describe functions that are called from external DLL or compiled EX5 libraries. EX5 libraries are compiled ex5 files, which have the library property. Only function described with the export modifier can be imported from EX5 libraries.

Please keep in mind that DLL and EX5 libraries should have different names (regardless of the directories they are located in) if they are imported together. All imported functions have the scope resolution corresponding to the library's "file name".

Example:

```
#import "kernel32.dll"
   int GetLastError();
#import "lib.ex5"
   int GetLastError();
#import

class CFoo
  {
public:
   int            GetLastError() { return(12345); }
   void           func()
     {
      Print(GetLastError());           // call of the class method
      Print(::GetLastError());         // call of the MQL5 function
      Print(kernel32::GetLastError()); // call of the DLL library function from kernel
      Print(lib::GetLastError());      // call of the EX5 library function from lib.ex
     }
  };

void OnStart()
  {
   CFoo foo;
   foo.func();
  }
```

Exporting Functions

A function declared in a mql5 program with the *export* postmodifier can be used in another mql5 program. Such a function is called exportable, and it can be called from other programs after compilation.

```
int Function() export
  {
  }
```

This modifier orders the compiler to add the function into the table of EX5 functions exported by this ex5 file. Only function with such a modifier are accessible ("visible") from other mql5 programs.

The library property tells the compiler that the EX5-file will be a library, and the compiler will show it in the header of EX5.

All functions that are planned as exportable ones must be marked with the *export* modifier.

Event Handling Functions

The MQL5 language provides processing of some predefined events. Functions for handling these events must be defined in a MQL5 program; function name, return type, composition of parameters (if there are any) and their types must strictly conform to the description of the event handler function.

The event handler of the client terminal identifies functions, handling this or that event, by the type of return value and type of parameters. If other parameters, not corresponding to below descriptions, are specified for a corresponding function, or another return type is indicated for it, such a function will not be used as an event handler.

OnStart

The OnStart() function is the Start event handler, which is automatically generated **only** for running **scripts**. It must be of void type, with no parameters:

```
void OnStart();
```

For the OnStart() function, the int return type can be specified.

OnInit

The OnInit() function is the Init event handler. It must be of void or int type, with no parameters:

```
void OnInit();
```

The Init event is generated immediately after an Expert Advisor or an indicator is downloaded; this event is not generated for scripts. The OnInit() function is used for initialization. If OnInit() has the int type of the return value, the non-zero return code means unsuccessful initialization, and it generates the Deinit event with the code of deinitialization reason REASON_INITFAILED.

When returning INIT_FAILED, the EA is forcibly unloaded from the chart.

When returning INIT_FAILED, the indicator is not unloaded from the chart. The indicator remaining on the chart is non-operational — event handlers are not called in the indicator.

To optimize input parameters of an Expert Advisor, it is recommended to use values of the ENUM_INIT_RETCODE enumeration as the return code. These values are used for organizing the course of optimization, including the selection of the most appropriate testing agents. During initialization of an Expert Advisor before the start of testing you can request information about the configuration and resources of an agent (the number of cores, amount of free memory, etc.) using the TerminalInfoInteger() function. Based on the information obtained, you can either allow to use this testing agent, or reject using it during the optimization of this Expert Advisor.

ENUM_INIT_RETCODE

Identifier	Description
INIT_SUCCEEDED	Successful initialization, testing of the Expert Advisor can be continued. This code means the same as a null value - the Expert Advisor has been successfully initialized in the tester.

Identifier	Description
INIT_FAILED	Initialization failed; there is no point in continuing testing because of fatal errors. For example, failed to create an indicator that is required for the work of the Expert Advisor. This return value means the same as a value other than zero - initialization of the Expert Advisor in the tester failed.
INIT_PARAMETERS_INCORRECT	This value means the incorrect set of input parameters. The result string containing this return code is highlighted in red in the general optimization table. Testing for the given set of parameters of the Expert Advisor will not be executed, the agent is free to receive a new task. Upon receiving this value, the strategy tester will reliably not pass this task to other agents for retry.
INIT_AGENT_NOT_SUITABLE	No errors during initialization, but for some reason the agent is not suitable for testing. For example, not enough memory, no OpenCL support, etc. After the return of this code, the agent will not receive tasks until the end of this optimization.

The OnInit() function of the void type always denotes successful initialization.

OnDeinit

The OnDeinit() function is called during deinitialization and is the Deinit event handler. It must be declared as the void type and should have one parameter of the const int type, which contains the code of deinitialization reason. If a different type is declared, the compiler will generate a warning, but the function will not be called. For scripts the Deinit event is not generated and therefore the OnDeinit() function can't be used in scripts.

```
void OnDeinit(const int reason);
```

The Deinit event is generated for Expert Advisors and indicators in the following cases:

- before reinitialization due to the change of a symbol or chart period, to which the mql5 program is attached;
- before reinitialization due to the change of input parameters;
- before unloading the mql5 program.

OnTick

The NewTick event is generated for **Expert Advisors only** when a new tick for a symbol is received, to the chart of which the Expert Advisor is attached. It's useless to define the OnTick() function in a custom indicator or script, because the NewTick event is not generated for them.

The Tick event is generated only for Expert Advisors, but this does not mean that Expert Advisors required the OnTick() function, since not only NewTick events are generated for Expert Advisors, but also events of Timer, BookEvent and ChartEvent are generated. It must be declared as the void type, with no parameters:

```
void OnTick();
```

OnTimer

The OnTimer() function is called when the Timer event occurs, which is generated by the system timer only for Expert Advisors and indicators - it can't be used in scripts. The frequency of the event occurrence is set when subscribing to notifications about this event to be received by the EventSetTimer() function.

You can unsubscribe from receiving timer events for a particular Expert Advisor using the EventKillTimer() function. The function must be defined with the void type, with no parameters:

```
void OnTimer();
```

It is recommended to call the EventSetTimer() function once in the OnInit() function, and the EventKillTimer() function should be called once in OnDeinit().

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as the mql5 program stops operating, the timer is destroyed forcibly, if it was created but hasn't been disabled by the EventKillTimer() function.

OnTrade

The function is called when the Trade event occurs, which appears when you change the list of placed orders and open positions, the history of orders and history of deals. When a trade activity is performed (pending order opening, position opening/closing, stops setting, pending order triggering, etc.) the history of orders and deals and/or list of positions and current orders is changed accordingly.

```
void OnTrade();
```

Users must independently implement in the code the verification of a trade account state when such an event is received (if this is required by the trade strategy conditions). If the OrderSend() function call has been completed successfully and returned a value of true, this means that the trading server has put the order into the queue for execution and assigned a ticket number to it. As soon as the server processes this order, the Trade event will be generated. And if a user remembers the ticket value, he/she will be able to find out what happened to the order using this value during OnTrade() event handling.

OnTradeTransaction

When performing some definite actions on a trade account, its state changes. Such actions include:

- Sending a trade request from any MQL5 application in the client terminal using OrderSend and OrderSendAsync functions and its further execution;
- Sending a trade request via the terminal graphical interface and its further execution;
- Pending orders and stop orders activation on the server;
- Performing operations on a trade server side.

The following trade transactions are performed as a result of these actions:

- handling a trade request;
- changing open orders;
- changing orders history;
- changing deals history;

- changing positions.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. All these actions are trade transactions. Arrival of such a transaction at the terminal is a TradeTransaction event. It calls OnTradeTransaction handler

```
void  OnTradeTransaction(
   const MqlTradeTransaction&    trans,        // trade transaction structure
   const MqlTradeRequest&        request,      // request structure
   const MqlTradeResult&         result        // result structure
   );
```

The handler contains three parameters:

- **trans** - this parameter gets MqlTradeTransaction structure describing a trade transaction applied to a trade account;
- **request** - this parameter gets MqlTradeRequest structure describing a trade request;
- **result** - this parameter gets MqlTradeResult structure describing a trade request execution result.

The last two **request** and **result** parameters are filled by values only for TRADE_TRANSACTION_REQUEST type transaction, data on transaction can be received from *type* parameter of **trans** variable. Note that in this case, *request_id* field in **result** variable contains ID of **request** trade request, after the execution of which the trade transaction described in **trans** variable has been performed. Request ID allows to associate the performed action (OrderSend or OrderSendAsync functions call) with the result of this action sent to OnTradeTransaction().

One trade request manually sent from the terminal or via OrderSend()/OrderSendAsync() functions can generate several consecutive transactions on the trade server. Priority of these transactions' arrival at the terminal is not guaranteed. Thus, you should not expect that one group of transactions will arrive after another one when developing your trading algorithm.

- All types of trade transactions are described in ENUM_TRADE_TRANSACTION_TYPE enumeration.
- MqlTradeTransaction structure describing a trade transaction is filled in different ways depending on a transaction type. For example, only type field (trade transaction type) must be analyzed for TRADE_TRANSACTION_REQUEST type transactions. The second and third parameters of OnTradeTransaction function (request and result) must be analyzed for additional data. For more information, see "Structure of a Trade Transaction".
- A trade transaction description does not deliver all available information concerning orders, deals and positions (e.g., comments). OrderGet*, HistoryOrderGet*, HistoryDealGet* and PositionGet* functions should be used to get extended information.

After applying trade transactions for a client account, they are consistently placed to the terminal trade transactions queue, from which they consistently sent to OnTradeTransaction entry point in order of arrival at the terminal.

When handling trade transactions by an Expert Advisor using OnTradeTransaction handler, the terminal continues handling newly arrived trade transactions. Therefore, the state of a trade account can change during OnTradeTransaction operation already. For example, while an MQL5 program handles an event of adding a new order, it may be executed, deleted from the list of the open ones and moved to the history. Further on, the application will be notified of these events.

Transactions queue length comprises 1024 elements. If OnTradeTransaction handles a new transaction for too long, the old ones in the queue may be superseded by the newer ones.

- Generally, there is no accurate ratio of the number of OnTrade and OnTradeTransaction calls. One OnTrade call corresponds to one or several OnTradeTransaction calls.
- OnTrade is called after appropriate OnTradeTransaction calls.

OnTester

The OnTester() function is the handler of the Tester event that is automatically generated after a history testing of an Expert Advisor on the chosen interval is over. The function must be defined with the double type, with no parameters:

```
double OnTester();
```

The function is called right before the call of OnDeinit() and has the same type of the return value - double. OnTester() can be used only in the testing of Expert Advisors. Its main purpose is to calculate a certain value that is used as the Custom max criterion in the genetic optimization of input parameters.

In the genetic optimization descending sorting is applied to results within one generation. I.e. from the point of view of the optimization criterion, the best results are those with largest values (for the Custom max optimization criterion values returned by the OnTester function are taken into account). In such a sorting, the worst values are positioned at the end and further thrown off and do not participate in the forming of the next generation.

OnTesterInit

The OnTesterInit() function is the handler of the TesterInit event, which is automatically generated before the start of Expert Advisor optimization in the strategy tester. The function must be defined with the void type. It has no parameters:

```
void OnTesterInit();
```

With the start of optimization, an Expert Advisor with the OnTesterDeinit() or OnTesterPass() handler is automatically loaded in a separate terminal chart with the symbol and period specified in the tester, and receives the TesterInit event. The function is used for Expert Advisor initialization before the start of optimization for further processing of optimization results.

OnTesterPass

The OnTesterPass() function is the handler of the TesterPass event, which is automatically generated when a frame is received during Expert Advisor optimization in the strategy tester. The function must be defined with the void type. It has no parameters:

```
void OnTesterPass();
```

An Expert Advisor with the OnTesterPass() handler is automatically loaded in a separate terminal chart with the symbol/period specified for testing, and gets TesterPass events when a frame is received during optimization. The function is used for dynamic handling of optimization results "on the spot" without waiting for its completion. Frames are added using the FrameAdd() function, which can be called after the end of a single pass in the OnTester() handler.

OnTesterDeinit

OnTesterDeinit() is the handler of the TesterDeinit event, which is automatically generated after the end of Expert Advisor optimization in the strategy tester. The function must be defined with the void type. It has no parameters:

```
void OnTesterDeinit();
```

An Expert Advisor with the TesterDeinit() handler is automatically loaded on a chart at the start of optimization, and receives TesterDeinit after its completion. The function is used for final processing of all optimization results.

OnBookEvent

The OnBookEvent() function is the BookEvent handler. BookEvent is generated for Expert Advisors and indicators when Depth of Market changes. It must be of the void type and have one parameter of the string type:

```
void OnBookEvent (const string& symbol);
```

To receive BookEvent events for any symbol, you just need to pre-subscribe to receive these events for this symbol using the MarketBookAdd() function. In order to unsubscribe from receiving the BookEvent events for a particular symbol, call MarketBookRelease().

Unlike other events, the BookEvent event is broadcast. This means that if one Expert Advisor subscribes to receiving BookEvent events using MarketBookAdd, all the other Experts Advisors that have the OnBookEvent() handler will receive this event. It is therefore necessary to analyze the name of the symbol, which is passed to the handler as the *const string& symbol* parameter.

OnChartEvent

OnChartEvent() is the handler of a group of ChartEvent events:

- CHARTEVENT_KEYDOWN — event of a keystroke, when the chart window is focused;
- CHARTEVENT_MOUSE_MOVE — mouse move events and mouse click events (if CHART_EVENT_MOUSE_MOVE=true is set for the chart);
- CHARTEVENT_OBJECT_CREATE — event of graphical object creation (if CHART_EVENT_OBJECT_CREATE=true is set for the chart);
- CHARTEVENT_OBJECT_CHANGE — event of change of an object property via the properties dialog;
- CHARTEVENT_OBJECT_DELETE — event of graphical object deletion (if CHART_EVENT_OBJECT_DELETE=true is set for the chart);
- CHARTEVENT_CLICK — event of a mouse click on the chart;
- CHARTEVENT_OBJECT_CLICK — event of a mouse click in a graphical object belonging to the chart;
- CHARTEVENT_OBJECT_DRAG — event of a graphical object move using the mouse;
- CHARTEVENT_OBJECT_ENDEDIT — event of the finished text editing in the entry box of the LabelEdit graphical object;
- CHARTEVENT_CHART_CHANGE — event of chart changes;
- CHARTEVENT_CUSTOM+n — ID of the user event, where n is in the range from 0 to 65535.

- CHARTEVENT_CUSTOM_LAST — the last acceptable ID of a custom event (CHARTEVENT_CUSTOM +65535).

The function can be called only in Expert Advisors and indicators. The function should be of void type with 4 parameters:

```
void OnChartEvent(const int id,          // Event ID
                  const long& lparam,    // Parameter of type long event
                  const double& dparam, // Parameter of type double event
                  const string& sparam  // Parameter of type string events
  );
```

For each type of event, the input parameters of the OnChartEvent() function have definite values that are required for the processing of this event. The events and values passed through these parameters are listed in the table below.

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
Event of a keystroke	CHARTEVENT_KEYDOWN	code of a pressed key	Repeat count (the number of times the keystroke is repeated as a result of the user holding down the key)	The string value of a bit mask describing the status of keyboard buttons
Mouse events (if property CHART_EVENT_MOUSE_MOVE=true is set for the chart)	CHARTEVENT_MOUSE_MOVE	the X coordinate	the Y coordinate	The string value of a bit mask describing the status of mouse buttons
Event of graphical object creation (if CHART_EVENT_OBJECT_CREATE=true is set for the chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of the created graphical object
Event of change of an object property via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of the modified graphical object
Event of graphical object deletion (if CHART_EVENT_O	CHARTEVENT_OBJECT_DELETE	—	—	Name of the deleted graphical object

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
BJECT_DELETE=true is set for the chart)				
Event of a mouse click on the chart	CHARTEVENT_CLICK	the X coordinate	the Y coordinate	—
Event of a mouse click in a graphical object belonging to the chart	CHARTEVENT_OBJECT_CLICK	the X coordinate	the Y coordinate	Name of the graphical object, on which the event occurred
Event of a graphical object dragging using the mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of the moved graphical object
Event of the finished text editing in the entry box of the LabelEdit graphical object	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the LabelEdit graphical object, in which text editing has completed
Event of chart Changes	CHARTEVENT_CHART_CHANGE	—	—	—
ID of the user event under the N number	CHARTEVENT_CUSTOM+N	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function

OnCalculate

The OnCalculate() function is called only in custom indicators when it's necessary to calculate the indicator values by the Calculate event. This usually happens when a new tick is received for the symbol, for which the indicator is calculated. This indicator is not required to be attached to any price chart of this symbol.

The OnCalculate() function must have a return type int. There are two possible definitions. Within one indicator you cannot use both versions of the function.

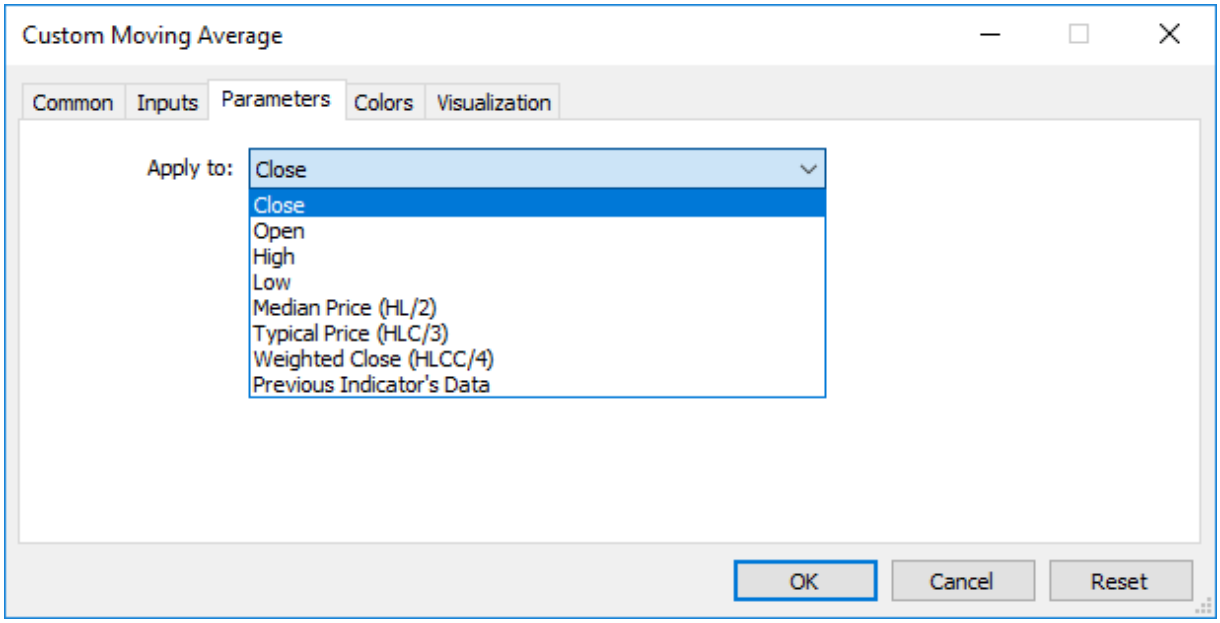
The first form is intended for those indicators that can be calculated on a single data buffer. An example of such an indicator is Custom Moving Average.

```
int OnCalculate (const int rates_total,      // size of the price[] array
                 const int prev_calculated,  // bars handled on a previous call
                 const int begin,            // where the significant data start from
```

```
                const double& price[]       // array to calculate
   );
```

As the price[] array, one of timeseries or a calculated buffer of some indicator can be passed. To determine the direction of indexing in the price[] array, call ArrayGetAsSeries(). In order not to depend on the default values, you must unconditionally call the ArraySetAsSeries() function for those arrays, that are expected to work with.

Necessary time series or an indicator to be used as the price[] array can be selected by the user in the "Parameters" tab when starting the indicator. To do this, you should specify the necessary item in the drop-down list of "Apply to" field.



To receive values of a custom indicator from other mql5 programs, the iCustom() function is used, which returns the indicator handle for subsequent operations. You can also specify the appropriate price[] array or the handle of another indicator. This parameter should be transmitted last in the list of input variables of the custom indicator.

Example:

```
void OnStart()
  {
//---
   string terminal_path=TerminalInfoString(STATUS_TERMINAL_PATH);
   int handle_customMA=iCustom(Symbol(),PERIOD_CURRENT, "Custom Moving Average",13,0,
   if(handle_customMA>0)
      Print("handle_customMA = ",handle_customMA);
   else
      Print("Cannot open or not EX5 file '"+terminal_path+"\\MQL5\\Indicators\\"+"Cust
  }
```

In this example, the last parameter passed is the PRICE_TYPICAL value (from the ENUM_APPLIED_PRICE enumeration), which indicates that the custom indicator will be built on typical prices obtained as (High+Low+Close)/3. If this parameter is not specified, the indicator is built based on PRICE_CLOSE values, i.e. closing prices of each bar.

Another example that shows passing of the indicator handler as the last parameter to specify the price[] array, is given in the description of the iCustom() function.

The second form is intended for all other indicators, in which more than one time series is used for calculations.

```
int OnCalculate (const int rates_total,      // size of input time series
                 const int prev_calculated,  // bars handled in previous call
                 const datetime& time[],     // Time
                 const double& open[],       // Open
                 const double& high[],       // High
                 const double& low[],        // Low
                 const double& close[],      // Close
                 const long& tick_volume[],  // Tick Volume
                 const long& volume[],       // Real Volume
                 const int& spread[]         // Spread
   );
```

Parameters of open[], high[], low[] and close[] contain arrays with open prices, high and low prices and close prices of the current time frame. The time[] parameter contains an array with open time values, the spread[] parameter has an array containing the history of spreads (if any spread is provided for the traded security). The parameters of volume[] and tick_volume[] contain the history of trade and tick volume, respectively.

To determine the indexing direction of time[], open[], high[], low[], close[], tick_volume[], volume[] and spread[], call ArrayGetAsSeries(). In order not to depend on default values, you should unconditionally call the ArraySetAsSeries() function for those arrays, which are expected to work with.

The first rates_total parameter contains the number of bars, available to the indicator for calculation, and corresponds to the number of bars available in the chart.

We should note the connection between the return value of OnCalculate() and the second input parameter prev_calculated. During the function call, the prev_calculated parameter contains a value **returned** by OnCalculate() during **previous** call. This allows for economical algorithms for calculating the custom indicator in order to avoid repeated calculations for those bars that haven't changed since the previous run of this function.

For this, it is usually enough to return the value of the rates_total parameter, which contains the number of bars in the current function call. If since the last call of OnCalculate() price data has changed (a deeper history downloaded or history blanks filled), the value of the input parameter prev_calculated will be set to zero by the terminal.

Note: if OnCalculate returns zero, then the indicator values are not shown in the DataWindow of the client terminal.

To understand it better, it would be useful to start the indicator, which code is attached below.

Indicator Example:

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
```

```
//---- plot Line
#property indicator_label1  "Line"
#property indicator_type1   DRAW_LINE
#property indicator_color1  clrDarkBlue
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- indicator buffers
double         LineBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,LineBuffer,INDICATOR_DATA);
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime& time[],
                const double& open[],
                const double& high[],
                const double& low[],
                const double& close[],
                const long& tick_volume[],
                const long& volume[],
                const int& spread[])
  {
//--- Get the number of bars available for the current symbol and chart period
   int bars=Bars(Symbol(),0);
   Print("Bars = ",bars,", rates_total = ",rates_total,",  prev_calculated = ",prev_ca
   Print("time[0] = ",time[0]," time[rates_total-1] = ",time[rates_total-1]);
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

Variables

Declaring Variables

Variables must be declared before they are used. Unique names are used to identify variables. To declare a variable, you must specify its type and a unique name. Declaration of variable is not an operator.

Simple types are:

- char, short, int, long, uchar, ushort, uint, ulong - integers;
- color - integer representing the RGB-color;
- datetime - the date and time, an unsigned integer containing the number of seconds since 0 hour January 1, 1970;
- bool - boolean values *true* and *false*;
- double - double-precision floating point number;
- float - single-precision floating point number;
- string - character strings.

Examples:

```
string szInfoBox;
int    nOrders;
double dSymbolPrice;
bool   bLog;
datetime tBegin_Data   = D'2004.01.01 00:00';
color    cModify_Color = C'0x44,0xB9,0xE6';
```

Complex or compound types:

Structures are composite data types, constructed using other types.

```
struct MyTime
  {
   int hour;    // 0-23
   int minute;  // 0-59
   int second;  // 0-59
  };
...
MyTime strTime; // Variable of the previously declared structure MyTime
```

You can't declare variables of the structure type until you declare the structure.

Arrays

Array is the indexed sequence of identical-type data:

```
int    a[50];       // One-dimensional array of 50 integers.
double m[7][50];    // Two-dimensional array of seven arrays,
                    // each of them consisting of 50 numbers.
MyTime t[100];      // Array containing elements such as MyTime
```

Only an integer can be an array index. No more than four-dimensional arrays are allowed. Numbering of array elements starts with 0. The last element of a one-dimensional array has the number which is 1 less than the array size. This means that call for the last element of an array consisting of 50 integers will appear as a[49]. The same concerns multidimensional arrays: A dimension is indexed from 0 to the dimension size-1. The last element of a two-dimensional array from the example will appear as m[6][49].

Static arrays can't be represented as timeseries, i.e., the ArraySetAsSeries() function, which sets access to array elements from the end to beginning, can't be applied to them. If you want to provide access to an array the same as in timeseries, use the dynamic array object.

If there is an attempt to access out of the array range, the executing subsystem will generate a critical error and the program will be stopped.

Built-in methods for working with arrays

The functions from the Array Functions section, as well as the built-in methods can be used to handle the arrays:

Method	Analog	Description
void array.Fill(const scalar value, const int start_pos=0, const int count=-1);	ArrayFill, ArrayInitialize	Fills the array with the specified value
void array.Free();	ArrayFree	Releases the dynamic array buffer and sets the zero dimension size to 0 (zero)
int array.Resize(const int range0_size, const int reserve); int array.Resize(const int range_sizes[], const int reserve);	ArrayResize	Sets a new size in the array first dimension
int array.Print();	ArrayPrint	Displays simple type array values in the journal
int array.Size(const int range=-1);	ArraySize, ArrayRange	Returns the number of elements in the entire array (range=-1) or in the specified array dimension
bool array.IsDynamic();	ArrayIsDynamic	Checks if the array is dynamic
bool array.IsIndicatorBuffer();		Checks if the array is an indicator buffer
bool array.IsSeries();	ArrayIsSeries	Checks if the array is a timeseries
bool array.AsSeries();	ArrayGetAsSeries	Checks the array indexing direction
bool array.AsSeries(const bool as_series);	ArraySetAsSeries	Sets the indexing direction in the array
int array.Copy(const src_array[], const int dst_start, const int	ArrayCopy	Copies array values to another array

Method	Analog	Description
src_start, const int cnt);		
int array.Compare(const src_array[], const int dst_start, const int src_start, const int cnt);	ArrayCompare	Returns the result of comparing two simple type arrays or custom structures
int array.Insert(const src_array[], const int dst_start, const int src_start, const int cnt);	ArrayInsert	Inserts the specified number of elements from a source array to a receiving one starting from a specified index
int array.Remove(const int start_pos, const int count);	ArrayRemove	Removes the specified number of elements from the array starting with a specified index
int array.Reverse(const int start_pos, const int count);	ArrayReverse	Reverses the specified number of elements in the array starting with a specified index
bool array.Swap(array& arr[]);	ArraySwap	Exchanges the content with another dynamic array of the same type
void array.Sort(sort_function);	ArraySort	Sorts numeric arrays by the first dimension
int array.Search(scalar value, search_function);	ArrayBsearch	Returns the index of the first element detected in the array first dimension
int array.Find((scalar value, search_function);		Performs a search in the array using the passed function and returns the index of the first detected element
array array.Select(scalar value, search_function);		Performs a search in the array using the passed function and returns the array with all detected elements

Access Specifiers

Access specifiers define how the compiler can access variables, members of structures or classes.

The const specifier declares a variable as a constant, and does not allow to change this variable during runtime. A single initialization of a variable is allowed when declaring it.

Example:

```
int OnCalculate (const int rates_total,      // size of the price[] array
                 const int prev_calculated,  // bars handled on a previous call
                 const int begin,            // where the significant data start from
                 const double& price[]       // array to calculate
   );
```

To access members of structures and classes use the following qualifiers:

- public – allows unrestricted access to the variable or class method
- protected – allows access from methods of this class, as well as from methods of publicly inherited classes. Other access is impossible;
- private – allows access to variables and class methods only from methods of the same class.
- virtual – applies only to class methods (but not to methods of structures) and tells the compiler that this method should be placed in the table of virtual functions of the class.

Storage Classes

There are three storage classes: static, input and extern. These modifiers of a storage class explicitly indicate to the compiler that corresponding variables are distributed in a pre-allocated area of memory, which is called the global pool. Besides, these modifiers indicate the special processing of variable data. If a variable declared on a local level is not a static one, memory for such a variable is allocated automatically at a program stack. Freeing of memory allocated for a non-static array is also performed automatically when going beyond the visibility area of the block, in which the array is declared.

Local Variables

A variable declared inside a function is local. The scope of a local variable is limited to the function range inside which it is declared. Local variable can be initialized by outcome of any expression. Every call of the function initializes a local variable. Local variables are stored in memory area of the corresponding function.

Example:

```
int somefunc()
  {
   int ret_code=0;
   ...
   return(ret_code);
  }
```

Scope of a variable is a program part, in which a variable can be referred to. Variables declared inside a block (at the internal level), have the block as their scope. The block scope start with the variable declaration and ends with the final right brace.

Local variables declared in the beginning of a function also have the scope of block, as well as function parameters that are local variables. Any block can contain variable declarations. If blocks are nested and the identifier in the external block has the same name as the identifier in the internal block, the external block identifier is hidden, until the operation of the internal block is over.

Example:

```
void OnStart()
  {
//---
   int i=5;       // local variable of the function
     {
      int i=10;  // function variable
      Print("Inside block i = ",i); // result is  i=10;
     }
   Print("Outside block i = ",i);  // result is  i=5;
  }
```

This means that while the internal block is running, it sees values of its own local identifiers, not the values of identifiers with identical names in the external block.

Example:

```
void OnStart()
  {
//---
   int i=5;       // local variable of the function
   for(int i=0;i<3;i++)
      Print("Inside for i = ",i);
   Print("Outside the block i = ",i);
  }
/* Execution result
```

```
Inside for i = 0
Inside for i = 1
Inside for i = 2
Outside block i = 5
*/
```

Local variables declared as static have the scope of the block, despite the fact that they exist since the program start.

Stack

In every MQL5 program, a special memory area called stack is allocated for storing local function variables that are created automatically. One stack is allocated for all functions, its default size for indicators is equal to 1Mb. In Expert Advisors and scripts, stack size can be managed using the #property stacksize compiler directive (which sets the stack size in bytes), a memory of 8Mb is allocated by default for the stack.

Static local variables are stored in the same place where other static and global variables are stored - in a special memory area, which exists separately from the stack. Dynamically created variables also use a memory area separate from the stack.

With each function call, a place on the stack is allocated for internal non-static variables. After exiting the function, the memory is available for use again.

If from the first function the second one is called, then the second function occupies the required size from the remaining stack memory for its variables. Thus, when using included functions, stack memory will be sequentially occupied for each function. This may lead to a shortage of memory during one of the function calls, such a situation is called stack overflow.

Therefore, for large local data you should better use dynamic memory - when entering a function, allocate the memory, which is required for local needs, in the system (new, ArrayResize()), and when exiting the function, release the memory (delete, ArrayFree()).

Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Formal Parameters

Parameters passed to the function are local. The scope is the function block. Formal parameters must have names differing from those of external variables and local variables defined within one function. Some values can be assigned to formal parameters in the function block. If a formal parameter is declared with the const modifier, its value can't be changed within the function.

Example:

```
void func(const int & x[], double y, bool z)
  {
   if(y>0.0 && !z)
      Print(x[0]);
   ...
  }
```

Formal parameters can be initialized by constants. In this case, the initializing value is considered as the default value. Parameters, next to the initialized one, must also be initialized.

Example:

```
void func(int x, double y = 0.0, bool z = true)
  {
   ...
  }
```

When calling such a function, the initialized parameters can be omitted, the defaults being substituted instead of them.

Example:

```
func(123, 0.5);
```

Parameters of simple types are passed by value, i.e., modifications of the corresponding local variable of this type inside the called function will not be reflected in the calling function. Arrays of any type and data of the structure type are always passed by reference. If it is necessary to prohibit modifying the array or structure contents, the parameters of these types must be declared with the *const* keyword.

There is an opportunity to pass parameters of simple types by reference. In this case, modification of such parameters inside the calling function will affect the corresponding variables passed by reference. In order to indicate that a parameter is passed by reference, put the & modifier after the data type.

Example:

```
void func(int& x, double& y, double & z[])
  {
   double calculated_tp;
   ...
   for(int i=0; i<OrdersTotal(); i++)
     {
      if(i==ArraySize(z))        break;
      if(OrderSelect(i)==false) break;
```

```
      z[i]=OrderOpenPrice();
     }
   x=i;
   y=calculated_tp;
  }
```

Parameters passed by reference can't be initialized by default values.

Maximum 64 parameters can be passed into a function.

See also

Input Variables, Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Static Variables

The storage class of static defines a static variable. The static modifier is indicated before the data type.

Example:

```
int somefunc()
  {
   static int flag=10;
   ...
   return(flag);
  }
```

A static variable can be initialized by a constant or constant expression corresponding to its type, unlike a simple local variable, which can be initialized by any expression.

Static variables exist from the moment of program execution and are initialized only once before the specialized functions OnInit() is called. If the initial values are not specified, variables of the static storage class are taking zero initial values.

Local variables declared with the *static* keyword retain their values throughout the function lifetime. With each next function call, such local variables contain the values that they had during the previous call.

Any variables in a block, except formal parameters of a function, can be defined as static. If a variable declared on a local level is not a static one, memory for such a variable is allocated automatically at a program stack.

Example:

```
int Counter()
  {
   static int count;
   count++;
   if(count%100==0) Print("Function Counter has been called ",count," times");
   return count;
  }
void OnStart()
  {
//---
   int c=345;
   for(int i=0;i<1000;i++)
     {
      int c=Counter();
     }
   Print("c =",c);
  }
```

See also

Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects, Static Class Members

Global Variables

Global variables are created by placing their declarations outside function descriptions. Global variables are defined at the same level as functions, i.e., they are not local in any block.

Example:

```
int GlobalFlag=10;   // Global variable
int OnStart()
  {
   ...
  }
```

The scope of global variables is the entire program. Global variables are accessible from all functions defined in the program. They are initialized to zero unless another initial value is explicitly defined. A global variable can be initialized only by a constant or constant expression that corresponds to its type.

Global variables are initialized only once after the program is loaded into the client terminal memory and before the first handling of the Init event. For global variables representing class objects, during their initialization the corresponding constructors are called. In scripts global variables are initialized before handling the Start event.

Note: Variables declared at global level must not be mixed up with the client terminal global variables that can be accessed using the GlobalVariable...() functions.

See also

Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Input Variables

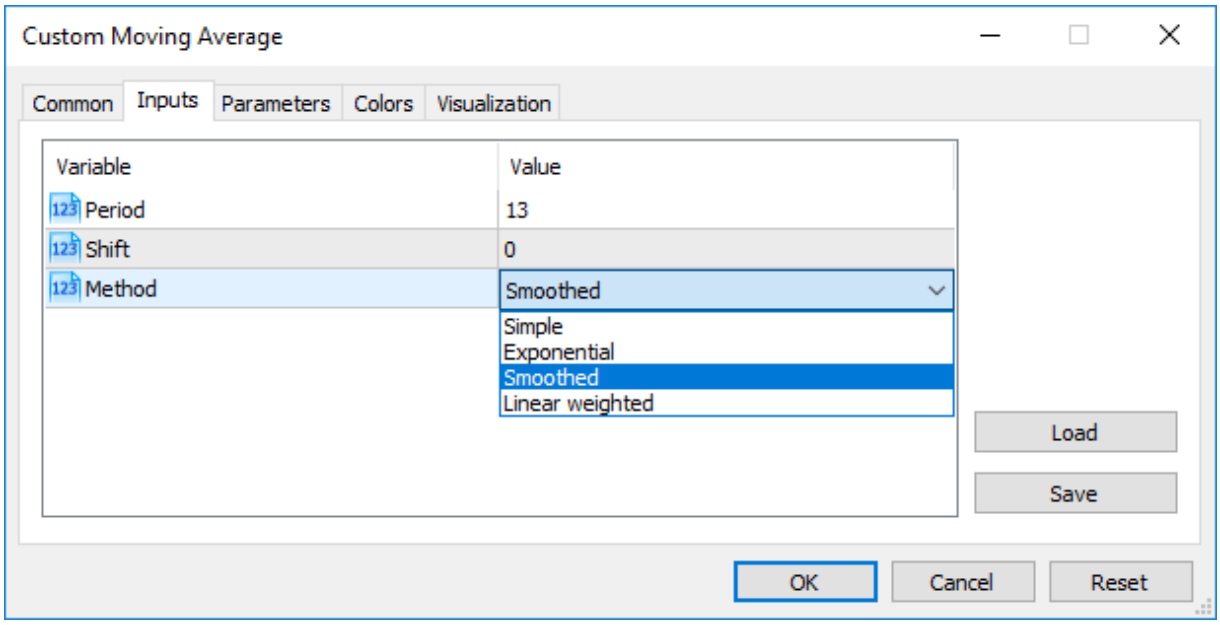
The input storage class defines the external variable. The *input* modifier is indicated before the data type. A variable with the input modifier can't be changed inside mql5-programs, such variables can be accessed for reading only. Values of input variables can be changed only by a user from the program properties window. External variables are always reinitialized immediately before the OnInit() is called.

The maximum length of input variable names is 63 characters. For the input parameter of string type, the **maximum** value length (string length) can be from 191 to 253 characters (see the Note). The minimum length is 0 characters (the value is not set).

Example:

```
//--- input parameters
input int             MA_Period=13;
input int             MA_Shift=0;
input ENUM_MA_METHOD MA_Method=MODE_SMMA;
```

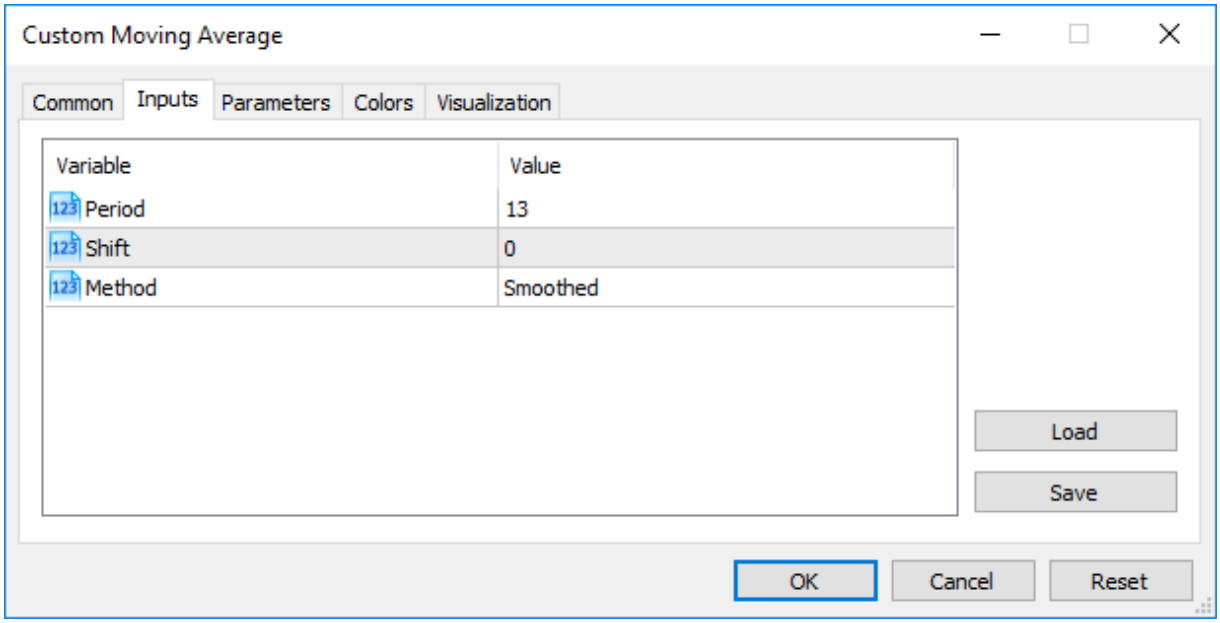
Input variables determine the input parameters of a program. They are available from the Properties window of a program.



There is another way to set how your input parameter will look like in the Inputs tab. For this, place a string comment after the description of an input parameter in the same line. In this way you can make names of input parameters more understandable for users.

Example:

```
//--- input parameters
input int             InpMAPeriod=13;         // Smoothing period
input int             InpMAShift=0;           // Line horizontal shift
input ENUM_MA_METHOD InpMAMethod=MODE_SMMA;  // Smoothing method
```



Note: Arrays and variables of complex types can't act as input variables.

Note: The length of a string comment for Input variables cannot exceed 63 characters.

Note: For input variables of string type, the limitation of the value length (string length) is set by the following conditions:

- the parameter value is represented by the "parameter_name=parameter_value" string ('=' is considered),
- maximum representation length of 255 characters (*total_length_max*=255 or 254 characters excluding '='),
- maximum length of the *parameter_name_length* string parameter = 63 characters.

Thus, the maximum string size for a string parameter is calculated using the equation:

```
parameter_value_length=total_length_max-parameter_name_length=254-parameter_name_lengt
```

This provides the maximum string size from 191 (parameter_name_length=63) to 253 characters (parameter_name_length=1).

Passing Parameters When Calling Custom Indicators from MQL5 Programs

Custom Indicators are called using the iCustom() function. After the name of the custom indicator, parameters should go in a strict accordance with the declaration of input variables of this custom indicator. If indicated parameters are less than input variables declared in the called custom indicator, the missing parameters are filled with values specified during the declaration of variables.

If the custom indicator uses the OnCalculate function of the first type (i.e., the indicator is calculated using the same array of data), then one of ENUM_APPLIED_PRICE values or handle of another indicator should be used as the last parameter when calling such a custom indicator. All parameters corresponding to input variables must be clearly indicated.

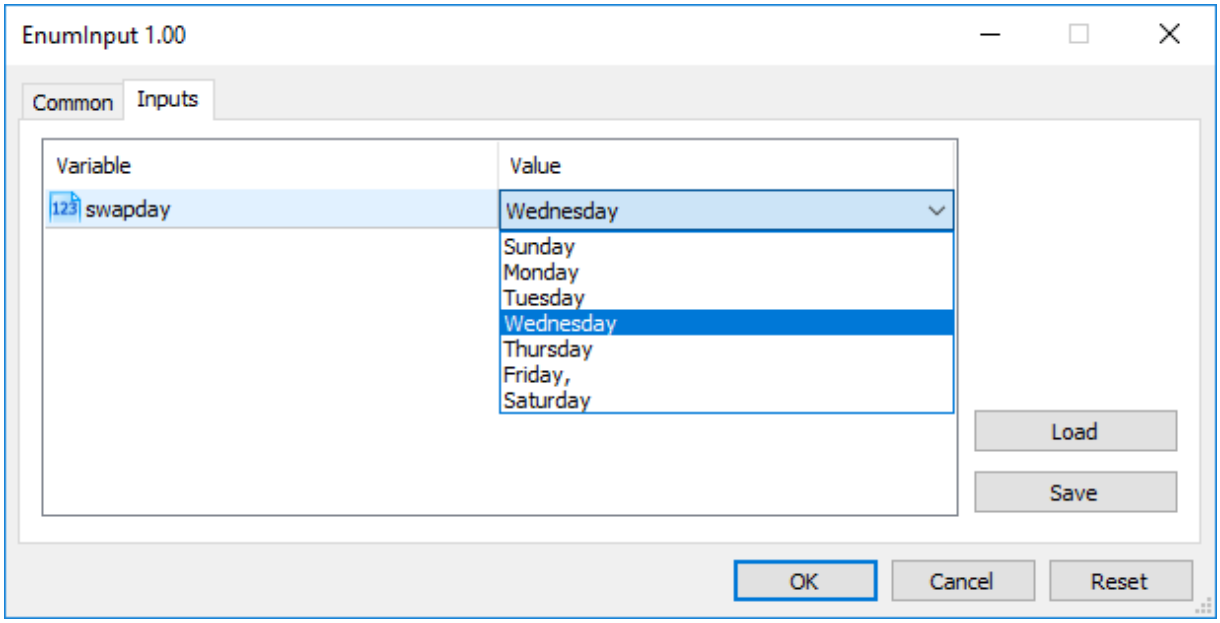
Enumerations as input Parameters

Not only built-in enumerations provided in MQL5, but also user defined variables can be used as input variables (input parameters for mql5 programs). For example, we can create the dayOfWeek enumeration, describing days of the week, and use the input variable to specify a particular day of the week, not as a number, but in a more common way.

Example:

```
#property script_show_inputs
//--- day of week
enum dayOfWeek
  {
   S=0,      // Sunday
   M=1,      // Monday
   T=2,      // Tuesday
   W=3,      // Wednesday
   Th=4,     // Thursday
   Fr=5,     // Friday,
   St=6,     // Saturday
  };
//--- input parameters
input dayOfWeek swapday=W;
```

In order to enable a user to select a necessary value from the properties window during the script startup, we use the preprocessor command #property script_show_inputs. We start the script and can choose one of values of the dayOfWeek enumeration from the list. We start the EnumInInput script and go to the Inputs tab. By default, the value of swapday (day of triple swap charge) is Wednesday (W = 3), but we can specify any other value, and use this value to change the program operation.



Number of possible values of an enumeration is limited. In order to select an input value the drop-down list is used. Mnemonic names of enumeration members are used for values displayed in the list.

If a comment is associated with a mnemonic name, as shown in this example, the comment content is used instead of the mnemonic name.

Each value of the dayOfWeek enumeration has its value from 0 to 6, but in the list of parameters, comments specified for each value will be shown. This provides additional flexibility for writing programs with clear descriptions of input parameters.

Variables with sinput Modifier

Variables with input modifier allow not only setting external parameters values when launching programs but are also necessary when optimizing trading strategies in the Strategy Tester. Each input variable excluding the one of a string type can be used in optimization.

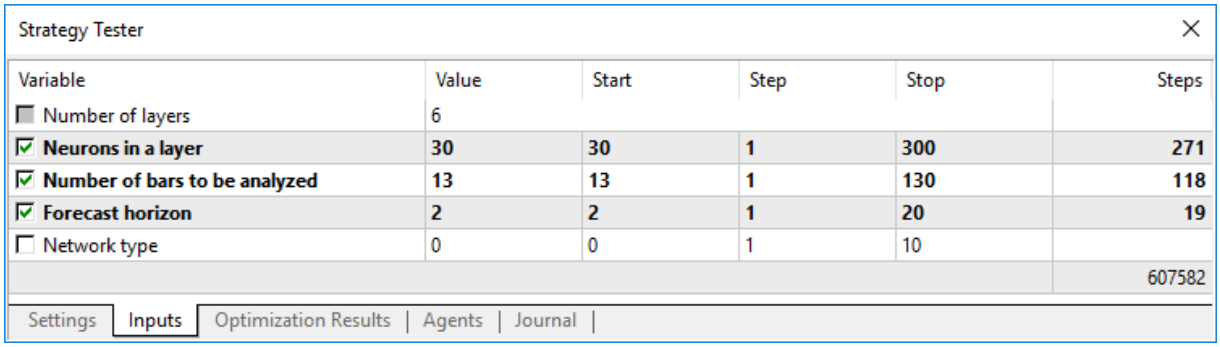
Sometimes, it is necessary to exclude some external program parameters from the area of all passes in the tester. sinput memory modifier has been introduced for such cases. sinput stands for static external variable declaration (sinput = static input). It means that the following declaration in an Expert Advisor code

```
sinput       int layers=6;    // Number of layers
```

will be equivalent to the full declaration

```
static input int layers=6;    // Number of layers
```

The variable declared with sinput modifier is an input parameter of MQL5 program. The value of this parameter can be changed when launching the program. However, this variable is not used in the optimization of input parameters. In other words, its values are not enumerated when searching for the best set of parameters fitting a specified condition.



The Expert Advisor shown above has 5 external parameters. "Number of layers" is declared to be sinput and equal to 6. This parameter cannot be changed during a trading strategy optimization. We can specify the necessary value for it to be used further on. Start, Step and Stop fields are not available for such a variable.

Therefore, users will not be able to optimize this parameter after we specify sinput modifier for the variable. In other words, the terminal users will not be able to set initial and final values for it in the Strategy Tester for automatic enumeration in the specified range during optimization.

However, there is one exception to this rule: sinput variables can be varied in optimization tasks using ParameterSetRange() function. This function has been introduced specifically for the program control of available values sets for any input variable including the ones declared as static input

(sinput). The ParameterGetRange() function allows to receive input variables values when optimization is launched (in OnTesterInit() handler) and to reset a change step value and a range, within which an optimized parameter values will be enumerated.

In this way, combining the sinput modifier and two functions that work with input parameters, allows to create a flexible rules for setting optimization intervals of input parameters that depend on values of another input parameters.

Arranging input parameters

For the convenience of working with MQL5 programs, the input parameters can be divided into named blocks using the group keyword. This allows for visual separation of some parameters from others based on the logic embedded in them.

```
input group             "Group name"
input int               variable1 = ...
input double            variable2 = ...
input double            variable3= ...
```

After such a declaration, all input parameters are visually joined into a specified group simplifying parameters configuration for MQL5 users when launching on a chart or in the strategy tester. Specification of each group is valid till a new group declaration appears:

```
input group             "Group name #1"
input int               group1_var1 = ...
input double            group1_var2 = ...
input double            group1_var3 = ...

input group             "Group name #2
input int               group2_var1 = ...
input double            group2_var2 = ...
input double            group2_var3 = ...
```

A sample EA featuring the block of inputs separated by their purpose:

```
input group             "Signal"
input int               ExtBBPeriod   = 20;       // Bollinger Bands period
input double            ExtBBDeviation= 2.0;      // deviation
input ENUM_TIMEFRAMES ExtSignalTF=PERIOD_M15;   // BB timeframe

input group             "Trend"
input int               ExtMAPeriod   = 13;       // Moving Average period
input ENUM_TIMEFRAMES ExtTrendTF=PERIOD_M15;    // MA timeframe

input group             "ExitRules"
input bool              ExtUseSL      = true;     // use StopLoss
input int               Ext_SL_Points = 50;       // StopLoss in points
input bool              ExtUseTP      = false;    // use TakeProfit
input int               Ext_TP_Points = 100;      // TakeProfit in points
```

```
input bool           ExtUseTS      = true;     // use Trailing Stop
input int            Ext_TS_Points = 30;       // Trailing Stop in points

input group          "MoneyManagement"
sinput double        ExtInitialLot = 0.1;      // initial lot value
input bool           ExtUseAutoLot = true;     // automatic lot calculation

input group          "Auxiliary"
sinput int           ExtMagicNumber = 123456;  // EA Magic Number
sinput bool          ExtDebugMessage= true;    // print debug messages
```

When launching such an EA in the strategy tester, you can double-click a group name to collapse/expand the inputs block, as well as click the group checkbox to select all its parameters for optimization.

iCustom, Enumerations, Properties of Programs

Extern Variables

The extern keyword is used for declaring variable identifiers as identifiers of the static storage class with global lifetime. These variables exist from the start of the program and memory for them is allocated and initialized immediately after the start of the program.

You can create programs that consist of multiple source files; in this case a directive to the preprocessor #include is used. Variables declared as an extern with the same type and identifier can exist in different source files of one project.

When compiling the whole project, all the extern variables with the same type and an identifier are associated with one part of memory of the global variable pool. Extern variables are useful for separate compilation of source files. Extern variables can be initialized, but only once - existence of several initialized extern variables of the same type and with the same identifier is prohibited.

See also

Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Initialization of Variables

Any variable can be initialized during definition. If a variable is not initialized explicitly, the value stored in this variable can be any. Implicit initialization is not used.

Global and static variables can be initialized only by a constant of the corresponding type or a constant expression. Local variables can be initialized by any expression, not just a constant.

Initialization of global and static variables is performed only once. Initialization of local variables is made every time you call the corresponding functions.

Examples:

```
int    n       = 1;
string s       = "hello";
double f[]     = { 0.0, 0.236, 0.382, 0.5, 0.618, 1.0 };
int    a[4][4] = { {1, 1, 1, 1}, {2, 2, 2, 2}, {3, 3, 3, 3}, {4, 4, 4, 4 } };
//--- from tetris
int    right[4]={WIDTH_IN_PIXELS+VERT_BORDER,WIDTH_IN_PIXELS+VERT_BORDER,
                 WIDTH_IN_PIXELS+VERT_BORDER,WIDTH_IN_PIXELS+VERT_BORDER};
//--- initialization of all fields of the structure with zero values
MqlTradeRequest request={};
```

List of values of the array elements must be enclosed in curly brackets. Missed initializing sequences are considered equal to 0.

If the size of the initialized array is not specified, it is determined by a compiler, based on the size of the initialization sequence.

Examples:

```
struct str3
  {
   int               low_part;
   int               high_part;
  };
struct str10
  {
   str3              s3;
   double            d1[10];
   int               i3;
  };
void OnStart()
  {
   str10 s10_1={{1,0},{1.0,2.1,3.2,4.4,5.3,6.1,7.8,8.7,9.2,10.0},100};
   str10 s10_2={{1,0},{},100};
   str10 s10_3={{1,0},{1.0}};
//---
   Print("1.  s10_1.d1[5] = ",s10_1.d1[5]);
   Print("2.  s10_2.d1[5] = ",s10_2.d1[5]);
   Print("3.  s10_3.d1[5] = ",s10_3.d1[5]);
```

```
   Print("4.  s10_3.d1[0] = ",s10_3.d1[0]);
  }
```

For structure type variable partial initialization is allowed, as well as for static arrays (with an implicitly set size). You can initialize one or more first elements of a structure or array, the other elements will be initialized with zeroes in this case.

Data Types, Encapsulation and Extensibility of Types, Visibility Scope and Lifetime of Variables, Creating and Deleting Objects

Visibility Scope and Lifetime of Variables

There are two basic types of scope: local scope and global scope.

A variable declared outside all functions is located into the global scope. Access to such variables can be done from anywhere in the program.These variables are located in the global pool of memory, so their lifetime coincides with the lifetime of the program.

A variable declared inside a block (part of code enclosed in curly brackets) belongs to the local scope. Such a variable is not visible (and therefore not available) outside the block, in which it is declared. The most common case of local declaration is a variable declared within a function. A variable declared locally, is located on the stack, and the lifetime of such a variable is equal to the lifetime of the function.

Since the scope of a local variable is the block in which it is declared, it is possible to declare variables with the same name, as those of variables declared in other blocks; as well as of those declared at upper levels, up to the global level.

Example:

```
void CalculateLWMA(int rates_total,int prev_calculated,int begin,const double &price[]
  {
   int        i,limit;
   static int weightsum=0;
   double     sum=0;
//---
   if(prev_calculated==0)
     {
      limit=MA_Period+begin;
      //--- set empty value for first limit bars
      for(i=0; i<limit; i++) LineBuffer[i]=0.0;
      //--- calculate first visible value
      double firstValue=0;
      for(int i=begin; i<limit; i++)
        {
         int k=i-begin+1;
         weightsum+=k;
         firstValue+=k*price[i];
        }
      firstValue/=(double)weightsum;
      LineBuffer[limit-1]=firstValue;
     }
   else
     {
      limit=prev_calculated-1;
     }

   for(i=limit;i<rates_total;i++)
     {
      sum=0;
```

```
      for(int j=0; j<MA_Period; j++) sum+=(MA_Period-j)*price[i-j];
      LineBuffer[i]=sum/weightsum;
     }
//---
  }
```

Pay attention to the variable i, declared in line

```
      for(int i=begin; i<limit; i++)
        {
         int k=i-begin+1;
         weightsum+=k;
         firstValue+=k*price[i];
        }
```

Its scope is only the for loop; outside of this loop there is another variable with the same name, declared at the beginning of the function. In addition, the k variable is declared in the loop body, its scope is the loop body.

Local variables can be declared with the access specifier static. In this case, the compiler has a variable in the global pool of memory. Therefore, the lifetime of a static variable is equal to the lifetime of the program. Here the scope of such a variable is limited to the block in which it is declared.

Data Types, Encapsulation and Extensibility of Types, Initialization of Variables, Creating and Deleting Objects

Creating and Deleting Objects

After a MQL5 program is loaded for execution, memory is allocated to each variable according to its type. According to the access level, all variables are divided into two types - global variables and local variables. According to the memory class, they can be input parameters of a MQL5 program, static and automatic. If necessary, each variable is initialized by a corresponding value. After being used a variable is unintialized and memory used by it is returned to the MQL5 executable system.

Initialization and Deinitialization of Global Variables

Global variables are initialized automatically right after a MQL5 program is loaded and before any of function is called. During initialization initial values are assigned to variables of simple types and a constructor (if there is any) is called for objects. Input variables are always declared at a global level, and are initialized by values set by a user in the dialog during the program start.

Despite the fact that static variables are usually declared at a local level, the memory for these variables is pre-allocated, and initialization is performed right after a program is loaded, the same as for global variables.

The initialization order corresponds to the variable declaration order in the program. Deinitialization is performed in the reverse order. This rule is true only for the variables that were not created by the new operator. Such variables are created and initialized automatically right after loading, and are deinitialized before the program unloading.

Initialization and Deinitialization of Local Variables

If a variable declared on a local level is not a static one, memory is allocated automatically for such a variable. Local variables, as well as global ones, are initialized automatically at the moment when the program execution meets their declaration. Thus the initialization order corresponds to the order of declaration.

Local variables are deinitialized at the end of the program block, in which they were declared, and in the order opposite to their declaration. A program block is a compound operator that can be a part of selection operator switch, loop operator (for, while, do-while), a function body or a part of the if-else operator.

Local variables are initialized only at the moment when the program execution meets the variable declaration. If during the program execution the block, in which the variable is declared, was not executed, such a variable is not initialized.

Initialization and Deinitialization of Objects Placed

A special case is that with object pointers, because declaration of a pointer does not entail initialization of a corresponding objects. Dynamically placed objects are initialized only at the moment when the class sample is created by the new operator. Initialization of objects presupposes call of a constructor of a corresponding class. If there is no corresponding constructor in the class, its members of a simple type will not be automatically initialized; members of types string, dynamic array and complex object will be automatically initialized.

Pointers can be declared on a local or global level; and they can be initialized by the empty value of NULL or by the value of the pointer of the same or inherited type. If the *new* operator is called for a

pointer declared on a local level, the *delete* operator for this pointer must be performed before exiting the level. Otherwise the pointer will be lost and the explicit deletion of the object will fail.

All objects created by the expression of *object_pointer*=new *Class_name*, must be then deleted by the delete(*object_pointer*) operator. If for some reasons such a variable is not deleted by the delete operator when the program is completed, the corresponding entry will appear in the "Experts" journal. One can declare several variables and assign a pointer of one object to all of them.

If a dynamically created object has a constructor, this constructor will be called at the moment of the *new* operator execution. If an object has a destructor, it will be called during the execution of the *delete* operator.

Thus dynamically placed objects are created only at the moment when the corresponding *new* operator is invoked, and are assuredly deleted either by the *delete* operator or automatically by the executing system of MQL5 during the program unloading. The order of declaration of pointers of dynamically created object doesn't influence the order of their initialization. The order of initialization and deinitialization is fully controlled by the programmer.

Dynamic memory allocation in MQL5

When working with dynamic arrays, released memory is immediately returned back to the operating system.

When working with dynamic class objects using the new operator, first memory is requested from the class memory pool the memory manager is working with. If there is not enough memory in the pool, memory is requested from the operating system. When deleting the dynamic object using the delete operator, released memory is immediately returned back to the class memory pool.

Memory manager releases memory back to the operating system immediately after exiting the following event handling functions: OnInit(), OnDeinit(), OnStart(), OnTick(), OnCalculate(), OnTimer(), OnTrade(), OnTester(), OnTesterInit(), OnTesterPass(), OnTesterDeinit(), OnChartEvent(), OnBookEvent().

Brief Characteristics of Variables

The main information about the order of creation, deletion, about calls of constructors and destructors is given in the below table.

	Global automatic variable	Local automatic variable	Dynamically created object
Initialization	right after a mql5 program is loaded	when the code line where it is declared is reached during execution	at the execution of the **new** operator
Initialization order	in the order of declaration	in the order of declaration	irrespective of the order of declaration
Deinitialization	before a mql5 program is unloaded	when execution exits the declaration block	when the **delete** operator is executed

	Global automatic variable	Local automatic variable	Dynamically created object
			or before a mql5 program is unloaded
Deinitialization order	in the order opposite to the initialization order	in the order opposite to the initialization order	irrespective of the initialization order
Constructor call	at mql5 program loading	at initialization	at the execution of the *new* operator
Destructor call	at mql5 program unloading	when exiting the block where the variable was initialized	at the execution of the *delete* operator
Error logs	log message in the "Experts" journal about the attempt to delete an automatically created object	log message in the "Experts" journal about the attempt to delete an automatically created object	log message in the "Experts" journal about undeleted dynamically created objects at the unload of a mql5 program

Preprocessor

Preprocessor is a special subsystem of the MQL5 compiler that is intended for preparation of the program source code immediately before the program is compiled.

Preprocessor allows enhancement of the source code readability. The code can be structured by including of specific files containing source codes of mql5-programs. The possibility to assign mnemonic names to specific constants contributes to enhancement of the code readability.

Preprocessor also allows determining specific parameters of mql5-programs:

- Declare constants
- Set program properties
- Include files in program text
- Import functions
- Conditional Compilation

The preprocessor directives are used by the compiler to preprocess the source code before compiling it. The directive always begins with #, therefore the compiler prohibits using the symbol in names of variables, functions etc.

Each directive is described by a separate entry and is valid until the line break. You cannot use several directives in one entry. If the directive entry is too big, it can be broken into several lines using the '\' symbol. In this case, the next line is considered a continuation of the directive entry.

```
//+------------------------------------------------------------------+
//|  foreach pseudo-operator                                         |
//+------------------------------------------------------------------+
#define ForEach(index, array) for (int index = 0,                    \
   max_##index=ArraySize((array));                                   \
   index<max_##index; index++)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string array[]={"12","23","34","45"};
//--- bypass the array using ForEach
   ForEach(i,array)
     {
      PrintFormat("%d: array[%d]=%s",i,i,array[i]);
     }
  }
//+------------------------------------------------------------------+
/* Output result
   0: array[0]=12
   1: array[1]=23
   2: array[2]=34
   3: array[3]=45
*/
```

For the compiler, all these three #define directive lines look like a single long line. The example above also applies ## character which is a merge operator used in the #define macros to merge the two macro tokens into one. The tokens merge operator cannot be the first or last one in a macro definition.

Macro substitution (#define)

The preprocessor directives are used by the compiler to preprocess the source code before compiling it. The directive always begins with #, therefore the compiler prohibits using the symbol in names of variables, functions etc.

Each directive is described by a separate entry and is valid until the line break. You cannot use several directives in one entry. If the directive entry is too big, it can be broken into several lines using the '\' symbol. In this case, the next line is considered a continuation of the directive entry.

The #define directive can be used to assign mnemonic names to constants. There are two forms:

```
#define identifier expression                    // parameter-free form
#define identifier(par1,... par8) expression     // parametric form
```

The #define directive substitutes **expression** for all further found entries of *identifier* in the source text. The *identifier* is replaced only if it is a separate token. The *identifier* is not replaced if it is part of a comment, part of a string, or part of another longer identifier.

The constant identifier is governed by the same rules as variable names. The value can be of any type:

```
#define ABC               100
#define PI                3.14
#define COMPANY_NAME      "MetaQuotes Software Corp."
...
void ShowCopyright()
  {
   Print("Copyright  2001-2009, ",COMPANY_NAME);
   Print("https://www.metaquotes.net");
  }
```

expression can consist of several tokens, such as keywords, constants, constant and non-constant expressions. **expression** ends with the end of the line and can't be transferred to the next line.

Example:

```
#define TWO         2
#define THREE       3
#define INCOMPLETE TWO+THREE
#define COMPLETE   (TWO+THREE)
void OnStart()
  {
   Print("2 + 3*2 = ",INCOMPLETE*2);
   Print("(2 + 3)*2 = ",COMPLETE*2);
  }
// Result
// 2 + 3*2 = 8
// (2 + 3)*2 = 10
```

Parametric Form #define

With the parametric form, all the subsequent found entries of identifier will be replaced by expression taking into account the actual parameters. For example:

```
 // example with two parameters a and b
#define A 2+3
#define B 5-1
#define MUL(a, b) ((a)*(b))

double c=MUL(A,B);
Print("c=",c);
/*
expression double c=MUL(A,B);
is equivalent to double c=((2+3)*(5-1));
*/
// Result
// c=20
```

Be sure to enclose parameters in parentheses when using the parameters in expression, as this will help avoid non-obvious errors that are hard to find. If we rewrite the code without using the brackets, the result will be different:

```
 // example with two parameters a and b
#define A 2+3
#define B 5-1
#define MUL(a, b) a*b

double c=MUL(A,B);
Print("c=",c);
/*
expression double c=MUL(A,B);
is equivalent to double c=2+3*5-1;
*/
// Result
// c=16
```

When using the parametric form, maximum 8 parameters are allowed.

```
 // correct parametric form
#define LOG(text)  Print(__FILE__,"(",__LINE__,") :",text)   // one parameter - 'text

 // incorrect parametric form
#define WRONG_DEF(p1, p2, p3, p4, p5, p6, p7, p8, p9)   p1+p2+p3+p4 // more than 8 pa
```

The #undef directive

The #undef directive cancels declaration of the macro substitution, defined before.

Example:

```
#define MACRO
```

```
void func1()
  {
#ifdef MACRO
   Print("MACRO is defined in ",__FUNCTION__);
#else
   Print("MACRO is not defined in ",__FUNCTION__);
#endif
  }

#undef MACRO

void func2()
  {
#ifdef MACRO
   Print("MACRO is defined in ",__FUNCTION__);
#else
   Print("MACRO is not defined in ",__FUNCTION__);
#endif
  }

void OnStart()
  {
   func1();
   func2();
  }

/* Result:
 MACRO is defined in func1
 MACRO is not defined in func2
*/
```

Identifiers, Character Constants

Program Properties (#property)

Every mql5-program allows to specify additional specific parameters named #property that help client terminal in proper servicing for programs without the necessity to launch them explicitly. This concerns external settings of indicators, first of all. Properties described in included files are completely ignored. Properties must be specified in the main mq5-file.

```
#property identifier value
```

The compiler will write declared values in the configuration of the module executed.

Constant	Type	Description
icon	string	Path to the file of an image that will be used as an icon of the EX5 program. Path specification rules are the same as for resources. The property must be specified in the main module with the MQL5 source code. The icon file must be in the ICO format.
link	string	Link to the company website
copyright	string	The company name
version	string	Program version, maximum 31 characters
description	string	Brief text description of a mql5-program. Several *description* can be present, each of them describes one line of the text. The total length of all *description* can not exceed 511 characters including line feed.
stacksize	int	MQL5 program stack size. The stack of sufficient size is necessary when executing function recursive calls. When launching a script or an Expert Advisor on the chart, the stack of at least 8 MB is allocated. In case of indicators, the stack size is always fixed and equal to 1 MB. When a program is launched in the strategy tester, the stack of 16 MB is always allocated for it.
library		A library; no start function is assigned, functions with the export modifier can be imported in other mql5-programs
indicator_applied_price	int	Specifies the default value for the "Apply to" field. You can specify one of the values of ENUM_APPLIED_PRICE. If the property is not specified, the default value is PRICE_CLOSE
indicator_chart_window		Show the indicator in the chart window
indicator_separate_window		Show the indicator in a separate window

Constant	Type	Description
indicator_height	int	Fixed height of the indicator subwindow in pixels (property INDICATOR_HEIGHT)
indicator_buffers	int	Number of buffers for indicator calculation
indicator_plots	int	Number of graphic series in the indicator
indicator_minimum	double	The bottom scaling limit for a separate indicator window
indicator_maximum	double	The top scaling limit for a separate indicator window
indicator_labelN	string	Sets a label for the N-th graphic series displayed in DataWindow. For graphic series requiring multiple indicator buffers (DRAW_CANDLES, DRAW_FILLING and others), the label names are defined using the separator ';'.
indicator_colorN	color	The color for displaying line N, where N is the number of graphic series; numbering starts from 1
indicator_widthN	int	Line thickness in graphic series, where N is the number of graphic series; numbering starts from 1
indicator_styleN	int	Line style in graphic series, specified by the values of ENUM_LINE_STYLE. N is the number of graphic series; numbering starts from 1
indicator_typeN	int	Type of graphical plotting, specified by the values of ENUM_DRAW_TYPE. N is the number of graphic series; numbering starts from 1
indicator_levelN	double	Horizontal level of N in a separate indicator window
indicator_levelcolor	color	Color of horizontal levels of the indicator
indicator_levelwidth	int	Thickness of horizontal levels of the indicator
indicator_levelstyle	int	Style of horizontal levels of the indicator
script_show_confirm		Display a confirmation window before running the script
script_show_inputs		Display a window with the properties before running the script and disable this confirmation window
tester_indicator	string	Name of a custom indicator in the format of "*indicator_name.ex5*". Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter

Constant	Type	Description
		that sets the indicator name) this property is required
tester_file	string	File name for a tester with the indication of extension, in double quotes (as a constant string). The specified file will be passed to tester. Input files to be tested, if there are necessary ones, must always be specified.
tester_library	string	Library name with the extension, in double quotes. A library can have 'dll' or 'ex5' as file extension. Libraries that require testing are defined automatically. However, if any of libraries is used by a custom indicator, this property is required
tester_set	string	Name of the set file with the values and the step of the input parameters. The file is passed to tester before testing and optimization. The file name is specified with an extension and double quotes as a constant string. If you specify the EA name and the version number as "<expert_name>_<number>.set" in a set file name, then it is automatically added to the parameter versions download menu under the <number> version number. For example, the name "MACD Sample_4.set" means that this is a set file for the "MACD Sample.mq5" EA with the version number equal to 4. To study the format, we recommend that you manually save the test/optimization settings in the strategy tester and then open the set file created in this way.
tester_no_cache	string	When performing optimization, the strategy tester saves all results of executed passes to the optimization cache, in which the test result is saved for each set of the input parameters. This allows using the ready-made results during re-optimization on the same parameters without wasting time on re-calculation. But in some tasks (for example, in math calculations), it may be necessary to carry out calculations regardless of the availability of ready-made results in the optimization cache. In this case, the file should include the *tester_no_cache* property. The test results are still stored in the

Constant	Type	Description
		cache, so that you can see all the data on performed passes in the strategy tester.
tester_everytick_calculate	string	In the Strategy Tester, indicators are only calculated when their data are accessed, i.e. when the values of indicator buffers are requested. This provides a significantly faster testing and optimization speed, if you do not need to obtain indicator values on each tick. By specifying the *tester_everytick_calculate* property, you can enable the forced calculation of the indicator on every tick. Indicators in the Strategy Tester are also forcibly calculated on every tick in the following cases: • when testing in the visual mode; • if the indicator has any of the following functions: EventChartCustom, OnChartEvent, OnTimer; • if the indicator was created using the compiler with build number below 1916. This feature only applies in the Strategy Tester, while in the terminal indicators are always calculated on each received tick.
optimization_chart_mode	string	Specifies the chart type and the names of two input parameters which will be used for the visualization of optimization results. For example, "3d, InpX, InpY" means that the results will be shown in a 3D chart with the coordinate axes based on the tested InpX and InpY parameter values. Thus, the property enables the specification of parameters that will be used to display the optimization chart and the chart type, directly in the program code. Possible options: • "3d, input_parameter_name1, input_parameter_name2" means a 3D visualization chart, which can be rotated, zoomed in and out. The chart is built using two parameters. • "2d, input_parameter_name1, input_parameter_name2" means a 2D grid chart, in which each cell is painted in a certain color depending on the result. The chart is built using two parameters.

Constant	Type	Description
		• "1d, input_parameter_name1, input_parameter_name2" means a linear chart, in which the results are sorted by the specified parameter. Each pass is displayed as a point. The chart is built based on one parameter. • "0d, input_parameter_name1, input_parameter_name2" means a regular chart with results sorted by the pass result arrival time. Each pass is displayed as a point in the chart. Parameter indication is not required, but the specified parameters can be used for the manual switch to other chart types. Optionally, you can indicate only the chart type, without specifying one or two input parameters. In this case, the terminal will select the required parameters to show the optimization chart.

Sample Task of Description and Version Number

```
#property version     "3.70"      // Current version of the Expert Advisor

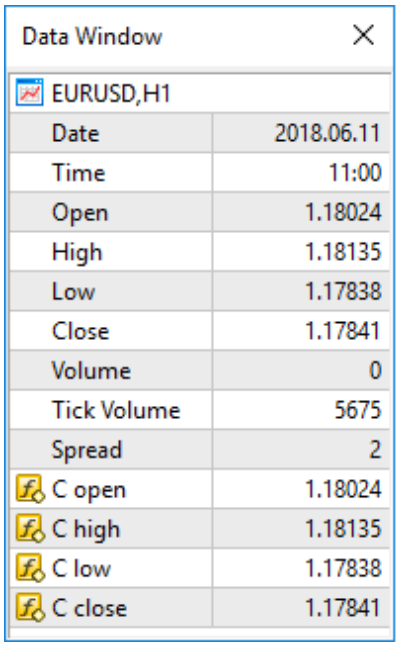
#property indicator_width1  3
#property indicator_label1  "C open;C high;C low;C close"
```



Including Files (#include)

The *#include* command line can be placed anywhere in the program, but usually all inclusions are placed at the beginning of the source code. Call format:

```
#include <file_name>
#include "file_name"
```

Examples:

```
#include <WinUser32.mqh>
#include "mylib.mqh"
```

The preprocessor replaces the line *#include* <*file_name*> with the content of the file WinUser32.mqh. Angle brackets indicate that the WinUser32.mqh file will be taken from the standard directory (usually it is *terminal_installation_directory\MQL5\Include*). The current directory is not included in the search.

If the file name is enclosed in quotation marks, the search is made in the current directory (which contains the main source file). The standard directory is not included in the search.

Standard Library, Importing Functions

Importing Function (#import)

Functions are imported from compiled MQL5 modules (*.ex5 files) and from operating system modules (*.dll files). The module name is specified in the *#import* directive. For compiler to be able to correctly form the imported function call and organize proper transmission parameters, the full description of functions is needed. Function descriptions immediately follow the *#import "module name"* directive. New command *#import* (can be without parameters) completes the block of imported function descriptions.

```
#import "file_name"
    func1 define;
    func2 define;
    ...
    funcN define;
#import
```

Imported functions can have any names. Functions having the same names but from different modules can be imported at the same time. Imported functions can have names that coincide with the names of built-in functions. Operation of scope resolution defines which of the functions should be called.

The order of searching for a file specified after the #import keyword is described in Call of Imported Functions.

Since the imported functions are outside the compiled module, the compiler can not verify the validity of passed parameters. Therefore, to avoid run-time errors, one must accurately describe the composition and order of parameters passed to imported functions. Parameters passed to imported functions (both from EX5, and from the DLL-module) can have default values.

The following can't be used for parameters in imported functions:

- pointers (*);
- links to objects that contain dynamic arrays and/or pointers.

Classes, string arrays or complex objects that contain strings and/or dynamic arrays of any types cannot be passed as a parameter to functions imported from DLL.

Examples:

```
#import "stdlib.ex5"
string ErrorDescription(int error_code);
int    RGB(int red_value,int green_value,int blue_value);
bool   CompareDoubles(double number1,double number2);
string DoubleToStrMorePrecision(double number,int precision);
string IntegerToHexString(int integer_number);
#import "ExpertSample.dll"
int    GetIntValue(int);
double GetDoubleValue(double);
string GetStringValue(string);
double GetArrayItemValue(double &arr[],int,int);
bool   SetArrayItemValue(double &arr[],int,int,double);
double GetRatesItemValue(double &rates[][6],int,int,int);
#import
```

To import functions during execution of a mql5 program, early binding is used. This means that the library is loaded during the loading of a program using its ex5 program.

It's not recommended to use a fully qualified name of the loadable module of type *Drive:\Directory\FileName.Ext*. MQL5 libraries are loaded from the *terminal_dir\MQL5\Libraries* folder.

If the imported function has different call versions for 32- and 64-bit Windows versions, both of them should be imported, and the right function version should be called explicitly using the _IsX64 variable.

Example:

```
#import "user32.dll"
//--- For the 32-bit system
int    MessageBoxW(uint hWnd,string lpText,string lpCaption,uint uType);
//--- For the 64-bit system
int    MessageBoxW(ulong hWnd,string lpText,string lpCaption,uint uType);
#import
//+------------------------------------------------------------------+
//|  MessageBox_32_64_bit uses the proper version of MessageBoxW()   |
//+------------------------------------------------------------------+
int MessageBox_32_64_bit()
  {
   int res=-1;
   //--- If we are using the 64-bit Windows
   if(_IsX64)
     {
      ulong hwnd=0;
      res=MessageBoxW(hwnd,"64-bit MessageBoxW call example","MessageBoxW 64 bit",MB_
     }
   else  // We are using the 32-bit Windows
     {
      uint hwnd=0;
      res=MessageBoxW(hwnd,"32-bit MessageBoxW call example","MessageBoxW 32 bit",MB_
     }
   return (res);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int ans=MessageBox_32_64_bit();
   PrintFormat("MessageBox_32_64_bit returned %d",ans);
  }
```

Importing functions from .NET libraries

To work with .NET library functions, simply import DLL itself without defining specific functions. MetaEditor automatically imports all functions it is possible to work with:

- Simple structures (POD, plain old data) — structures that contain only simple data types.
- Public static functions having parameters, in which only simple types and POD structures or their arrays are used

To call functions from the library, simply import it:

```
#import "TestLib.dll"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   int x=41;
   TestClass::Inc(x);
   Print(x);
  }
```

The C# code of the Inc function of the TestClass looks as follows:

```
public class TestClass
  {
   public static void Inc(ref int x)
      {
       x++;
      }
  }
```

As a result of execution, the script returns the value of 42.

Conditional Compilation (#ifdef, #ifndef, #else, #endif)

The preprocessor directives are used by the compiler to preprocess the source code before compiling it. The directive always begins with #, therefore the compiler prohibits using the symbol in names of variables, functions etc.

Each directive is described by a separate entry and is valid until the line break. You cannot use several directives in one entry. If the directive entry is too big, it can be broken into several lines using the '\' symbol. In this case, the next line is considered a continuation of the directive entry.

Preprocessor conditional compilation directives allow compiling or skipping a part of the program depending on the fulfillment of a certain condition.

That condition can take one of the following forms.

```
#ifdef identifier
   // the code located here is compiled if the identifier has already been defined fo
#endif
```

```
#ifndef identifier
   // the code located here is compiled if the identifier is not currently defined by
#endif
```

Any of the conditional compilation directives can be followed by any number of lines possibly containing #else directive and ending with #endif. If the verified condition is true, the lines between #else and #endif are ignored. If the verified condition is not fulfilled, all lines between checking and #else directive (or #endif directive if the former is absent) are ignored.

Example:

```
#ifndef TestMode
   #define TestMode
#endif
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   #ifdef TestMode
      Print("Test mode");
   #else
      Print("Normal mode");
   #endif
  }
```

Depending on the program type and compilation mode, the standard macros are defined the following way:

__MQL5__ macro is defined when compiling *.mq5 file, __MQL4__ macro is defined when compiling *.mq4 one.
_DEBUG macro is defined when compiling in debug mode.
_RELEASE macro is defined when compiling in release mode.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   #ifdef __MQL5__
      #ifdef _DEBUG
         Print("Hello from MQL5 compiler [DEBUG]");
      #else
        #ifdef _RELEASE
           Print("Hello from MQL5 compiler [RELEASE]");
        #endif
     #endif
   #else
      #ifdef __MQL4__
         #ifdef _DEBUG
           Print("Hello from MQL4 compiler [DEBUG]");
        #else
           #ifdef _RELEASE
              Print("Hello from MQL4 compiler [RELEASE]");
           #endif
        #endif
     #endif
   #endif
  }
```

Object-Oriented Programming

Object-oriented programming (OOP) is programming primarily focused on data, while data and behavior are being inseparably linked. Data and behavior together constitute a class, while objects are class instances.

The components of the object-oriented approach are:

- Encapsulation and type extensibility
- Inheritance
- Polymorphism
- Overloading
- Virtual functions

OOP considers computation as modeling of behavior. The modeled item is the object represented by computational abstractions. Suppose we want to write a well known game "Tetris". To do this, we must learn how to model the appearance of random shapes composed of four squares joined together by edges. Also we need to regulate the falling speed of shapes, define operations of rotation and shift of shapes. Moving of shapes on the screen is limited by the well's boundaries, this requirement must also be modeled. Besides that, filled rows of cubes must be destroyed and achieved points must be counted.

Thus, this easy-to-understand game requires the creation of several models - shape model, well model, shape movement model and so on. All these models are abstractions, represented by calculations in the computer. To describe these models, the concept of Abstract Data Type, ADT (or complex data type) is used. Strictly speaking, the model of the "shapes" motion in the DOM is not a data type, but it is a set of operations on the "shape" data type, using the restrictions of the "well" data type.

Objects are class variables. Object-oriented programming allows you to easily create and use ADT. Object-oriented programming uses the inheritance mechanism. The benefit of inheritance is in the fact that it allows obtaining derivative types from data types already defined by a user.

For example, to create Tetris shapes, it's convenient to create a base class Shape first. The other classes representing all seven possible shape types can be derived on its basis. Behavior of shapes is defined in the base class, while implementation of behavior of each separate shape is defined in derivative classes.

In OOP objects are responsible for their behavior. ADT developer should include a code to describe any behavior that would normally be expected from the corresponding objects. The fact that the object itself is responsible for its behavior, greatly simplifies the task of programming for the user of this object.

If we want to draw a shape on the screen, we need to know where the center will be and how to draw it. If a separate shape knows how to draw itself, the programmer should send a "draw" message when using such a shape.

The MQL5 Language is a C++ like, and it also has the encapsulation mechanism for the implementation of ADT. On the one hand encapsulation combines the internal details of the implementation of a particular type, and on the other hand it combines externally accessible functions that can influence objects of this type. Implementation details may be inaccessible for a program that uses this type.

The concept of OOP has a set of related concepts, including the following:

- Simulation of actions from the real world
- User-defined data types
- Hiding the implementation details
- Possibility of the code reuse through inheritance
- Interpretation of function calls during execution

Some of these concepts are rather vague, some are abstract, others are general.

Encapsulation and Extensibility of Types

OOP is a balanced approach to writing software. Data and behavior are packed together. This encapsulation creates user-defined data types, extending the language data types and interacting with them. Types extensibility is an opportunity to add to the language user-defined data types, which are also easy to use, as well as basic types.

An abstract data type, for example, a string, is a description of the ideal, well known behavior type.

The string user knows that the string operations, such as concatenation or print, have a certain behavior. Concatenation and print operations are called methods.

A certain implementation of ADT may have some restrictions, for example, strings can be limited in length. These limitations affect the behavior opened to all. At the same time, internal or private implementation details do not affect directly the way the user sees the object. For example, the string is often implemented as an array, while the internal base address of this array and its name are not essential for the user.

Encapsulation is the ability to hide the implementation details when the open interfaces to user-defined type is provided. In MQL5, as well as in C++, class and structure definitions (class and struct) are used for the encapsulation provisions in combination with access keywords private, protected and public.

The public keyword shows that access to the members that stand behind it is open without restrictions. Without this keyword, class members are locked by default. Private members are accessible only by member functions only of its class.

Protected class functions are available to class functions not only in its class, but also in its inheritor classes. Public class functions are available for any function within the scope of the class declaration. The protection makes possible to hide part of the class implementation, thus preventing unexpected changes in the structure of data. Access restriction or data hiding is a feature of the object-oriented programming.

Usually, class functions are protected and declared with the protected modifier, the reading and writing of the values are performed by using special so-called set-and get-methods that are defined by the public access modifier.

Example:

```
class CPerson
  {
protected:
   string            m_name;                    // name
public:
   void              SetName(string n){m_name=n;}// sets name
   string            GetName(){return (m_name);} // returns name
  };
```

This approach offers several advantages. First, by function name we can understand what it does - sets or gets the value of a class member. Secondly, perhaps in the future we will need to change the type of the m_name variable in the CPerson class or in any of its derivative classes.

In this case, we'll need just to change the implementation of functions SetName() and GetName(), while objects of the CPerson class will be available for using in a program without any code changes because the user will not even know that the data type of m_name has changed.

Example:

```
struct Name
  {
   string            first_name;                  // name
   string            last_name;                   // last name
  };

class CPerson
  {
protected:
   Name              m_name;                      // name
public:
   void              SetName(string n);
   string            GetName(){return(m_name.first_name+" "+m_name.last_name);}
private:
   string            GetFirstName(string full_name);
   string            GetLastName(string full_name);
  };

void CPerson::SetName(string n)
  {
   m_name.first_name=GetFirstName(n);
   m_name.last_name=GetLastName(n);
  }

string CPerson::GetFirstName(string full_name)
  {
   int pos=StringFind(full_name," ");
   if(pos>0) StringSetCharacter(full_name,pos,0);
   return(full_name);
  }

string CPerson::GetLastName(string full_name)
  {
   string ret_string;
   int pos=StringFind(full_name," ");
   if(pos>0) ret_string=StringSubstr(full_name,pos+1);
   else      ret_string=full_name;
   return(ret_string);
  }
```

Data Types

Inheritance

The characteristic feature of OOP is the encouragement of code reuse through inheritance. A new class is made from the existing, which is called the base class. The derived class uses the members of the base class, but can also modify and supplement them.

Many types are variations of the existing types. It is often tedious to develop a new code for each of them. In addition, the new code implies new errors. The derived class inherits the description of the base class, thus any re-development and re-testing of code is unnecessary. The inheritance relationships are hierarchical.

Hierarchy is a method that allows to copy the elements in all their diversity and complexity. It introduces the objects classification. For example, the periodic table of elements has gases. They possess to properties inherent to all periodic elements.

Inert gases constitute the next important subclass. The hierarchy is that the inert gas, such as argon is a gas, and gas, in its turn, is part of the system. Such a hierarchy allows to interpret behaviour of inert gases easily. We know that their atoms contain protons and electrons, that is true for all other elements.

We know that they are in a gaseous state at room temperature, like all the gases. We know that no gas from inert gas subclass enters usual chemical reaction with other elements, and it is a property of all inert gases.

Consider an example of the inheritance of geometric shapes. To describe the whole variety of simple shapes (circle, triangle, rectangle, square etc.), the best way is to create a base class (ADT), which is the ancestor of all the derived classes.

Let's create a base class CShape, which contains just the most common members describing the shape. These members describe properties that are characteristic of any shape - the type of the shape and main anchor point coordinates.

Example:

```
//--- The base class Shape
class CShape
  {
protected:
   int       m_type;                    // Shape type
   int       m_xpos;                    // X - coordinate of the base point
   int       m_ypos;                    // Y - coordinate of the base point
public:
             CShape(){m_type=0; m_xpos=0; m_ypos=0;} // constructor
   void      SetXPos(int x){m_xpos=x;} // set X
   void      SetYPos(int y){m_ypos=y;} // set Y
  };
```

Next, create new classes derived from the base class, in which we will add necessary fields, each specifying a certain class. For the Circle shape it is necessary to add a member that contains the radius value. The Square shape is characterized by the side value. Therefore, derived classes, inherited from the base class CShape will be declared as follows:

```
//--- The derived class circle
class CCircle : public CShape        // After a colon we define the base class
  {                                    // from which inheritance is made
private:
   int             m_radius;           // circle radius

public:
                   CCircle(){m_type=1;}// constructor, type 1
  };
```

For the Square shape class declaration is similar:

```
//--- the derived class Square
class CSquare : public CShape        // After a colon we define the base class
  {                                    // from which inheritance is made
private:
   int             m_square_side;      // square side

public:
                   CSquare(){m_type=2;} // constructor, type 2
  };
```

It should be noted that while object is created the base class constructor is called first, and then the constructor of the derived class is called. When an object is destroyed first the destructor of the derived class is called, and then a base class destructor is called.

Thus, by declaring the most general members in the base class, we can add an additional members in derived classes, which specify a particular class. Inheritance allows creating powerful code libraries that can be reused many times.

The syntax for creating a derived class from an already existing one is as follows:

```
class class_name :
          (public | protected | private) opt  base_class_name
  {
    class members declaration
  };
```

One of aspects of the derived class is the visibility (openness) of its members successors (heirs). The public, protected and private keywords are used to indicate the extent, to which members of the base class will be available for the derived one. The public keyword after a colon in the header of a derived class indicates that the protected and public members of the base class CShape should be inherited as protected and public members of the derived class CCircle.

The private class members of the base class are not available for the derived class. The public inheritance also means that derived classes (CCircle and CSquare) are CShapes. That is, the Square (CSquare) is a shape (CShape), but the shape does not necessarily have to be a square.

The derived class is a modification of the base class, it inherits the protected and public members of the base class. The constructors and destructors of the base class cannot be inherited. In addition to members of the base class, new members are added in a derivative class.

The derived class may include the implementation of member functions, different from the base class. It has nothing common with an overload, when the meaning of the same function name may be different for different signatures.

In protected inheritance, public and protected members of base class become protected members of derived class. In private inheritance, the public and protected members of base class become private members of the derived class.

In protected and private inheritance, the relation that "the object of a derivative class is object of a base class" is not true. The protected and private inheritance types are rare, and each of them needs to be used carefully.

It should be understood that the type of inheritance (public, protected or private) does not affect the ways of **accessing the members of base classes in the hierarchy of inheritance from a derived class**. With any type of inheritance, only base class members declared with public and protected access specifiers will be available out of the derived classes. Let's consider it in the following example:

```
#property copyright "Copyright 2000-2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com"
#property version   "1.00"
//+------------------------------------------------------------------+
//| Example class with a few access types                            |
//+------------------------------------------------------------------+
class CBaseClass
  {
private:              //--- The private member is not available from derived classes
   int                m_member;
protected:            //--- The protected method is available from the base class and i
   int                Member(){return(m_member);}
public:               //--- Class constructor is available to all members of classes
                      CBaseClass(){m_member=5;return;};
private:              //--- A private method for assigning a value to m_member
   void               Member(int value) { m_member=value;};

  };
//+------------------------------------------------------------------+
//| Derived class with errors                                        |
//+------------------------------------------------------------------+
class CDerived: public CBaseClass // specification of public inheritance can be omitte
  {
public:
   void Func() // In the derived class, define a function with calls to base class mer
     {
      //--- An attempt to modify a private member of the base class
      m_member=0;         // Error, the private member of the base class is not availab
      Member(0);          // Error, the private method of the base class is not availab
```

```
      //--- Reading the member of the base class
      Print(m_member);    // Error, the private member of the base class is not availab
      Print(Member());    // No error, protected method is available from the base clas
     }
  };
```

In the above example, CBaseClass has only a public method - the constructor. Constructors are called automatically when creating a class object. Therefore, the private member m_member and the protected methods Member() cannot be called from the outside. But in case of public inheritance, the Member() method of the base class will be available from the derived classes.

In case of protected inheritance, all the members of the base class with public and protected access become protected. It means that if public data members and methods of the base class were accessible from the outside, with protected inheritance they are available only from the classes of the derived class and its further derivatives.

```
//+------------------------------------------------------------------+
//| Example class with a few access types                            |
//+------------------------------------------------------------------+
class CBaseMathClass
  {
private:              //--- The private member is not available from derived classes
   double             m_Pi;
public:               //--- Getting and setting a value for m_Pi
   void               SetPI(double v){m_Pi=v;return;};
   double             GetPI(){return m_Pi;};
public:               // The class constructor is available to all members
                      CBaseMathClass() {SetPI(3.14);  PrintFormat("%s",__FUNCTION__);};
  };
//+------------------------------------------------------------------+
//| Derived class, in which m_Pi cannot be modified                  |
//+------------------------------------------------------------------+
class CProtectedChildClass: protected CBaseMathClass // Protected inheritance
  {
private:
   double             m_radius;
public:               //--- Public methods in the derived class
   void               SetRadius(double r){m_radius=r; return;};
   double             GetCircleLength(){return GetPI()*m_radius;};
  };
//+------------------------------------------------------------------+
//| Script starting function                                         |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- When creating a derived class, the constructor of the base class will be called
   CProtectedChildClass pt;
//--- Specify radius
   pt.SetRadius(10);
   PrintFormat("Length=%G",pt.GetCircleLength());
```

```
//--- If we uncomment the line below, we will get an error at the stage of compilation
// pt.SetPI(3);

//--- Now declare a variable of the base class and try to set the Pi constant equal to
   CBaseMathClass bc;
   bc.SetPI(10);
//--- Here is the result
   PrintFormat("bc.GetPI()=%G",bc.GetPI());
  }
```

The example shows that methods SetPI() and GetPi() in the base class CBaseMathClass are open and available for calling from any place of the program. But at the same time, for CProtectedChildClass which is derived from it these methods can be called only from the methods of the CProtectedChildClass class or its derived classes.

In case of private inheritance, all the members of the basic class with the public and protected access become private, and calling them becomes impossible in further inheritance.

MQL5 has no multiple inheritance.

Structures and Classes

Polymorphism

Polymorphism is an opportunity for different classes of objects, related through inheritance, to respond in various ways when calling the same function element. It helps to create a universal mechanism describing the behavior of not only the base class, but also descendant classes.

Let's continue to develop a base class CShape, and define a member function GetArea(), designed to calculate the area of a shape. In all the descendant classes, produced by inheritance from the base class, we redefine this function in accordance with rules of calculating the area of a particular shape.

For a square (class CSquare), the area is calculated through its sides, for a circle (class CCircle), area is expressed through its radius etc. We can create an array to store objects of CShape type, in which both objects of a base class and those of all descendant classes can be stored. Further we can call the same function for each element of the array.

Example:

```
//--- Base class
class CShape
  {
protected:
   int            m_type;                // Shape type
   int            m_xpos;                // X - coordinate of the base point
   int            m_ypos;                // Y - coordinate of the base point
public:
   void           CShape(){m_type=0;};   // constructor, type=0
   int            GetType(){return(m_type);};// returns type of the shape
virtual
   double         GetArea(){return (0); }// returns area of the shape
  };
```

Now, all of the derived classes have a member function getArea(), which returns a zero value. The implementation of this function in each descendant will vary.

```
//--- The derived class Circle
class CCircle : public CShape             // After a colon we define the base class
  {                                       // from which inheritance is made
private:
   double         m_radius;              // circle radius

public:
   void           CCircle(){m_type=1;};  // constructor, type=1
   void           SetRadius(double r){m_radius=r;};
   virtual double GetArea(){return (3.14*m_radius*m_radius);}// circle area
  };
```

For the class Square the declaration is the same:

```
//--- The derived class Square
class CSquare : public CShape             // After a colon we define the base class
  {                                       // from which inheritance is made
```

```
private:
   double           m_square_side;         // square side

public:
   void             CSquare(){m_type=2;}; // constructor, type=1
   void             SetSide(double s){m_square_side=s;};
   virtual double   GetArea(){return (m_square_side*m_square_side);}// square area
  };
```

For calculating the area of the square and circle, we need the corresponding values of m_radius and m_square_side, so we have added the functions SetRadius() and SetSide() in the declaration of the corresponding class.

It is assumed that object of different types (CCircle and CSquare) derived from one base type CShape are used in our program. Polymorphism allows creating an array of objects of the base CShape class, but when declaring this array, these objects are yet unknown and their type is undefined.

The decision on what type of object will be contained in each element of the array will be taken directly during program execution. This involves the dynamic creation of objects of the appropriate classes, and hence the necessity to use object pointers instead of objects.

The new operator is used for dynamic creation of objects. Each such object must be individually and explicitly deleted using the delete operator. Therefore we will declare an array of pointers of CShape type, and create an object of a proper type for each element (**new Class_Name**), as shown in the following script example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Declare an array of object pointers of the base type
   CShape *shapes[5];   // An array of pointers to CShape object

//--- Here fill in the array with derived objects
//--- Declare a pointer to the object of CCircle type
   CCircle *circle=new CCircle();
//--- Set object properties at the circle pointer
   circle.SetRadius(2.5);
//--- Place the pointer value in shapes[0]
   shapes[0]=circle;

//--- Create another CCircle object and write down its pointer in shapes[1]
   circle=new CCircle();
   shapes[1]=circle;
   circle.SetRadius(5);

//--- Here we intentionally "forget" to set a value for shapes[2]
//circle=new CCircle();
//circle.SetRadius(10);
//shapes[2]=circle;
```

```
//--- Set NULL for the element that is not used
   shapes[2]=NULL;

//--- Create a CSquare object and write down its pointer to shapes[3]
   CSquare *square=new CSquare();
   square.SetSide(5);
   shapes[3]=square;

//--- Create a CSquare object and write down its pointer to shapes[4]
   square=new CSquare();
   square.SetSide(10);
   shapes[4]=square;

//--- We have an array of pointers, get its size
   int total=ArraySize(shapes);
//--- Pass in a loop through all pointers in the array
   for(int i=0; i<5;i++)
     {
      //--- If the pointer at the specified index is valid
      if(CheckPointer(shapes[i])!=POINTER_INVALID)
        {
         //--- Log the type and square of the shape
         PrintFormat("The object of type %d has the square %G",
               shapes[i].GetType(),
               shapes[i].GetArea());
        }
      //--- If the pointer has type POINTER_INVALID
      else
        {
         //--- Notify of an error
         PrintFormat("Object shapes[%d] has not been initialized! Its pointer is %s",
                     i,EnumToString(CheckPointer(shapes[i])));
        }
     }

//--- We must delete all created dynamic objects
   for(int i=0;i<total;i++)
     {
      //--- We can delete only the objects with pointers of POINTER_DYNAMIC type
      if(CheckPointer(shapes[i])==POINTER_DYNAMIC)
        {
         //--- Notify of deletion
         PrintFormat("Deleting shapes[%d]",i);
         //--- Delete an object by its pointer
         delete shapes[i];
        }
     }
  }
```

Please note that when deleting an object using the delete operator, the type of its pointer must be checked. Only objects with the POINTER_DYNAMIC pointer can be deleted using delete. For pointers of other type, an error will be returned.

But besides the redefining of functions during inheritance, polymorphism also includes the implementation of one and the same functions with different sets of parameters within a class. This means that the class may have several functions with the same name but with a different type and/or set of parameters. In this case, polymorphism is implemented through the function overload.

Standard Library

Overload

Within one class it is possible to define two or more methods that use the same name, but have different numbers of parameters. When this occurs, methods are called overloaded and such a process is referred to as method overloading.

Method overloading is one of ways of polymorphism realization. Overloading of methods is performed according to the same rules as the function overloading.

If the called function has no exact match, the compiler searches for a suitable function on three levels sequentially:

1. search within class methods.
2. search within the base class methods, consistently from the nearest ancestor to the very first.
3. search among other functions.

If there is no exact correspondence at all levels, but several suitable functions at different levels have been found, the function found at the least level is used. Within one level, there can't be more than one suitable function.

Function Overloading

Virtual Functions

The virtual keyword is the function specifier, which provides a mechanism to select dynamically at runtime an appropriate function-member among the functions of basic and derived classes. Structures cannot have virtual functions. It can be used to change the declarations for function-members only.

The virtual function, like an ordinary function, must have an executable body. When called, its semantic is the same as that of other functions.

A virtual function may be overridden in a derived class. The choice of what function definition should be called for a virtual function is made dynamically (at runtime). A typical case is when a base class contains a virtual function, and derived classes have their own versions of this function.

The pointer to the base class can indicate either a base class object or the object of a derived class. The choice of the member-function to call will be performed at runtime and will depend on the type of the object, not the type of the pointer. If there is no member of a derived type, the virtual function of the base class is used by default.

Destructors are always virtual, regardless of whether they are declared with the virtual keyword or not.

Let's consider the use of virtual functions on the example of MT5_Tetris.mq5. The base class CTetrisShape with the virtual function Draw is defined in the included file MT5_TetrisShape.mqh.

```
//+------------------------------------------------------------------+
class CTetrisShape
  {
protected:
   int               m_type;
   int               m_xpos;
   int               m_ypos;
   int               m_xsize;
   int               m_ysize;
   int               m_prev_turn;
   int               m_turn;
   int               m_right_border;
public:
   void              CTetrisShape();
   void              SetRightBorder(int border) { m_right_border=border; }
   void              SetYPos(int ypos)          { m_ypos=ypos;           }
   void              SetXPos(int xpos)          { m_xpos=xpos;           }
   int               GetYPos()                  { return(m_ypos);        }
   int               GetXPos()                  { return(m_xpos);        }
   int               GetYSize()                 { return(m_ysize);       }
   int               GetXSize()                 { return(m_xsize);       }
   int               GetType()                  { return(m_type);        }
   void              Left()                     { m_xpos-=SHAPE_SIZE;    }
   void              Right()                    { m_xpos+=SHAPE_SIZE;    }
   void              Rotate()                   { m_prev_turn=m_turn; if(++m_turn>3) r
   virtual void      Draw()                     { return;                }
   virtual bool      CheckDown(int& pad_array[]);
   virtual bool      CheckLeft(int& side_row[]);
```

```
   virtual bool      CheckRight(int& side_row[]);
  };
```

Further, for each derived class, this function is implemented in accordance with characteristics of a descendant class. For example, the first shape CTetrisShape1 has its own implementation of the Draw() function:

```
class CTetrisShape1 : public CTetrisShape
  {
public:
   //--- shape drawing
   virtual void      Draw()
     {
      int    i;
      string name;
      //---
      if(m_turn==0 || m_turn==2)
        {
         //--- horizontal
         for(i=0; i<4; i++)
           {
            name=SHAPE_NAME+(string)i;
            ObjectSetInteger(0,name,OBJPROP_XDISTANCE,m_xpos+i*SHAPE_SIZE);
            ObjectSetInteger(0,name,OBJPROP_YDISTANCE,m_ypos);
           }
        }
      else
        {
         //--- vertical
         for(i=0; i<4; i++)
           {
            name=SHAPE_NAME+(string)i;
            ObjectSetInteger(0,name,OBJPROP_XDISTANCE,m_xpos);
            ObjectSetInteger(0,name,OBJPROP_YDISTANCE,m_ypos+i*SHAPE_SIZE);
           }
        }
     }
  }
```

The Square shape is described by class CTetrisShape6 and has its own implementation of the Draw() method:

```
class CTetrisShape6 : public CTetrisShape
  {
public:
   //--- Shape drawing
   virtual void      Draw()
     {
      int    i;
      string name;
```

```
      //---
      for(i=0; i<2; i++)
        {
         name=SHAPE_NAME+(string)i;
         ObjectSetInteger(0,name,OBJPROP_XDISTANCE,m_xpos+i*SHAPE_SIZE);
         ObjectSetInteger(0,name,OBJPROP_YDISTANCE,m_ypos);
        }
      for(i=2; i<4; i++)
        {
         name=SHAPE_NAME+(string)i;
         ObjectSetInteger(0,name,OBJPROP_XDISTANCE,m_xpos+(i-2)*SHAPE_SIZE);
         ObjectSetInteger(0,name,OBJPROP_YDISTANCE,m_ypos+SHAPE_SIZE);
        }
     }
  };
```

Depending on the class, to which the created object belongs, it calls the virtual function of this or that derived class.

```
void CTetrisField::NewShape()
  {
//--- creating one of the 7 possible shapes randomly
   int nshape=rand()%7;
   switch(nshape)
     {
      case 0: m_shape=new CTetrisShape1; break;
      case 1: m_shape=new CTetrisShape2; break;
      case 2: m_shape=new CTetrisShape3; break;
      case 3: m_shape=new CTetrisShape4; break;
      case 4: m_shape=new CTetrisShape5; break;
      case 5: m_shape=new CTetrisShape6; break;
      case 6: m_shape=new CTetrisShape7; break;
     }
//--- draw
   m_shape.Draw();
//---
  }
```

Modifier 'override'

The 'override' modifier means that the declared function must override the method of a parent class. Use of this method allows you to avoid overriding errors, for example it allows you to avoid accidental modification of the method signature. Suppose, the 'func' method is defined in the base class. The method accepts an int variable as an argument:

```
class CFoo
  {
   void virtual func(int x) const { }
  };
```

Next, the method is overridden in the child class:

```
class CBar : public CFoo
  {
   void func(short x) { }
  };
```

However, the argument type is mistakenly changed from int to short. In fact, this is not method overriding, but it is method overloading. Acting in accordance with the overloaded function defining algorithm, the compiler can in certain situations choose a method defined in the base class instead of the overridden method.

In order to avoid such errors, you should explicitly add the 'override' modifier to the method you want to override.

```
class CBar : public CFoo
  {
   void func(short x) override { }
  };
```

If the method signature is changed during overriding, the compiler will not be able to find a method with the same signature in the parent class, and it will return a compilation error:

```
'CBar::func' method is declared with 'override' specifier but does not override any ba
```

Modifier 'final'

The 'final' modifier does the opposite — it prohibits method overriding in child classes. If a method implementation is sufficient and fully complete, declare this method with the 'final' modifier so as to make sure that it will not be modified later.

```
class CFoo
  {
   void virtual func(int x) final { }
  };

class CBar : public CFoo
  {
   void func(int) { }
  };
```

If you try to override a method with the 'final' modifier as shown in the above example, the compiler will return an error:

```
'CFoo::func' method declared as 'final' cannot be overridden by 'CBar::func'
see declaration of 'CFoo::func'
```

Static members of a Class/Structure

Static Members

The members of a class can be declared using the storage class modifier static. These data members are shared by all instances of this class and are stored in one place. Non-static data members are created for each class object variable.

The inability to declare static members of a class would have led to the need to declare these data on the the global level of the program. It would break the relationship between the data and their class, and is not consistent with the basic paradigm of the OOP - joining data and methods for handling them in a class. The static member allows class data that are not specific to a particular instance to exist in the class scope.

Since a static class member does not depend on the particular instance, the reference to it is as follows:

```
class_name::variable
```

where *class_name* is the name of the class, and *variable* is the name of the class member.

As you see, to access the static member of a class, context resolution operator :: is used. When you access a static member within class methods, the context operator is optional.

Static member of a class has to be explicitly initialized with desired value. For this it must be declared and initialized in global scope. The sequence of static members initialization will correspond to the sequence of their declaration in global scope.

For example, we have a class *CParser* used for parsing the text, and we need to count the total number of processed words and characters. We only need to declare the necessary class members as static and initialize them at the global level. Then all instances of the class will use common counters of words and characters.

```
//+------------------------------------------------------------------+
//| Class "Text analyzer"                                            |
//+------------------------------------------------------------------+
class CParser
  {
public:
   static int        s_words;
   static int        s_symbols;
   //--- Constructor and destructor
                     CParser(void);
                    ~CParser(void){};
  };
...
//--- Initialization of static members of the Parser class at the global level
int CParser::s_words=0;
int CParser::s_symbols=0;
```

A static class member can be declared with the *const* keyword. Such static constants must be initialized at the global level with the *const* keyword:

```
//+------------------------------------------------------------------+
//| Class "Stack" for storing processed data                         |
//+------------------------------------------------------------------+
class CStack
  {
public:
                     CStack(void);
                    ~CStack(void){};
...
private:
   static const int  s_max_length; // Maximum stack capacity
  };

//--- Initialization of the static constant of the CStack class
const int CStack::s_max_length=1000;
```

Pointer this

The keyword this denotes an implicitly declared pointer to itself - to a specific instance of the class, in the context of which the method is executed. It can be used only in non-static methods of the class. Pointer this is an implicit non-static member of any class.

In static functions you can access only static members/methods of a class.

Static Methods

In MQL5 member functions of type static can be used. The *static* modifier must precede the return type of a function in the declaration inside a class.

```
class CStack
  {
public:
   //--- Constructor and destructor
                     CStack(void){};
                    ~CStack(void){};
   //--- Maximum stack capacity
   static int        Capacity();
private:
   int               m_length;     // The number of elements in the stack
   static const int  s_max_length; // Maximum stack capacity
  };
//+------------------------------------------------------------------+
//| Returns the maximum number of elements to store in the stack     |
//+------------------------------------------------------------------+
int CStack::Capacity(void)
  {
   return(s_max_length);
  }
//--- Initialization of the static constant of the CStack class
const int CStack::s_max_length=1000;
```

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare CStack type variable
   CStack stack;
//--- call the object's static method
   Print("CStack.s_max_length=",stack.Capacity());
//--- it can also be called the following way, as the method is static and does not re
   Print("CStack.s_max_length=",CStack::Capacity());
  }
```

A method with the const modifier is called constant and cannot modify implicit members of its class. Declaration of constant functions of a class and constant parameters is called *const-correctness* control. Through this control you can be sure that the compiler will ensure the consistency of values of objects and will return an error during compilation if there is something wrong.

The const modifier is placed after the list of arguments inside a class declaration. Definition outside a class should also include the *const* modifier:

```
//+------------------------------------------------------------------+
//| Class "Rectangle"                                                |
//+------------------------------------------------------------------+
class CRectangle
  {
private:
   double            m_width;       // Width
   double            m_height;      // Height
public:
   //--- Constructors and destructor
                     CRectangle(void):m_width(0),m_height(0){};
                     CRectangle(const double w,const double h):m_width(w),m_height(h)
                    ~CRectangle(void){};
   //--- Calculating the area
   double            Square(void) const;
   static double     Square(const double w,const double h);// { return(w*h); }
  };
//+------------------------------------------------------------------+
//| Returns the area of the "Rectangle" object                       |
//+------------------------------------------------------------------+
double CRectangle::Square(void) const
  {
   return(Square(m_width,m_height));
  }
//+------------------------------------------------------------------+
//| Returns the product of two variables                             |
//+------------------------------------------------------------------+
static double CRectangle::Square(const double w,const double h)
  {
```

```
    return(w*h);
   }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
   {
//--- Create a rectangle rect with the sides equal to 5 and 6
    CRectangle rect(5,6);
//--- Find the rectangle area using a constant method
    PrintFormat("rect.Square()=%.2f",rect.Square());
//--- Find the product of numbers using the static method of class CRectangle
    PrintFormat("CRectangle::Square(2.0,1.5)=%f",CRectangle::Square(2.0,1.5));
   }
```

An additional argument in favor of using the constancy control is the fact that in this case, the compiler generates a special optimization, for example, places a constant object in read-only memory.

A static function cannot be determined with the const modifier, because this modifier ensures the constancy of the instance members when calling this function. But, as mentioned above, the static function cannot access non-static class members.

Function templates

Overloaded functions are commonly used to perform similar operations on various data types. ArraySize() is a simple example of such function in MQL5. It returns size of any type of array. In fact, this system function is overloaded and the entire implementation of such an overload is hidden from MQL5 application developers:

```
int  ArraySize(
   void&  array[]      // checked array
   );
```

It means that MQL5 language compiler inserts necessary implementation for each call of this function. For example, that is how it can be done for integer type arrays:

```
int  ArraySize(
   int&  array[]      // array with int type elements
   );
```

ArraySize() function can be displayed the following way for MqlRates type array for working with quotations in historical data format:

```
int  ArraySize(
   MqlRates&  array[] // array filled with MqlRates type values
   );
```

Thus, it is very convenient to use the same function for working with different types. However, all preliminary work should be carried out - the necessary function should be overloaded for all data types it should correctly work with.

There is a convenient solution. If similar operations should be executed for each data type, it is possible to use function templates. In this case, a programmer needs to write only one function template description. When describing the template in such a way, we should specify only some formal parameter instead of some definite data type the function should work with. The compiler will automatically generate various functions for the appropriate handling of each type based on the types of the arguments used when calling the function.

Function template definition starts with the template keyword followed by the list of formal parameters in angle brackets. Each formal parameter is preceded by the typename keyword. Formal parameter types are built-in or user-defined types. They are used:

- to specify the types of function arguments,
- to specify the types of function's return value,
- to declare the variables inside the function definition

Number of template parameters cannot exceed eight. Each formal parameter in the template definition should appear in the list of function parameters at least once. Each name of the formal parameter should be unique.

Below is an example of a function template for searching the highest value in the array of any numeric type (integer and real numbers):

```
template<typename T>
T ArrayMax(T &arr[])
  {
   uint size=ArraySize(arr);
   if(size==0) return(0);

   T max=arr[0];
   for(uint n=1;n<size;n++)
      if(max<arr[n]) max=arr[n];
//---
   return(max);
  }
```

This template defines the function that finds the highest value in the passed array and returns this value as a result. Keep in mind that the ArrayMaximum() function built in MQL5 returns only the highest value index that can be used to find the value itself. For example:

```
//--- create an array
   double array[];
   int size=50;
   ArrayResize(array,size);
//---  fill with random values
   for(int i=0;i<size;i++)
     {
      array[i]=MathRand();
     }

//--- find position of the highest value in the array
   int max_position=ArrayMaximum(array);
//--- now, get the highest value itself in the array
   double max=array[max_position];
//--- display the found value
   Print("Max value = ",max);
```

Thus, we have performed two steps to get the highest value in the array. With ArrayMax() function template, we can get the result of the necessary type just by passing the array of an appropriate type into this function. It means that instead of two last lines

```
//--- find position of the highest value in the array
   int max_position=ArrayMaximum(array);
//--- now, get the highest value itself in the array
   double max=array[max_position];
```

we now can use only one line, in which the returned result has the same type as the array passed into function:

```
//--- find the highest value
   double max=ArrayMax(array);
```

In this case, the type of result returned by the ArrayMax() function will automatically match the type of array.

Use the typename keyword to get the argument type as a string in order to create general purpose methods of working with various data types. Let's consider a specific example of the function that returns data type as a string:

```
#include <Trade\Trade.mqh>
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   CTrade trade;
   double d_value=M_PI;
   int i_value=INT_MAX;
   Print("d_value: type=",GetTypeName(d_value), ",   value=", d_value);
   Print("i_value: type=",GetTypeName(i_value), ",   value=", i_value);
   Print("trade: type=",GetTypeName(trade));
//---
  }
//+------------------------------------------------------------------+
//| Type is returned as a line                                       |
//+------------------------------------------------------------------+
template<typename T>
string GetTypeName(const T &t)
  {
//--- return the type as a line
   return(typename(T));
//---
  }
```

Function templates can also be used for class methods, for example:

```
class CFile
  {
   ...
public:
   ...
   template<typename T>
   uint WriteStruct(T &data);
  };

template<typename T>
uint CFile::WriteStruct(T &data)
  {
   ...
   return(FileWriteStruct(m_handle,data));
  }
```

Function templates should not be declared with export, virtual and #import keywords.

Template function overload

A template function overload may be necessary sometimes. For example, we have a template function that writes the value of the second parameter to the first one using typecasting. MQL5 does not allow typecasting string to bool. We can do that ourselves - let's create an overload of a template function. For example:

```
//+------------------------------------------------------------------+
//| Template function                                                |
//+------------------------------------------------------------------+
template<typename T1,typename T2>
string Assign(T1 &var1,T2 var2)
  {
   var1=(T1)var2;
   return(__FUNCSIG__);
  }
//+------------------------------------------------------------------+
//| Special overload for bool+string                                 |
//+------------------------------------------------------------------+
string Assign(bool &var1,string var2)
  {
   var1=(StringCompare(var2,"true",false) || StringToInteger(var2)!=0);
   return(__FUNCSIG__);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   int i;
   bool b;
   Print(Assign(i,"test"));
   Print(Assign(b,"test"));
  }
```

As a result of the code execution, we can see that the Assign() template function has been used for the int+string pair, while the overloaded version has already been used for the bool+string pair during the second call.

```
string Assign<int,string>(int&,string)
string Assign(bool&,string)
```

Overload

Template advantages

Function templates are used when you need to perform similar operations on various data types, for example, searching for a maximum element in the array. The main advantage of applying the templates is that you do not have to code a separate overload for each type. Instead of declaring multiple overloads of each type

```
double ArrayMax(double array[])
  {
   ...
  }
int ArrayMax(int array[])
  {
   ...
  }
uint ArrayMax(uint array[])
  {
   ...
  }
long ArrayMax(long array[])
  {
   ...
  }
datetime ArrayMax(datetime array[])
  {
   ...
  }
```

we need to write only one template function

```
template<typename T>
T ArrayMax(T array[])
  {
   if(ArraySize()==0)
      return(0);
   uint max_index=ArrayMaximum(array);
   return(array[max_index]);
  }
```

to use it in your code:

```
double high[];
datetime time[];
....
double max_high=ArrayMax(high);
datetime lasttime=ArrayMax(time);
```

Here, the *T* formal parameter specifying a type of used data is replaced with an actually applied type during compilation, i.e. the compiler automatically generates a separate function for each type - double, datetime, etc. MQL5 also allows you to develop class templates using all the advantages of the approach.

Class templates

A class template is declared using the template keyword followed by angle brackets<> enumerating the list of formal parameters with the typename keyword. This entry informs the compiler that it deals with a generic class with the *T* formal parameter defining a real variable type when implementing a class. For example, let's create a vector class for storing an array with *T* type elements:

```
#define TOSTR(x) #x+" "   // macro for displaying an object name
//+------------------------------------------------------------------+
//| Vector class for storing T-type elements                         |
//+------------------------------------------------------------------+
template <typename T>
class TArray
  {
protected:
   T                 m_array[];
public:
   //--- constructor creates an array for 10 elements by default
   void TArray(void){ArrayResize(m_array,10);}
   //--- constructor for creating a vector with a specified array size
   void TArray(int size){ArrayResize(m_array,size);}
   //--- return a type and amount of data stored in the TArray type object
   string Type(void){return(typename(m_array[0])+":"+(string)ArraySize(m_array));};
  };
```

Next, let's apply different methods to create three *TArray* objects in the program for working with various types

```
void OnStart()
  {
   TArray<double> double_array;   // vector has a default size of 10
   TArray<int> int_array(15);     // vector has a size of 15
   TArray<string> *string_array;  // pointer to TArray<string> vector
//--- create a dynamic object
   string_array=new TArray<string>(20);
//--- display an object name, data type and vector size in the Journal
   PrintFormat("%s (%s)",TOSTR(double_array),double_array.Type());
   PrintFormat("%s (%s)",TOSTR(int_array),int_array.Type());
   PrintFormat("%s (%s)",TOSTR(string_array),string_array.Type());
//--- remove a dynamic object before completing the program
   delete(string_array);
  }
```

Script execution results:

```
  double_array  (double:10)
  int_array  (int:15)
  string_array  (string:20)
```

Now, we have 3 vectors with different data types: double, int and string.

Class templates are well suited for developing containers - objects designed for encapsulating other objects of any type. Container objects are collections already containing objects of one certain type. Usually, working with stored data is instantly built into the container.

For example, you can create a class template that does not allow accessing an element outside the array, thus avoiding the "out of range" critical error.

```
//+------------------------------------------------------------------+
//| Class for a free access to an array element                      |
//+------------------------------------------------------------------+
template<typename T>
class TSafeArray
  {
protected:
   T                 m_array[];
public:
   //--- default constructor
   void              TSafeArray(void){}
   //--- constructor for creating the array of a specified size
   void              TSafeArray(int size){ArrayResize(m_array,size);}
   //--- array size
   int               Size(void){return(ArraySize(m_array));}
   //--- change the array size
   int               Resize(int size,int reserve){return(ArrayResize(m_array,size,rese
   //--- release the array
   void              Erase(void){ZeroMemory(m_array);}
   //--- operator for accessing the array element by index
   T                 operator[](int index);
   //--- assignment operator for receiving all elements from the array at once
   void              operator=(const T  &array[]); // T type array
  };
//+------------------------------------------------------------------+
//| Receiving an element by index                                    |
//+------------------------------------------------------------------+
template<typename T>
T TSafeArray::operator[](int index)
  {
   static T invalid_value;
//---
   int max=ArraySize(m_array)-1;
   if(index<0 || index>=ArraySize(m_array))
     {
      PrintFormat("%s index %d is not in range (0-%d)!",__FUNCTION__,index,max);
      return(invalid_value);
     }
//---
   return(m_array[index]);
  }
//+------------------------------------------------------------------+
```

```
//| Assigning for the array                                          |
//+------------------------------------------------------------------+
template<typename T>
void TSafeArray::operator=(const T  &array[])
  {
   int size=ArraySize(array);
   ArrayResize(m_array,size);
//--- T type should support the copying operator
   for(int i=0;i<size;i++)
      m_array[i]=array[i];
//---
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   int copied,size=15;
   MqlRates rates[];
//--- copy the array of quotes
   if((copied=CopyRates(_Symbol,_Period,0,size,rates))!=size)
     {
      PrintFormat("CopyRates(%s,%s,0,%d) returned %d error code",
      _Symbol,EnumToString(_Period),size,GetLastError());
      return;
     }
//--- create a container and insert the MqlRates value array to it
   TSafeArray<MqlRates> safe_rates;
   safe_rates=rates;
   //--- index within the array
   int index=3;
   PrintFormat("Close[%d]=%G",index,safe_rates[index].close);
   //--- index outside the array
   index=size;
   PrintFormat("Close[%d]=%G",index,safe_rates[index].close);
  }
```

Please note that template declaration should also be used when describing methods outside the class declaration:

```
template<typename T>
T TSafeArray::operator[](int index)
  {
   ...
  }
template<typename T>
void TSafeArray::operator=(const T  &array[])
  {
   ...
```

```
  }
```

Class and function templates allow you to define multiple comma-separated formal parameters, for example, Map collection for storing "key – value" pairs:

```
template<typename Key, template Value>
class TMap
  {
   ...
  }
```

Function templates, Overload

Abstract Classes and Pure Virtual Functions

Abstract classes are used for creating generic entities, that you expect to use for creating more specific derived classes. An abstract class can only be used as the base class for some other class, that is why it is impossible to create an object of the abstract class type.

A class which contains at least one pure virtual function in it is abstract. Therefore, classes derived from the abstract class must implement all its pure virtual functions, otherwise they will also be abstract classes.

A virtual function is declared as "pure" by using the pure-specifier syntax. Consider the example of the CAnimal class, which is only created to provide common functions - the objects of the CAnimal type are too general for practical use. Thus, CAnimal is a good example for an abstract class:

```
class CAnimal
  {
public:
                     CAnimal();      // Constructor
   virtual void      Sound() = 0;    // A pure virtual function
private:
   double            m_legs_count;   // The number of the animal's legs
  };
```

Here Sound() is a pure virtual function, because it is declared with the specifier of the pure virtual function PURE (=0).

Pure virtual functions are only the virtual functions for which the PURE specifier is set: (=NULL) or (=0). Example of abstract class declaration and use:

```
class CAnimal
  {
public:
   virtual void      Sound()=NULL;   // PURE method, should be overridden in the deri
  };
//--- Derived from an abstract class
class CCat : public CAnimal
 {
public:
  virtual void       Sound() { Print("Myau"); } // PURE is overridden, CCat is not ab
 };

//--- Examples of wrong use
new CAnimal;          // Error of 'CAnimal' - the compiler returns the "cannot instanti
CAnimal some_animal; // Error of 'CAnimal' - the compiler returns the "cannot instanti

//--- Examples of proper use
new CCat;  // No error - the CCat class is not abstract
CCat cat;  // No error - the CCat class is not abstract
```

Restrictions on abstract classes

If the constructor for an abstract class calls a pure virtual function (either directly or indirectly), the result is undefined.

```
//+------------------------------------------------------------------+
//| An abstract base class                                           |
//+------------------------------------------------------------------+
class CAnimal
  {
public:
   //--- A pure virtual function
   virtual void      Sound(void)=NULL;
   //--- Function
   void              CallSound(void) { Sound(); }
   //--- Constructor
   CAnimal()
    {
     //--- An explicit call of the virtual method
     Sound();
     //--- An implicit call (using a third function)
     CallSound();
     //--- A constructor and/or destructor always calls its own functions,
     //--- even if they are virtual and overridden by a called function in a derived c
     //--- If the called function is pure virtual,
     //--- its call will cause a critical runtime error: "pure virtual function call"
    }
  };
```

However, constructors and destructors for abstract classes can call other member functions.

Namespaces

A namespace is a specially declared area, within which various IDs are defined: variables, functions, classes, etc. It is set using the namespace keyword:

```
namespace name of_space {
  // list of function, class and variable definitions
}
```

Applying 'namespace' allows splitting the global namespace into subspaces. All IDs within the namespace are available to each other without a specification. The :: operator (context resolution operation) is used to access namespace members from the outside.

```
namespace ProjectData
{
class DataManager
  {
public:
   void              LoadData() {}
  };
void Func(DataManager& manager) {}
}
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- working with ProjectData namespace
   ProjectData::DataManager mgr;
   mgr.LoadData();
   ProjectData::Func(mgr);
  }
```

Namespaces are used to arrange a code in the form of logical groups and to avoid name conflicts that may occur when several libraries are used in a program. In such cases, each library can be declared in its namespace to explicitly access the necessary functions and classes of each library.

A namespace can be declared in several blocks in one or several files. The compiler combines all parts together during a preprocessing and the resulting namespace contains all the members declared in all parts. Suppose that we have A class implemented in the Sample.mqh include file:

```
//+------------------------------------------------------------------+
//|                                                   Sample.mqh |
//+------------------------------------------------------------------+
class A
  {
public:
                     A() {Print(__FUNCTION__);}
  };
```

We want to use this class in our project, but we already have A class. To be able to use both classes and avoid ID conflict, simply wrap the included file in a namespace:

```
//--- declare the first A class
class A
  {
public:
                     A() {Print(__FUNCTION__);}
  };
//--- wrap the A class from the Sample.mqh file in the Library namespace to avoid a co
namespace Library
{
#include "Sample.mqh"
}
//--- add yet another class to the Library namespace
namespace Library
{
class B
  {
public:
                     B() {Print(__FUNCTION__);}
  };
}
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- use the A class from the global namespace
   A a1;
//--- use the A and B classes from the Library namespace
   Library::A a2;
   Library::B b;
  }
//+------------------------------------------------------------------+

/*
Result:
   A::A
   Library::A::A
   Library::B::B
*/
```

Namespaces can be nested. A nested namespace has unlimited access to members of its parent space, but members of the parent space do not have unlimited access to the nested namespace.

```
namespace General
{
int Func();
```

```
namespace Details
{
 int Counter;
 int Refresh()  {return Func(); }
}

int GetBars()   {return(iBars(Symbol(), Period()));};
int Size(int i) {return Details::Counter;}
}
```

Global namespace

If the ID is not explicitly declared in the namespace, it is considered to be an implicit part of the global namespace. To set the global ID explicitly, use the scope resolution operator without a name. This will allow you to distinguish this ID from any other element with the same name located in a different namespace. For example, when importing a function:

```
#import "lib.dll"
int Func();
#import
//+------------------------------------------------------------------+
//|  Some function                                                   |
//+------------------------------------------------------------------+
int Func()
  {
   return(0);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//+--- call the imported function
   Print(lib::Func());
//+--- call our function
   Print(::Func());
  }
```

In this case, all the functions imported from the DLL function were included in the namespace of the same name. This allowed the compiler to clearly determine the function to be called.

Constants, Enumerations and Structures

To simplify the program writing and to make program texts more convenient for perception, the MQL5 language provides predefined standard constants and enumerations. Besides that, service structures are used for storing information.

Standard constants are similar to macros and are of int type.

The constants are grouped by their purposes:

- Chart constants are used when working with price charts: opening, navigation, setting parameters;
- Objects constants are intended for processing graphical objects that can be created and displayed in charts;
- Indicators constants are used for working with standard and custom indicators;
- Environment state constants describe properties of a MQL5-program, show information about a client terminal, financial instrument and current account;
- Trade constants allow to specify a variety of information in the course of trading;
- Named constants are constants of the MQL5 language;
- Data structures describe data storage formats used;
- Codes of errors and warnings describe compiler messages and trading server answers to trade requests;
- In/out constants are designed for working with file functions and displaying messages on the screen by the MessageBox() function.

Chart Constants

Constants describing various properties of charts are divided into the following groups:

- Types of events – events that occur when working with charts;
- Chart timeframes – standard built-in periods;
- Properties of chart – identifiers that are used as parameters of chart functions;
- Positioning constants - value of a parameter of the ChartNavigate() function;
- Displaying charts - setting the chart appearance.

Types of Chart Events

There are 11 types of events that can be processed using the predefined function OnChartEvent(). For custom events 65535 identifiers are provided in the range of CHARTEVENT_CUSTOM to CHARTEVENT_CUSTOM_LAST inclusive. To generate a custom event, the EventChartCustom() function should be used.

ENUM_CHART_EVENT

ID	Description
CHARTEVENT_KEYDOWN	Keystrokes
CHARTEVENT_MOUSE_MOVE	Mouse move, mouse clicks (if CHART_EVENT_MOUSE_MOVE=true is set for the chart)
CHARTEVENT_MOUSE_WHEEL	Pressing or scrolling the mouse wheel (if CHART_EVENT_MOUSE_WHEEL=True for the chart)
CHARTEVENT_OBJECT_CREATE	Graphical object created (if CHART_EVENT_OBJECT_CREATE=true is set for the chart)
CHARTEVENT_OBJECT_CHANGE	Graphical object property changed via the properties dialog
CHARTEVENT_OBJECT_DELETE	Graphical object deleted (if CHART_EVENT_OBJECT_DELETE=true is set for the chart)
CHARTEVENT_CLICK	Clicking on a chart
CHARTEVENT_OBJECT_CLICK	Clicking on a graphical object
CHARTEVENT_OBJECT_DRAG	Drag and drop of a graphical object
CHARTEVENT_OBJECT_ENDEDIT	End of text editing in the graphical object Edit
CHARTEVENT_CHART_CHANGE	Change of the chart size or modification of chart properties through the Properties dialog
CHARTEVENT_CUSTOM	Initial number of an event from a range of custom events
CHARTEVENT_CUSTOM_LAST	The final number of an event from a range of custom events

For each type of event, the input parameters of the OnChartEvent() function have definite values that are required for the processing of this event. The events and values passed through this parameters are listed in the below table.

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
Event of a keystroke	CHARTEVENT_KEYDOWN	code of a pressed key	Repeat count (the number of times the keystroke is repeated as a result of the user holding down the key)	The string value of a bit mask describing the status of keyboard buttons
Mouse events (if CHART_EVENT_MOUSE_MOVE=true is set for the chart)	CHARTEVENT_MOUSE_MOVE	the X coordinate	the Y coordinate	The string value of a bit mask describing the status of mouse buttons
Mouse wheel event (if CHART_EVENT_MOUSE_WHEEL=true for the chart)	CHARTEVENT_MOUSE_WHEEL	Flags of states of keys and mouse buttons, the X and Y coordinates of the mouse pointer. See description in the example below	The Delta value of the mouse wheel scroll	—
event of graphical object creation (if CHART_EVENT_OBJECT_CREATE=true is set for the chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of the created graphical object
Event of change of an object property via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of the modified graphical object
Event of graphical object deletion (if CHART_EVENT_OBJECT_DELETE=true is set for the chart)	CHARTEVENT_OBJECT_DELETE	—	—	Name of the deleted graphical object
Event of a mouse click on	CHARTEVENT_CLICK	the X coordinate	the Y coordinate	—

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
the chart				
Event of a mouse click in a graphical object belonging to the chart	CHARTEVENT_OBJECT_CLICK	the X coordinate	the Y coordinate	Name of the graphical object, on which the event occurred
Event of a graphical object dragging using the mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of the moved graphical object
Event of the finished text editing in the entry box of the LabelEdit graphical object	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the LabelEdit graphical object, in which text editing has completed
Event of change of the chart size or modification of chart properties through the Properties dialog	CHARTEVENT_CHART_CHANGE	—	—	—
ID of the user event under the N number	CHARTEVENT_CUSTOM+N	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function

Example:

```
#define KEY_NUMPAD_5        12
#define KEY_LEFT            37
#define KEY_UP              38
#define KEY_RIGHT           39
#define KEY_DOWN            40
#define KEY_NUMLOCK_DOWN    98
#define KEY_NUMLOCK_LEFT   100
#define KEY_NUMLOCK_5      101
#define KEY_NUMLOCK_RIGHT  102
#define KEY_NUMLOCK_UP     104
//+------------------------------------------------------------------+

//--- the text in the Edit of object has been changed
   if(id==CHARTEVENT_OBJECT_ENDEDIT)
     {
      Print("The text in the Edit field of the object with name ",sparam," has been ch
     }
  }
```

For CHARTEVENT_MOUSE_MOVE event the **sparam** string parameter contains information about state of the keyboard and mouse buttons:

Bit	Description
1	State of the left mouse button
2	State of the right mouse button
3	State of the SHIFT button
4	State of the CTRL button
5	State of the middle mouse button
6	State of the first extra mouse button
7	State of the second extra mouse button

Example:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- enable CHART_EVENT_MOUSE_MOVE messages
   ChartSetInteger(0,CHART_EVENT_MOUSE_MOVE,1);
//--- disable the context menu of the chart (on the right)
```

```
   ChartSetInteger(0,CHART_CONTEXT_MENU,0);
//--- disable the crosshair (by the middle button)
   ChartSetInteger(0,CHART_CROSSHAIR_TOOL,0);
//--- forced updating of chart properties ensures readiness for event processing
   ChartRedraw();
  }
//+------------------------------------------------------------------+
//| MouseState                                                       |
//+------------------------------------------------------------------+
string MouseState(uint state)
  {
   string res;
   res+="\nML: "   +(((state& 1)== 1)?"DN":"UP");   // mouse left
   res+="\nMR: "   +(((state& 2)== 2)?"DN":"UP");   // mouse right
   res+="\nMM: "   +(((state&16)==16)?"DN":"UP");   // mouse middle
   res+="\nMX: "   +(((state&32)==32)?"DN":"UP");   // mouse first X key
   res+="\nMY: "   +(((state&64)==64)?"DN":"UP");   // mouse second X key
   res+="\nSHIFT: "+(((state& 4)== 4)?"DN":"UP");   // shift key
   res+="\nCTRL: " +(((state& 8)== 8)?"DN":"UP");   // control key
   return(res);
  }
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,const long &lparam,const double &dparam,const string &s
  {
   if(id==CHARTEVENT_MOUSE_MOVE)
      Comment("POINT: ",(int)lparam,",",(int)dparam,"\n",MouseState((uint)sparam));
  }
```

For the CHARTEVENT_MOUSE_WHEEL event, parameters **lparam** and **dparam** contain information about the states of the **Ctrl** and **Shift** keys, of mouse buttons, cursor coordinates and the mouse wheel scroll value. For a better understanding, run this Expert Advisor on a chart and scroll the mouse wheel, while pressing different buttons and holding down the keys described in the code.

Example of CHARTEVENT_MOUSE_WHEEL event processing:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
init OnInit()
  {
//--- Enabling mouse wheel scrolling messages
   ChartSetInteger(0,CHART_EVENT_MOUSE_WHEEL,1);
//--- Forced updating of chart properties ensures readiness for event processing
   ChartRedraw();
//---
   return(INIT_SUCCEEDED);
```

```
  }
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,const long &lparam,const double &dparam,const string &s
  {
   if(id==CHARTEVENT_MOUSE_WHEEL)
     {
      //--- Consider the state of mouse buttons and wheel for this event
      int flg_keys = (int)(lparam>>32);          // The flag of states of the Ctrl and
      int x_cursor = (int)(short)lparam;         // the X coordinate where the mousse
      int y_cursor = (int)(short)(lparam>>16);   // the Y coordinate where the mousse
      int delta    = (int)dparam;                // the total value of mouse scroll, t
      //--- Processing the flag
      string str_keys="";
      if((flg_keys&0x0001)!=0) str_keys+="LMOUSE ";
      if((flg_keys&0x0002)!=0) str_keys+="RMOUSE ";
      if((flg_keys&0x0004)!=0) str_keys+="SHIFT ";
      if((flg_keys&0x0008)!=0) str_keys+="CTRL ";
      if((flg_keys&0x0010)!=0) str_keys+="MMOUSE ";
      if((flg_keys&0x0020)!=0) str_keys+="X1MOUSE ";
      if((flg_keys&0x0040)!=0) str_keys+="X2MOUSE ";

      if(str_keys!="")
         str_keys=", keys='"+StringSubstr(str_keys,0,StringLen(str_keys)-1) + "'";
      PrintFormat("%s: X=%d, Y=%d, delta=%d%s",EnumToString(CHARTEVENT_MOUSE_WHEEL),x_
     }
  }
//+------------------------------------------------------------------+ /*
   Example of the output
   CHARTEVENT_MOUSE_WHEEL: Ctrl pressed: X=193, Y=445, delta=-120
   CHARTEVENT_MOUSE_WHEEL: Shift pressed: X=186, Y=446, delta=120
   CHARTEVENT_MOUSE_WHEEL:  X=178, Y=447, delta=-120
   CHARTEVENT_MOUSE_WHEEL:  X=231, Y=449, delta=120
   CHARTEVENT_MOUSE_WHEEL: MiddleButton pressed: X=231, Y=449, delta=120
   CHARTEVENT_MOUSE_WHEEL: LeftButton pressed: X=279, Y=320, delta=-120
   CHARTEVENT_MOUSE_WHEEL: RightButton pressed: X=253, Y=330, delta=120  */

Event Handling Functions, Working with events

Chart Timeframes

All predefined timeframes of charts have unique identifiers. The PERIOD_CURRENT identifier means the current period of a chart, at which a mql5-program is running.

ENUM_TIMEFRAMES

ID	Description
PERIOD_CURRENT	Current timeframe
PERIOD_M1	1 minute
PERIOD_M2	2 minutes
PERIOD_M3	3 minutes
PERIOD_M4	4 minutes
PERIOD_M5	5 minutes
PERIOD_M6	6 minutes
PERIOD_M10	10 minutes
PERIOD_M12	12 minutes
PERIOD_M15	15 minutes
PERIOD_M20	20 minutes
PERIOD_M30	30 minutes
PERIOD_H1	1 hour
PERIOD_H2	2 hours
PERIOD_H3	3 hours
PERIOD_H4	4 hours
PERIOD_H6	6 hours
PERIOD_H8	8 hours
PERIOD_H12	12 hours
PERIOD_D1	1 day
PERIOD_W1	1 week
PERIOD_MN1	1 month

Example:

```
   string chart_name="test_Object_Chart";
   Print("Let's try to create a Chart object with the name ",chart_name);
//--- If such an object does not exist - create it
   if(ObjectFind(0,chart_name)<0)ObjectCreate(0,chart_name,OBJ_CHART,0,0,0,0,0);
```

```
//--- Define symbol
   ObjectSetString(0,chart_name,OBJPROP_SYMBOL,"EURUSD");
//--- Set X coordinate of the anchor point
   ObjectSetInteger(0,chart_name,OBJPROP_XDISTANCE,100);
//--- Set Y coordinate of the anchor point
   ObjectSetInteger(0,chart_name,OBJPROP_YDISTANCE,100);
//--- Set the width of chart
   ObjectSetInteger(0,chart_name,OBJPROP_XSIZE,400);
//--- Set the height
   ObjectSetInteger(0,chart_name,OBJPROP_YSIZE,300);
//--- Set the timeframe
   ObjectSetInteger(0,chart_name,OBJPROP_PERIOD,PERIOD_D1);
//--- Set scale (from 0 to 5)
   ObjectSetDouble(0,chart_name,OBJPROP_SCALE,4);
//--- Disable selection by a mouse
   ObjectSetInteger(0,chart_name,OBJPROP_SELECTABLE,false);
```

Timeseries identifiers

The identifiers of timeseries are used in the iHighest() and iLowest() functions. They can be equal to a value the enumeration

ENUM_SERIESMODE

Identifier	Description
MODE_OPEN	Opening price
MODE_LOW	Low price
MODE_HIGH	High price
MODE_CLOSE	Close price
MODE_VOLUME	Tick volume
MODE_REAL_VOLUME	Real volume
MODE_SPREAD	Spread

PeriodSeconds, Period, Date and Time, Visibility of objects

Chart Properties

Identifiers of ENUM_CHART_PROPERTY enumerations are used as parameters of functions for working with charts. The abbreviation of r/o in the "Property Type" column means that this property is read-only and cannot be changed. The w/o abbreviation in the "Property Type" column means that this property is write-only and it cannot be received. When accessing certain properties, it's necessary to specify an additional parameter-modifier (modifier), which serves to indicate the number of chart subwindows. 0 means the main window.

The functions defining the chart properties are actually used for sending change commands to the chart. If these functions are executed successfully, the command is included in the common queue of the chart events. The changes are implemented to the chart when handling the queue of the chart events.

Thus, do not expect an immediate visual update of the chart after calling these functions. Generally, the chart is updated automatically by the terminal following the change events - a new quote arrival, resizing the chart window, etc. Use ChartRedraw() function to forcefully update the chart.

For functions ChartSetInteger() and ChartGetInteger()

ENUM_CHART_PROPERTY_INTEGER

ID	Description	Property Type
CHART_SHOW	Price chart drawing. If false, drawing any price chart attributes is disabled and all chart border indents are eliminated, including time and price scales, quick navigation bar, Calendar event labels, trade labels, indicator and bar tooltips, indicator subwindows, volume histograms, etc. Disabling the drawing is a perfect solution for creating a custom program interface using the graphical resources. The graphical objects are always drawn regardless of the CHART_SHOW property value.	bool
CHART_IS_OBJECT	Identifying "Chart" (OBJ_CHART) object - returns true for a graphical object. Returns false for a real chart	bool r/o
CHART_BRING_TO_TOP	Show chart on top of other charts	bool
CHART_CONTEXT_MENU	Enabling/disabling access to the context menu using the right click. When CHART_CONTEXT_MENU=false, only the chart context menu is disabled. The context menu of objects on the chart remains available.	bool (default is true)

ID	Description	Property Type
CHART_CROSSHAIR_TOOL	Enabling/disabling access to the Crosshair tool using the middle click.	bool (default is true)
CHART_MOUSE_SCROLL	Scrolling the chart horizontally using the left mouse button. Vertical scrolling is also available if the value of any following properties is set to true: CHART_SCALEFIX, CHART_SCALEFIX_11 or CHART_SCALE_PT_PER_BAR When CHART_MOUSE_SCROLL=false, chart scrolling with the mouse wheel is unavailable	bool
CHART_EVENT_MOUSE_WHEEL	Sending messages about mouse wheel events (CHARTEVENT_MOUSE_WHEEL) to all mql5 programs on a chart	bool (default is true)
CHART_EVENT_MOUSE_MOVE	Send notifications of mouse move and mouse click events (CHARTEVENT_MOUSE_MOVE) to all mql5 programs on a chart	bool
CHART_EVENT_OBJECT_CREATE	Send a notification of an event of new object creation (CHARTEVENT_OBJECT_CREATE) to all mql5-programs on a chart	bool
CHART_EVENT_OBJECT_DELETE	Send a notification of an event of object deletion (CHARTEVENT_OBJECT_DELETE) to all mql5-programs on a chart	bool
CHART_MODE	Chart type (candlesticks, bars or line)	enum ENUM_CHART_MODE
CHART_FOREGROUND	Price chart in the foreground	bool
CHART_SHIFT	Mode of price chart indent from the right border	bool
CHART_AUTOSCROLL	Mode of automatic moving to the right border of the chart	bool
CHART_KEYBOARD_CONTROL	Allow managing the chart using a keyboard ("Home", "End", "PageUp", "+", "-", "Up arrow", etc.). Setting CHART_KEYBOARD_CONTROL to false disables chart scrolling and scaling while leaving intact the ability to receive the keys pressing events in OnChartEvent().	bool
CHART_QUICK_NAVIGATION	Allow the chart to intercept Space and Enter key strokes to activate the quick navigation bar. The quick navigation bar	bool

ID	Description	Property Type
	automatically appears at the bottom of the chart after double-clicking the mouse or pressing Space/Enter. It allows you to quickly change a symbol, timeframe and first visible bar date.	
CHART_SCALE	Scale	int from 0 to 5
CHART_SCALEFIX	Fixed scale mode	bool
CHART_SCALEFIX_11	Scale 1:1 mode	bool
CHART_SCALE_PT_PER_BAR	Scale to be specified in points per bar	bool
CHART_SHOW_TICKER	Display a symbol ticker in the upper left corner. Setting CHART_SHOW_TICKER to 'false' also sets CHART_SHOW_OHLC to 'false' and disables OHLC	bool
CHART_SHOW_OHLC	Display OHLC values in the upper left corner. Setting CHART_SHOW_OHLC to 'true' also sets CHART_SHOW_TICKER to 'true' and enables the ticker	bool
CHART_SHOW_BID_LINE	Display Bid values as a horizontal line in a chart	bool
CHART_SHOW_ASK_LINE	Display Ask values as a horizontal line in a chart	bool
CHART_SHOW_LAST_LINE	Display Last values as a horizontal line in a chart	bool
CHART_SHOW_PERIOD_SEP	Display vertical separators between adjacent periods	bool
CHART_SHOW_GRID	Display grid in the chart	bool
CHART_SHOW_VOLUMES	Display volume in the chart	enum ENUM_CHART_VOLUME_MODE
CHART_SHOW_OBJECT_DESCR	Display textual descriptions of objects (not available for all objects)	bool
CHART_SHOW_TRADE_HISTORY	Display trades from the trading history as entry/exit arrows on a chart. See the "Show trading history" option descriptions in the platform settings.	bool
CHART_VISIBLE_BARS	The number of bars on the chart that can be displayed	int r/o

ID	Description	Property Type
CHART_WINDOWS_TOTAL	The total number of chart windows, including indicator subwindows	int r/o
CHART_WINDOW_IS_VISIBLE	Visibility of subwindows	bool r/o modifier - subwindow number
CHART_WINDOW_HANDLE	Chart window handle (HWND)	int r/o
CHART_WINDOW_YDISTANCE	The distance between the upper frame of the indicator subwindow and the upper frame of the main chart window, along the vertical Y axis, in pixels. In case of a mouse event, the cursor coordinates are passed in terms of the coordinates of the main chart window, while the coordinates of graphical objects in an indicator subwindow are set relative to the upper left corner of the subwindow. The value is required for converting the absolute coordinates of the main chart to the local coordinates of a subwindow for correct work with the graphical objects, whose coordinates are set relative to the upper left corner of the subwindow frame.	int r/o modifier - subwindow number
CHART_FIRST_VISIBLE_BAR	Number of the first visible bar in the chart. Indexing of bars is the same as for timeseries.	int r/o
CHART_WIDTH_IN_BARS	Chart width in bars	int r/o
CHART_WIDTH_IN_PIXELS	Chart width in pixels	int r/o
CHART_HEIGHT_IN_PIXELS	Chart height in pixels	int modifier - subwindow number
CHART_COLOR_BACKGROUND	Chart background color	color
CHART_COLOR_FOREGROUND	Color of axes, scales and OHLC line	color
CHART_COLOR_GRID	Grid color	color
CHART_COLOR_VOLUME	Color of volumes and position opening levels	color
CHART_COLOR_CHART_UP	Color for the up bar, shadows and body borders of bull candlesticks	color

ID	Description	Property Type
CHART_COLOR_CHART_DOWN	Color for the down bar, shadows and body borders of bear candlesticks	color
CHART_COLOR_CHART_LINE	Line chart color and color of "Doji" Japanese candlesticks	color
CHART_COLOR_CANDLE_BULL	Body color of a bull candlestick	color
CHART_COLOR_CANDLE_BEAR	Body color of a bear candlestick	color
CHART_COLOR_BID	Bid price level color	color
CHART_COLOR_ASK	Ask price level color	color
CHART_COLOR_LAST	Line color of the last executed deal price (Last)	color
CHART_COLOR_STOP_LEVEL	Color of stop order levels (Stop Loss and Take Profit)	color
CHART_SHOW_TRADE_LEVELS	Displaying trade levels in the chart (levels of open positions, Stop Loss, Take Profit and pending orders)	bool
CHART_DRAG_TRADE_LEVELS	Permission to drag trading levels on a chart with a mouse. The drag mode is enabled by default (true value)	bool
CHART_SHOW_DATE_SCALE	Showing the time scale on a chart	bool
CHART_SHOW_PRICE_SCALE	Showing the price scale on a chart	bool
CHART_SHOW_ONE_CLICK	Showing the "One click trading" panel on a chart	bool
CHART_IS_MAXIMIZED	Chart window is maximized	bool r/o
CHART_IS_MINIMIZED	Chart window is minimized	bool r/o
CHART_IS_DOCKED	The chart window is docked. If set to false, the chart can be dragged outside the terminal area	bool
CHART_FLOAT_LEFT	The left coordinate of the undocked chart window relative to the virtual screen	int
CHART_FLOAT_TOP	The top coordinate of the undocked chart window relative to the virtual screen	int
CHART_FLOAT_RIGHT	The right coordinate of the undocked chart window relative to the virtual screen	int

ID	Description	Property Type
CHART_FLOAT_BOTTOM	The bottom coordinate of the undocked chart window relative to the virtual screen	int

For functions ChartSetDouble() and ChartGetDouble()

ENUM_CHART_PROPERTY_DOUBLE

ID	Description	Property Type
CHART_SHIFT_SIZE	The size of the zero bar indent from the right border in percents	double (from 10 to 50 percents)
CHART_FIXED_POSITION	Chart fixed position from the left border in percent value. Chart fixed position is marked by a small gray triangle on the horizontal time axis. It is displayed only if the automatic chart scrolling to the right on tick incoming is disabled (see CHART_AUTOSCROLL property). The bar on a fixed position remains in the same place when zooming in and out.	double
CHART_FIXED_MAX	Fixed chart maximum	double
CHART_FIXED_MIN	Fixed chart minimum	double
CHART_POINTS_PER_BAR	Scale in points per bar	double
CHART_PRICE_MIN	Chart minimum	double r/o modifier - subwindow number
CHART_PRICE_MAX	Chart maximum	double r/o modifier - subwindow number

For functions ChartSetString() and ChartGetString()

ENUM_CHART_PROPERTY_STRING

ID	Description	Property Type
CHART_COMMENT	Text of a comment in a chart	string
CHART_EXPERT_NAME	The name of the Expert Advisor running on the chart with the specified chart_id	string r/o
CHART_SCRIPT_NAME	The name of the script running on the chart with the specified chart_id	string r/o

Example:

```
int chartMode=ChartGetInteger(0,CHART_MODE);
switch(chartMode)
  {
   case(CHART_BARS):    Print("CHART_BARS");   break;
   case(CHART_CANDLES): Print("CHART_CANDLES");break;
   default:Print("CHART_LINE");
  }
bool shifted=ChartGetInteger(0,CHART_SHIFT);
if(shifted) Print("CHART_SHIFT = true");
else Print("CHART_SHIFT = false");
bool autoscroll=ChartGetInteger(0,CHART_AUTOSCROLL);
if(autoscroll) Print("CHART_AUTOSCROLL = true");
else Print("CHART_AUTOSCROLL = false");
int chartHandle=ChartGetInteger(0,CHART_WINDOW_HANDLE);
Print("CHART_WINDOW_HANDLE = ",chartHandle);
int windows=ChartGetInteger(0,CHART_WINDOWS_TOTAL);
Print("CHART_WINDOWS_TOTAL = ",windows);
if(windows>1)
  {
   for(int i=0;i<windows;i++)
     {
      int height=ChartGetInteger(0,CHART_HEIGHT_IN_PIXELS,i);
      double priceMin=ChartGetDouble(0,CHART_PRICE_MIN,i);
      double priceMax=ChartGetDouble(0,CHART_PRICE_MAX,i);
      Print(i+": CHART_HEIGHT_IN_PIXELS = ",height," pixels");
      Print(i+": CHART_PRICE_MIN = ",priceMin);
      Print(i+": CHART_PRICE_MAX = ",priceMax);
     }
```

```
   }
```

Examples of Working with the Chart

Positioning Constants

Three identifiers from the ENUM_CHART_POSITION list are the possible values of the *position* parameter for the ChartNavigate() function.

ENUM_CHART_POSITION

ID	Description
CHART_BEGIN	Chart beginning (the oldest prices)
CHART_CURRENT_POS	Current position
CHART_END	Chart end (the latest prices)

Example:

```
long handle=ChartOpen("EURUSD",PERIOD_H12);
if(handle!=0)
  {
   ChartSetInteger(handle,CHART_AUTOSCROLL,false);
   ChartSetInteger(handle,CHART_SHIFT,true);
   ChartSetInteger(handle,CHART_MODE,CHART_LINE);
   ResetLastError();
   bool res=ChartNavigate(handle,CHART_END,150);
   if(!res) Print("Navigate failed. Error = ",GetLastError());
   ChartRedraw();
  }
```

Chart Representation

Price charts can be displayed in three ways:

- as bars;
- as candlesticks;
- as a line.

The specific way of displaying the price chart is set by the function ChartSetInteger(chart_handle,CHART_MODE, chart_mode), where chart_mode is one of the values of the ENUM_CHART_MODE enumeration.

ENUM_CHART_MODE

ID	Description
CHART_BARS	Display as a sequence of bars
CHART_CANDLES	Display as Japanese candlesticks
CHART_LINE	Display as a line drawn by Close prices

To specify the mode of displaying volumes in the price chart the function ChartSetInteger(chart_handle, CHART_SHOW_VOLUMES, volume_mode) is used, where volume_mode is one of values of the ENUM_CHART_VOLUME_MODE enumeration.

ENUM_CHART_VOLUME_MODE

ID	Description
CHART_VOLUME_HIDE	Volumes are not shown
CHART_VOLUME_TICK	Tick volumes
CHART_VOLUME_REAL	Trade volumes

Example:

```
//--- Get the handle of the current chart
   long handle=ChartID();
   if(handle>0) // If it succeeded, additionally customize
     {
      //--- Disable autoscroll
      ChartSetInteger(handle,CHART_AUTOSCROLL,false);
      //--- Set the indent of the right border of the chart
      ChartSetInteger(handle,CHART_SHIFT,true);
      //--- Display as candlesticks
      ChartSetInteger(handle,CHART_MODE,CHART_CANDLES);
      //--- Scroll by 100 bars from the beginning of history
      ChartNavigate(handle,CHART_CURRENT_POS,100);
      //--- Set the tick volume display mode
      ChartSetInteger(handle,CHART_SHOW_VOLUMES,CHART_VOLUME_TICK);
```

```
      }
```

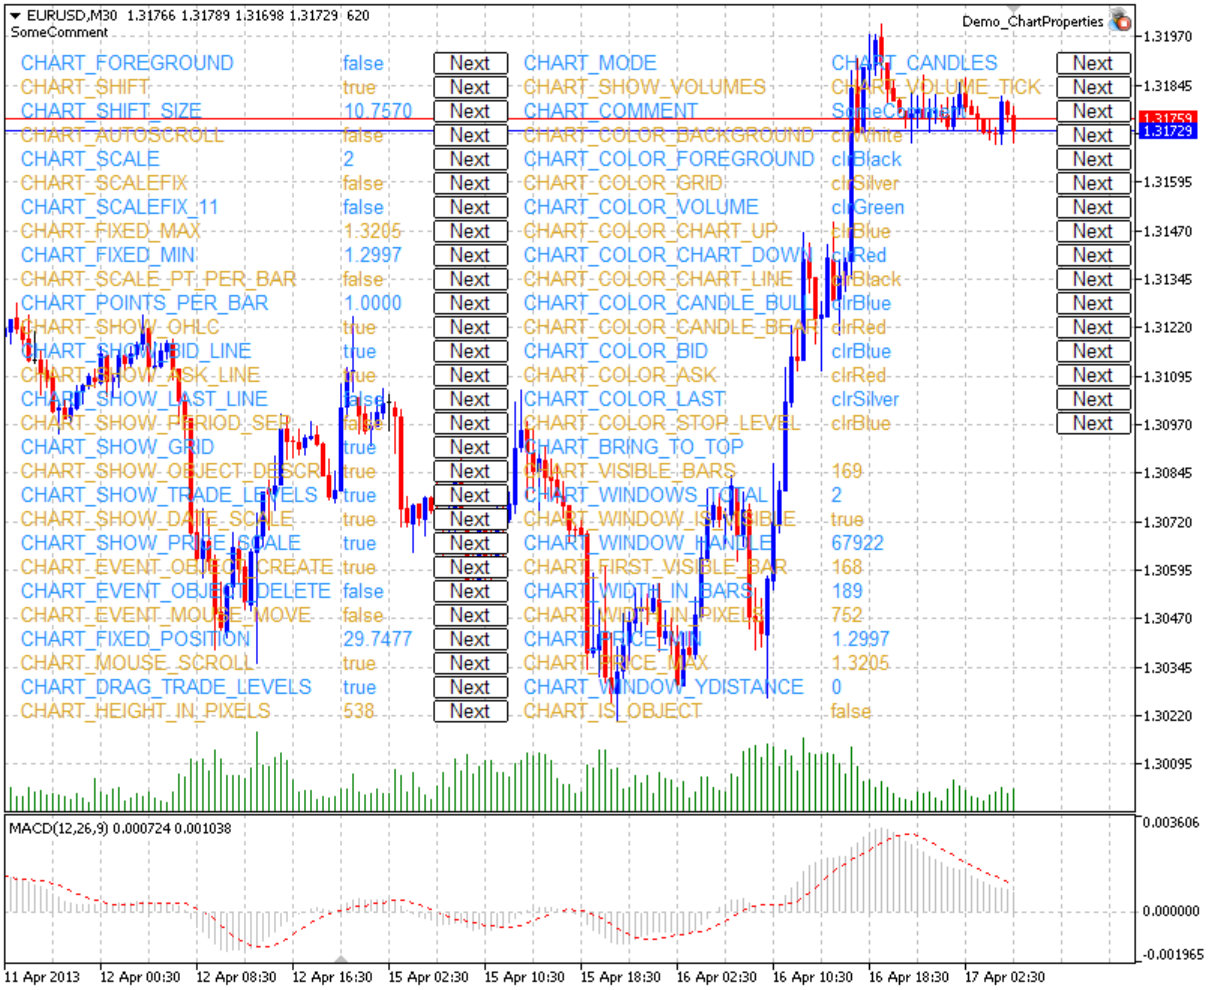
Examples of Working with the Chart

This section contains examples of working with chart properties. One or two complete functions are displayed for each property. These functions allow setting/receiving the value of the property. These functions can be used "as is" in custom mql5 applications.

The screenshot below demonstrates the graphic panel illustrating how changing of the chart property changes its appearance. Clicking Next button allows setting the new value of the appropriate property and view the changes in the chart window.



The panel's source code is located below.

Chart Properties and Sample Functions for Working with Them

- **CHART_IS_OBJECT** defines if an object is a real chart or a graphic object.

```
//+------------------------------------------------------------------+
//| Checks if an object is a chart. If it is a graphic object,       |
//| the result is true. If it is a real chart, the result variable   |
//| has the value of false.                                          |
//+------------------------------------------------------------------+
bool ChartIsObject(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- get the chart property
   if(!ChartGetInteger(chart_ID,CHART_IS_OBJECT,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      //--- return false
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
```

- **CHART_BRING_TO_TOP** shows the chart on top of all others.

```
//+------------------------------------------------------------------+
//| Sends command to the terminal to display the chart above all others  |
//+------------------------------------------------------------------+
bool ChartBringToTop(const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- show the chart on top of all others
   if(!ChartSetInteger(chart_ID,CHART_BRING_TO_TOP,0,true))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_MOUSE_SCROLL** is a property for scrolling the chart using left mouse button.

```
//+------------------------------------------------------------------------+
//| Checks if scrolling of chart using left mouse button is enabled        |
//+------------------------------------------------------------------------+
bool ChartMouseScrollGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_MOUSE_SCROLL,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables scrolling of chart using left mouse button      |
//+------------------------------------------------------------------+
bool ChartMouseScrollSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_MOUSE_SCROLL,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_EVENT_MOUSE_MOVE** is a property of sending messages concerning move events and mouse clicks to mql5 applications (CHARTEVENT_MOUSE_MOVE).

```
//+------------------------------------------------------------------+
//| Checks if messages concerning move events and mouse clicks       |
//| are sent to all MQL5 applications on the chart                   |
//+------------------------------------------------------------------+
```

```
bool ChartEventMouseMoveGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_EVENT_MOUSE_MOVE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------------------+
//| Enables/disables the mode of sending messages concerning move events and     |
//| mouse clicks to MQL5 applications on the chart                               |
//+------------------------------------------------------------------------------+
bool ChartEventMouseMoveSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_EVENT_MOUSE_MOVE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_EVENT_OBJECT_CREATE** is a property of sending messages concerning the event of a graphic object creation to mql5 applications (CHARTEVENT_OBJECT_CREATE).

```
//+------------------------------------------------------------------+
//| Checks if messages concerning the event of a graphic             |
//| object creation are sent to all MQL5 applications on the chart   |
//+------------------------------------------------------------------+
bool ChartEventObjectCreateGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
```

```
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_EVENT_OBJECT_CREATE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------------+
//| Enables/disables the mode of sending messages concerning the event of a  |
//| graphic object creation to all mql5 applications on the chart            |
//+------------------------------------------------------------------------+
bool ChartEventObjectCreateSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_EVENT_OBJECT_CREATE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_EVENT_OBJECT_DELETE** is a property of sending messages concerning the event of a graphic object deletion to mql5 applications (CHARTEVENT_OBJECT_DELETE).

```
//+------------------------------------------------------------------+
//| Checks if messages concerning the event of a graphic object      |
//| deletion are sent to all mql5 applications on the chart          |
//+------------------------------------------------------------------+
bool ChartEventObjectDeleteGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_EVENT_OBJECT_DELETE,0,value))
```

```
      {
       //--- display the error message in Experts journal
       Print(__FUNCTION__+", Error Code = ",GetLastError());
       return(false);
      }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------------+
//| Enables/disables the mode of sending messages concerning the event of a  |
//| graphic object deletion to all mql5 applications on the chart            |
//+------------------------------------------------------------------------+
bool ChartEventObjectDeleteSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_EVENT_OBJECT_DELETE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_MODE** - type of the chart (candlesticks, bars or line).

```
//+------------------------------------------------------------------+
//| Gets chart display type (candlesticks, bars or line)             |
//+------------------------------------------------------------------+
ENUM_CHART_MODE ChartModeGet(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=WRONG_VALUE;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_MODE,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((ENUM_CHART_MODE)result);
```

```
  }
//+------------------------------------------------------------------+
//| Sets chart display type (candlesticks, bars or line)             |
//+------------------------------------------------------------------+
bool ChartModeSet(const long value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_MODE,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_FOREGROUND** is a property of displaying a price chart in the foreground.

```
//+------------------------------------------------------------------+
//| Checks if a price chart is displayed in the foreground           |
//+------------------------------------------------------------------+
bool ChartForegroundGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_FOREGROUND,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables displaying of a price chart on the foreground   |
//+------------------------------------------------------------------+
bool ChartForegroundSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
```

```
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_FOREGROUND,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHIFT** - mode of shift of the price chart from the right border.

```
//+------------------------------------------------------------------+
//| Checks if shifting a price chart from the right border is enabled |
//+------------------------------------------------------------------+
bool ChartShiftGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SHIFT,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+-----------------------------------------------------------------------------------+
//| Enables/disables displaying of a price chart with a shift from the right border |
//+-----------------------------------------------------------------------------------+
bool ChartShiftSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHIFT,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
```

```
      }
//--- successful execution
   return(true);
  }
```

- **CHART_AUTOSCROLL** - the mode of automatic shift to the right border of the chart.

```
//+------------------------------------------------------------------+
//| Checks if automatic scrolling of a chart to the right            |
//| on new ticks arrival is enabled                                  |
//+------------------------------------------------------------------+
bool ChartAutoscrollGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_AUTOSCROLL,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables automatic scrolling of a chart to the right     |
//| on new ticks arrival                                             |
//+------------------------------------------------------------------+
bool ChartAutoscrollSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_AUTOSCROLL,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

```
```

- **CHART_SCALE** - chart scale property.

```
//+------------------------------------------------------------------+
//| Gets chart scale (from 0 to 5)                                   |
//+------------------------------------------------------------------+
int ChartScaleGet(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SCALE,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
//+------------------------------------------------------------------+
//| Sets chart scale (from 0 to 5)                                   |
//+------------------------------------------------------------------+
bool ChartScaleSet(const long value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SCALE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SCALEFIX** - the mode of fixed chart scale.

```
//+------------------------------------------------------------------+
//| Checks if the fixed scale mode is enabled                        |
//+------------------------------------------------------------------+
```

```
bool ChartScaleFixGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SCALEFIX,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables the fixed scale mode                            |
//+------------------------------------------------------------------+
bool ChartScaleFixSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SCALEFIX,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SCALEFIX_11** - 1:1 chart scale mode.

```
//+------------------------------------------------------------------+
//| Checks if the "1:1" scale is enabled                             |
//+------------------------------------------------------------------+
bool ChartScaleFix11Get(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
```

```
   if(!ChartGetInteger(chart_ID,CHART_SCALEFIX_11,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables the "1:1" scale mode                            |
//+------------------------------------------------------------------+
bool ChartScaleFix11Set(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SCALEFIX_11,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SCALE_PT_PER_BAR** - the mode of specifying the chart scale in points per bar.

```
//+------------------------------------------------------------------+
//| Checks if the "points per bar" chart scaling mode is enabled     |
//+------------------------------------------------------------------+
bool ChartScalePerBarGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value

      return(false);
     }
//--- store the value of the chart property in memory
```

```
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables the "points per bar" chart scaling mode         |
//+------------------------------------------------------------------+
bool ChartScalePerBarSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SCALE_PT_PER_BAR,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHOW_OHLC** - the property of displaying OHLC values in the upper left corner.

```
//+------------------------------------------------------------------------------------+
//| Checks if displaying of OHLC values in the upper left corner of chart is enabled   |
//+------------------------------------------------------------------------------------+
bool ChartShowOHLCGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SHOW_OHLC,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------------------------+
//| Enables/disables displaying of OHLC values in the upper left corner of chart      |
//+------------------------------------------------------------------------------------+
```

```
bool ChartShowOHLCSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHOW_OHLC,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHOW_BID_LINE** - the property of displaying Bid value as a horizontal line on the chart.

```
//+------------------------------------------------------------------+
//| Checks if displaying of Bid line on chart is enabled             |
//+------------------------------------------------------------------+
bool ChartShowBidLineGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SHOW_BID_LINE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables displaying of Bid line on chart                 |
//+------------------------------------------------------------------+
bool ChartShowBidLineSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHOW_BID_LINE,0,value))
     {
```

```
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHOW_ASK_LINE** - the property of displaying Ask value as a horizontal line on a chart.

```
//+------------------------------------------------------------------+
//| Checks if displaying of Ask line on chart is enabled             |
//+------------------------------------------------------------------+
bool ChartShowAskLineGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SHOW_ASK_LINE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
//| Enables/disables displaying of Ask line on chart                 |
//+------------------------------------------------------------------+
bool ChartShowAskLineSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHOW_ASK_LINE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHOW_LAST_LINE** - the property of displaying Last value as a horizontal line on a chart.

```
//+------------------------------------------------------------------------------+
//| Checks if displaying of line for the last performed deal's price is enabled |
//+------------------------------------------------------------------------------+
bool ChartShowLastLineGet(bool &result,const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_SHOW_LAST_LINE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------------------+
//| Enables/disables displaying of line for the last performed deal's price |
//+------------------------------------------------------------------------------+
bool ChartShowLastLineSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHOW_LAST_LINE,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_SHOW_PERIOD_SEP** - the property of displaying vertical separators between adjacent periods.

```
//+------------------------------------------------------------------------------+
//| Checks if displaying of vertical separators between adjacent periods is enabled |
```

```
//+------------------------------------------------------------------------------------+

      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
//+------------------------------------------------------------------+
```

```
//| Enables/disables displaying of pop-up descriptions of graphical objects |
//| when hovering mouse over them                                            |
//+--------------------------------------------------------------------------+
bool ChartShowObjectDescriptionSet(const bool value,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_SHOW_OBJECT_DESCR,0,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_VISIBLE_BARS** defines the number of bars on a chart that are available for display.

```
//+--------------------------------------------------------------------------+
//| Gets the number of bars that are displayed (visible) in chart window |
//+--------------------------------------------------------------------------+
int ChartVisibleBars(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_VISIBLE_BARS,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_WINDOWS_TOTAL** defines the total number of chart windows including indicator subwindows.

```
//+--------------------------------------------------------------------------+
//| Gets the total number of chart windows including indicator subwindows |
//+--------------------------------------------------------------------------+
int ChartWindowsTotal(const long chart_ID=0)
  {
```

```
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WINDOWS_TOTAL,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_WINDOW_IS_VISIBLE** defines the subwindow's visibility.

```
//+------------------------------------------------------------------+
//| Checks if the current chart window or subwindow is visible       |
//+------------------------------------------------------------------+
bool ChartWindowsIsVisible(bool &result,const long chart_ID=0,const int sub_window=0)
  {
//--- prepare the variable to get the property value
   long value;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WINDOW_IS_VISIBLE,sub_window,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- store the value of the chart property in memory
   result=value;
//--- successful execution
   return(true);
  }
```

- **CHART_WINDOW_HANDLE** returns the chart handle.

```
//+------------------------------------------------------------------+
//| Gets the chart handle                                            |
//+------------------------------------------------------------------+
int ChartWindowsHandle(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
```

```
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WINDOW_HANDLE,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_WINDOW_YDISTANCE** defines the distance in pixels between the upper frame of the indicator subwindow and the upper frame of the chart's main window.

```
//+------------------------------------------------------------------+
//| Gets the distance in pixels between the upper border of          |
//| subwindow and the upper border of chart's main window            |
//+------------------------------------------------------------------+
int ChartWindowsYDistance(const long chart_ID=0,const int sub_window=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WINDOW_YDISTANCE,sub_window,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_FIRST_VISIBLE_BAR** returns the number of the first visible bar on the chart (bar indexing corresponds to the time series).

```
//+------------------------------------------------------------------------------+
//| Gets the index of the first visible bar on chart.                            |
//| Indexing is performed like in timeseries: latest bars have smallest indices. |
//+------------------------------------------------------------------------------+
int ChartFirstVisibleBar(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
```

```
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_FIRST_VISIBLE_BAR,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_WIDTH_IN_BARS** returns the chart width in bars.

```
//+------------------------------------------------------------------+
//| Gets the width of chart (in bars)                                |
//+------------------------------------------------------------------+
int ChartWidthInBars(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WIDTH_IN_BARS,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_WIDTH_IN_PIXELS** returns the chart width in pixels.

```
//+------------------------------------------------------------------+
//| Gets the width of chart (in pixels)                              |
//+------------------------------------------------------------------+
int ChartWidthInPixels(const long chart_ID=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_WIDTH_IN_PIXELS,0,result))
     {
      //--- display the error message in Experts journal
```

```
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
```

- **CHART_HEIGHT_IN_PIXELS** - chart height property in pixels.

```
//+------------------------------------------------------------------+
//| Gets the height of chart (in pixels)                             |
//+------------------------------------------------------------------+
int ChartHeightInPixelsGet(const long chart_ID=0,const int sub_window=0)
  {
//--- prepare the variable to get the property value
   long result=-1;
//--- reset the error value
   ResetLastError();
//--- receive the property value
   if(!ChartGetInteger(chart_ID,CHART_HEIGHT_IN_PIXELS,sub_window,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((int)result);
  }
//+------------------------------------------------------------------+
//| Sets the height of chart (in pixels)                             |
//+------------------------------------------------------------------+
bool ChartHeightInPixelsSet(const int value,const long chart_ID=0,const int sub_windo
  {
//--- reset the error value
   ResetLastError();
//--- set property value
   if(!ChartSetInteger(chart_ID,CHART_HEIGHT_IN_PIXELS,sub_window,value))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_COLOR_BACKGROUND** - chart background color.

```
//+------------------------------------------------------------------+
```

```
//| Gets the background color of chart                               |
//+------------------------------------------------------------------+
color ChartBackColorGet(const long chart_ID=0)
  {
//--- prepare the variable to receive the color
   long result=clrNONE;
//--- reset the error value

//--- receive chart background color
   if(!ChartGetInteger(chart_ID,CHART_COLOR_BACKGROUND,0,result))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
     }
//--- return the value of the chart property
   return((color)result);
  }
//+------------------------------------------------------------------+
//| Sets the background color of chart                               |
//+------------------------------------------------------------------+
bool ChartBackColorSet(const color clr,const long chart_ID=0)
  {
//--- reset the error value
   ResetLastError();
//--- set the chart background color
   if(!ChartSetInteger(chart_ID,CHART_COLOR_BACKGROUND,clr))
     {
      //--- display the error message in Experts journal
      Print(__FUNCTION__+", Error Code = ",GetLastError());
      return(false);
     }
//--- successful execution
   return(true);
  }
```

- **CHART_COLOR_FOREGROUND** - color of axes, scale and OHLC line.

```
//+------------------------------------------------------------------+
//| Gets the color of axes, scale and OHLC line                      |
//+------------------------------------------------------------------+
color ChartForeColorGet(const long chart_ID=0)
  {
//--- prepare the variable to receive the color
   long result=clrNONE;
//--- reset the error value
   ResetLastError();
//--- receive the color of axes, scale and OHLC line
   if(!ChartGetInteger(chart_ID,CHART_COLOR_FOREGROUND,0,result))
```

```
      {

Object Constants

There are 44 graphical objects that can be created and displayed in the price chart. All constants for working with objects are divided into 9 groups:

- Object types - Identifiers of graphical objects;
- Object properties - setting and getting properties of graphical objects;
- Methods of object binding - constants of object positioning in the chart;
- Binding corner - setting the corner relative to which an object is positioned on chart;
- Visibility of objects - setting timeframes in which an object is visible;
- Levels of Elliott Waves - gradation of waves;
- Gann objects - trend constants for Gann fan and Gann grid;
- Web colors - constants of predefined web colors;
- Wingdings - codes of characters of the Wingdings font.

Object Types

When a graphical object is created using the ObjectCreate() function, it's necessary to specify the type of object being created, which can be one of the values of the ENUM_OBJECT enumeration. Further specifications of object properties are possible using functions for working with graphical objects.

ENUM_OBJECT

ID		Description
OBJ_VLINE		Vertical Line
OBJ_HLINE		Horizontal Line
OBJ_TREND		Trend Line
OBJ_TRENDBYANGLE		Trend Line By Angle
OBJ_CYCLES		Cycle Lines
OBJ_ARROWED_LINE		Arrowed Line
OBJ_CHANNEL		Equidistant Channel
OBJ_STDDEVCHANNEL		Standard Deviation Channel
OBJ_REGRESSION		Linear Regression Channel
OBJ_PITCHFORK		Andrews' Pitchfork
OBJ_GANNLINE		Gann Line
OBJ_GANNFAN		Gann Fan
OBJ_GANNGRID		Gann Grid
OBJ_FIBO		Fibonacci Retracement
OBJ_FIBOTIMES		Fibonacci Time Zones
OBJ_FIBOFAN		Fibonacci Fan
OBJ_FIBOARC		Fibonacci Arcs
OBJ_FIBOCHANNEL		Fibonacci Channel
OBJ_EXPANSION		Fibonacci Expansion
OBJ_ELLIOTWAVE5		Elliott Motive Wave
OBJ_ELLIOTWAVE3		Elliott Correction Wave
OBJ_RECTANGLE		Rectangle
OBJ_TRIANGLE		Triangle
OBJ_ELLIPSE		Ellipse
OBJ_ARROW_THUMB_UP		Thumbs Up
OBJ_ARROW_THUMB_DOWN		Thumbs Down

ID		Description
OBJ_ARROW_UP		Arrow Up
OBJ_ARROW_DOWN		Arrow Down
OBJ_ARROW_STOP		Stop Sign
OBJ_ARROW_CHECK		Check Sign
OBJ_ARROW_LEFT_PRICE		Left Price Label
OBJ_ARROW_RIGHT_PRICE		Right Price Label
OBJ_ARROW_BUY		Buy Sign
OBJ_ARROW_SELL		Sell Sign
OBJ_ARROW		Arrow
OBJ_TEXT		Text
OBJ_LABEL		Label
OBJ_BUTTON		Button
OBJ_CHART		Chart
OBJ_BITMAP		Bitmap
OBJ_BITMAP_LABEL		Bitmap Label
OBJ_EDIT		Edit
OBJ_EVENT		The "Event" object corresponding to an event in the economic calendar
OBJ_RECTANGLE_LABEL		The "Rectangle label" object for creating and designing the custom graphical interface.

OBJ_VLINE

Vertical Line.

Note

When drawing a vertical line, it is possible to set the line display mode for all chart windows (property OBJPROP_RAY).

Example

The following script creates and moves the vertical line on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Vertical Line\" graphical object."
#property description "Anchor point date is set in percentage of"
#property description "the chart window width in bars."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="VLine";      // Line name
input int             InpDate=25;           // Event date, %
input color           InpColor=clrRed;      // Line color
input ENUM_LINE_STYLE InpStyle=STYLE_DASH;  // Line style
input int             InpWidth=3;           // Line width
input bool            InpBack=false;        // Background line
input bool            InpSelection=true;    // Highlight to move
input bool            InpRay=true;          // Line's continuation down
```

```
input bool            InpHidden=true;      // Hidden in the object list
input long            InpZOrder=0;         // Priority for mouse click
//+------------------------------------------------------------------+
//| Create the vertical line                                         |
//+------------------------------------------------------------------+
bool VLineCreate(const long            chart_ID=0,        // chart's ID
                 const string          name="VLine",      // line name
                 const int             sub_window=0,      // subwindow index
                 datetime              time=0,            // line time
                 const color           clr=clrRed,        // line color
                 const ENUM_LINE_STYLE style=STYLE_SOLID, // line style
                 const int             width=1,           // line width
                 const bool            back=false,        // in the background
                 const bool            selection=true,    // highlight to move
                 const bool            ray=true,          // line's continuation down
                 const bool            hidden=true,       // hidden in the object list

OBJ_TREND

Trend Line.

Note

For Trend Line, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

Example

The following script creates and moves the trend line on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Trend Line\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Trend";      // Line name
input int             InpDate1=35;          // 1 st point's date, %
input int             InpPrice1=60;         // 1 st point's price, %
input int             InpDate2=65;          // 2 nd point's date, %
input int             InpPrice2=40;         // 2 nd point's price, %
input color           InpColor=clrRed;      // Line color
input ENUM_LINE_STYLE InpStyle=STYLE_DASH; // Line style
```

```
input int              InpWidth=2;          // Line width
input bool             InpBack=false;       // Background line
input bool             InpSelection=true;   // Highlight to move
input bool             InpRayLeft=false;    // Line's continuation to the left
input bool             InpRayRight=false;   // Line's continuation to the right
input bool             InpHidden=true;      // Hidden in the object list
input long             InpZOrder=0;         // Priority for mouse click
//+------------------------------------------------------------------+
//| Create a trend line by the given coordinates                     |
//+------------------------------------------------------------------+
bool TrendCreate(const long            chart_ID=0,        // chart's ID
                 const string          name="TrendLine",  // line name
                 const int             sub_window=0,      // subwindow index

OBJ_TRENDBYANGLE

Trend Line By Angle.

Note

For Trend Line By Angle, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

Both angle and the second anchor point's coordinates can be used to set the slope of the line.

Example

The following script creates and moves the trend line on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Trend Line By Angle\" graphical object."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Trend";      // Line name
input int             InpDate1=50;          // 1 st point's date, %
input int             InpPrice1=75;         // 1 st point's price, %
input int             InpAngle=0;           // Line's slope angle
input color           InpColor=clrRed;      // Line color
input ENUM_LINE_STYLE InpStyle=STYLE_DASH; // Line style
```

```
input int              InpWidth=2;          // Line width
input bool             InpBack=false;       // Background line
input bool             InpSelection=true;   // Highlight to move
input bool             InpRayLeft=false;    // Line's continuation to the left
input bool             InpRayRight=true;    // Line's continuation to the right
input bool             InpHidden=true;      // Hidden in the object list
input long             InpZOrder=0;         // Priority for mouse click
//+------------------------------------------------------------------+
//| Create a trend line by angle                                     |

OBJ_CHANNEL

Equidistant Channel

Note

For an equidistant channel, it is possible to specify the mode of its continuation to the right and/or to the left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly). The mode of filling the channel with color can also be set.

Example

The following script creates and moves an equidistant channel on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Equidistant Channel\" graphical object."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Channel";   // Channel name
input int             InpDate1=25;         // 1 st point's date, %
input int             InpPrice1=60;        // 1 st point's price, %
input int             InpDate2=65;         // 2 nd point's date, %
input int             InpPrice2=80;        // 2 nd point's price, %
input int             InpDate3=30;         // 3 rd point's date, %
```

```
input int              InpPrice3=40;         // 3 rd point's price, %
input color            InpColor=clrRed;      // Channel color
input ENUM_LINE_STYLE  InpStyle=STYLE_DASH;  // Style of channel lines
input int              InpWidth=2;           // Channel line width
input bool             InpBack=false;        // Background channel
input bool             InpFill=false;        // Filling the channel with color
input bool             InpSelection=true;    // Highlight to move
input bool             InpRayLeft=false;     // Channel's continuation to the left
input bool             InpRayRight=false;    // Channel's continuation to the right

OBJ_STDDEVCHANNEL

Standard Deviation Channel.

Note

For Standard Deviation Channel, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly). The mode of filling the channel with color can also be set.

OBJPROP_DEVIATION property is used to change the value of the channel deviation.

Example

The following script creates and moves Standard Deviation Channel on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Standard Deviation Channel\" graphical object."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script

OBJ_REGRESSION

Linear Regression Channel.

Note

For Linear Regression Channel, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly). The mode of filling the channel with color can also be set.

Example

The following script creates and moves Linear Regression Channel on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Linear Regression Channel\" graphical object."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Regression"; // Channel name
input int             InpDate1=10;          // 1 st point's date, %
input int             InpDate2=40;          // 2 nd point's date, %
input color           InpColor=clrRed;      // Channel color
input ENUM_LINE_STYLE InpStyle=STYLE_DASH;  // Style of channel lines
input int             InpWidth=2;           // Width of channel lines
```

```
input bool             InpFill=false;        // Filling the channel with color
input bool             InpBack=false;        // Background channel
input bool             InpSelection=true;    // Highlight to move
input bool             InpRayLeft=false;     // Channel's continuation to the left
input bool             InpRayRight=false;    // Channel's continuation to the right
input bool             InpHidden=true;       // Hidden in the object list

```

OBJ_PITCHFORK

Andrews' Pitchfork.

Note

For Andrews' Pitchfork, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

You can also specify the number of line-levels, their values and color.

Example

The following script creates and moves Andrews' Pitchfork on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Andrews' Pitchfork\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Pitchfork";  // Pitchfork name
input int             InpDate1=14;          // 1 st point's date, %
input int             InpPrice1=40;         // 1 st point's price, %
input int             InpDate2=18;          // 2 nd point's date, %
input int             InpPrice2=50;         // 2 nd point's price, %
input int             InpDate3=18;          // 3 rd point's date, %
input int             InpPrice3=30;         // 3 rd point's price, %
```

```
input color           InpColor=clrRed;      // Pitchfork color
input ENUM_LINE_STYLE InpStyle=STYLE_SOLID; // Style of pitchfork lines
input int             InpWidth=1;           // Width of pitchfork lines
input bool            InpBack=false;        // Background pitchfork
input bool            InpSelection=true;    // Highlight to move
input bool            InpRayLeft=false;     // Pitchfork's continuation to the left
input bool            InpRayRight=false;    // Pitchfork's continuation to the right
input bool            InpHidden=true;       // Hidden in the object list

```

OBJ_GANNFAN

Gann Fan.

Note

For Gann Fan, it is possible to specify trend type from ENUM_GANN_DIRECTION enumeration. By adjusting the scale value (OBJPROP_SCALE), it is possible to change slope angle of the fan lines.

Example

The following script creates and moves Gann Fan on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Gann Fan\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="GannFan";          // Fan name
input int             InpDate1=15;                // 1 st point's date, %
input int             InpPrice1=25;               // 1 st point's price, %
input int             InpDate2=85;                // 2 nd point's date, %
input double          InpScale=2.0;               // Scale
input bool            InpDirection=false;         // Trend direction
input color           InpColor=clrRed;            // Fan color
```

```
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Style of fan lines
input int             InpWidth=1;                // Width of fan lines
input bool            InpBack=false;             // Background fan

OBJ_GANNGRID

Gann Grid.

Note

For Gann Grid, it is possible to specify trend type from ENUM_GANN_DIRECTION. By adjusting the scale value (OBJPROP_SCALE), it is possible to change slope angle of the grid lines.

Example

The following script creates and moves Gann Grid on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Gann Grid\" graphical object."
#property description "Anchor point coordinates of the grid are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="GannGrid";        // Grid name
input int             InpDate1=15;               // 1 st point's date, %
input int             InpPrice1=25;              // 1 st point's price, %
input int             InpDate2=35;               // 2 nd point's date, %
input double          InpScale=3.0;              // Scale
input bool            InpDirection=false;        // Trend direction
input color           InpColor=clrRed;           // Grid color
```

```
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Style of grid lines
input int             InpWidth=1;                // Width of fan lines
input bool            InpBack=false;             // Background grid
input bool            InpSelection=true;         // Highlight to move

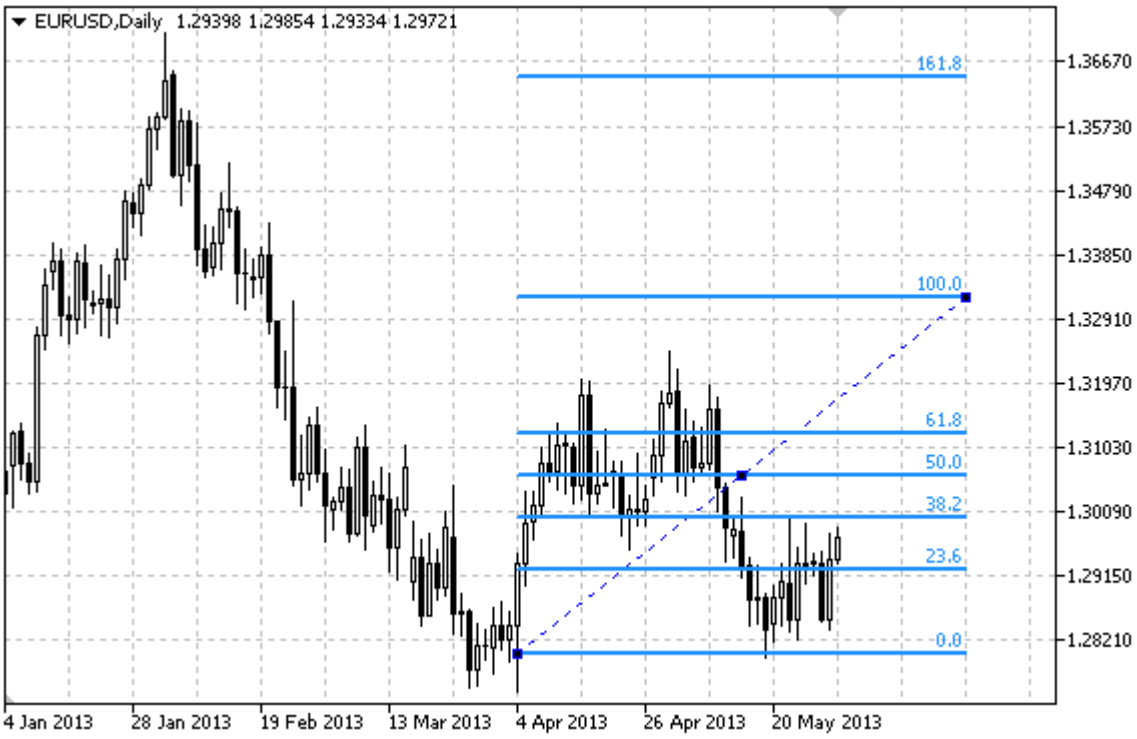
OBJ_FIBO

Fibonacci Retracement.



Note

For Fibonacci Retracement, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

You can also specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Retracement on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Retracement\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboLevels";      // Object name
input int             InpDate1=10;               // 1 st point's date, %
input int             InpPrice1=65;              // 1 st point's price, %
input int             InpDate2=90;               // 2 nd point's date, %
input int             InpPrice2=85;              // 2 nd point's price, %
input color           InpColor=clrRed;           // Object color
```

```
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Line style
input int             InpWidth=2;                // Line width
input bool            InpBack=false;             // Background object

OBJ_FIBOTIMES

Fibonacci Time Zones.

Note

For "Fibonacci Time Zones", it is possible to specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Time Zones on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Time Zones\" graphical object."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboTimes";       // Object name
input int             InpDate1=10;               // 1 st point's date, %
input int             InpPrice1=45;              // 1 st point's price, %
input int             InpDate2=20;               // 2 nd point's date, %
input int             InpPrice2=55;              // 2 nd point's price, %
input color           InpColor=clrRed;           // Object color
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Line style
input int             InpWidth=2;                // Line width
```

```
input bool            InpBack=false;             // Background object

OBJ_FIBOFAN

Fibonacci Fan.

Note

For "Fibonacci Fan", it is possible to specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Fan on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Fan\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboFan";          // Fan name
input int             InpDate1=10;                // 1 st point's date, %
input int             InpPrice1=25;               // 1 st point's price, %
input int             InpDate2=30;                // 2 nd point's date, %
input int             InpPrice2=50;               // 2 nd point's price, %
input color           InpColor=clrRed;            // Fan line color
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Line style
input int             InpWidth=2;                 // Line width
```

```
input bool             InpBack=false;             // Background object
input bool             InpSelection=true;         // Highlight to move

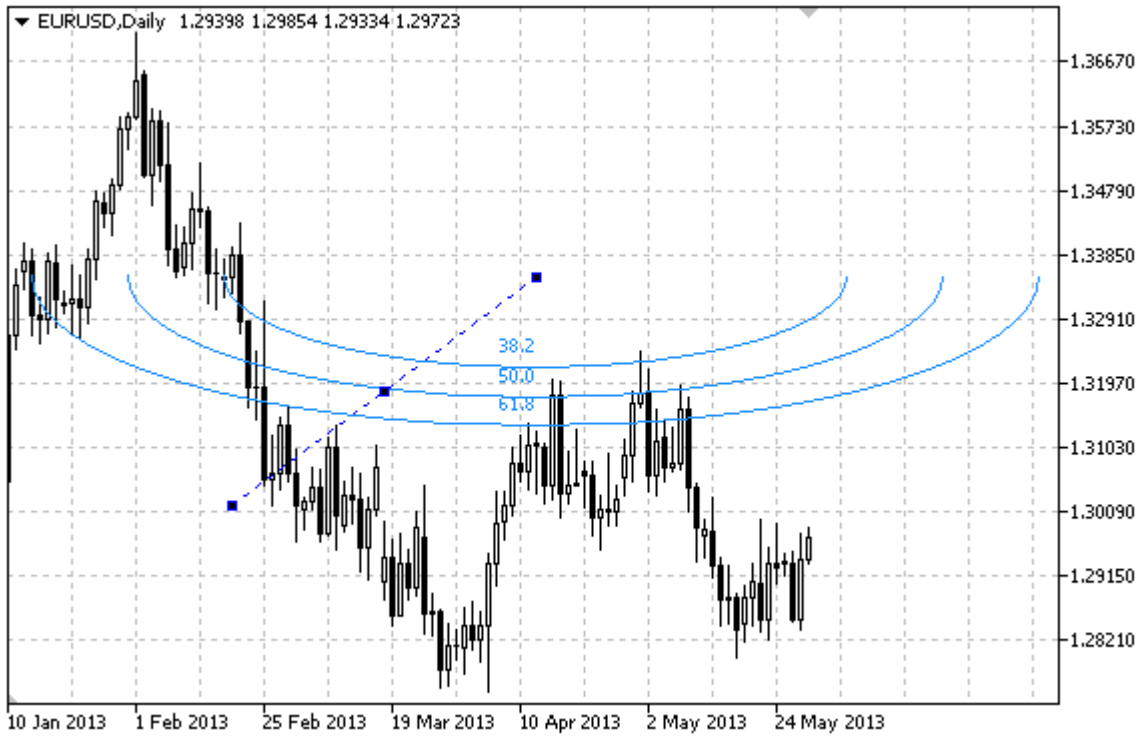
OBJ_FIBOARC

Fibonacci Arcs.



Note

For "Fibonacci Arcs", it is possible to specify the display mode of the entire ellipse. Curvature radius can be specified by changing the scale and coordinates of the anchor points.

You can also specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Arcs on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Arcs\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboArc";         // Object name
input int             InpDate1=25;               // 1 st point's date, %
input int             InpPrice1=25;              // 1 st point's price, %
input int             InpDate2=35;               // 2 nd point's date, %
input int             InpPrice2=55;              // 2 nd point's price, %
input double          InpScale=3.0;              // Scale
```

```
input bool             InpFullEllipse=true;       // Shape of the arcs
input color            InpColor=clrRed;           // Line color
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Line style
input int              InpWidth=2;                // Line width
input bool             InpBack=false;             // Background object

OBJ_FIBOCHANNEL

Fibonacci Channel.

Note

For Fibonacci Channel, it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

You can also specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Channel on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Channel\" graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboChannel";     // Channel name
input int             InpDate1=20;               // 1 st point's date, %
input int             InpPrice1=10;              // 1 st point's price, %
input int             InpDate2=60;               // 2 nd point's date, %
input int             InpPrice2=30;              // 2 nd point's price, %
input int             InpDate3=20;               // 3 rd point's date, %
```

```
input int              InpPrice3=25;              // 3 rd point's price, %
input color            InpColor=clrRed;           // Channel color
input ENUM_LINE_STYLE  InpStyle=STYLE_DASHDOTDOT; // Style of channel lines
input int              InpWidth=2;                // Width of channel lines
input bool             InpBack=false;             // Background channel

```

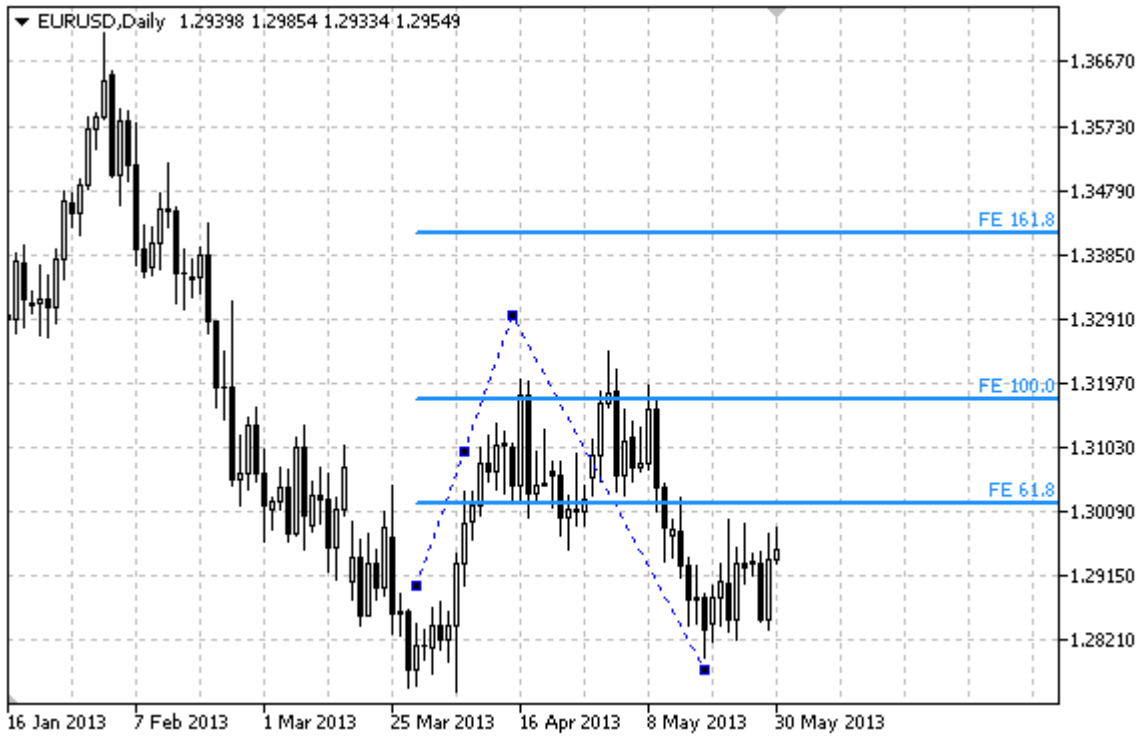
OBJ_EXPANSION

Fibonacci Expansion.



Note

For "Fibonacci Expansion", it is possible to specify the mode of continuation of its display to the right and/or left (OBJPROP_RAY_RIGHT and OBJPROP_RAY_LEFT properties accordingly).

You can also specify the number of line-levels, their values and color.

Example

The following script creates and moves Fibonacci Expansion on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Fibonacci Expansion\"graphical object."
#property description "Anchor point coordinates are set in percentage of"
#property description "the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="FiboExpansion";   // Object name
input int             InpDate1=10;               // 1 st point's date, %
input int             InpPrice1=55;              // 1 st point's price, %
input int             InpDate2=30;               // 2 nd point's date, %
input int             InpPrice2=10;              // 2 nd point's price, %
input int             InpDate3=80;               // 3 rd point's date, %
```

```
input int              InpPrice3=75;              // 3 rd point's price, %
input color            InpColor=clrRed;           // Object color
input ENUM_LINE_STYLE  InpStyle=STYLE_DASHDOTDOT; // Style of lines
input int              InpWidth=2;                // Width of the lines
input bool             InpBack=false;             // Background object
input bool             InpSelection=true;         // Highlight to move
input bool             InpRayLeft=false;          // Object's continuation to the left
input bool             InpRayRight=false;         // Object's continuation to the right

OBJ_ELLIOTWAVE5

Elliott Motive Wave.

Note

For "Elliott Motive Wave", it is possible to enable/disable the mode of connecting points by lines (OBJPROP_DRAWLINES property), as well as set the level of wave positioning (from ENUM_ELLIOT_WAVE_DEGREE enumeration).

Example

The following script creates and moves Elliott motive wave on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Elliott Motive Wave\"."
#property description "Anchor point coordinates are set in percentage of the size of"
#property description "the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string                InpName="ElliotWave5";   // Object name

OBJ_ELLIOTWAVE3

Elliott Correction Wave.

Note

For "Elliott Correction Wave", it is possible to enable/disable the mode of connecting points by lines (OBJPROP_DRAWLINES property), as well as set the level of wave positioning (from ENUM_ELLIOT_WAVE_DEGREE enumeration).

Example

The following script creates and moves Elliott correction wave on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Elliott Correction Wave\" graphical object."
#property description "Anchor point coordinates are set in percentage of the chart's w
#property description "size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string                InpName="ElliotWave3";   // Object name
input int                   InpDate1=10;             // 1 st point's date, %
input int                   InpPrice1=90;            // 1 st point's price, %
input int                   InpDate2=30;             // 2 nd point's date, %
input int                   InpPrice2=10;            // 2 nd point's price, %
input int                   InpDate3=50;             // 3 rd point's date, %
```

OBJ_RECTANGLE

Rectangle.

Note

For rectangle, the mode of filling with color can be set using OBJPROP_FILL property.

Example

The following script creates and moves the rectangle on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates rectangle on the chart."
#property description "Anchor point coordinates are set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Rectangle"; // Rectangle name
input int             InpDate1=40;         // 1 st point's date, %
input int             InpPrice1=40;        // 1 st point's price, %
input int             InpDate2=60;         // 2 nd point's date, %
input int             InpPrice2=60;        // 2 nd point's price, %
input color           InpColor=clrRed;     // Rectangle color
input ENUM_LINE_STYLE InpStyle=STYLE_DASH; // Style of rectangle lines
input int             InpWidth=2;          // Width of rectangle lines
```

```
input bool             InpFill=true;        // Filling the rectangle with color
input bool             InpBack=false;       // Background rectangle

OBJ_TRIANGLE

Triangle.

Note

For triangle, the mode of filling with color can be set using OBJPROP_FILL property.

Example

The following script creates and moves the triangle on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates triangle on the chart."
#property description "Anchor point coordinates are set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpName="Triangle";        // Triangle name
input int             InpDate1=25;               // 1 st point's date, %
input int             InpPrice1=50;              // 1 st point's price, %
input int             InpDate2=70;               // 2 nd point's date, %
input int             InpPrice2=70;              // 2 nd point's price, %
input int             InpDate3=65;               // 3 rd point's date, %
input int             InpPrice3=20;              // 3 rd point's price, %
input color           InpColor=clrRed;           // Triangle color
```

```
input ENUM_LINE_STYLE InpStyle=STYLE_DASHDOTDOT; // Style of triangle lines
input int             InpWidth=2;                // Width of triangle lines

OBJ_ARROW_UP

Arrow Up sign.

Note

Anchor point position relative to the sign can be selected from ENUM_ARROW_ANCHOR enumeration.

Large signs (more than 5) can only be created by setting the appropriate OBJPROP_WIDTH property value when writing a code in MetaEditor.

Example

The following script creates and moves Arrow Up sign on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Arrow Up\" sign."
#property description "Anchor point coordinate is set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string             InpName="ArrowUp";     // Sign name
input int                InpDate=25;            // Anchor point date in %
input int                InpPrice=25;           // Anchor point price in %
input ENUM_ARROW_ANCHOR  InpAnchor=ANCHOR_TOP;  // Anchor type
input color              InpColor=clrRed;       // Sign color
```

```
input ENUM_LINE_STYLE   InpStyle=STYLE_DOT;   // Border line style
input int               InpWidth=5;           // Sign size
input bool              InpBack=false;        // Background sign
input bool              InpSelection=false;   // Highlight to move
input bool              InpHidden=true;       // Hidden in the object list
input long              InpZOrder=0;          // Priority for mouse click
//+------------------------------------------------------------------+
//| Create Arrow Up sign                                             |

```

OBJ_ARROW_STOP

Stop sign.

Note

Anchor point position relative to the sign can be selected from ENUM_ARROW_ANCHOR enumeration.

Large signs (more than 5) can only be created by setting the appropriate OBJPROP_WIDTH property value when writing a code in MetaEditor.

Example

The following script creates and moves Stop sign on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Stop\" sign."
#property description "Anchor point coordinate is set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string            InpName="ArrowStop";      // Sign name
input int               InpDate=10;               // Anchor point date in %
input int               InpPrice=50;              // Anchor point price in %
input ENUM_ARROW_ANCHOR InpAnchor=ANCHOR_BOTTOM; // Anchor type
input color             InpColor=clrRed;          // Sign color
```

```
input ENUM_LINE_STYLE   InpStyle=STYLE_DOT;      // Border line style
input int               InpWidth=5;              // Sign size
input bool              InpBack=false;           // Background sign
input bool              InpSelection=false;      // Highlight to move

//--- 1 second of delay
   Sleep(1000);
//---
  }
```

OBJ_ARROW_CHECK

Check sign.

Note

Anchor point position relative to the sign can be selected from ENUM_ARROW_ANCHOR enumeration.

Large signs (more than 5) can only be created by setting the appropriate OBJPROP_WIDTH property value when writing a code in MetaEditor.

Example

The following script creates and moves Check sign on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Check\" sign."
#property description "Anchor point coordinate is set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string             InpName="ArrowCheck"; // Sign name
input int                InpDate=10;           // Anchor point date in %
input int                InpPrice=50;          // Anchor point price in %
input ENUM_ARROW_ANCHOR  InpAnchor=ANCHOR_TOP; // Anchor type
input color              InpColor=clrRed;      // Sign color
```

```
input ENUM_LINE_STYLE   InpStyle=STYLE_DOT;   // Border line style
input int               InpWidth=5;           // Sign size
input bool              InpBack=false;        // Background sign
input bool              InpSelection=false;   // Highlight to move
input bool              InpHidden=true;       // Hidden in the object list
input long              InpZOrder=0;          // Priority for mouse click
//+------------------------------------------------------------------+
//| Create Check sign                                                |
//+------------------------------------------------------------------+
bool ArrowCheckCreate(const long              chart_ID=0,           // chart's ID
                      const string            name="ArrowCheck",    // sign name
                      const int               sub_window=0,         // subwindow index
                      datetime                time=0,               // anchor point ti
                      double                  price=0,              // anchor point pr
                      const ENUM_ARROW_ANCHOR anchor=ANCHOR_BOTTOM, // anchor type
                      const color             clr=clrRed,           // sign color
                      const ENUM_LINE_STYLE   style=STYLE_SOLID,    // border line sty
                      const int               width=3,              // sign size

//---
  }
```

OBJ_ARROW

Arrow object.

Note

Anchor point position relative to the object can be selected from ENUM_ARROW_ANCHOR.

Large arrows (more than 5) can only be created by setting the appropriate OBJPROP_WIDTH property value when writing a code in MetaEditor.

The necessary arrow type can be selected by setting one of the Wingdings font's symbol codes.

Example

The following script creates Arrow object on the chart and changes its type. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates a random arrow in the chart window."
#property description "Anchor point coordinate is set in"
#property description "percentage of the chart window size."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string             InpName="Arrow";        // Arrow name
input int                InpDate=50;             // Anchor point date in %
input int                InpPrice=50;            // Anchor point price in %
input ENUM_ARROW_ANCHOR  InpAnchor=ANCHOR_TOP;   // Anchor type
```

```
input color             InpColor=clrDodgerBlue; // Arrow color
input ENUM_LINE_STYLE   InpStyle=STYLE_SOLID;   // Border line style
input int               InpWidth=10;            // Arrow size
input bool              InpBack=false;          // Background arrow
input bool              InpSelection=false;     // Highlight to move
input bool              InpHidden=true;         // Hidden in the object list
input long              InpZOrder=0;            // Priority for mouse click
//+------------------------------------------------------------------+
//| Create the arrow                                                 |
//+------------------------------------------------------------------+

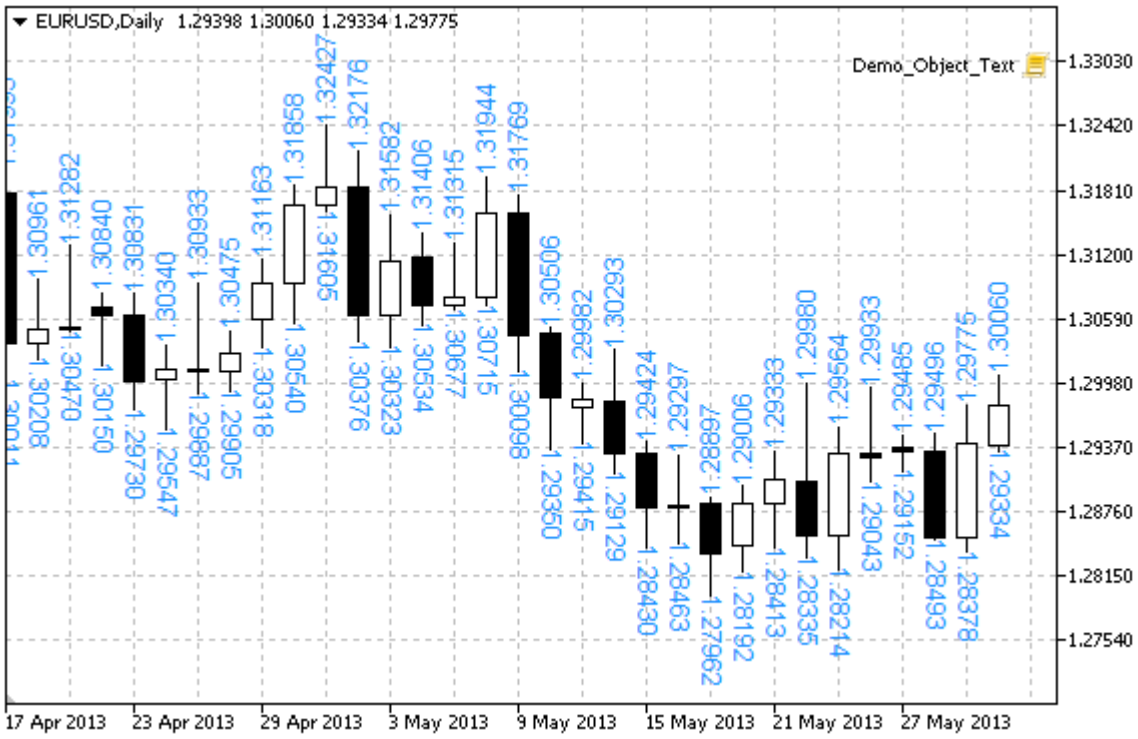
OBJ_TEXT

Text object.



Note

Anchor point position relative to the text can be selected from ENUM_ANCHOR_POINT enumeration. You can also change text slope angle using OBJPROP_ANGLE property.

Example

The following script creates several Text objects on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Text\" graphical object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string            InpFont="Arial";         // Font
input int               InpFontSize=10;          // Font size
input color             InpColor=clrRed;         // Color
input double            InpAngle=90.0;           // Slope angle in degrees
input ENUM_ANCHOR_POINT InpAnchor=ANCHOR_LEFT;   // Anchor type
input bool              InpBack=false;           // Background object
input bool              InpSelection=false;      // Highlight to move
input bool              InpHidden=true;          // Hidden in the object list
input long              InpZOrder=0;             // Priority for mouse click
```

```
//+------------------------------------------------------------------+
//| Creating Text object                                             |
//+------------------------------------------------------------------+

OBJ_LABEL

Label object.

Note

Anchor point position relative to the label can be selected from ENUM_ANCHOR_POINT enumeration. Anchor point coordinates are set in pixels.

You can also select text label anchoring corner from ENUM_BASE_CORNER enumeration.

Example

The following script creates and moves Edit object on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Label\" graphical object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string             InpName="Label";          // Label name
input int                InpX=150;                 // X-axis distance
input int                InpY=150;                 // Y-axis distance
input string             InpFont="Arial";          // Font
input int                InpFontSize=14;           // Font size
input color              InpColor=clrRed;          // Color
input double             InpAngle=0.0;             // Slope angle in degrees
input ENUM_ANCHOR_POINT InpAnchor=ANCHOR_CENTER; // Anchor type
```

```
input bool              InpBack=false;           // Background object
input bool              InpSelection=true;       // Highlight to move
input bool              InpHidden=true;          // Hidden in the object list
input long              InpZOrder=0;             // Priority for mouse click
//+------------------------------------------------------------------+
//| Create a text label                                              |
//+------------------------------------------------------------------+

OBJ_CHART

Chart object.

Note

" OBJ_CHART" type object is not supported (not displayed) during a visual test.

Anchor point coordinates are set in pixels. You can select anchoring corner from ENUM_BASE_CORNER enumeration.

Symbol, period and scale can be selected for Chart object. Price scale and date display mode can also be enabled/disabled.

Example

The following script creates and moves Chart object on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Chart\" object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string           InpName="Chart";              // Object name
input string           InpSymbol="EURUSD";           // Symbol
input ENUM_TIMEFRAMES  InpPeriod=PERIOD_H1;          // Period
input ENUM_BASE_CORNER InpCorner=CORNER_LEFT_UPPER; // Anchoring corner
input int              InpScale=2;                   // Scale
```

```
input bool              InpDateScale=true;           // Time scale display
input bool              InpPriceScale=true;          // Price scale display
input color             InpColor=clrRed;             // Border color when highlighted
input ENUM_LINE_STYLE   InpStyle=STYLE_DASHDOTDOT;   // Line style when highlighted
input int               InpPointWidth=1;             // Point size to move
input bool              InpBack=false;               // Background object
input bool              InpSelection=true;           // Highlight to move

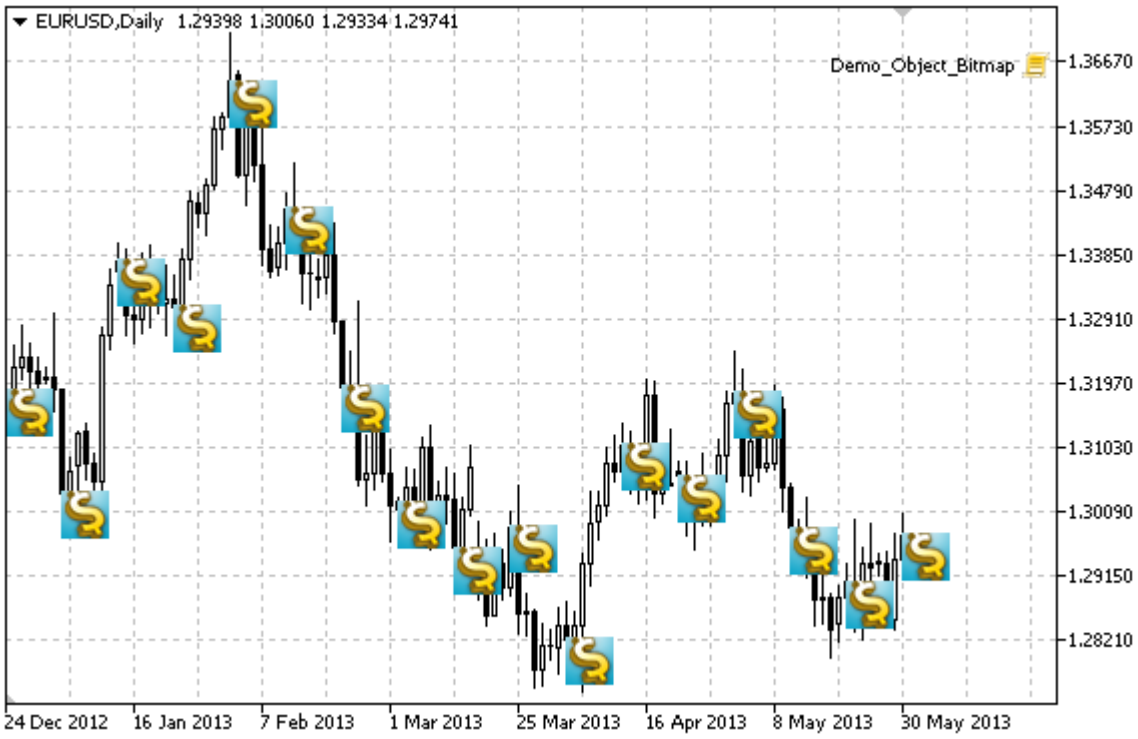
OBJ_BITMAP

Bitmap object.



Note

For Bitmap object, you can select visibility scope of an image.

Example

The following script creates several bitmaps on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates a bitmap in the chart window."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string          InpFile="\\Images\\dollar.bmp"; // Bitmap file name
input int             InpWidth=24;                    // Visibility scope X coordinate
input int             InpHeight=24;                   // Visibility scope Y coordinate
input int             InpXOffset=4;                   // Visibility scope shift by X a
input int             InpYOffset=4;                   // Visibility scope shift by Y a
input color           InpColor=clrRed;                // Border color when highlighted
input ENUM_LINE_STYLE InpStyle=STYLE_SOLID;           // Line style when highlighted
input int             InpPointWidth=1;                // Point size to move
input bool            InpBack=false;                  // Background object
input bool            InpSelection=false;             // Highlight to move
```

```
input bool            InpHidden=true;                  // Hidden in the object list
input long            InpZOrder=0;                     // Priority for mouse click
//+------------------------------------------------------------------+
//| Create a bitmap in the chart window                              |
//+------------------------------------------------------------------+
bool BitmapCreate(const long            chart_ID=0,        // chart's ID

OBJ_BITMAP_LABEL

Bitmap Label object.

Note

Anchor point position relative to the label can be selected from ENUM_ANCHOR_POINT enumeration. Anchor point coordinates are set in pixels.

You can also select bitmap anchoring corner from ENUM_BASE_CORNER enumeration.

For bitmap label, you can select visibility scope of an image.

Example

The following script creates several bitmaps on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Bitmap Label\" object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string            InpName="BmpLabel";              // Label name
input string            InpFileOn="\\Images\\dollar.bmp"; // File name for On mode
input string            InpFileOff="\\Images\\euro.bmp";  // File name for Off mode
input bool              InpState=false;                   // Label pressed/released
input ENUM_BASE_CORNER  InpCorner=CORNER_LEFT_UPPER;      // Chart corner for anchorir
input ENUM_ANCHOR_POINT InpAnchor=ANCHOR_CENTER;          // Anchor type
input color             InpColor=clrRed;                  // Border color when highlig
```

```
input ENUM_LINE_STYLE   InpStyle=STYLE_SOLID;             // Line style when highlight
input int               InpPointWidth=1;                  // Point size to move
input bool              InpBack=false;                    // Background object
input bool              InpSelection=false;               // Highlight to move
input bool              InpHidden=true;                   // Hidden in the object list
input long              InpZOrder=0;                      // Priority for mouse click
//+------------------------------------------------------------------+
//| Create Bitmap Label object                                       |

OBJ_EDIT

Edit object.

Note

Anchor point coordinates are set in pixels. You can select Edit anchoring corner from ENUM_BASE_CORNER enumeration.

You can also select one of the text alignment types inside Edit from ENUM_ALIGN_MODE enumeration.

Example

The following script creates and moves Edit object on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Edit\" object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string            InpName="Edit";              // Object name
input string            InpText="Text";              // Object text
input string            InpFont="Arial";             // Font
input int               InpFontSize=14;              // Font size
input ENUM_ALIGN_MODE   InpAlign=ALIGN_CENTER;       // Text alignment type
input bool              InpReadOnly=false;           // Permission to edit
input ENUM_BASE_CORNER  InpCorner=CORNER_LEFT_UPPER; // Chart corner for anchoring
input color             InpColor=clrBlack;           // Text color
```

```
input color             InpBackColor=clrWhite;       // Background color
input color             InpBorderColor=clrBlack;     // Border color
input bool              InpBack=false;               // Background object
input bool              InpSelection=false;          // Highlight to move

OBJ_EVENT

Event object.

Note

When hovering mouse over the event, its text appears.

Example

The following script creates and moves Event object on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script draws \"Event\" graphical object."
#property description "Anchor point date is set in percentage of"
#property description "the chart window width in bars."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string           InpName="Event";     // Event name
input int              InpDate=25;          // Event date, %
input string           InpText="Text";      // Event text
input color            InpColor=clrRed;     // Event color
input int              InpWidth=1;          // Point size when highlighted
input bool             InpBack=false;       // Background event
input bool             InpSelection=false; // Highlight to move
input bool             InpHidden=true;      // Hidden in the object list
```

```
input long            InpZOrder=0;        // Priority for mouse click
//+------------------------------------------------------------------+
//| Create Event object on the chart                                 |
//+------------------------------------------------------------------+

```

OBJ_RECTANGLE_LABEL

Rectangle Label object.

Note

Anchor point coordinates are set in pixels. You can select rectangle label's anchoring corner from ENUM_BASE_CORNER enumeration. Rectangle label's border type can be selected from ENUM_BORDER_TYPE enumeration.

The object is used to create and design the custom graphical interface.

Example

The following script creates and moves Rectangle Label object on the chart. Special functions have been developed to create and change graphical object's properties. You can use these functions "as is" in your own applications.

```
//--- description
#property description "Script creates \"Rectangle Label\" graphical object."
//--- display window of the input parameters during the script's launch
#property script_show_inputs
//--- input parameters of the script
input string           InpName="RectLabel";          // Label name
input color            InpBackColor=clrSkyBlue;      // Background color
input ENUM_BORDER_TYPE InpBorder=BORDER_FLAT;        // Border type
input ENUM_BASE_CORNER InpCorner=CORNER_LEFT_UPPER; // Chart corner for anchoring
input color            InpColor=clrDarkBlue;         // Flat border color (Flat)
input ENUM_LINE_STYLE  InpStyle=STYLE_SOLID;         // Flat border style (Flat)
input int              InpLineWidth=3;               // Flat border width (Flat)
```

```
input bool              InpBack=false;              // Background object
input bool              InpSelection=true;          // Highlight to move
input bool              InpHidden=true;             // Hidden in the object list
input long              InpZOrder=0;                // Priority for mouse click

  }
```

Object Properties

Graphical objects can have various properties depending on the object type. Values of object properties are set up and received by corresponding functions for working with graphical objects.

All objects used in technical analysis are bound to the time and price coordinates: trendline, channels, Fibonacci tools, etc. But there is a number of auxiliary objects intended to improve the user interface that are bound to the always visible part of a chart (main chart windows or indicator subwindows):

Object	ID	X/Y	Width/ Height	Date/Price	OBJPROP_CORNER	OBJPROP_ANCHOR	OBJPROP_ANGLE
Text	OBJ_TEXT	–	–	Yes	–	Yes	Yes
Label	OBJ_LABEL	Yes	Yes (read only)	–	Yes	Yes	Yes
Button	OBJ_BUTTON	Yes	Yes	–	Yes	–	–
Bitmap	OBJ_BITMAP	–	Yes (read only)	Yes	–	Yes	–
Bitmap Label	OBJ_BITMAP_LABEL	Yes	Yes (read only)	–	Yes	Yes	–
Edit	OBJ_EDIT	Yes	Yes	–	Yes	–	–
Rectangle Label	OBJ_RECTANGLE_LABEL	Yes	Yes	–	Yes	–	–

The following designations are used in the table:

- **X/Y** - coordinates of anchor points specified in pixels relative to a chart corner;
- **Width/Height** - objects have width and height. For "read only", the width and height values are calculated only once the object is rendered on chart;
- **Date/Price** - anchor point coordinates are specified using the date and price values;
- **OBJPROP_CORNER** - defines the chart corner relative to which the anchor point coordinates are specified. Can be one of the 4 values of the ENUM_BASE_CORNER enumeration;
- **OBJPROP_ANCHOR** - defines the anchor point in object itself and can be one of the 9 values of the ENUM_ANCHOR_POINT enumeration. Coordinates in pixels are specified from this very point to selected chart corner;
- **OBJPROP_ANGLE** - defines the object rotation angle counterclockwise.

The functions defining the properties of graphical objects, as well as ObjectCreate() and ObjectMove() operations for creating and moving objects along the chart are actually used for sending commands to the chart. If these functions are executed successfully, the command is included in the common queue

of the chart events. Visual changes in the properties of graphical objects are implemented when handling the queue of the chart events.

Thus, do not expect an immediate visual update of graphical objects after calling these functions. Generally, the graphical objects on the chart are updated automatically by the terminal following the change events - a new quote arrival, resizing the chart window, etc. Use ChartRedraw() function to forcefully update the graphical objects.

For functions ObjectSetInteger() and ObjectGetInteger()

ENUM_OBJECT_PROPERTY_INTEGER

Identifier	Description	Property Type
OBJPROP_COLOR	Color	color
OBJPROP_STYLE	Style	ENUM_LINE_STYLE
OBJPROP_WIDTH	Line thickness	int
OBJPROP_BACK	Object in the background	bool
OBJPROP_ZORDER	Priority of a graphical object for receiving events of clicking on a	long

Identifier	Description	Property Type
	chart (CHARTEVENT_CLICK). The default zero value is set when creating an object; the priority can be increased if necessary. When objects are placed one atop another, only one	

Identifier	Description	Property Type
	of them with the highest priority will receive the CHARTEVENT_CLICK event.	
OBJPROP_FILL	Fill an object with color (for OBJ_RECTANGLE, OBJ_TRIANGLE, OBJ_ELLIPSE, OBJ_CHANNEL, OBJ	bool

Identifier	Description	Property Type
	_STDDEVCHANNEL, OBJ_REGRESSION)	
OBJPROP_HIDDEN	Prohibit showing of the name of a graphical object in the list of objects from the terminal menu "Charts" - "Objects" - "List of objects"	bool

Identifier	Description	Property Type
	. The true value allows to hide an object from the list. By default, true is set to the objects that display calendar events, trading history and to the objects created from MQL	

Identifier	Description	Property Type
	5 programs. To see such graphical objects and access their properties, click on the "All" button in the "List of objects" window.	
OBJPROP_SELECTED	Object is selected	bool
OBJPROP_READONLY	Ability to edit text in	bool

Identifier	Description	Property Type
	the Edit object	
OBJPROP_TYPE	Object type	ENUM_OBJECT r/o
OBJPROP_TIME	Time coordinate	datetime modifier=number of anchor point
OBJPROP_SELECTABLE	Object availability	bool
OBJPROP_CREATETIME	Time of object creation	datetime r/o
OBJPROP_LEVELS	Number of levels	int
OBJPROP_LEVELCOLOR	Color of the line-level	color modifier=level number
OBJPROP_LEVELSTYLE	Style of the line-level	ENUM_LINE_STYLE modifier=level number
OBJPROP_LEVELWIDTH	Thicknes	int modifier=level number

Identifier	Description	Property Type
	s of the line-level	
OBJPROP_ALIGN	Horizontal text alignment in the "Edit" object (OBJ_EDIT)	ENUM_ALIGN_MODE
OBJPROP_FONTSIZE	Font size	int
OBJPROP_RAY_LEFT	Ray goes to the left	bool
OBJPROP_RAY_RIGHT	Ray goes to the right	bool
OBJPROP_RAY	A vertical line goes through all the win	bool

Identifier	Description	Property Type
	dows of a chart	
OBJPROP_ELLIPSE	Showing the full ellipse of the Fibonacci Arc object (OBJ_FIBOARC)	bool
OBJPROP_ARROWCODE	Arrow code for the Arrow object	uchar
OBJPROP_TIMEFRAMES	Visibility of an object at timefra mes	set of flags flags

Identifier	Description	Property Type
OBJPROP_ANCHOR	Location of the anchor point of a graphical object	ENUM_ARROW_ANCHOR (for OBJ_ARROW), ENUM_ANCHOR_POINT (for OBJ_LABEL, OBJ_BITMAP_LABEL and OBJ_TEXT)
OBJPROP_XDISTANCE	The distance in pixels along the X axis from the binding corner (see note)	int
OBJPROP_YDISTANCE	The distance in pixels along the Y axis	int

Identifier	Description	Property Type
	from the binding corner (see note)	
OBJPROP_DIRECTION	Trend of the Gann object	ENUM_GANN_DIRECTION
OBJPROP_DEGREE	Level of the Elliott Wave Marking	ENUM_ELLIOT_WAVE_DEGREE
OBJPROP_DRAWLINES	Displaying lines for marking the Elliott Wave	bool
OBJPROP_STATE	Button state (pre	bool

Identifier	Description	Property Type
	ssed / depressed)	
OBJPROP_CHART_ID	ID of the "Chart" object (OBJ_CHART). It allows working with the properties of this object like with a normal chart using the functions described in Cha	long r/o

Identifier	Description	Property Type
	rt Operations, but there some exceptions.	
OBJPROP_XSIZE	The object's width along the X axis in pixels. Specified for OBJ_LABEL (read only), OBJ_BUTTON, OBJ_CHART, OBJ_BITMAP	int

Identifier	Description	Property Type
	, OBJ_BITMAP_LABEL, OBJ_EDIT, OBJ_RECTANGLE_LABEL objects.	
OBJPROP_YSIZE	The object's height along the Y axis in pixels. Specified for OBJ_LABEL (read only), OBJ_BUTTON, OBJ	int

Identifier	Description	Property Type
	_CHART, OBJ_BITMAP, OBJ_BITMAP_LABEL, OBJ_EDIT, OBJ_RECTANGLE_LABEL objects.	
OBJPROP_XOFFSET	The X coordinate of the upper left corner of the rectangular visible area in the grap	int

Identifier	Description	Property Type
	hical objects "BitmapLabel" and "Bitmap" (OBJ_BITMAP_LABEL and OBJ_BITMAP). The value is set in pixels relative to the upper left corner of the original image.	
OBJPROP_YOFFSET	The Y coor	int

Identifier	Description	Property Type
	dinate of the upper left corner of the rectangular visible area in the graphical objects "BitmapLabel" and "Bitmap" (OBJ_BITMAP_LABEL and OBJ_BITMAP). The value is set in	

Identifier	Description	Property Type
	pixels relative to the upper left corner of the original image.	
OBJPROP_PERIOD	Timeframe for the Chart object	ENUM_TIMEFRAMES
OBJPROP_DATE_SCALE	Displaying the time scale for the Chart object	bool
OBJPROP_PRICE_SCALE	Displaying the pric	bool

Identifier	Description	Property Type
	e scale for the Chart object	
OBJPROP_CHART_SCALE	The scale for the Chart object	int value in the range 0-5
OBJPROP_BGCOLOR	The background color for OBJ_EDIT, OBJ_BUTTON, OBJ_RECTANGLE_LABEL	color
OBJPROP_CORNER	The corner of the chart to	ENUM_BASE_CORNER

Identifier	Description	Property Type
	link a graphical object	
OBJPROP_BORDER_TYPE	Border type for the "Rectangle label" object	ENUM_BORDER_TYPE
OBJPROP_BORDER_COLOR	Border color for the OBJ_EDIT and OBJ_BUTTON objects	color

When using chart operations for the "Chart" object (OBJ_CHART), the following limitations are imposed:

- It cannot be closed using ChartClose();
- Symbol/period cannot be changed using the ChartSetSymbolPeriod() function;
- The following properties are ineffective CHART_SCALE, CHART_BRING_TO_TOP, CHART_SHOW_DATE_SCALE and CHART_SHOW_PRICE_SCALE (ENUM_CHART_PROPERTY_INTEGER).

You can set a special mode of image display for OBJ_BITMAP_LABEL and OBJ_BITMAP objects. In this mode, only part of an original image (at which a rectangular visible area is applied) is displayed, while the rest of the image becomes invisible. The size of this area should be set using the properties OBJPROP_XSIZE and OBJPROP_YSIZE. The visible area can be "moved" only within the original image using the properties OBJPROP_XOFFSET and OBJPROP_YOFFSET.

For the fixed-sized objects: OBJ_BUTTON, OBJ_RECTANGLE_LABEL, OBJ_EDIT and OBJ_CHART, properties OBJPROP_XDISTANCE and OBJPROP_YDISTANCE set the position of the top left point of the object relative to the chart corner (OBJPROP_CORNER), from which the X and Y coordinates will be counted in pixels.

For functions ObjectSetDouble() and ObjectGetDouble()

ENUM_OBJECT_PROPERTY_DOUBLE

Identifier	Description	Property Type
OBJPROP_PRICE	Price coordinate	double modifier=number of anchor point
OBJPROP_LEVELVALUE	Level value	double modifier=level number
OBJPROP_SCALE	Scale (properties of Gann objects and Fibonacci Arcs)	double
OBJPROP_ANGLE	Angle.	double

Identifier	Description	Property Type
	For the objects with no angle specified, created from a program, the value is equal to EMPTY_VALUE	
OBJPROP_DEVIATION	Deviation for the Standard Deviation Channel	double

For functions ObjectSetString() and ObjectGetString()

ENUM_OBJECT_PROPERTY_STRING

Identifier	Description	Property Type
OBJPROP_NAME	Object name	string
OBJPROP_TEXT	Description of the object (the text contained in the object)	string
OBJPROP_TOOLTIP	The text of a tooltip. If the property is not set, then the tooltip generated automatically by the terminal is	string

Identifier	Description	Property Type
	shown. A tooltip can be disabled by setting the "\n" (linefeed) value to it	
OBJPROP_LEVELTEXT	Level description	string modifier=level number
OBJPROP_FONT	Font	string
OBJPROP_BMPFILE	The name of BMP-file for Bitmap Label. See also Resources	string modifier: 0-state ON, 1-state OFF
OBJPROP_SYMBOL	Symbol for the	string

Identifier	Description	Property Type
	Chart object	

For the OBJ_RECTANGLE_LABEL object ("Rectangle label") one of the three design modes can be set, to which the following values of ENUM_BORDER_TYPE correspond.

ENUM_BORDER_TYPE

Identifier	Description
BORDER_FLAT	Flat form
BORDER_RAISED	Prominent form
BORDER_SUNKEN	Concave form

For the OBJ_EDIT object ("Edit") and for the ChartScreenShot() function, you can specify the horizontal alignment type using the values of the ENUM_ALIGN_MODE enumeration.

ENUM_ALIGN_MODE

Identifier	Description
ALIGN_LEFT	Left alignment
ALIGN_CENTER	Centered (only for the Edit object)
ALIGN_RIGHT	Right alignment

Example:

```
#define  UP          "\x0431"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   string label_name="my_OBJ_LABEL_object";
   if(ObjectFind(0,label_name)<0)
     {
      Print("Object ",label_name," not found. Error code = ",GetLastError());
      //--- create Label object
      ObjectCreate(0,label_name,OBJ_LABEL,0,0,0);
```

```
      //--- set X coordinate
      ObjectSetInteger(0,label_name,OBJPROP_XDISTANCE,200);
      //--- set Y coordinate
      ObjectSetInteger(0,label_name,OBJPROP_YDISTANCE,300);
      //--- define text color
      ObjectSetInteger(0,label_name,OBJPROP_COLOR,clrWhite);
      //--- define text for object Label
      ObjectSetString(0,label_name,OBJPROP_TEXT,UP);
      //--- define font
      ObjectSetString(0,label_name,OBJPROP_FONT,"Wingdings");
      //--- define font size
      ObjectSetInteger(0,label_name,OBJPROP_FONTSIZE,10);
      //--- 45 degrees rotation clockwise
      ObjectSetDouble(0,label_name,OBJPROP_ANGLE,-45);
      //--- disable for mouse selecting
      ObjectSetInteger(0,label_name,OBJPROP_SELECTABLE,false);
      //--- draw it on the chart
      ChartRedraw(0);
     }
  }
```

Methods of Object Binding

Graphical objects Text, Label, Bitmap and Bitmap Label (OBJ_TEXT, OBJ_LABEL, OBJ_BITMAP and OBJ_BITMAP_LABEL) can have one of the 9 different ways of coordinate binding defined by the OBJPROP_ANCHOR property.

Object	ID	X/Y	Width/Height	Date/Price	OBJPROP_CORNER	OBJPROP_ANCHOR	OBJPROP_ANGLE
Text	OBJ_TEXT	—	—	Yes	—	**Yes**	Yes
Label	OBJ_LABEL	Yes	Yes (read only)	—	Yes	**Yes**	Yes
Button	OBJ_BUTTON	Yes	Yes	—	Yes	—	—
Bitmap	OBJ_BITMAP	—	Yes (read only)	Yes	—	**Yes**	—
Bitmap Label	OBJ_BITMAP_LABEL	Yes	Yes (read only)	—	Yes	**Yes**	—
Edit	OBJ_EDIT	Yes	Yes	—	Yes	—	—
Rectangle Label	OBJ_RECTANGLE_LABEL	Yes	Yes	—	Yes	—	—

The following designations are used in the table:

- **X/Y** - coordinates of anchor points specified in pixels relative to a chart corner;
- **Width/Height** - objects have width and height. For "read only", the width and height values are calculated only once the object is rendered on chart;
- **Date/Price** - anchor point coordinates are specified using the date and price values;
- **OBJPROP_CORNER** - defines the chart corner relative to which the anchor point coordinates are specified. Can be one of the 4 values of the ENUM_BASE_CORNER enumeration;
- **OBJPROP_ANCHOR** - defines the anchor point in object itself and can be one of the 9 values of the ENUM_ANCHOR_POINT enumeration. Coordinates in pixels are specified from this very point to selected chart corner;
- **OBJPROP_ANGLE** - defines the object rotation angle counterclockwise.

The necessary variant can be specified using the function ObjectSetInteger(chart_handle, object_name, OBJPROP_ANCHOR, anchor_point_mode), where anchor_point_mode is one of the values of ENUM_ANCHOR_POINT.

ENUM_ANCHOR_POINT

ID	Description
ANCHOR_LEFT_UPPER	Anchor point at the upper left corner

ID	Description
ANCHOR_LEFT	Anchor point to the left in the center
ANCHOR_LEFT_LOWER	Anchor point at the lower left corner
ANCHOR_LOWER	Anchor point below in the center
ANCHOR_RIGHT_LOWER	Anchor point at the lower right corner
ANCHOR_RIGHT	Anchor point to the right in the center
ANCHOR_RIGHT_UPPER	Anchor point at the upper right corner
ANCHOR_UPPER	Anchor point above in the center
ANCHOR_CENTER	Anchor point strictly in the center of the object

The OBJ_BUTTON, OBJ_RECTANGLE_LABEL, OBJ_EDIT and OBJ_CHART objects have a fixed anchor point in the upper left corner (ANCHOR_LEFT_UPPER).

Example:

```
string text_name="my_OBJ_TEXT_object";
if(ObjectFind(0,text_name)<0)
  {
   Print("Object ",text_name," not found. Error code = ",GetLastError());
   //--- Get the maximal price of the chart
   double chart_max_price=ChartGetDouble(0,CHART_PRICE_MAX,0);
   //--- Create object Label
   ObjectCreate(0,text_name,OBJ_TEXT,0,TimeCurrent(),chart_max_price);
   //--- Set color of the text
   ObjectSetInteger(0,text_name,OBJPROP_COLOR,clrWhite);
   //--- Set background color
   ObjectSetInteger(0,text_name,OBJPROP_BGCOLOR,clrGreen);
   //--- Set text for the Label object
   ObjectSetString(0,text_name,OBJPROP_TEXT,TimeToString(TimeCurrent()));
   //--- Set text font
   ObjectSetString(0,text_name,OBJPROP_FONT,"Trebuchet MS");
   //--- Set font size
   ObjectSetInteger(0,text_name,OBJPROP_FONTSIZE,10);
   //--- Bind to the upper right corner
   ObjectSetInteger(0,text_name,OBJPROP_ANCHOR,ANCHOR_RIGHT_UPPER);
   //--- Rotate 90 degrees counter-clockwise
   ObjectSetDouble(0,text_name,OBJPROP_ANGLE,90);
   //--- Forbid the selection of the object by mouse
   ObjectSetInteger(0,text_name,OBJPROP_SELECTABLE,false);
   //--- redraw object
   ChartRedraw(0);
  }
```

Graphical objects Arrow (OBJ_ARROW) have only 2 ways of linking their coordinates. Identifiers are listed in ENUM_ARROW_ANCHOR.

ENUM_ARROW_ANCHOR

ID	Description
ANCHOR_TOP	Anchor on the top side
ANCHOR_BOTTOM	Anchor on the bottom side

Example:

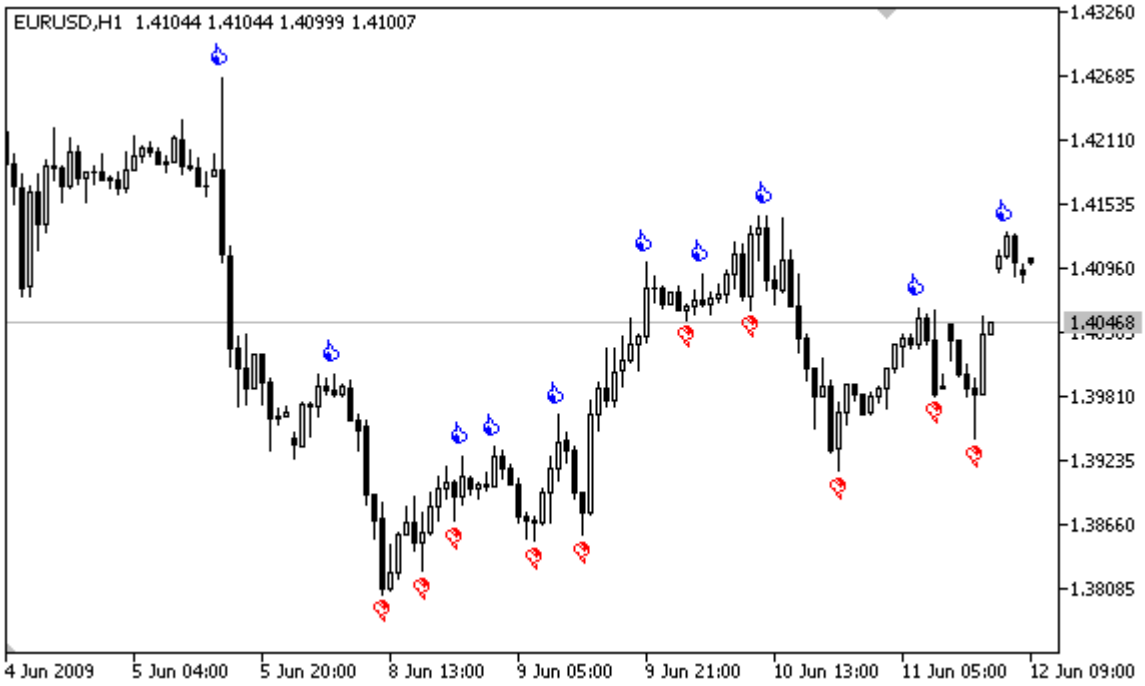
```
void OnStart()
  {
//--- Auxiliary arrays
   double Ups[],Downs[];
   datetime Time[];
//--- Set the arrays as timeseries
   ArraySetAsSeries(Ups,true);
   ArraySetAsSeries(Downs,true);
   ArraySetAsSeries(Time,true);
//--- Create handle of the Indicator Fractals
   int FractalsHandle=iFractals(NULL,0);
   Print("FractalsHandle = ",FractalsHandle);
//--- Set Last error value to Zero
   ResetLastError();
//--- Try to copy the values of the indicator
   int copied=CopyBuffer(FractalsHandle,0,0,1000,Ups);
   if(copied<=0)
     {
      Print("Unable to copy the upper fractals. Error = ",GetLastError());
      return;
     }

   ResetLastError();
//--- Try to copy the values of the indicator
   copied=CopyBuffer(FractalsHandle,1,0,1000,Downs);
   if(copied<=0)
     {
      Print("Unable to copy the bottom fractals. Error = ",GetLastError());
      return;
     }

   ResetLastError();
//--- Copy timeseries containing the opening bars of the last 1000 ones
   copied=CopyTime(NULL,0,0,1000,Time);
   if(copied<=0)
     {
      Print("Unable to copy the Opening Time of the last 1000 bars");
      return;
     }
```

```
   int upcounter=0,downcounter=0; // count there the number of arrows
   bool created;// receive the result of attempts to create an object
   for(int i=2;i<copied;i++)// Run through the values of the indicator iFractals
     {
      if(Ups[i]!=EMPTY_VALUE)// Found the upper fractal
        {
         if(upcounter<10)// Create no more than 10 "Up" arrows
           {
            //--- Try to create an "Up" object
            created=ObjectCreate(0,string(Time[i]),OBJ_ARROW_THUMB_UP,0,Time[i],Ups[i]
            if(created)// If set up - let's make tuning for it
              {
               //--- Point anchor is below in order not to cover bar
               ObjectSetInteger(0,string(Time[i]),OBJPROP_ANCHOR,ANCHOR_BOTTOM);
               //--- Final touch - painted
               ObjectSetInteger(0,string(Time[i]),OBJPROP_COLOR,clrBlue);
               upcounter++;
              }
           }
        }
      if(Downs[i]!=EMPTY_VALUE)// Found a lower fractal
        {
         if(downcounter<10)// Create no more than 10 arrows "Down"
           {
            //--- Try to create an object "Down"
            created=ObjectCreate(0,string(Time[i]),OBJ_ARROW_THUMB_DOWN,0,Time[i],Down
            if(created)// If set up - let's make tuning for it
              {
               //--- Point anchor is above in order not to cover bar
               ObjectSetInteger(0,string(Time[i]),OBJPROP_ANCHOR,ANCHOR_TOP);
               //--- Final touch - painted
               ObjectSetInteger(0,string(Time[i]),OBJPROP_COLOR,clrRed);
               downcounter++;
              }
           }
        }
     }
  }
```

After the script execution the chart will look like in this figure.



The Chart Corner to Which an Object Is Attached

There is a number of graphical objects for which you can set a chart corner, relative to which the coordinates are specified in pixels. These are the following types of objects (in brackets object type identifiers are specified):

- Label (OBJ_LABEL);
- Button (OBJ_BUTTON);
- Bitmap Label (OBJ_BITMAP_LABEL);
- Edit (OBJ_EDIT).
- Rectangle Label (OBJ_RECTANGLE_LABEL);

Object	ID	X/Y	Width/Height	Date/Price	OBJPROP_CORNER	OBJPROP_ANCHOR	OBJPROP_ANGLE
Text	OBJ_TEXT	–	–	Yes	–	Yes	Yes
Label	OBJ_LABEL	Yes	Yes (read only)	–	**Yes**	Yes	Yes
Button	OBJ_BUTTON	Yes	Yes	–	**Yes**	–	–
Bitmap	OBJ_BITMAP	–	Yes (read only)	Yes	–	Yes	–
Bitmap Label	OBJ_BITMAP_LABEL	Yes	Yes (read only)	–	**Yes**	Yes	–
Edit	OBJ_EDIT	Yes	Yes	–	**Yes**	–	–
Rectangle Label	OBJ_RECTANGLE_LABEL	Yes	Yes	–	**Yes**	–	–

The following designations are used in the table:

- **X/Y** - coordinates of anchor points specified in pixels relative to a chart corner;
- **Width/Height** - objects have width and height. For "read only", the width and height values are calculated only once the object is rendered on chart;
- **Date/Price** - anchor point coordinates are specified using the date and price values;
- **OBJPROP_CORNER** - defines the chart corner relative to which the anchor point coordinates are specified. Can be one of the 4 values of the ENUM_BASE_CORNER enumeration;
- **OBJPROP_ANCHOR** - defines the anchor point in object itself and can be one of the 9 values of the ENUM_ANCHOR_POINT enumeration. Coordinates in pixels are specified from this very point to selected chart corner;
- **OBJPROP_ANGLE** - defines the object rotation angle counterclockwise.

In order to specify the chart corner, from which X and Y coordinates will be measured in pixels, use ObjectSetInteger(chartID, name, OBJPROP_CORNER, **chart_corner**), where:

- chartID - chart identifier;
- name - name of a graphical object;
- OBJPROP_CORNER - property ID to specify the corner for binding;
- **chart_corner** - the desired chart corner, can be one of the values of the ENUM_BASE_CORNER enumeration.

ENUM_BASE_CORNER

ID	Description
CORNER_LEFT_UPPER	Center of coordinates is in the upper left corner of the chart
CORNER_LEFT_LOWER	Center of coordinates is in the lower left corner of the chart
CORNER_RIGHT_LOWER	Center of coordinates is in the lower right corner of the chart
CORNER_RIGHT_UPPER	Center of coordinates is in the upper right corner of the chart

Example:

```
void CreateLabel(long   chart_id,
                 string name,
                 int    chart_corner,
                 int    anchor_point,
                 string text_label,
                 int    x_ord,
                 int    y_ord)
  {
//---
   if(ObjectCreate(chart_id,name,OBJ_LABEL,0,0,0))
     {
      ObjectSetInteger(chart_id,name,OBJPROP_CORNER,chart_corner);
      ObjectSetInteger(chart_id,name,OBJPROP_ANCHOR,anchor_point);
      ObjectSetInteger(chart_id,name,OBJPROP_XDISTANCE,x_ord);
      ObjectSetInteger(chart_id,name,OBJPROP_YDISTANCE,y_ord);
      ObjectSetString(chart_id,name,OBJPROP_TEXT,text_label);
     }
   else
      Print("Failed to create the object OBJ_LABEL ",name,", Error code = ", GetLastEr
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int height=(int)ChartGetInteger(0,CHART_HEIGHT_IN_PIXELS,0);
```

```
   int width=(int)ChartGetInteger(0,CHART_WIDTH_IN_PIXELS,0);
   string arrows[4]={"LEFT_UPPER","RIGHT_UPPER","RIGHT_LOWER","LEFT_LOWER"};
   CreateLabel(0,arrows[0],CORNER_LEFT_UPPER,ANCHOR_LEFT_UPPER,arrows[0],50,50);
   CreateLabel(0,arrows[1],CORNER_RIGHT_UPPER,ANCHOR_RIGHT_UPPER,arrows[1],50,50);
   CreateLabel(0,arrows[2],CORNER_RIGHT_LOWER,ANCHOR_RIGHT_LOWER,arrows[2],50,50);
   CreateLabel(0,arrows[3],CORNER_LEFT_LOWER,ANCHOR_LEFT_LOWER,arrows[3],50,50);
  }
```

Visibility of Objects

The combination of object visibility flags determines chart timeframes, where the object is visible. To set/get the value of the OBJPROP_TIMEFRAMES property, you can use functions ObjectSetInteger()/ObjectGetInteger().

ID	Value	Description
OBJ_NO_PERIODS	0	The object is not drawn in all timeframes
OBJ_PERIOD_M1	0x00000001	The object is drawn in 1-minute chart
OBJ_PERIOD_M2	0x00000002	The object is drawn in 2-minute chart
OBJ_PERIOD_M3	0x00000004	The object is drawn in 3-minute chart
OBJ_PERIOD_M4	0x00000008	The object is drawn in 4-minute chart
OBJ_PERIOD_M5	0x00000010	The object is drawn in 5-minute chart
OBJ_PERIOD_M6	0x00000020	The object is drawn in 6-minute chart
OBJ_PERIOD_M10	0x00000040	The object is drawn in 10-minute chart
OBJ_PERIOD_M12	0x00000080	The object is drawn in 12-minute chart
OBJ_PERIOD_M15	0x00000100	The object is drawn in 15-minute chart
OBJ_PERIOD_M20	0x00000200	The object is drawn in 20-minute chart
OBJ_PERIOD_M30	0x00000400	The object is drawn in 30-minute chart
OBJ_PERIOD_H1	0x00000800	The object is drawn in 1-hour chart
OBJ_PERIOD_H2	0x00001000	The object is drawn in 2-hour chart
OBJ_PERIOD_H3	0x00002000	The object is drawn in 3-hour chart
OBJ_PERIOD_H4	0x00004000	The object is drawn in 4-hour chart

ID	Value	Description
OBJ_PERIOD_H6	0x00008000	The object is drawn in 6-hour chart
OBJ_PERIOD_H8	0x00010000	The object is drawn in 8-hour chart
OBJ_PERIOD_H12	0x00020000	The object is drawn in 12-hour chart
OBJ_PERIOD_D1	0x00040000	The object is drawn in day charts
OBJ_PERIOD_W1	0x00080000	The object is drawn in week charts
OBJ_PERIOD_MN1	0x00100000	The object is drawn in month charts
OBJ_ALL_PERIODS	0x001fffff	The object is drawn in all timeframes

Visibility flags can be combined using the symbol "|", for example, the combination of flags OBJ_PERIOD_M10|OBJ_PERIOD_H4 means that the object will be visible on the 10-minute and 4-hour timeframes.

Example:

```
void OnStart()
  {
//---
   string highlevel="PreviousDayHigh";
   string lowlevel="PreviousDayLow";
   double prevHigh;           // The previous day High
   double prevLow;            // The previous day Low
   double highs[],lows[];     // Arrays for High and Low

//--- Reset the last error
   ResetLastError();
//--- Get the last 2 High values on the daily timeframe
   int highsgot=CopyHigh(Symbol(),PERIOD_D1,0,2,highs);
   if(highsgot>0) // If copying was successful
     {
      Print("High prices for the last 2 days were obtained successfully");
      prevHigh=highs[0]; // The previous day High
      Print("prevHigh = ",prevHigh);
      if(ObjectFind(0,highlevel)<0) // Object with the name highlevel not found
        {
         ObjectCreate(0,highlevel,OBJ_HLINE,0,0,0); // Create the Horizontal Line obje
        }
      //--- Set value for the price level for the line highlevel
      ObjectSetDouble(0,highlevel,OBJPROP_PRICE,0,prevHigh);
```

```
      //--- Set the visibility only PERIOD_M10 and PERIOD_H4
      ObjectSetInteger(0,highlevel,OBJPROP_TIMEFRAMES,OBJ_PERIOD_M10|OBJ_PERIOD_H4);
     }
   else
     {
      Print("Could not get High prices over the past 2 days, Error = ",GetLastError())
     }

//--- Reset the last error
   ResetLastError();
//--- Get the 2 days values Low on the daily timeframe
   int lowsgot=CopyLow(Symbol(),PERIOD_D1,0,2,lows);
   if(lowsgot>0) // If copying was successful
     {
      Print("Low prices for the last 2 days were obtained successfully");
      prevLow=lows[0]; // The previous day Low
      Print("prevLow = ",prevLow);
      if(ObjectFind(0,lowlevel)<0) // Object with the name lowlevel not found
        {
         ObjectCreate(0,lowlevel,OBJ_HLINE,0,0,0); // Create the Horizontal Line objec
        }
      //--- Set value for the price level for the line lowlevel
      ObjectSetDouble(0,lowlevel,OBJPROP_PRICE,0,prevLow);
      //--- Set the visibility only PERIOD_M10 and PERIOD_H4
      ObjectSetInteger(0,lowlevel,OBJPROP_TIMEFRAMES,OBJ_PERIOD_M10|OBJ_PERIOD_H4);
     }
   else Print("Could not get Low prices for the last 2 days, Error = ",GetLastError())

   ChartRedraw(0); // redraw the chart forcibly
  }
```

Levels of Elliott Wave

Elliott Waves are represented by two graphical objects of types OBJ_ELLIOTWAVE5 and OBJ_ELLIOTWAVE3. To set the wave size (method of wave labeling), the OBJPROP_DEGREE property is used, to which one of values of the ENUM_ELLIOT_WAVE_DEGREE enumeration can be assigned.

ENUM_ELLIOT_WAVE_DEGREE

ID	Description
ELLIOTT_GRAND_SUPERCYCLE	Grand Supercycle
ELLIOTT_SUPERCYCLE	Supercycle
ELLIOTT_CYCLE	Cycle
ELLIOTT_PRIMARY	Primary
ELLIOTT_INTERMEDIATE	Intermediate
ELLIOTT_MINOR	Minor
ELLIOTT_MINUTE	Minute
ELLIOTT_MINUETTE	Minuette
ELLIOTT_SUBMINUETTE	Subminuette

Example:

```
   for(int i=0;i<ObjectsTotal(0);i++)
     {
      string currobj=ObjectName(0,i);
      if((ObjectGetInteger(0,currobj,OBJPROP_TYPE)==OBJ_ELLIOTWAVE3) ||
          ((ObjectGetInteger(0,currobj,OBJPROP_TYPE)==OBJ_ELLIOTWAVE5)))
        {
         //--- set the marking level in INTERMEDIATE
         ObjectSetInteger(0,currobj,OBJPROP_DEGREE,ELLIOTT_INTERMEDIATE);
         //--- show lines between tops of waves
         ObjectSetInteger(0,currobj,OBJPROP_DRAWLINES,true);
         //--- set line color
         ObjectSetInteger(0,currobj,OBJPROP_COLOR,clrBlue);
         //--- set line width
         ObjectSetInteger(0,currobj,OBJPROP_WIDTH,5);
         //--- set description
         ObjectSetString(0,currobj,OBJPROP_TEXT,"test script");
        }
     }
```

Gann Objects

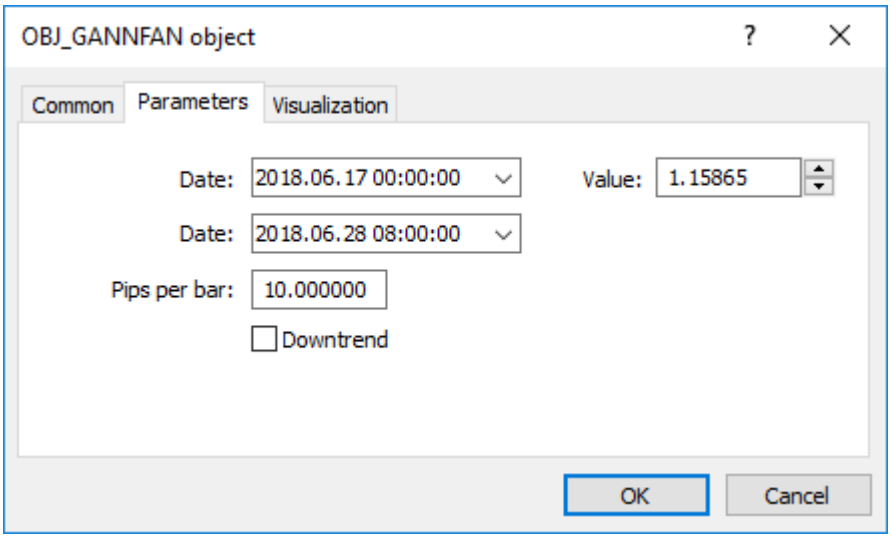
For Gann Fan (OBJ_GANNFAN) and Gann Grid (OBJ_GANNGRID) objects you can specify two values of the ENUM_GANN_DIRECTION enumeration that sets the trend direction.

ENUM_GANN_DIRECTION

ID	Description
GANN_UP_TREND	Line corresponding to the uptrend line
GANN_DOWN_TREND	Line corresponding to the downward trend

To set the scale of the main line as 1x1, use function ObjectSetDouble(chart_handle, gann_object_name, OBJPROP_SCALE, scale), where:

- chart_handle - chart window where the object is located;
- gann_object_name - object name;
- OBJPROP_SCALE - identifier of the "Scale" property;
- scale - required scale in units of Pips/Bar.



Example of creating Gann Fan:

```
void OnStart()
  {
//---
   string my_gann="OBJ_GANNFAN object";
   if(ObjectFind(0,my_gann)<0)// Object not found
     {
      //--- Inform about the failure
      Print("Object ",my_gann," not found. Error code = ",GetLastError());
      //--- Get the maximal price of the chart
      double chart_max_price=ChartGetDouble(0,CHART_PRICE_MAX,0);
      //--- Get the minimal price of the chart
      double chart_min_price=ChartGetDouble(0,CHART_PRICE_MIN,0);
      //--- How many bars are shown in the chart?
```

```
      int bars_on_chart=ChartGetInteger(0,CHART_VISIBLE_BARS);
      //--- Create an array, to write the opening time of each bar to
      datetime Time[];
      //--- Arrange access to the array as that of timeseries
      ArraySetAsSeries(Time,true);
      //--- Now copy data of bars visible in the chart into this array
      int times=CopyTime(NULL,0,0,bars_on_chart,Time);
      if(times<=0)
        {
         Print("Could not copy the array with the open time!");
         return;
        }
      //--- Preliminary preparations completed

      //--- Index of the central bar in the chart
      int center_bar=bars_on_chart/2;
      //--- Chart equator - between the maximum and minimum
      double mean=(chart_max_price+chart_min_price)/2.0;
      //--- Set the coordinates of the first anchor point to the center
      ObjectCreate(0,my_gann,OBJ_GANNFAN,0,Time[center_bar],mean,
                   //--- Second anchor point to the right
                   Time[center_bar/2],(mean+chart_min_price)/2.0);
      Print("Time[center_bar] = "+(string)Time[center_bar]+"  Time[center_bar/2] = "+
      //Print("Time[center_bar]/="+Time[center_bar]+"  Time[center_bar/2]="+Time[cente
      //--- Set the scale in units of Pips / Bar
      ObjectSetDouble(0,my_gann,OBJPROP_SCALE,10);
      //--- Set the line trend
      ObjectSetInteger(0,my_gann,OBJPROP_DIRECTION,GANN_UP_TREND);
      //--- Set the line width
      ObjectSetInteger(0,my_gann,OBJPROP_WIDTH,1);
      //--- Define the line style
      ObjectSetInteger(0,my_gann,OBJPROP_STYLE,STYLE_DASHDOT);
      //--- Set the line color
      ObjectSetInteger(0,my_gann,OBJPROP_COLOR,clrYellowGreen);
      //--- Allow the user to select an object
      ObjectSetInteger(0,my_gann,OBJPROP_SELECTABLE,true);
      //--- Select it yourself
      ObjectSetInteger(0,my_gann,OBJPROP_SELECTED,true);
      //--- Draw it on the chart
      ChartRedraw(0);
     }
  }
```

Web Colors

The following color constants are defined for the color type:

clrBlack	clrDarkGreen	clrDarkSlateGray	clrOlive	clrGreen	clrTeal	clrNavy	clrPurple
clrMaroon	clrIndigo	clrMidnightBlue	clrDarkBlue	clrDarkOliveGreen	clrSaddleBrown	clrForestGreen	clrOliveDrab
clrSeaGreen	clrDarkGoldenrod	clrDarkSlateBlue	clrSienna	clrMediumBlue	clrBrown	clrDarkTurquoise	clrDimGray
clrLightSeaGreen	clrDarkViolet	clrFireBrick	clrMediumVioletRed	clrMediumSeaGreen	clrChocolate	clrCrimson	clrSteelBlue
clrGoldenrod	clrMediumSpringGreen	clrLawnGreen	clrCadetBlue	clrDarkOrchid	clrYellowGreen	clrLimeGreen	clrOrangeRed
clrDarkOrange	clrOrange	clrGold	clrYellow	clrChartreuse	clrLime	clrSpringGreen	clrAqua
clrDeepSkyBlue	clrBlue	clrMagenta	clrRed	clrGray	clrSlateGray	clrPeru	clrBlueViolet
clrLightSlateGray	clrDeepPink	clrMediumTurquoise	clrDodgerBlue	clrTurquoise	clrRoyalBlue	clrSlateBlue	clrDarkKhaki
clrIndianRed	clrMediumOrchid	clrGreenYellow	clrMediumAquamarine	clrDarkSeaGreen	clrTomato	clrRosyBrown	clrOrchid
clrMediumPurple	clrPaleVioletRed	clrCoral	clrCornflowerBlue	clrDarkGray	clrSandyBrown	clrMediumSlateBlue	clrTan
clrDarkSalmon	clrBurlyWood	clrHotPink	clrSalmon	clrViolet	clrLightCoral	clrSkyBlue	clrLightSalmon
clrPlum	clrKhaki	clrLightGreen	clrAquamarine	clrSilver	clrLightSkyBlue	clrLightSteelBlue	clrLightBlue
clrPaleGreen	clrThistle	clrPowderBlue	clrPaleGoldenrod	clrPaleTurquoise	clrLightGray	clrWheat	clrNavajoWhite
clrMoccasin	clrLightPink	clrGainsboro	clrPeachPuff	clrPink	clrBisque	clrLightGoldenrod	clrBlanchedAlmond
clrLemonChiffon	clrBeige	clrAntiqueWhite	clrPapayaWhip	clrCornsilk	clrLightYellow	clrLightCyan	clrLinen
clrLavender	clrMistyRose	clrOldLace	clrWhiteSmoke	clrSeashell	clrIvory	clrHoneydew	clrAliceBlue
clrLavenderBlush	clrMintCream	clrSnow	clrWhite				

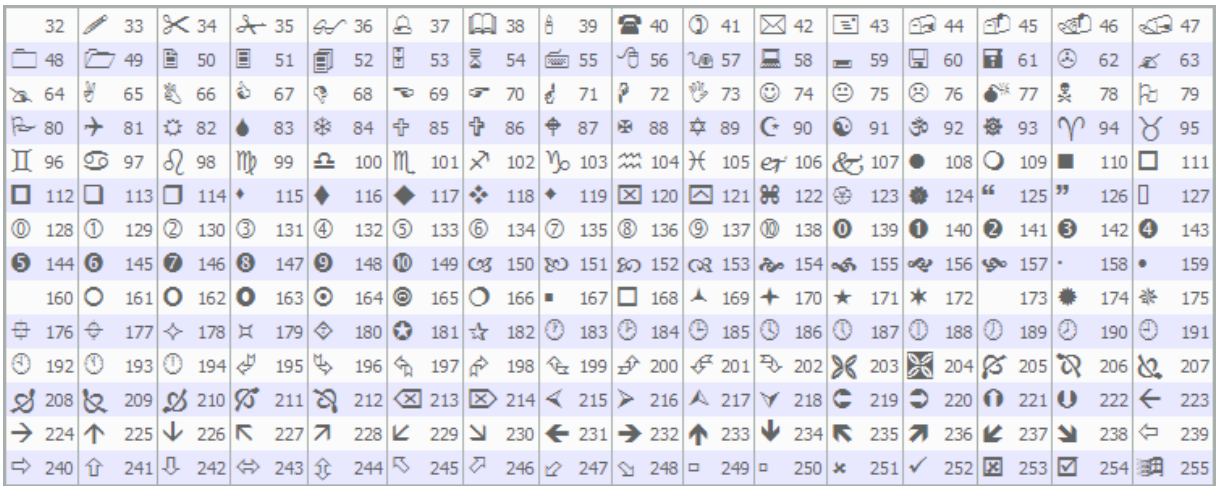
Color can be set to an object using the ObjectSetInteger() function. For setting color to custom indicators the PlotIndexSetInteger() function is used. For getting color values there are similar functions ObjectGetInteger() and PlotIndexGetInteger().

Example:

```
//---- indicator settings
#property indicator_chart_window
#property indicator_buffers 3
#property indicator_plots   3
#property indicator_type1   DRAW_LINE
#property indicator_type2   DRAW_LINE
#property indicator_type3   DRAW_LINE
#property indicator_color1  clrBlue
#property indicator_color2  clrRed
#property indicator_color3  clrLime
```

Wingdings

Characters of Wingdings used with the OBJ_ARROW object:



A necessary character can be set using the ObjectSetInteger() function.

Example:

```
void OnStart()
  {
//---
   string up_arrow="up_arrow";
   datetime time=TimeCurrent();
   double lastClose[1];
   int close=CopyClose(Symbol(),Period(),0,1,lastClose);      // Get the Close price
//--- If the price was obtained
   if(close>0)
     {
      ObjectCreate(0,up_arrow,OBJ_ARROW,0,0,0,0,0);           // Create an arrow
      ObjectSetInteger(0,up_arrow,OBJPROP_ARROWCODE,241);     // Set the arrow code
      ObjectSetInteger(0,up_arrow,OBJPROP_TIME,time);         // Set time
      ObjectSetDouble(0,up_arrow,OBJPROP_PRICE,lastClose[0]);// Set price
      ChartRedraw(0);                                         // Draw arrow now
     }
   else
      Print("Unable to get the latest Close price!");
  }
```

Indicators Constants

There are 37 predefined technical indicators, which can be used in programs written in the MQL5 language. In addition, there is an opportunity to create custom indicators using the iCustom() function. All constants required for that are divided into 5 groups:

- Price constants - for selecting the type of price or volume, on which an indicator is calculated;
- Smoothing methods - built-in smoothing methods used in indicators;
- Indicator lines - identifiers of indicator buffers when accessing indicator values using CopyBuffer();
- Drawing styles - for indicating one of 18 types of drawing and setting the line drawing style;
- Custom indicators properties are used in functions for working with custom indicators;
- Types of indicators are used for specifying the type of technical indicator when creating a handle using IndicatorCreate();
- Identifiers of data types are used for specifying the type of data passed in an array of the MqlParam type into the IndicatorCreate() function.

Price Constants

Calculations of technical indicators require price values and/or values of volumes, on which calculations will be performed. There are 7 predefined identifiers from the ENUM_APPLIED_PRICE enumeration, used to specify the desired price base for calculations.

ENUM_APPLIED_PRICE

ID	Description
PRICE_CLOSE	Close price
PRICE_OPEN	Open price
PRICE_HIGH	The maximum price for the period
PRICE_LOW	The minimum price for the period
PRICE_MEDIAN	Median price, (high + low)/2
PRICE_TYPICAL	Typical price, (high + low + close)/3
PRICE_WEIGHTED	Average price, (high + low + close + close)/4

If the volume is used in calculations, it's necessary to specify one of the two values from the ENUM_APPLIED_VOLUME enumeration.

ENUM_APPLIED_VOLUME

ID	Description
VOLUME_TICK	Tick volume
VOLUME_REAL	Trade volume

The iStochastic() technical Indicator can be calculated in two ways using:

- either only Close prices;
- or High and Low prices.

To select a necessary variant for calculation, specify one of the values of the ENUM_STO_PRICE enumeration.

ENUM_STO_PRICE

ID	Description
STO_LOWHIGH	Calculation is based on Low/High prices
STO_CLOSECLOSE	Calculation is based on Close/Close prices

If a technical indicator uses for calculations price data, type of which is set by ENUM_APPLIED_PRICE, then handle of any indicator (built in the terminal or written by a user) can be used as the input price series. In this case, values of the zero buffer of the indicator will be used for calculations. This makes it easy to build values of one indicator using values of another indicator. The handle of a custom indicator is created by calling the iCustom() function.

Example:

```
#property indicator_separate_window
#property indicator_buffers 2
#property indicator_plots   2
//--- input parameters
input int      RSIperiod=14;         // Period for calculating the RSI
input int      Smooth=8;             // Smoothing period RSI
input ENUM_MA_METHOD meth=MODE_SMMA; // Method of smoothing
//---- plot RSI
#property indicator_label1  "RSI"
#property indicator_type1   DRAW_LINE
#property indicator_color1  clrRed
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//---- plot RSI_Smoothed
#property indicator_label2  "RSI_Smoothed"
#property indicator_type2   DRAW_LINE
#property indicator_color2  clrNavy
#property indicator_style2  STYLE_SOLID
#property indicator_width2  1
//--- indicator buffers
double         RSIBuffer[];          // Here we store the values of RSI
double         RSI_SmoothedBuffer[]; // Here will be smoothed values of RSI
int            RSIhandle;            // Handle to the RSI indicator
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,RSIBuffer,INDICATOR_DATA);
   SetIndexBuffer(1,RSI_SmoothedBuffer,INDICATOR_DATA);
   IndicatorSetString(INDICATOR_SHORTNAME,"iRSI");
   IndicatorSetInteger(INDICATOR_DIGITS,2);
//---
   RSIhandle=iRSI(NULL,0,RSIperiod,PRICE_CLOSE);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[]
                )

  {
```

```
//---  Reset the value of the last error
   ResetLastError();
//--- Get RSI indicator data in an array RSIBuffer []
   int copied=CopyBuffer(RSIhandle,0,0,rates_total,RSIBuffer);
   if(copied<=0)
     {
      Print("Unable to copy the values of the indicator RSI. Error = ",
            GetLastError(),",  copied =",copied);
      return(0);
     }
//--- Create the indicator of average values using values of RSI
   int RSI_MA_handle=iMA(NULL,0,Smooth,0,meth,RSIhandle);
   copied=CopyBuffer(RSI_MA_handle,0,0,rates_total,RSI_SmoothedBuffer);
   if(copied<=0)
     {
      Print("Unable to copy the smoothed indicator of RSI. Error = ",
            GetLastError(),",  copied =",copied);
      return(0);
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Smoothing Methods

Many technical indicators are based on various methods of the price series smoothing. Some standard technical indicators require specification of the smoothing type as an input parameter. For specifying the desired type of smoothing, identifiers listed in the ENUM_MA_METHOD enumeration are used.

ENUM_MA_METHOD

ID	Description
MODE_SMA	Simple averaging
MODE_EMA	Exponential averaging
MODE_SMMA	Smoothed averaging
MODE_LWMA	Linear-weighted averaging

Example:

```
double ExtJaws[];
double ExtTeeth[];
double ExtLips[];
//---- handles for moving averages
int    ExtJawsHandle;
int    ExtTeethHandle;
int    ExtLipsHandle;
//--- get MA's handles
ExtJawsHandle=iMA(NULL,0,JawsPeriod,0,MODE_SMMA,PRICE_MEDIAN);
ExtTeethHandle=iMA(NULL,0,TeethPeriod,0,MODE_SMMA,PRICE_MEDIAN);
ExtLipsHandle=iMA(NULL,0,LipsPeriod,0,MODE_SMMA,PRICE_MEDIAN);
```

Indicators Lines

Some technical indicators have several buffers drawn in the chart. Numbering of indicator buffers starts with 0. When copying indicator values using the CopyBuffer() function into an array of the double type, for some indicators one may indicate the identifier of a copied buffer instead of its number.

Identifiers of indicator lines permissible when copying values of iMACD(), iRVI() and iStochastic().

Constant	Value	Description
MAIN_LINE	0	Main line
SIGNAL_LINE	1	Signal line

Identifiers of indicator lines permissible when copying values of ADX() and ADXW().

Constant	Value	Description
MAIN_LINE	0	Main line
PLUSDI_LINE	1	Line +DI
MINUSDI_LINE	2	Line -DI

Identifiers of indicator lines permissible when copying values of iBands().

Constant	Value	Description
BASE_LINE	0	Main line
UPPER_BAND	1	Upper limit
LOWER_BAND	2	Lower limit

Identifiers of indicator lines permissible when copying values of iEnvelopes() and iFractals().

Constant	Value	Description
UPPER_LINE	0	Upper line
LOWER_LINE	1	Bottom line

Identifiers of indicator lines permissible when copying values of iGator()

Constant	Value	Description
UPPER_HISTOGRAM	0	Upper histogram
LOWER_HISTOGRAM	2	Bottom histogram

Identifiers of indicator lines permissible when copying values of iAlligator().

Constant	Value	Description
GATORJAW_LINE	0	Jaw line
GATORTEETH_LINE	1	Teeth line
GATORLIPS_LINE	2	Lips line

Identifiers of indicator lines permissible when copying values of iIchimoku().

Constant	Value	Description
TENKANSEN_LINE	0	Tenkan-sen line
KIJUNSEN_LINE	1	Kijun-sen line
SENKOUSPANA_LINE	2	Senkou Span A line
SENKOUSPANB_LINE	3	Senkou Span B line
CHIKOUSPAN_LINE	4	Chikou Span line

Drawing Styles

When creating a custom indicator, you can specify one of 18 types of graphical plotting (as displayed in the main chart window or a chart subwindow), whose values are specified in the ENUM_DRAW_TYPE enumeration.

In one custom indicator, it is permissible to use any indicator building/drawing types. Each construction type requires specification of one to five global arrays for storing data necessary for drawing. These data arrays must be bound with indicator buffers using the SetIndexBuffer() function. The type of data from ENUM_INDEXBUFFER_TYPE should be specified for each buffer.

Depending on the drawing style, you may need one to four value buffers (marked as INDICATOR_DATA). If a style admits dynamic alternation of colors (all styles contain COLOR in their names), then you'll need one more buffer of color (indicated type INDICATOR_COLOR_INDEX). The color buffers are always bound after value buffers corresponding to the style.

ENUM_DRAW_TYPE

ID	Description	Data buffers	Color buffers
DRAW_NONE	Not drawn	1	0
DRAW_LINE	Line	1	0
DRAW_SECTION	Section	1	0
DRAW_HISTOGRAM	Histogram from the zero line	1	0
DRAW_HISTOGRAM2	Histogram of the two indicator buffers	2	0
DRAW_ARROW	Drawing arrows	1	0
DRAW_ZIGZAG	Style Zigzag allows vertical section on the bar	2	0
DRAW_FILLING	Color fill between the two levels	2	0

ID	Description	Data buffers	Color buffers
DRAW_BARS	Display as a sequence of bars	4	0
DRAW_CANDLES	Display as a sequence of candlesticks	4	0
DRAW_COLOR_LINE	Multicolored line	1	1
DRAW_COLOR_SECTION	Multicolored section	1	1
DRAW_COLOR_HISTOGRAM	Multicolored histogram from the zero line	1	1
DRAW_COLOR_HISTOGRAM2	Multicolored histogram of the two indicator buffers	2	1
DRAW_COLOR_ARROW	Drawing multicolored arrows	1	1
DRAW_COLOR_ZIGZAG	Multicolored ZigZag	2	1
DRAW_COLOR_BARS	Multicolored bars	4	1
DRAW_COLOR_CANDLES	Multicolored candlesticks	4	1

To refine the display of the selected drawing type identifiers listed in ENUM_PLOT_PROPERTY are used.

For functions PlotIndexSetInteger() and PlotIndexGetInteger()

ENUM_PLOT_PROPERTY_INTEGER

ID	Description	Property type
PLOT_ARROW	Arrow code for style DRAW_ARROW	uchar
PLOT_ARROW_SHIFT	Vertical shift of arrows for style DRAW_ARROW	int
PLOT_DRAW_BEGIN	Number of initial bars without drawing and values in the DataWindow	int
PLOT_DRAW_TYPE	Type of graphical construction	ENUM_DRAW_TYPE
PLOT_SHOW_DATA	Sign of display of construction values in the DataWindow	bool
PLOT_SHIFT	Shift of indicator plotting along the time axis in bars	int
PLOT_LINE_STYLE	Drawing line style	ENUM_LINE_STYLE
PLOT_LINE_WIDTH	The thickness of the drawing line	int
PLOT_COLOR_INDEXES	The number of colors	int
PLOT_LINE_COLOR	The index of a buffer containing the drawing color	color modifier = index number of colors

For the function PlotIndexSetDouble()

ENUM_PLOT_PROPERTY_DOUBLE

ID	Description	Property type
PLOT_EMPTY_VALUE	An empty value for plotting, for	double

ID	Description	Property type
	which there is no drawing	

For the function PlotIndexSetString()

ENUM_PLOT_PROPERTY_STRING

ID	Description	Property type
PLOT_LABEL	The name of the indicator graphical series to display in the DataWindow. When working with complex graphical styles requiring several indicator buffers for display, the names for each buffer can be specified using ";" as a separator. Sample code is shown in DRAW_CANDLES	string

5 styles can be used for drawing lines in custom indicators. They are valid only for the line thickness 0 or 1.

ENUM_LINE_STYLE

ID	Description
STYLE_SOLID	Solid line
STYLE_DASH	Broken line
STYLE_DOT	Dotted line
STYLE_DASHDOT	Dash-dot line
STYLE_DASHDOTDOT	Dash - two points

To set the line drawing style and the type of drawing, the PlotIndexSetInteger() function is used. For the Fibonacci extensions the thickness and drawing style of levels can be indicated using the ObjectSetInteger() function.

Example:

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//--- indicator buffers
double         MABuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- Bind the Array to the indicator buffer with index 0
   SetIndexBuffer(0,MABuffer,INDICATOR_DATA);
//--- Set the line drawing
   PlotIndexSetInteger(0,PLOT_DRAW_TYPE,DRAW_LINE);
//--- Set the style line
   PlotIndexSetInteger(0,PLOT_LINE_STYLE,STYLE_DOT);
//--- Set line color
   PlotIndexSetInteger(0,PLOT_LINE_COLOR,clrRed);
//--- Set line thickness
   PlotIndexSetInteger(0,PLOT_LINE_WIDTH,1);
//--- Set labels for the line
   PlotIndexSetString(0,PLOT_LABEL,"Moving Average");
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//---
   for(int i=prev_calculated;i<rates_total;i++)
     {
      MABuffer[i]=close[i];
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Custom Indicators Properties

The number of indicator buffers that can be used in a custom indicator is unlimited. But for each array, which is designated as the indicator buffer using the SetIndexBuffer() function, it's necessary to specify the data type that it will store. This may be one of the values of the ENUM_INDEXBUFFER_TYPE enumeration.

ENUM_INDEXBUFFER_TYPE

ID	Description
INDICATOR_DATA	Data to draw
INDICATOR_COLOR_INDEX	Color
INDICATOR_CALCULATIONS	Auxiliary buffers for intermediate calculations

A custom indicator has a lot of settings to provide convenient displaying. These settings are made through the assignment of corresponding indicator properties using functions IndicatorSetDouble(), IndicatorSetInteger() and IndicatorSetString(). Identifiers of indicator properties are listed in the ENUM_CUSTOMIND_PROPERTY enumeration.

ENUM_CUSTOMIND_PROPERTY_INTEGER

ID	Description	Property type
INDICATOR_DIGITS	Accuracy of drawing of indicator values	int
INDICATOR_HEIGHT	Fixed height of the indicator's window (the prep	int

ID	Description	Property type
	rocessor command #property indicator_height)	
INDICATOR_LEVELS	Number of levels in the indicator window	int
INDICATOR_LEVELCOLOR	Color of the level line	color modifier = level number
INDICATOR_LEVELSTYLE	Style of the level line	ENUM_LINE_STYLE modifier = level number
INDICATOR_LEVELWIDTH	Thickness of the level line	int modifier = level number

ID	Description	Property type
INDICATOR_FIXED_MINIMUM	Fixed minimum for the indicator window. The property can only be written by the IndicatorSetInteger() function	bool
INDICATOR_FIXED_MAXIMUM	Fixed maximum for the indicator window. The property	bool

ID	Description	Property type
	can only be written by the IndicatorSetInteger() function	

ENUM_CUSTOMIND_PROPERTY_DOUBLE

ID	Description	Property type
INDICATOR_MINIMUM	Minimum of the indicator window	double
INDICATOR_MAXIMUM	Maximum of the indicator window	double
INDICATOR_LEVELVALUE	Level value	double modifier = level number

ENUM_CUSTOMIND_PROPERTY_STRING

ID	Description	Property type
INDICATOR_SHORTNAME	Short indicator name	string
INDICATOR_LEVELTEXT	Level description	string modifier = level number

Examples:

```
//--- indicator settings
#property indicator_separate_window
#property indicator_buffers 4
#property indicator_plots   2
#property indicator_type1   DRAW_LINE
#property indicator_type2   DRAW_LINE
#property indicator_color1  clrLightSeaGreen
#property indicator_color2  clrRed
//--- input parameters
extern int KPeriod=5;
extern int DPeriod=3;
extern int Slowing=3;
//--- indicator buffers
double MainBuffer[];
double SignalBuffer[];
double HighesBuffer[];
double LowesBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,MainBuffer,INDICATOR_DATA);
   SetIndexBuffer(1,SignalBuffer,INDICATOR_DATA);
   SetIndexBuffer(2,HighesBuffer,INDICATOR_CALCULATIONS);
   SetIndexBuffer(3,LowesBuffer,INDICATOR_CALCULATIONS);
//--- set accuracy
   IndicatorSetInteger(INDICATOR_DIGITS,2);
```

```
//--- set levels
   IndicatorSetInteger(INDICATOR_LEVELS,2);
   IndicatorSetDouble(INDICATOR_LEVELVALUE,0,20);
   IndicatorSetDouble(INDICATOR_LEVELVALUE,1,80);
//--- set maximum and minimum for subwindow
   IndicatorSetDouble(INDICATOR_MINIMUM,0);
   IndicatorSetDouble(INDICATOR_MAXIMUM,100);
//--- sets first bar from which index will be drawn
   PlotIndexSetInteger(0,PLOT_DRAW_BEGIN,KPeriod+Slowing-2);
   PlotIndexSetInteger(1,PLOT_DRAW_BEGIN,KPeriod+Slowing+DPeriod);
//--- set style STYLE_DOT for second line
   PlotIndexSetInteger(1,PLOT_LINE_STYLE,STYLE_DOT);
//--- name for DataWindow and indicator subwindow label
   IndicatorSetString(INDICATOR_SHORTNAME,"Stoch("+KPeriod+","+DPeriod+","+Slowing+")"
   PlotIndexSetString(0,PLOT_LABEL,"Main");
   PlotIndexSetString(1,PLOT_LABEL,"Signal");
//--- sets drawing line to empty value
   PlotIndexSetDouble(0,PLOT_EMPTY_VALUE,0.0);
   PlotIndexSetDouble(1,PLOT_EMPTY_VALUE,0.0);
//--- initialization done
  }
```

Types of Technical Indicators

There are two ways to create an indicator handle for further accessing to its values. The first way is to directly specify a function name from the list of technical indicators. The second method using the IndicatorCreate() is to uniformly create a handle of any indicator by assigning an identifier from the ENUM_INDICATOR enumeration. Both ways of handle creation are equal, you can use the one that is most convenient in a particular case when writing a program in MQL5.

When creating an indicator of type IND_CUSTOM, the *type* field of the first element of an array of input parameters MqlParam must have the TYPE_STRING value of the enumeration ENUM_DATATYPE, while the field *string_value* of the first element must contain the name of the custom indicator.

ENUM_INDICATOR

Identifier	Indicator
IND_AC	Accelerator Oscillator
IND_AD	Accumulation/Distribution
IND_ADX	Average Directional Index
IND_ADXW	ADX by Welles Wilder
IND_ALLIGATOR	Alligator
IND_AMA	Adaptive Moving Average
IND_AO	Awesome Oscillator
IND_ATR	Average True Range
IND_BANDS	Bollinger Bands®
IND_BEARS	Bears Power
IND_BULLS	Bulls Power
IND_BWMFI	Market Facilitation Index
IND_CCI	Commodity Channel Index
IND_CHAIKIN	Chaikin Oscillator
IND_CUSTOM	Custom indicator
IND_DEMA	Double Exponential Moving Average
IND_DEMARKER	DeMarker
IND_ENVELOPES	Envelopes
IND_FORCE	Force Index
IND_FRACTALS	Fractals
IND_FRAMA	Fractal Adaptive Moving Average
IND_GATOR	Gator Oscillator

Identifier	Indicator
IND_ICHIMOKU	Ichimoku Kinko Hyo
IND_MA	Moving Average
IND_MACD	MACD
IND_MFI	Money Flow Index
IND_MOMENTUM	Momentum
IND_OBV	On Balance Volume
IND_OSMA	OsMA
IND_RSI	Relative Strength Index
IND_RVI	Relative Vigor Index
IND_SAR	Parabolic SAR
IND_STDDEV	Standard Deviation
IND_STOCHASTIC	Stochastic Oscillator
IND_TEMA	Triple Exponential Moving Average
IND_TRIX	Triple Exponential Moving Averages Oscillator
IND_VIDYA	Variable Index Dynamic Average
IND_VOLUMES	Volumes
IND_WPR	Williams' Percent Range

Data Type Identifiers

When creating an indicator handle using the IndicatorCreate() function, an array of MqlParam type must be specified as the last parameter. Accordingly, the MqlParam structure, describing indicator, contains a special field *type*. This field contains information about the data type (real, integer or string type) that are passed by a particular element of the array. The value of this field of the MqlParam structure may be one of ENUM_DATATYPE values.

ENUM_DATATYPE

Identifier	Data type
TYPE_BOOL	bool
TYPE_CHAR	char
TYPE_UCHAR	uchar
TYPE_SHORT	short
TYPE_USHORT	ushort
TYPE_COLOR	color
TYPE_INT	int
TYPE_UINT	uint
TYPE_DATETIME	datetime
TYPE_LONG	long
TYPE_ULONG	ulong
TYPE_FLOAT	float
TYPE_DOUBLE	double
TYPE_STRING	string

Each element of the array describes the corresponding input parameter of a created technical indicator, so the type and order of elements in the array must be strictly maintained in accordance with the description.

Environment State

Constants describing the current runtime environment of an mql5-program are divided into groups:

- Client terminal properties - information about the client terminal;
- Executed MQL5-program properties - mql5 program properties, which help to control its execution;
- Symbol properties - obtaining information about a symbol;
- Account properties - information about the current account;
- Testing Statistics - results of Expert Advisor testing.

Client Terminal Properties

Information about the client terminal can be obtained by two functions: TerminalInfoInteger() and TerminalInfoString(). For parameters, these functions accept values from ENUM_TERMINAL_INFO_INTEGER and ENUM_TERMINAL_INFO_STRING respectively.

ENUM_TERMINAL_INFO_INTEGER

Identifier	Description	Type
TERMINAL_BUILD	The client terminal build number	int
TERMINAL_COMMUNITY_ACCOUNT	The flag indicates the presence of MQL5.community authorization data in the terminal	bool
TERMINAL_COMMUNITY_CONNECTION	Connection to MQL5.community	bool
TERMINAL_CONNECTED	Connection to a trade server	bool
TERMINAL_DLLS_ALLOWED	Permission to use DLL	bool
TERMINAL_TRADE_ALLOWED	Permission to trade	bool
TERMINAL_EMAIL_ENABLED	Permission to send e-mails using SMTP-server and login, specified in the terminal settings	bool
TERMINAL_FTP_ENABLED	Permission to send reports using FTP-server and login, specified in the terminal settings	bool
TERMINAL_NOTIFICATIONS_ENABLED	Permission to send notifications to smartphone	bool
TERMINAL_MAXBARS	The maximal bars count on the chart	int
TERMINAL_MQID	The flag indicates the presence of MetaQuotes ID data for Push notifications	bool
TERMINAL_CODEPAGE	Number of the code page of the language installed in the client terminal	int
TERMINAL_CPU_CORES	The number of CPU cores in the system	int
TERMINAL_DISK_SPACE	Free disk space for the MQL5\Files folder of the terminal (agent), MB	int
TERMINAL_MEMORY_PHYSICAL	Physical memory in the system, MB	int
TERMINAL_MEMORY_TOTAL	Memory available to the process of the terminal (agent), MB	int

Identifier	Description	Type
TERMINAL_MEMORY_AVAILABLE	Free memory of the terminal (agent) process, MB	int
TERMINAL_MEMORY_USED	Memory used by the terminal (agent), MB	int
TERMINAL_X64	Indication of the "64-bit terminal"	bool
TERMINAL_OPENCL_SUPPORT	The version of the supported OpenCL in the format of 0x00010002 = 1.2. "0" means that OpenCL is not supported	int
TERMINAL_SCREEN_DPI	The resolution of information display on the screen is measured as number of Dots in a line per Inch (DPI). Knowing the parameter value, you can set the size of graphical objects so that they look the same on monitors with different resolution characteristics.	int
TERMINAL_SCREEN_LEFT	The left coordinate of the virtual screen. A virtual screen is a rectangle that covers all monitors. If the system has two monitors ordered from right to left, then the left coordinate of the virtual screen can be on the border of two monitors.	int
TERMINAL_SCREEN_TOP	The top coordinate of the virtual screen	int
TERMINAL_SCREEN_WIDTH	Terminal width	int
TERMINAL_SCREEN_HEIGHT	Terminal height	int
TERMINAL_LEFT	The left coordinate of the terminal relative to the virtual screen	int
TERMINAL_TOP	The top coordinate of the terminal relative to the virtual screen	int
TERMINAL_RIGHT	The right coordinate of the terminal relative to the virtual screen	int
TERMINAL_BOTTOM	The bottom coordinate of the terminal relative to the virtual screen	int

Identifier	Description	Type
TERMINAL_PING_LAST	The last known value of a ping to a trade server in microseconds. One second comprises of one million microseconds	int
TERMINAL_VPS	Indication that the terminal is launched on the MetaTrader Virtual Hosting server (MetaTrader VPS)	bool
Key identifier	**Description**	
TERMINAL_KEYSTATE_LEFT	State of the "Left arrow" key	int
TERMINAL_KEYSTATE_UP	State of the "Up arrow" key	int
TERMINAL_KEYSTATE_RIGHT	State of the "Right arrow" key	int
TERMINAL_KEYSTATE_DOWN	State of the "Down arrow" key	int
TERMINAL_KEYSTATE_SHIFT	State of the "Shift" key	int
TERMINAL_KEYSTATE_CONTROL	State of the "Ctrl" key	int
TERMINAL_KEYSTATE_MENU	State of the "Windows" key	int
TERMINAL_KEYSTATE_CAPSLOCK	State of the "CapsLock" key	int
TERMINAL_KEYSTATE_NUMLOCK	State of the "NumLock" key	int
TERMINAL_KEYSTATE_SCRLOCK	State of the "ScrollLock" key	int
TERMINAL_KEYSTATE_ENTER	State of the "Enter" key	int
TERMINAL_KEYSTATE_INSERT	State of the "Insert" key	int
TERMINAL_KEYSTATE_DELETE	State of the "Delete" key	int
TERMINAL_KEYSTATE_HOME	State of the "Home" key	int
TERMINAL_KEYSTATE_END	State of the "End" key	int
TERMINAL_KEYSTATE_TAB	State of the "Tab" key	int
TERMINAL_KEYSTATE_PAGEUP	State of the "PageUp" key	int
TERMINAL_KEYSTATE_PAGEDOWN	State of the "PageDown" key	int
TERMINAL_KEYSTATE_ESCAPE	State of the "Escape" key	int

Call to TerminalInfoInteger(TERMINAL_KEYSTATE_XXX) returns the same state code of a key as the GetKeyState() function in MSDN.

Example of scaling factor calculation:

```
//--- Creating a 1.5 inch wide button on a screen
int screen_dpi = TerminalInfoInteger(TERMINAL_SCREEN_DPI); // Find DPI of the user mor
```

```
int base_width = 144;                                    // The basic width in the s
int width      = (button_width * screen_dpi) / 96;       // Calculate the button wid
...

//--- Calculating the scaling factor as a percentage
int scale_factor=(TerminalInfoInteger(TERMINAL_SCREEN_DPI) * 100) / 96;
//--- Use of the scaling factor
width=(base_width * scale_factor) / 100;
```

In the above example, the graphical resource looks the same on monitors with different resolution characteristics. The size of control elements (buttons, dialog windows, etc.) corresponds to personalization settings.

ENUM_TERMINAL_INFO_DOUBLE

Identifier	Description	Type
TERMINAL_COMMUNITY_BALANCE	Balance in MQL5.community	double
TERMINAL_RETRANSMISSION	Percentage of resent network packets in the TCP/IP protocol for all running applications and services on the given computer. Packet loss occurs even in the fastest and correctly configured networks. In this case, there is no confirmation of packet delivery between the recipient and the sender, therefore lost packets are resent. It is not an indication of the connection quality between a particular terminal and a trade server, since the percentage is calculated for the entire network activity, including system and background activity. The TERMINAL_RETRANSMISSION value is requested from the operating system once per minute. The terminal itself does not calculate this value.	double

File operations can be performed only in two directories; corresponding paths can be obtained using the request for TERMINAL_DATA_PATH and TERMINAL_COMMONDATA_PATH properties.

ENUM_TERMINAL_INFO_STRING

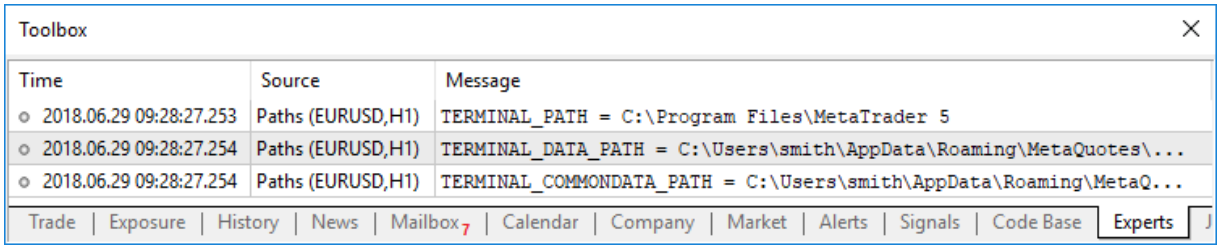
Identifier	Description	Type
TERMINAL_LANGUAGE	Language of the terminal	string
TERMINAL_COMPANY	Company name	string
TERMINAL_NAME	Terminal name	string
TERMINAL_PATH	Folder from which the terminal is started	string
TERMINAL_DATA_PATH	Folder in which terminal data are stored	string
TERMINAL_COMMONDATA_PATH	Common path for all of the terminals installed on a computer	string
TERMINAL_CPU_NAME	CPU name	string
TERMINAL_CPU_ARCHITECTURE	CPU architecture	string
TERMINAL_OS_VERSION	User's OS name	string

For a better understanding of paths, stored in properties of TERMINAL_PATH, TERMINAL_DATA_PATH and TERMINAL_COMMONDATA_PATH parameters, it is recommended to execute the script, which will return these values for the current copy of the client terminal, installed on your computer

Example: Script returns information about the client terminal paths

```
//+------------------------------------------------------------------+
//|                                          Check_TerminalPaths.mq5 |
//|                        Copyright 2009, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "2009, MetaQuotes Software Corp."
#property link      "https://www.mql5.com"
#property version   "1.00"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   Print("TERMINAL_PATH = ",TerminalInfoString(TERMINAL_PATH));
   Print("TERMINAL_DATA_PATH = ",TerminalInfoString(TERMINAL_DATA_PATH));
   Print("TERMINAL_COMMONDATA_PATH = ",TerminalInfoString(TERMINAL_COMMONDATA_PATH));
  }
```

As result of the script execution in the Experts Journal you will see a messages, like the following:



Running MQL5 Program Properties

To obtain information about the currently running mql5 program, constants from ENUM_MQL_INFO_INTEGER and ENUM_MQL_INFO_STRING are used.

For function MQLInfoInteger

ENUM_MQL_INFO_INTEGER

Identifier	Description	Type
MQL_HANDLES_USED	The current number of active object handles. These include both dynamic (created via new) and non-dynamic objects, global/local variables or class members. The more handles a program uses, the more resources it consumes.	int
MQL_MEMORY_LIMIT	Maximum possible amount of dynamic memory for MQL5 program in MB	int
MQL_MEMORY_USED	Memory used by MQL5 program in MB	int
MQL_PROGRAM_TYPE	Type of the MQL5 program	ENUM_PROGRAM_TYPE
MQL_DLLS_ALLOWED	The permission to use DLL for the given running program	bool
MQL_TRADE_ALLOWED	The permission to trade for the given running program	bool
MQL_SIGNALS_ALLOWED	The permission to modify the Signals for the	bool

Identifier	Description	Type
	given running program	
MQL_DEBUG	Indication that the program is running in the debugging mode	bool
MQL_PROFILER	Indication that the program is running in the code profiling mode	bool
MQL_TESTER	Indication that the program is running in the tester	bool
MQL_FORWARD	Indication that the program is running in the forward testing process	bool
MQL_OPTIMIZATION	Indication that the program is running in the optimization mode	bool
MQL_VISUAL_MODE	Indication that the program is running in the visual testing mode	bool
MQL_FRAME_MODE	Indication that the Expert Advisor is running in gathering optimization result frames mode	bool
MQL_LICENSE_TYPE	Type of license of the EX5 module. The license refers to the EX5 module, from which a request is made using	ENUM_LICENSE_TYPE

Identifier	Description	Type
	MQLInfoInteger(MQL_LICENSE_TYPE).	

For function MQLInfoString

ENUM_MQL_INFO_STRING

Identifier	Description	Type
MQL_PROGRAM_NAME	Name of the running mql5-program	string
MQL5_PROGRAM_PATH	Path for the given running program	string

For information about the type of the running program, values of ENUM_PROGRAM_TYPE are used.

ENUM_PROGRAM_TYPE

Identifier	Description
PROGRAM_SCRIPT	Script
PROGRAM_EXPERT	Expert
PROGRAM_INDICATOR	Indicator
PROGRAM_SERVICE	Service

ENUM_LICENSE_TYPE

Identifier	Description
LICENSE_FREE	A free unlimited version
LICENSE_DEMO	A trial version of a paid product from the Market. It works only in the strategy tester
LICENSE_FULL	A purchased licensed version allows at least 5 activations. The number of activations is specified by seller. Seller may increase the allowed number of activations
LICENSE_TIME	A version with a limited term license

Example:

```
ENUM_PROGRAM_TYPE mql_program=(ENUM_PROGRAM_TYPE)MQLInfoInteger(MQL_PROGRAM_TYPE);
```

```
   switch(mql_program)
     {
      case PROGRAM_SCRIPT:
        {
         Print(__FILE__+" is script");
         break;
        }
      case PROGRAM_EXPERT:
        {
         Print(__FILE__+" is Expert Advisor");
         break;
        }
      case PROGRAM_INDICATOR:
        {
         Print(__FILE__+" is custom indicator");
         break;
        }
      default:Print("MQL5 type value is ",mql_program);
   //---
   Print("MQLInfoInteger(MQL_MEMORY_LIMIT)=", MQLInfoInteger(MQL_MEMORY_LIMIT), " MB")
   Print("MQLInfoInteger(MQL_MEMORY_USED)=", MQLInfoInteger(MQL_MEMORY_USED), " MB");
   Print("MQLInfoInteger(MQL_HANDLES_USED)=", MQLInfoInteger(MQL_HANDLES_USED), " hand
```

Symbol Properties

To obtain the current market information there are several functions: SymbolInfoInteger(), SymbolInfoDouble() and SymbolInfoString(). The first parameter is the symbol name, the values of the second function parameter can be one of the identifiers of ENUM_SYMBOL_INFO_INTEGER, ENUM_SYMBOL_INFO_DOUBLE and ENUM_SYMBOL_INFO_STRING.

For function SymbolInfoInteger()

ENUM_SYMBOL_INFO_INTEGER

Identifier	Description	Type
SYMBOL_SUBSCRIPTION_DELAY	Symbol data arrives with a delay. The property can be requested only for symbols selected in MarketWatch (SYMBOL_SELECT = true).	bool

Identifier	Description	Type
	The ERR_MARKET_NOT_SELECTED (4302) error is generated for other symbols	
SYMBOL_SECTOR	The sector of the economy to which the asset belongs	ENUM_SYMBOL_SECTOR
SYMBOL_INDUSTRY	The industry or the economy bran	ENUM_SYMBOL_INDUSTRY

Identifier	Description	Type
	ch to which the symbol belongs	
SYMBOL_CUSTOM	It is a custom symbol - the symbol has been created synthetically based on other symbols from the Market Watch and/or external data	bool

Identifier	Description	Type
	sources	
SYMBOL_BACKGROUND_COLOR	The color of the background used for the symbol in MarketWatch	color
SYMBOL_CHART_MODE	The price type used for generating symbols bars, i.e. Bid or Last	ENUM_SYMBOL_CHART_MODE
SYMBOL_EXIST	Symbol with this name	bool

Identifier	Description	Type
	exists	
SYMBOL_SELECT	Symbol is selected in MarketWatch	bool
SYMBOL_VISIBLE	Symbol is visible in MarketWatch. Some symbols (mostly, these are cross rates required for calculation of margin	bool

Identifier	Description	Type
	requirements or profits in deposit currency) are selected automatically, but may not be visible in MarketWatch. To be displayed such symbols have to be explicitly sele	

Identifier	Description	Type
	cted.	
SYMBOL_SESSION_DEALS	Number of deals in the current session	long
SYMBOL_SESSION_BUY_ORDERS	Number of Buy orders at the moment	long
SYMBOL_SESSION_SELL_ORDERS	Number of Sell orders at the moment	long
SYMBOL_VOLUME	Volume of the last deal	long
SYMBOL_VOLUMEHIGH	Maximal day	long

Identifier	Description	Type
	volume	
SYMBOL_VOLUMELOW	Minimal day volume	long
SYMBOL_TIME	Time of the last quote	datetime
SYMBOL_TIME_MSC	Time of the last quote in milliseconds since 1970.01.01	long
SYMBOL_DIGITS	Digits after a decimal point	int
SYMBOL_SPREAD_FLOAT	Indication of a floating spread	bool

Identifier	Description	Type
SYMBOL_SPREAD	Spread value in points	int
SYMBOL_TICKS_BOOKDEPTH	Maximal number of requests shown in Depth of Market. For symbols that have no queue of requests, the value is equal to zero.	int
SYMBOL_TRADE_CALC_MODE	Contract price	ENUM_SYMBOL_CALC_MODE

Identifier	Description	Type
	calculation mode	
SYMBOL_TRADE_MODE	Order execution type	ENUM_SYMBOL_TRADE_MODE
SYMBOL_START_TIME	Date of the symbol trade beginning (usually used for futures)	datetime
SYMBOL_EXPIRATION_TIME	Date of the symbol trade end (usually used for futures)	datetime

Identifier	Description	Type
SYMBOL_TRADE_STOPS_LEVEL	Minimal indention in points from the current close price to place Stop orders	int
SYMBOL_TRADE_FREEZE_LEVEL	Distance to freeze trade operations in points	int
SYMBOL_TRADE_EXEMODE	Deal execution mode	ENUM_SYMBOL_TRADE_EXECUTION
SYMBOL_SWAP_MODE	Swap calculati	ENUM_SYMBOL_SWAP_MODE

Identifier	Description	Type
	on model	
SYMBOL_SWAP_ROLLOVER3DAYS	The day of week to charge 3-day swap rollover	ENUM_DAY_OF_WEEK

Identifier	Description	Type
	properties in the terminal	
SYMBOL_PATH	Path in the symbol tree	string

A symbol price chart can be based on Bid or Last prices. The price selected for symbol charts also affects the generation and display of bars in the terminal. Possible values of the SYMBOL_CHART_MODE property are described in ENUM_SYMBOL_CHART_MODE

ENUM_SYMBOL_CHART_MODE

Identifier	Description
SYMBOL_CHART_MODE_BID	Bars are based on Bid prices
SYMBOL_CHART_MODE_LAST	Bars are based on Last prices

For each symbol several expiration modes of pending orders can be specified. A flag is matched to each mode. Flags can be combined using the operation of logical **OR** (|), for example, SYMBOL_EXPIRATION_GTC|SYMBOL_EXPIRATION_SPECIFIED. In order to check whether a certain mode is allowed for the symbol, the result of the logical **AND** (&) should be compared to the mode flag.

If flag SYMBOL_EXPIRATION_SPECIFIED is specified for a symbol, then while sending a pending order, you may specify the moment this pending order is valid till.

Identifier	Value	Description
SYMBOL_EXPIRATION_GTC	1	The order is valid during the unlimited time period, until it is explicitly canceled
SYMBOL_EXPIRATION_DAY	2	The order is valid till the end of the day
SYMBOL_EXPIRATION_SPECIFIED	4	The expiration time is specified in the order
SYMBOL_EXPIRATION_SPECIFIED_DAY	8	The expiration date is specified in the order

Example:

```
//+------------------------------------------------------------------+
//| Checks if the specified expiration mode is allowed               |
```

```
//+------------------------------------------------------------------+
bool IsExpirationTypeAllowed(string symbol,int exp_type)
  {
//--- Obtain the value of the property that describes allowed expiration modes
   int expiration=(int)SymbolInfoInteger(symbol,SYMBOL_EXPIRATION_MODE);
//--- Return true, if mode exp_type is allowed
   return((expiration&exp_type)==exp_type);
  }
```

If the SYMBOL_EXPIRATION_MODE property is set to SYMBOL_EXPIRATION_GTC (good till canceled), the expiration of pending orders, as well as of Stop Loss/Take Profit orders should be additionally set using the ENUM_SYMBOL_ORDER_GTC_MODE enumeration.

ENUM_SYMBOL_ORDER_GTC_MODE

Identifier	Description
SYMBOL_ORDERS_GTC	Pending orders and Stop Loss/Take Profit levels are valid for an unlimited period until their explicit cancellation
SYMBOL_ORDERS_DAILY	Orders are valid during one trading day. At the end of the day, all Stop Loss and Take Profit levels, as well as pending orders are deleted.
SYMBOL_ORDERS_DAILY_EXCLUDING_STOPS	When a trade day changes, only pending orders are deleted, while Stop Loss and Take Profit levels are preserved.

When sending an order, we can specify the filling policy of a volume set in the order. The possible volume-based order execution options for each symbol are specified in the table. It is possible to set several modes for each instrument via a combination of flags. The combination of flags is expressed by the logical **OR** (|) operation, for example SYMBOL_FILLING_FOK|SYMBOL_FILLING_IOC. To check if a specific mode is allowed for an instrument, compare the logical **AND** (&) result with the mode flag - example.

Fill policy	ID	Value	Description
			on_SYMBOL_TRADE_EXECUTION_MARKET).

When sending a trade request using the OrderSend() function, the necessary volume execution policy can be set in the *type_filling* field, namely in the special MqlTradeRequest structure. The values from the ENUM_ORDER_TYPE_FILLING enumeration are available. If no filling type is specified, ORDER_FILLING_RETURN is automatically set in the trade request. The ORDER_FILLING_RETURN filling

type is enabled in any execution mode except for "Market execution" (SYMBOL_TRADE_EXECUTION_MARKET).

While sending a trade request for execution **at the current time** (time in force), we should keep in mind that financial markets provide no guarantee that the entire requested volume is available for a certain financial instrument at the desired price. Therefore, trading operations in real time are regulated using the price and volume execution modes. The modes, or execution policies, define the rules for cases when the price has changed or the requested volume cannot be completely fulfilled **at the moment**.

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
Execution mode (Request Execution)	Executing a market order at the price previously received from the broker. Prices for a certain market order are requested from the broker before the order is sent. Upon receiving the prices, order execution at the given price can be	SYMBOL_TRADE_EXECUTION_REQUEST

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	either confirmed or rejected.	
Instant Execution	Executing a market order at the specified price immediately. When sending a trade request to be executed, the platform automatically adds the current prices to the order. • If the broker ac	SYMBOL_TRADE_EXECUTION_INSTANT

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	cepts the price, the order is executed. • If the broker does	

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	not accept the requested price, a "Requote" is sent_ the b	

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	r o k e r r e t u r n s p r i c e s , a t w h i c h t h i s o r d e r c a n b e e x e c u t e	

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	d.	
Market Execution	A broker makes a decision about the order execution price without any additional discussion with the trader. Sending the order in such a mode means advance consent to its execution at this price.	SYMBOL_TRADE_EXECUTION_MARKET
Exchange Execution	Trade operations are executed at the prices of the current	SYMBOL_TRADE_EXECUTION_EXCHANGE

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	market offers.	

Before sending an order with the current execution time, for the correct setting of the ORDER_TYPE_FILLING value (volume execution type), you can use the SymbolInfoInteger() function with each financial instrument to get the SYMBOL_FILLING_MODE property value, which shows volume execution types allowed for the symbol as a combination of flags. The ORDER_FILLING_RETURN filling type is enabled at all times except for the "Market execution" mode (SYMBOL_TRADE_EXECUTION_MARKET).

The use of filling types depending on the execution mode can be shown as the following table:

Type of Execution\Fill Policy	Fill or Kill (FOK ORDER_FILLING_FOK)	Immediate or Cancel (IOC ORDER_FILLING_IOC)	Return (Return ORDER_FILLING_RETURN)
Instant Execution (SYMBOL_TRADE_EXECUTION_INSTANT)	+ (regardless of a symbol setting)	+ (regardless of a symbol setting)	+ (always)
Request Execution SYMBOL_TRADE_EXECUTION_REQUEST	+ (regardless of a symbol setting)	+ (regardless of a symbol setting)	+ (always)
Market Execution SYMBOL_TRADE_EXECUTION_MARKET	+ (set in the symbol settings)	+ (set in the symbol settings)	- (disabled regardless of the symbol settings)
Exchange Execution SYMBOL_TRADE_EXECUTION_EXCHANGE	+ (set in the symbol settings)	+ (set in the symbol settings)	+ (always)

In case of pending orders, the ORDER_FILLING_RETURN filling type should be used regardless of an execution type (SYMBOL_TRADE_EXEMODE), since such orders are not meant for execution at the time of sending. When using pending orders, a trader agrees in advance that, when conditions for a deal on this order are met, the broker will use the filling type supported by the exchange.

Example:

```
//+------------------------------------------------------------------+
//| check if a given filling mode is allowed                         |
//+------------------------------------------------------------------+
bool IsFillingTypeAllowed(string symbol,int fill_type)
  {
//--- get the value of the property describing the filling mode
   int filling=(int)SymbolInfoInteger(symbol,SYMBOL_FILLING_MODE);
//--- return 'true' if the fill_type mode is allowed
```

```
   return((filling&fill_type)==fill_type);
  }
```

When sending a trade request using OrderSend() function, an order type from ENUM_ORDER_TYPE enumeration should be specified for some operations. Not all types of orders may be allowed for a specific symbol. SYMBOL_ORDER_MODE property describes the flags of the allowed order types.

Identifier	Value	Description
SYMBOL_ORDER_MARKET	1	Market orders are allowed (Buy and Sell)
SYMBOL_ORDER_LIMIT	2	Limit orders are allowed (Buy Limit and Sell Limit)
SYMBOL_ORDER_STOP	4	Stop orders are allowed (Buy Stop and Sell Stop)
SYMBOL_ORDER_STOP_LIMIT	8	Stop-limit orders are allowed (Buy Stop Limit and Sell Stop Limit)
SYMBOL_ORDER_SL	16	Stop Loss is allowed
SYMBOL_ORDER_TP	32	Take Profit is allowed
SYMBOL_ORDER_CLOSEBY	64	Close By operation is allowed, i.e. closing a position by another open position on the same instruments but in the opposite direction. The property is set for accounts with the hedging accounting system (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)

Example:

```
//+------------------------------------------------------------------+
//| The function prints out order types allowed for a symbol         |
//+------------------------------------------------------------------+
void Check_SYMBOL_ORDER_MODE(string symbol)
  {
//--- receive the value of the property describing allowed order types
   int symbol_order_mode=(int)SymbolInfoInteger(symbol,SYMBOL_ORDER_MODE);
//--- check for market orders (Market Execution)
   if((SYMBOL_ORDER_MARKET&symbol_order_mode)==SYMBOL_ORDER_MARKET)
      Print(symbol+": Market orders are allowed (Buy and Sell)");
//--- check for Limit orders
   if((SYMBOL_ORDER_LIMIT&symbol_order_mode)==SYMBOL_ORDER_LIMIT)
      Print(symbol+": Buy Limit and Sell Limit orders are allowed");
//--- check for Stop orders
   if((SYMBOL_ORDER_STOP&symbol_order_mode)==SYMBOL_ORDER_STOP)
      Print(symbol+": Buy Stop and Sell Stop orders are allowed");
```

```
//--- check for Stop Limit orders
   if((SYMBOL_ORDER_STOP_LIMIT&symbol_order_mode)==SYMBOL_ORDER_STOP_LIMIT)
      Print(symbol+": Buy Stop Limit and Sell Stop Limit orders are allowed");
//--- check if placing a Stop Loss orders is allowed
   if((SYMBOL_ORDER_SL&symbol_order_mode)==SYMBOL_ORDER_SL)
      Print(symbol+": Stop Loss orders are allowed");
//--- check if placing a Take Profit orders is allowed
   if((SYMBOL_ORDER_TP&symbol_order_mode)==SYMBOL_ORDER_TP)
      Print(symbol+": Take Profit orders are allowed");
//--- check if closing a position by an opposite one is allowed
   if((SYMBOL_ORDER_TP&symbol_order_mode)==SYMBOL_ORDER_CLOSEBY)
      Print(symbol+": Close by allowed");
//---
  }
```

The ENUM_SYMBOL_CALC_MODE enumeration is used for obtaining information about how the margin requirements for a symbol are calculated.

ENUM_SYMBOL_CALC_MODE

Identifier	Description	Formula

Identifier	Description	Formula
	the volume, current market price, contract size and liquidity ratio. The value is included into Assets, which are added to Equity. Open positions of such symbols increase the Free Margin amount and are	

Identifier	Description	Formula
	used as additional margin (collateral) for open positions of tradable instruments.	

There are several symbol trading modes. Information about trading modes of a certain symbol is reflected in the values of enumeration ENUM_SYMBOL_TRADE_MODE.

ENUM_SYMBOL_TRADE_MODE

Identifier	Description
SYMBOL_TRADE_MODE_DISABLED	Trade is disabled for the symbol
SYMBOL_TRADE_MODE_LONGONLY	Allowed only long positions
SYMBOL_TRADE_MODE_SHORTONLY	Allowed only short positions
SYMBOL_TRADE_MODE_CLOSEONLY	Allowed only position close operations
SYMBOL_TRADE_MODE_FULL	No trade restrictions

Possible deal execution modes for a certain symbol are defined in enumeration ENUM_SYMBOL_TRADE_EXECUTION.

ENUM_SYMBOL_TRADE_EXECUTION

Identifier	Description
SYMBOL_TRADE_EXECUTION_REQUEST	Execution by request
SYMBOL_TRADE_EXECUTION_INSTANT	Instant execution

Identifier	Description
SYMBOL_TRADE_EXECUTION_MARKET	Market execution
SYMBOL_TRADE_EXECUTION_EXCHANGE	Exchange execution

Methods of swap calculation at position transfer are specified in enumeration ENUM_SYMBOL_SWAP_MODE. The method of swap calculation determines the units of measure of the SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT parameters. For example, if swaps are charged in the client deposit currency, then the values of those parameters are specified as an amount of money in the client deposit currency.

ENUM_SYMBOL_SWAP_MODE

Identifier	Description
SYMBOL_SWAP_MODE_DISABLED	Swaps disabled (no swaps)
SYMBOL_SWAP_MODE_POINTS	Swaps are charged in points
SYMBOL_SWAP_MODE_CURRENCY_SYMBOL	Swaps are charged in money in base currency of the symbol
SYMBOL_SWAP_MODE_CURRENCY_MARGIN	Swaps are charged in money in margin currency of the symbol
SYMBOL_SWAP_MODE_CURRENCY_DEPOSIT	Swaps are charged in money, in client deposit currency
SYMBOL_SWAP_MODE_INTEREST_CURRENT	Swaps are charged as the specified annual interest from the instrument price at calculation of swap (standard bank year is 360 days)
SYMBOL_SWAP_MODE_INTEREST_OPEN	Swaps are charged as the specified annual interest from the open price of position (standard bank year is 360 days)
SYMBOL_SWAP_MODE_REOPEN_CURRENT	Swaps are charged by reopening positions. At the end of a trading day the position is closed. Next day it is reopened by the close price +/- specified number of points (parameters SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT)
SYMBOL_SWAP_MODE_REOPEN_BID	Swaps are charged by reopening positions. At the end of a trading day the position is closed. Next day it is reopened by the current Bid price +/- specified number of points (parameters SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT)

Values of the ENUM_DAY_OF_WEEK enumeration are used for specifying days of week.

ENUM_DAY_OF_WEEK

Identifier	Description
SUNDAY	Sunday
MONDAY	Monday
TUESDAY	Tuesday
WEDNESDAY	Wednesday
THURSDAY	Thursday
FRIDAY	Friday
SATURDAY	Saturday

An option is a contract, which gives the right, but not the obligation, to buy or sell an underlying asset (goods, stocks, futures, etc.) at a specified price on or before a specific date. The following enumerations describe option properties, including the option type and the right arising from it.

ENUM_SYMBOL_OPTION_RIGHT

Identifier	Description
SYMBOL_OPTION_RIGHT_CALL	A call option gives you the right to buy an asset at a specified price
SYMBOL_OPTION_RIGHT_PUT	A put option gives you the right to sell an asset at a specified price

ENUM_SYMBOL_OPTION_MODE

Identifier	Description
SYMBOL_OPTION_MODE_EUROPEAN	European option may only be exercised on a specified date (expiration, execution date, delivery date)
SYMBOL_OPTION_MODE_AMERICAN	American option may be exercised on any trading day or before expiry. The period within which a buyer can exercise the option is specified for it

Financial instruments are categorized by sectors of the economy. An economic sector is a part of economic activity which has specific characteristics, economic goals, functions and behavior, which allow separating this sector from other parts of the economy. ENUM_SYMBOL_SECTOR lists the economic sectors which a trading instruments can belong to.

ENUM_SYMBOL_SECTOR

ID	Description
SECTOR_UNDEFINED	Undefined
SECTOR_BASIC_MATERIALS	Basic materials
SECTOR_COMMUNICATION_SERVICES	Communication services
SECTOR_CONSUMER_CYCLICAL	Consumer cyclical
SECTOR_CONSUMER_DEFENSIVE	Consumer defensive
SECTOR_CURRENCY	Currencies
SECTOR_CURRENCY_CRYPTO	Cryptocurrencies
SECTOR_ENERGY	Energy
SECTOR_FINANCIAL	Finance
SECTOR_HEALTHCARE	Healthcare
SECTOR_INDUSTRIALS	Industrials
SECTOR_REAL_ESTATE	Real estate
SECTOR_TECHNOLOGY	Technology
SECTOR_UTILITIES	Utilities

Each financial instrument can be assigned to a specific type of industry or economy branch. An industry is a branch of an economy that produces a closely related set of raw materials, goods, or services. ENUM_SYMBOL_INDUSTRY lists industries which a trading instrument can belong to.

ENUM_SYMBOL_INDUSTRY

ID	Description
INDUSTRY_UNDEFINED	Undefined
Basic materials	
INDUSTRY_AGRICULTURAL_INPUTS	Agricultural inputs
INDUSTRY_ALUMINIUM	Aluminium
INDUSTRY_BUILDING_MATERIALS	Building materials
INDUSTRY_CHEMICALS	Chemicals
INDUSTRY_COKING_COAL	Coking coal
INDUSTRY_COPPER	Copper
INDUSTRY_GOLD	Gold
INDUSTRY_LUMBER_WOOD	Lumber and wood production

ID	Description
INDUSTRY_INDUSTRIAL_METALS	Other industrial metals and mining
INDUSTRY_PRECIOUS_METALS	Other precious metals and mining
INDUSTRY_PAPER	Paper and paper products
INDUSTRY_SILVER	Silver
INDUSTRY_SPECIALTY_CHEMICALS	Specialty chemicals
INDUSTRY_STEEL	Steel
Communication services	
INDUSTRY_ADVERTISING	Advertising agencies
INDUSTRY_BROADCASTING	Broadcasting
INDUSTRY_GAMING_MULTIMEDIA	Electronic gaming and multimedia
INDUSTRY_ENTERTAINMENT	Entertainment
INDUSTRY_INTERNET_CONTENT	Internet content and information
INDUSTRY_PUBLISHING	Publishing
INDUSTRY_TELECOM	Telecom services
Consumer cyclical	
INDUSTRY_APPAREL_MANUFACTURING	Apparel manufacturing
INDUSTRY_APPAREL_RETAIL	Apparel retail
INDUSTRY_AUTO_MANUFACTURERS	Auto manufacturers
INDUSTRY_AUTO_PARTS	Auto parts
INDUSTRY_AUTO_DEALERSHIP	Auto and truck dealerships
INDUSTRY_DEPARTMENT_STORES	Department stores
INDUSTRY_FOOTWEAR_ACCESSORIES	Footwear and accessories
INDUSTRY_FURNISHINGS	Furnishing, fixtures and appliances
INDUSTRY_GAMBLING	Gambling
INDUSTRY_HOME_IMPROV_RETAIL	Home improvement retail
INDUSTRY_INTERNET_RETAIL	Internet retail
INDUSTRY_LEISURE	Leisure
INDUSTRY_LODGING	Lodging
INDUSTRY_LUXURY_GOODS	Luxury goods
INDUSTRY_PACKAGING_CONTAINERS	Packaging and containers

ID	Description
INDUSTRY_PERSONAL_SERVICES	Personal services
INDUSTRY_RECREATIONAL_VEHICLES	Recreational vehicles
INDUSTRY_RESIDENT_CONSTRUCTION	Residential construction
INDUSTRY_RESORTS_CASINOS	Resorts and casinos
INDUSTRY_RESTAURANTS	Restaurants
INDUSTRY_SPECIALTY_RETAIL	Specialty retail
INDUSTRY_TEXTILE_MANUFACTURING	Textile manufacturing
INDUSTRY_TRAVEL_SERVICES	Travel services
Consumer defensive	
INDUSTRY_BEVERAGES_BREWERS	Beverages - Brewers
INDUSTRY_BEVERAGES_NON_ALCO	Beverages - Non-alcoholic
INDUSTRY_BEVERAGES_WINERIES	Beverages - Wineries and distilleries
INDUSTRY_CONFECTIONERS	Confectioners
INDUSTRY_DISCOUNT_STORES	Discount stores
INDUSTRY_EDUCATION_TRAINIG	Education and training services
INDUSTRY_FARM_PRODUCTS	Farm products
INDUSTRY_FOOD_DISTRIBUTION	Food distribution
INDUSTRY_GROCERY_STORES	Grocery stores
INDUSTRY_HOUSEHOLD_PRODUCTS	Household and personal products
INDUSTRY_PACKAGED_FOODS	Packaged foods
INDUSTRY_TOBACCO	Tobacco
Energy	
INDUSTRY_OIL_GAS_DRILLING	Oil and gas drilling
INDUSTRY_OIL_GAS_EP	Oil and gas extraction and processing
INDUSTRY_OIL_GAS_EQUIPMENT	Oil and gas equipment and services
INDUSTRY_OIL_GAS_INTEGRATED	Oil and gas integrated
INDUSTRY_OIL_GAS_MIDSTREAM	Oil and gas midstream
INDUSTRY_OIL_GAS_REFINING	Oil and gas refining and marketing
INDUSTRY_THERMAL_COAL	Thermal coal
INDUSTRY_URANIUM	Uranium

ID	Description
Finance	
INDUSTRY_EXCHANGE_TRADED_FUND	Exchange traded fund
INDUSTRY_ASSETS_MANAGEMENT	Assets management
INDUSTRY_BANKS_DIVERSIFIED	Banks - Diversified
INDUSTRY_BANKS_REGIONAL	Banks - Regional
INDUSTRY_CAPITAL_MARKETS	Capital markets
INDUSTRY_CLOSE_END_FUND_DEBT	Closed-End fund - Debt
INDUSTRY_CLOSE_END_FUND_EQUITY	Closed-end fund - Equity
INDUSTRY_CLOSE_END_FUND_FOREIGN	Closed-end fund - Foreign
INDUSTRY_CREDIT_SERVICES	Credit services
INDUSTRY_FINANCIAL_CONGLOMERATE	Financial conglomerates
INDUSTRY_FINANCIAL_DATA_EXCHANGE	Financial data and stock exchange
INDUSTRY_INSURANCE_BROKERS	Insurance brokers
INDUSTRY_INSURANCE_DIVERSIFIED	Insurance - Diversified
INDUSTRY_INSURANCE_LIFE	Insurance - Life
INDUSTRY_INSURANCE_PROPERTY	Insurance - Property and casualty
INDUSTRY_INSURANCE_REINSURANCE	Insurance - Reinsurance
INDUSTRY_INSURANCE_SPECIALTY	Insurance - Specialty
INDUSTRY_MORTGAGE_FINANCE	Mortgage finance
INDUSTRY_SHELL_COMPANIES	Shell companies
Healthcare	
INDUSTRY_BIOTECHNOLOGY	Biotechnology
INDUSTRY_DIAGNOSTICS_RESEARCH	Diagnostics and research
INDUSTRY_DRUGS_MANUFACTURERS	Drugs manufacturers - general
INDUSTRY_DRUGS_MANUFACTURERS_SPEC	Drugs manufacturers - Specialty and generic
INDUSTRY_HEALTHCARE_PLANS	Healthcare plans
INDUSTRY_HEALTH_INFORMATION	Health information services
INDUSTRY_MEDICAL_FACILITIES	Medical care facilities
INDUSTRY_MEDICAL_DEVICES	Medical devices
INDUSTRY_MEDICAL_DISTRIBUTION	Medical distribution

ID	Description
INDUSTRY_MEDICAL_INSTRUMENTS	Medical instruments and supplies
INDUSTRY_PHARM_RETAILERS	Pharmaceutical retailers
Industrials	
INDUSTRY_AEROSPACE_DEFENSE	Aerospace and defense
INDUSTRY_AIRLINES	Airlines
INDUSTRY_AIRPORTS_SERVICES	Airports and air services
INDUSTRY_BUILDING_PRODUCTS	Building products and equipment
INDUSTRY_BUSINESS_EQUIPMENT	Business equipment and supplies
INDUSTRY_CONGLOMERATES	Conglomerates
INDUSTRY_CONSULTING_SERVICES	Consulting services
INDUSTRY_ELECTRICAL_EQUIPMENT	Electrical equipment and parts
INDUSTRY_ENGINEERING_CONSTRUCTION	Engineering and construction
INDUSTRY_FARM_HEAVY_MACHINERY	Farm and heavy construction machinery
INDUSTRY_INDUSTRIAL_DISTRIBUTION	Industrial distribution
INDUSTRY_INFRASTRUCTURE_OPERATIONS	Infrastructure operations
INDUSTRY_FREIGHT_LOGISTICS	Integrated freight and logistics
INDUSTRY_MARINE_SHIPPING	Marine shipping
INDUSTRY_METAL_FABRICATION	Metal fabrication
INDUSTRY_POLLUTION_CONTROL	Pollution and treatment controls
INDUSTRY_RAILROADS	Railroads
INDUSTRY_RENTAL_LEASING	Rental and leasing services
INDUSTRY_SECURITY_PROTECTION	Security and protection services
INDUSTRY_SPEALITY_BUSINESS_SERVICES	Specialty business services
INDUSTRY_SPEALITY_MACHINERY	Specialty industrial machinery
INDUSTRY_STUFFING_EMPLOYMENT	Stuffing and employment services
INDUSTRY_TOOLS_ACCESSORIES	Tools and accessories
INDUSTRY_TRUCKING	Trucking
INDUSTRY_WASTE_MANAGEMENT	Waste management
Real estate	
INDUSTRY_REAL_ESTATE_DEVELOPMENT	Real estate - Development

ID	Description
INDUSTRY_REAL_ESTATE_DIVERSIFIED	Real estate - Diversified
INDUSTRY_REAL_ESTATE_SERVICES	Real estate services
INDUSTRY_REIT_DIVERSIFIED	REIT - Diversified
INDUSTRY_REIT_HEALTCARE	REIT - Healthcase facilities
INDUSTRY_REIT_HOTEL_MOTEL	REIT - Hotel and motel
INDUSTRY_REIT_INDUSTRIAL	REIT - Industrial
INDUSTRY_REIT_MORTAGE	REIT - Mortgage
INDUSTRY_REIT_OFFICE	REIT - Office
INDUSTRY_REIT_RESIDENTAL	REIT - Residential
INDUSTRY_REIT_RETAIL	REIT - Retail
INDUSTRY_REIT_SPECIALITY	REIT - Specialty
Technology	
INDUSTRY_COMMUNICATION_EQUIPMENT	Communication equipment
INDUSTRY_COMPUTER_HARDWARE	Computer hardware
INDUSTRY_CONSUMER_ELECTRONICS	Consumer electronics
INDUSTRY_ELECTRONIC_COMPONENTS	Electronic components
INDUSTRY_ELECTRONIC_DISTRIBUTION	Electronics and computer distribution
INDUSTRY_IT_SERVICES	Information technology services
INDUSTRY_SCIENTIFIC_INSTRUMENTS	Scientific and technical instruments
INDUSTRY_SEMICONDUCTOR_EQUIPMENT	Semiconductor equipment and materials
INDUSTRY_SEMICONDUCTORS	Semiconductors
INDUSTRY_SOFTWARE_APPLICATION	Software - Application
INDUSTRY_SOFTWARE_INFRASTRUCTURE	Software - Infrastructure
INDUSTRY_SOLAR	Solar
Utilities	
INDUSTRY_UTILITIES_DIVERSIFIED	Utilities - Diversified
INDUSTRY_UTILITIES_POWERPRODUCERS	Utilities - Independent power producers
INDUSTRY_UTILITIES_RENEWABLE	Utilities - Renewable
INDUSTRY_UTILITIES_REGULATED_ELECTRIC	Utilities - Regulated electric
INDUSTRY_UTILITIES_REGULATED_GAS	Utilities - Regulated gas

ID	Description
INDUSTRY_UTILITIES_REGULATED_WATER	Utilities - Regulated water
INDUSTRY_UTILITIES_FIRST	Start of the utilities services types enumeration. Corresponds to INDUSTRY_UTILITIES_DIVERSIFIED.
INDUSTRY_UTILITIES_LAST	End of the utilities services types enumeration. Corresponds to INDUSTRY_UTILITIES_REGULATED_WATER.

Account Properties

To obtain information about the current account there are several functions: AccountInfoInteger(), AccountInfoDouble() and AccountInfoString(). The function parameter values can accept values from the corresponding ENUM_ACCOUNT_INFO enumerations.

For the function AccountInfoInteger()

ENUM_ACCOUNT_INFO_INTEGER

Identifier	Description	Type
ACCOUNT_LOGIN	Account number	long
ACCOUNT_TRADE_MODE	Account trade mode	ENUM_ACCOUNT_TRADE_MODE
ACCOUNT_LEVERAGE	Account leverage	long
ACCOUNT_LIMIT_ORDERS	Maximum allowed number of active pending orders	int
ACCOUNT_MARGIN_SO_MODE	Mode for setting the minimal allowed margin	ENUM_ACCOUNT_STOPOUT_MODE
ACCOUNT_TRADE_ALLOWED	Allowed trade for the current account	bool
ACCOUNT_TRADE_EXPERT	Allowed trade for an Expert Advisor	bool

Identifier	Description	Type
ACCOUNT_MARGIN_MODE	Margin calculation mode	ENUM_ACCOUNT_MARGIN_MODE
ACCOUNT_CURRENCY_DIGITS	The number of decimal places in the account currency, which are required for an accurate display of trading results	int
ACCOUNT_FIFO_CLOSE	An indication showing that positions can only be closed by FIFO rule. If the property value is set to true, then each symbol positions will be closed in the	bool

Identifier	Description	Type
	same order, in which they are opened, starting with the oldest one. In case of an attempt to close positions in a different order, the trader will receive an appropriate error. For accounts with the non-hedging position accounting mode (ACCOUNT_MARGIN_MODE!=ACCOUN	

Identifier	Description	Type
	T_MARGIN_MODE_RETAIL_HEDGING), the property value is always false.	
ACCOUNT_HEDGE_ALLOWED	Allowed opposite positions on a single symbol	bool

For the function AccountInfoDouble()

ENUM_ACCOUNT_INFO_DOUBLE

Identifier	Description	Type
ACCOUNT_BALANCE	Account balance in the deposit currency	double
ACCOUNT_CREDIT	Account credit in the deposit currency	double
ACCOUNT_PROFIT	Current profit of an account in the deposit currency	double

Identifier	Description	Type
ACCOUNT_EQUITY	Account equity in the deposit currency	double
ACCOUNT_MARGIN	Account margin used in the deposit currency	double
ACCOUNT_MARGIN_FREE	Free margin of an account in the deposit currency	double
ACCOUNT_MARGIN_LEVEL	Account margin level in percents	double
ACCOUNT_MARGIN_SO_CALL	Margin call level. Depending on the set ACCOUNT_MARGIN_SO_MODE is expressed in percents or in the deposit currency	double

Identifier	Description	Type
ACCOUNT_MARGIN_SO_SO	Margin stop out level. Depending on the set ACCOUNT_MARGIN_SO_MODE is expressed in percents or in the deposit currency	double
ACCOUNT_MARGIN_INITIAL	Initial margin. The amount reserved on an account to cover the margin of all pending orders	double
ACCOUNT_MARGIN_MAINTENANCE	Maintenance margin. The minimum equity reserved on an account to cover the	double

Identifier	Description	Type
	minimum amount of all open positions	
ACCOUNT_ASSETS	The current assets of an account	double
ACCOUNT_LIABILITIES	The current liabilities on an account	double
ACCOUNT_COMMISSION_BLOCKED	The current blocked commission amount on an account	double

For function AccountInfoString()

ENUM_ACCOUNT_INFO_STRING

Identifier	Description	Type
ACCOUNT_NAME	Client name	string
ACCOUNT_SERVER	Trade server name	string
ACCOUNT_CURRENCY	Account currency	string
ACCOUNT_COMPANY	Name of a compan	string

Identifier	Description	Type
	y that serves the account	

There are several types of accounts that can be opened on a trade server. The type of account on which an MQL5 program is running can be found out using the ENUM_ACCOUNT_TRADE_MODE enumeration.

ENUM_ACCOUNT_TRADE_MODE

Identifier	Description
ACCOUNT_TRADE_MODE_DEMO	Demo account
ACCOUNT_TRADE_MODE_CONTEST	Contest account
ACCOUNT_TRADE_MODE_REAL	Real account

In case equity is not enough for maintaining open positions, the Stop Out situation, i.e. forced closing occurs. The minimum margin level at which Stop Out occurs can be set in percentage or in monetary terms. To find out the mode set for the account use the ENUM_ACCOUNT_STOPOUT_MODE enumeration.

ENUM_ACCOUNT_STOPOUT_MODE

Identifier	Description
ACCOUNT_STOPOUT_MODE_PERCENT	Account stop out mode in percents
ACCOUNT_STOPOUT_MODE_MONEY	Account stop out mode in money

ENUM_ACCOUNT_MARGIN_MODE

Identifier	Description
ACCOUNT_MARGIN_MODE_RETAIL_NETTING	Used for the OTC markets to interpret positions in the "netting" mode (only one position can exist for one symbol). The margin is calculated based on the symbol type (SYMBOL_TRADE_CALC_MODE).
ACCOUNT_MARGIN_MODE_EXCHANGE	Used for the exchange markets. Margin is calculated based on the discounts specified in symbol settings. Discounts are set by the broker, but not less than the values set by the exchange.
ACCOUNT_MARGIN_MODE_RETAIL_HEDGING	Used for the exchange markets where individual positions are possible (hedging, multiple positions can exist for one symbol). The margin is calculated based on the symbol

Identifier	Description
	type (SYMBOL_TRADE_CALC_MODE) taking into account the hedged margin (SYMBOL_MARGIN_HEDGED).

An example of the script that outputs a brief account information.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Name of the company
   string company=AccountInfoString(ACCOUNT_COMPANY);
//--- Name of the client
   string name=AccountInfoString(ACCOUNT_NAME);
//--- Account number
   long login=AccountInfoInteger(ACCOUNT_LOGIN);
//--- Name of the server
   string server=AccountInfoString(ACCOUNT_SERVER);
//--- Account currency
   string currency=AccountInfoString(ACCOUNT_CURRENCY);
//--- Demo, contest or real account
   ENUM_ACCOUNT_TRADE_MODE account_type=(ENUM_ACCOUNT_TRADE_MODE)AccountInfoInteger(AC
//--- Now transform the value of  the enumeration into an understandable form
   string trade_mode;
   switch(account_type)
     {
      case  ACCOUNT_TRADE_MODE_DEMO:
         trade_mode="demo";
         break;
      case  ACCOUNT_TRADE_MODE_CONTEST:
         trade_mode="contest";
         break;
      default:
         trade_mode="real";
         break;
     }
//--- Stop Out is set in percentage or money
   ENUM_ACCOUNT_STOPOUT_MODE stop_out_mode=(ENUM_ACCOUNT_STOPOUT_MODE)AccountInfoInteg
//--- Get the value of the levels when Margin Call and Stop Out occur
   double margin_call=AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL);
   double stop_out=AccountInfoDouble(ACCOUNT_MARGIN_SO_SO);
//--- Show brief account information
   PrintFormat("The account of the client '%s' #%d %s opened in '%s' on the server '%s
               name,login,trade_mode,company,server);
   PrintFormat("Account currency - %s, MarginCall and StopOut levels are set in %s",
               currency,(stop_out_mode==ACCOUNT_STOPOUT_MODE_PERCENT)?"percentage":" r
```

```
   PrintFormat("MarginCall=%G, StopOut=%G",margin_call,stop_out);
  }
```

Testing Statistics

After the testing is over, different parameters of the trading results statistics are calculated. The values of the parameters can be obtained using the TesterStatistics() function, by specifying the parameter ID from the ENUM_STATISTICS enumeration.

Although two types of parameters (int and double) are used for calculating statistics, the function returns all values in the double form. All the statistic values of the double type are expressed in the deposit currency by default, unless otherwise specified.

ENUM_STATISTICS

ID	Description of a statistic parameter	Type
STAT_INITIAL_DEPOSIT	The value of the initial deposit	double
STAT_WITHDRAWAL	Money withdrawn from an account	double
STAT_PROFIT	Net profit after testing, the sum of STAT_GROSS_PROFIT and STAT_GROSS_LOSS (STAT_GROSS_LOSS is always less than or equal to zero)	double
STAT_GROSS_PROFIT	Total profit, the sum of all profitable (positive) trades. The value is greater than or equal to zero	double
STAT_GROSS_LOSS	Total loss, the sum of all negative trades. The value is less than or equal to zero	double
STAT_MAX_PROFITTRADE	Maximum profit - the largest value of all profitable trades. The value is greater than or equal to zero	double
STAT_MAX_LOSSTRADE	Maximum loss - the lowest value of all losing trades. The value is less than or equal to zero	double

ID	Description of a statistic parameter	Type
STAT_CONPROFITMAX	Maximum profit in a series of profitable trades. The value is greater than or equal to zero	double
STAT_CONPROFITMAX_TRADES	The number of trades that have formed STAT_CONPROFITMAX (maximum profit in a series of profitable trades)	int
STAT_MAX_CONWINS	The total profit of the longest series of profitable trades	double
STAT_MAX_CONPROFIT_TRADES	The number of trades in the longest series of profitable trades STAT_MAX_CONWINS	int
STAT_CONLOSSMAX	Maximum loss in a series of losing trades. The value is less than or equal to zero	double
STAT_CONLOSSMAX_TRADES	The number of trades that have formed STAT_CONLOSSMAX (maximum loss in a series of losing trades)	int
STAT_MAX_CONLOSSES	The total loss of the longest series of losing trades	double
STAT_MAX_CONLOSS_TRADES	The number of trades in the longest series of losing trades STAT_MAX_CONLOSSES	int
STAT_BALANCEMIN	Minimum balance value	double
STAT_BALANCE_DD	Maximum balance drawdown in monetary terms. In the process of trading, a balance may have numerous	double

ID	Description of a statistic parameter	Type
	drawdowns; here the largest value is taken	
STAT_BALANCEDD_PERCENT	Balance drawdown as a percentage that was recorded at the moment of the maximum balance drawdown in monetary terms (STAT_BALANCE_DD).	double
STAT_BALANCE_DDREL_PERCENT	Maximum balance drawdown as a percentage. In the process of trading, a balance may have numerous drawdowns, for each of which the relative drawdown value in percents is calculated. The greatest value is returned	double
STAT_BALANCE_DD_RELATIVE	Balance drawdown in monetary terms that was recorded at the moment of the maximum balance drawdown as a percentage (STAT_BALANCE_DDREL_PERCENT).	double
STAT_EQUITYMIN	Minimum equity value	double
STAT_EQUITY_DD	Maximum equity drawdown in monetary terms. In the process of trading, numerous drawdowns may appear on the equity; here the largest value is taken	double
STAT_EQUITYDD_PERCENT	Drawdown in percent that was recorded at the moment of the maximum equity drawdown in monetary	double

ID	Description of a statistic parameter	Type
	terms (STAT_EQUITY_DD).	
STAT_EQUITY_DDREL_PERCENT	Maximum equity drawdown as a percentage. In the process of trading, an equity may have numerous drawdowns, for each of which the relative drawdown value in percents is calculated. The greatest value is returned	double
STAT_EQUITY_DD_RELATIVE	Equity drawdown in monetary terms that was recorded at the moment of the maximum equity drawdown in percent (STAT_EQUITY_DDREL_PERCENT).	double
STAT_EXPECTED_PAYOFF	Expected payoff	double
STAT_PROFIT_FACTOR	Profit factor, equal to the ratio of STAT_GROSS_PROFIT/STAT_GROSS_LOSS. If STAT_GROSS_LOSS=0, the profit factor is equal to DBL_MAX	double
STAT_RECOVERY_FACTOR	Recovery factor, equal to the ratio of STAT_PROFIT/STAT_BALANCE_DD	double
STAT_SHARPE_RATIO	Sharpe ratio	double
STAT_MIN_MARGINLEVEL	Minimum value of the margin level	double
STAT_CUSTOM_ONTESTER	The value of the calculated custom optimization criterion returned by the OnTester() function	double
STAT_DEALS	The number of deals	int

ID	Description of a statistic parameter	Type
STAT_TRADES	The number of trades	int
STAT_PROFIT_TRADES	Profitable trades	int
STAT_LOSS_TRADES	Losing trades	int
STAT_SHORT_TRADES	Short trades	int
STAT_LONG_TRADES	Long trades	int
STAT_PROFIT_SHORTTRADES	Profitable short trades	int
STAT_PROFIT_LONGTRADES	Profitable long trades	int
STAT_PROFITTRADES_AVGCON	Average length of a profitable series of trades	int
STAT_LOSSTRADES_AVGCON	Average length of a losing series of trades	int
STAT_COMPLEX_CRITERION	Complex optimization criterion	

Trade Constants

Various constants used for programming trading strategies are divided into the following groups:

- History Database Properties – receiving general information on a symbol;
- Order properties – obtaining information about trade orders;
- Position properties – obtaining information about current positions;
- Deal properties – obtaining information about deals;
- Trade operation types – description of trade operations available;
- Trade transaction types - description of possible trade transactions types;
- Trade orders in DOM – separation of orders according to the direction of a requested operation.

History Database Properties

When accessing timeseries the SeriesInfoInteger() function is used for obtaining additional symbol information. Identifier of a required property is passed as the function parameter. The identifier can be one of values of ENUM_SERIES_INFO_INTEGER.

ENUM_SERIES_INFO_INTEGER

Identifier	Description	Type
SERIES_BARS_COUNT	Bars count for the symbol-period for the current moment	long
SERIES_FIRSTDATE	The very first date for the symbol-period for the current moment	datetime
SERIES_LASTBAR_DATE	Open time of the last bar of the symbol-period	datetime
SERIES_SERVER_FIRSTDATE	The very first date in the history of the symbol on the server regardless of the timeframe	datetime
SERIES_TERMINAL_FIRSTDATE	The very first date in the history of the symbol in the client terminal, regardless of the timeframe	datetime
SERIES_SYNCHRONIZED	Symbol/period data synchronization flag for the current moment	bool

Order Properties

Requests to execute trade operations are formalized as orders. Each order has a variety of properties for reading. Information on them can be obtained using functions OrderGet...() and HistoryOrderGet...().

For functions OrderGetInteger() and HistoryOrderGetInteger()

ENUM_ORDER_PROPERTY_INTEGER

Identifier	Description	Type
ORDER_TICKET	Order ticket. Unique number assigned to each order	long
ORDER_TIME_SETUP	Order setup time	datetime
ORDER_TYPE	Order type	ENUM_ORDER_TYPE
ORDER_STATE	Order state	ENUM_ORDER_STATE
ORDER_TIME_EXPIRATION	Order expiration time	datetime
ORDER_TIME_DONE	Order execution or cancellation time	datetime
ORDER_TIME_SETUP_MSC	The time of placing an order for execution in milliseconds since 01.01.1970	long
ORDER_TIME_DONE_MSC	Order execution/cancellation time in milliseconds since 01.01.1970	long
ORDER_TYPE_FILLING	Order filling type	ENUM_ORDER_TYPE_FILLING
ORDER_TYPE_TIME	Order lifetime	ENUM_ORDER_TYPE_TIME

Identifier	Description	Type
ORDER_MAGIC	ID of an Expert Advisor that has placed the order (designed to ensure that each Expert Advisor places its own unique number)	long
ORDER_REASON	The reason or source for placing an order	ENUM_ORDER_REASON
ORDER_POSITION_ID	Position identifier that is set to an order as soon as it is executed. Each executed order results in a deal that opens or modifies an already existing position. The identifier of exactly this position is set to the executed order at this moment.	long
ORDER_POSITION_BY_ID	Identifier of an opposite position used for closing by order ORDER_TYPE_CLOSE_BY	long

For functions OrderGetDouble() and HistoryOrderGetDouble()

ENUM_ORDER_PROPERTY_DOUBLE

Identifier	Description	Type
ORDER_VOLUME_INITIAL	Order initial volume	double
ORDER_VOLUME_CURRENT	Order current volume	double
ORDER_PRICE_OPEN	Price specified in the order	double
ORDER_SL	Stop Loss value	double
ORDER_TP	Take Profit value	double
ORDER_PRICE_CURRENT	The current price of the order symbol	double
ORDER_PRICE_STOPLIMIT	The Limit order price for the StopLimit order	double

For functions OrderGetString() and HistoryOrderGetString()

ENUM_ORDER_PROPERTY_STRING

Identifier	Description	Type
ORDER_SYMBOL	Symbol of the order	string
ORDER_COMMENT	Order comment	string
ORDER_EXTERNAL_ID	Order identifier in an external trading system (on the Exchange)	string

When sending a trade request using the OrderSend() function, some operations require the indication of the order type. The order type is specified in the *type* field of the special structure MqlTradeRequest, and can accept values of the ENUM_ORDER_TYPE enumeration.

ENUM_ORDER_TYPE

Identifier	Description
ORDER_TYPE_BUY	Market Buy order

Identifier	Description
ORDER_TYPE_SELL	Market Sell order
ORDER_TYPE_BUY_LIMIT	Buy Limit pending order
ORDER_TYPE_SELL_LIMIT	Sell Limit pending order
ORDER_TYPE_BUY_STOP	Buy Stop pending order
ORDER_TYPE_SELL_STOP	Sell Stop pending order
ORDER_TYPE_BUY_STOP_LIMIT	Upon reaching the order price, a pending Buy Limit order is placed at the StopLimit price
ORDER_TYPE_SELL_STOP_LIMIT	Upon reaching the order price, a pending Sell Limit order is placed at the StopLimit price
ORDER_TYPE_CLOSE_BY	Order to close a position by an opposite one

Each order has a status that describes its state. To obtain information, use OrderGetInteger() or HistoryOrderGetInteger() with the ORDER_STATE modifier. Allowed values are stored in the ENUM_ORDER_STATE enumeration.

ENUM_ORDER_STATE

Identifier	Description
ORDER_STATE_STARTED	Order checked, but not yet accepted by broker
ORDER_STATE_PLACED	Order accepted
ORDER_STATE_CANCELED	Order canceled by client
ORDER_STATE_PARTIAL	Order partially executed
ORDER_STATE_FILLED	Order fully executed
ORDER_STATE_REJECTED	Order rejected
ORDER_STATE_EXPIRED	Order expired
ORDER_STATE_REQUEST_ADD	Order is being registered (placing to the trading system)
ORDER_STATE_REQUEST_MODIFY	Order is being modified (changing its parameters)
ORDER_STATE_REQUEST_CANCEL	Order is being deleted (deleting from the trading system)

When sending a trade request for execution **at the current time** (time in force), the price and the required buy/sell volume should be specified. Also, keep in mind that financial markets provide no guarantee that the entire requested volume is available for a certain financial instrument at the desired price. Therefore, trading operations in real time are regulated using the price and volume execution modes. The modes, or execution policies, define the rules for cases when the price has changed or the requested volume cannot be completely fulfilled **at the moment**.

Price execution mode can be obtained from the SYMBOL_TRADE_EXEMODE symbol property containing the combination of flags from the ENUM_SYMBOL_TRADE_EXECUTION enumeration.

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
Execution mode (Request Execution)	Executing a market order at the price previously received from the broker. Prices for a certain market order are requested from the broker before the order is sent. Upon receiving the prices, order execution at the given price can be either confirmed or rejected.	SYMBOL_TRADE_EXECUTION_REQUEST

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
Instant Execution (Instant Execution)	Executing a market order at the specified price immediately. When sending a trade request to be executed, the platform automatically adds the current prices to the order. • If the broker accept st	SYMBOL_TRADE_EXECUTION_INSTANT

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	hepriice, theorderisexecuted. • Ifthebrokerdoesnotacc	

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	eturnspricess,atwhichthisorderc anbeexecuted.	
Market Execution (Market Execution)	A broker makes a	SYMBOL_TRADE_EXECUTION_MARKET

Execution mode	Description	The value in ENUM_SYMBOL_TRADE_EXECUTION
	decision about the order execution price without any additional discussion with the trader. Sending the order in such a mode means advance consent to its execution at this price.	
Exchange Execution (Exchange Execution)	Trade operations are executed at the prices of the current market offers.	SYMBOL_TRADE_EXECUTION_EXCHANGE

Volume filling policy is specified in the ORDER_TYPE_FILLING order property and may contain only the values from the ENUM_ORDER_TYPE_FILLING enumeration

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
Fill or Kill	An order can be executed in the specified volume only. If the necessary amount of a financial instrument is currently unavailable in the market, the order will not be executed. The desired volume can be made up of several available offers. The possibi	ORDER_FILLING_FOK

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
	lity of using FOK orders is determined at the trade server.	
Immediate or Cancel	A trader agrees to execute a deal with the volume maximally available in the market within that indicated in the order. If the request cannot be filled completely, an order with the available volume	ORDER_FILLING_IOC

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
	will be executed, and the remaining volume will be canceled. The possibility of using IOC orders is determined at the trade server.	
Passive (Book or Cancel)	The BoC order assumes that the order can only be placed in the Depth of Market and cannot be immediately executed. If the order	ORDER_FILLING_BOC

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
	can be executed immediately when placed, then it is canceled. In fact, the BOC policy guarantees that the price of the placed order will be worse than the current market. BoC orders are used to implement passive trading, so that the order is not executed	

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
	immediately when placed and does not affect current liquidity. Only limit and stop limit orders are supported (ORDER_TYPE_BUY_LIMIT, ORDER_TYPE_SELL_LIMIT, ORDER_TYPE_BUY_STOP_LIMIT, ORDER_TYPE_SELL_STOP_LIMIT).	
Return	In case of partial filling, an order with	ORDER_FILLING_RETURN

Fill policy	Description	The value in ENUM_ORDER_TYPE_FILLING
	remaining volume is not canceled but processed further. Return orders are not allowed in the Market Execution mode (market execution — SYMBOL_TRADE_EXECUTION_MARKET).	

When sending a trade request using the OrderSend() function, the necessary volume execution policy can be set in the *type_filling* field, namely in the special MqlTradeRequest structure. The values from the ENUM_ORDER_TYPE_FILLING enumeration are available. To get the property value in a specific active/completed order, use the OrderGetInteger() or HistoryOrderGetInteger() function with the ORDER_TYPE_FILLING modifier.

Before sending an order with the current execution time, for the correct setting of the ORDER_TYPE_FILLING value (volume execution type), you can use the SymbolInfoInteger() function with each financial instrument to get the SYMBOL_FILLING_MODE property value, which shows volume execution types allowed for the symbol as a combination of flags. The ORDER_FILLING_RETURN filling type is enabled at all times except for the "Market execution" mode (SYMBOL_TRADE_EXECUTION_MARKET).

The use of filling types depending on the execution mode can be shown as the following table:

Type of Execution\Fill Policy	Fill or Kill (FOK ORDER_FILLING_FOK)	Immediate or Cancel (IOC ORDER_FILLING_IOC)	Return (Return ORDER_FILLING_RETURN)
Instant Execution (SYMBOL_TRADE_EXECUTION_INSTANT)	+ (regardless of a symbol setting)	+ (regardless of a symbol setting)	+ (always)
Request Execution SYMBOL_TRADE_EXECUTION_REQUEST	+ (regardless of a symbol setting)	+ (regardless of a symbol setting)	+ (always)
Market Execution SYMBOL_TRADE_EXECUTION_MARKET	+ (set in the symbol settings)	+ (set in the symbol settings)	- (disabled regardless of the symbol settings)
Exchange Execution SYMBOL_TRADE_EXECUTION_EXCHANGE	+ (set in the symbol settings)	+ (set in the symbol settings)	+ (always)

In case of pending orders, the ORDER_FILLING_RETURN filling type should be used regardless of an execution type (SYMBOL_TRADE_EXEMODE), since such orders are not meant for execution at the time of sending. When using pending orders, a trader agrees in advance that, when conditions for a deal on this order are met, the broker will use the filling type supported by the exchange.

The order validity period can be set in the *type_time* field of the special structure MqlTradeRequest when sending a trade request using the OrderSend() function. Values of the ENUM_ORDER_TYPE_TIME enumeration are allowed. To obtain the value of this property use the function OrderGetInteger() or HistoryOrderGetInteger() with the ORDER_TYPE_TIME modifier.

ENUM_ORDER_TYPE_TIME

Identifier	Description
ORDER_TIME_GTC	Good till cancel order
ORDER_TIME_DAY	Good till current trade day order
ORDER_TIME_SPECIFIED	Good till expired order
ORDER_TIME_SPECIFIED_DAY	The order will be effective till 23:59:59 of the specified day. If this time is outside a trading session, the order expires in the nearest trading time.

The reason for order placing is contained in the ORDER_REASON property. An order can be placed by an MQL5 program, from a mobile application, as a result of StopOut, etc. Possible values of ORDER_REASON are described in the ENUM_ORDER_REASON enumeration.

ENUM_ORDER_REASON

Identifier	Description
ORDER_REASON_CLIENT	The order was placed from a desktop terminal
ORDER_REASON_MOBILE	The order was placed from a mobile application
ORDER_REASON_WEB	The order was placed from a web platform
ORDER_REASON_EXPERT	The order was placed from an MQL5-program, i.e. by an Expert Advisor or a script
ORDER_REASON_SL	The order was placed as a result of Stop Loss activation
ORDER_REASON_TP	The order was placed as a result of Take Profit activation
ORDER_REASON_SO	The order was placed as a result of the Stop Out event

Position Properties

Execution of trade operations results in the opening of a position, changing of its volume and/or direction, or its disappearance. Trade operations are conducted based on orders, sent by the OrderSend() function in the form of trade requests. For each financial security (symbol) only one open position is possible. A position has a set of properties available for reading by the PositionGet...() functions.

For the function PositionGetInteger()

ENUM_POSITION_PROPERTY_INTEGER

Identifier	Description	Type
POSITION_TICKET	Position ticket. Unique number assigned to each newly opened position. It usually matches the ticket of an order used to open the position except when the ticket is changed as a result of service operations on the server, for example, when charging swaps with position re-opening. To find an order used to open a position, apply the POSITION_IDENTIFIER property. POSITION_TICKET value corresponds to MqlTradeRequest::position.	long
POSITION_TIME	Position open time	datetime
POSITION_TIME_MSC	Position opening time in milliseconds since 01.01.1970	long

Identifier	Description	Type
POSITION_TIME_UPDATE	Position changing time	datetime
POSITION_TIME_UPDATE_MSC	Position changing time in milliseconds since 01.01.1970	long
POSITION_TYPE	Position type	ENUM_POSITION_TYPE
POSITION_MAGIC	Position magic number (see ORDER_MAGIC)	long
POSITION_IDENTIFIER	Position identifier is a unique number assigned to each re-opened position. It does not change throughout its life cycle and corresponds to the ticket of an order used to open a position. Position identifier is specified in each order (ORDER_POSITION_ID) and deal (DEAL_POSITION_ID) used to open, modify, or close it. Use this property to search for orders and deals related to the position. When reversing a position in netting mode (using a single in/out trade), POSITION_IDENTIFIER does not change. However, POSITION_TICKET is replaced with	long

Identifier	Description	Type
	the ticket of the order that led to the reversal. Position reversal is not provided in hedging mode.	
POSITION_REASON	The reason for opening a position	ENUM_POSITION_REASON

For the function PositionGetDouble()

ENUM_POSITION_PROPERTY_DOUBLE

Identifier	Description	Type
POSITION_VOLUME	Position volume	double
POSITION_PRICE_OPEN	Position open price	double
POSITION_SL	Stop Loss level of opened position	double
POSITION_TP	Take Profit level of opened position	double
POSITION_PRICE_CURRENT	Current price of the position symbol	double
POSITION_SWAP	Cumulative swap	double
POSITION_PROFIT	Current profit	double

For the function PositionGetString()

ENUM_POSITION_PROPERTY_STRING

Identifier	Description	Type
POSITION_SYMBOL	Symbol of the position	string
POSITION_COMMENT	Position comment	string
POSITION_EXTERNAL_ID	Position identifier in an external trading system (on the Exchange)	string

Direction of an open position (buy or sell) is defined by the value from the ENUM_POSITION_TYPE enumeration. In order to obtain the type of an open position use the PositionGetInteger() function with the POSITION_TYPE modifier.

ENUM_POSITION_TYPE

Identifier	Description
POSITION_TYPE_BUY	Buy
POSITION_TYPE_SELL	Sell

The reason for opening a position is contained in the POSITION_REASON property. A position can be opened as a result of activation of an order placed from a desktop terminal, a mobile application, by an Expert Advisor, etc. Possible values of POSITION_REASON are described in the ENUM_POSITION_REASON enumeration.

ENUM_POSITION_REASON

Identifier	Description
POSITION_REASON_CLIENT	The position was opened as a result of activation of an order placed from a desktop terminal
POSITION_REASON_MOBILE	The position was opened as a result of activation of an order placed from a mobile application
POSITION_REASON_WEB	The position was opened as a result of activation of an order placed from the web platform
POSITION_REASON_EXPERT	The position was opened as a result of activation of an order placed from an MQL5 program, i.e. an Expert Advisor or a script

Deal Properties

A deal is the reflection of the fact of a trade operation execution based on an order that contains a trade request. Each trade is described by properties that allow to obtain information about it. In order to read values of properties, functions of the HistoryDealGet...() type are used, that return values from corresponding enumerations.

For the function HistoryDealGetInteger()

ENUM_DEAL_PROPERTY_INTEGER

Identifier	Description	Type
DEAL_TICKET	Deal ticket. Unique number assigned to each deal	long
DEAL_ORDER	Deal order number	long
DEAL_TIME	Deal time	datetime
DEAL_TIME_MSC	The time of a deal execution in milliseconds since 01.01.1970	long
DEAL_TYPE	Deal type	ENUM_DEAL_TYPE
DEAL_ENTRY	Deal entry - entry in, entry out, reverse	ENUM_DEAL_ENTRY
DEAL_MAGIC	Deal magic number (see ORDER_MAGIC)	long
DEAL_REASON	The reason or source for deal execution	ENUM_DEAL_REASON
DEAL_POSITION_ID	Identifier of a position, in the opening, modification or closing of which this deal took part. Each position has a unique identifier that is assigned to all deals executed for the symbol during the entire lifetime of the position.	long

For the function HistoryDealGetDouble()

ENUM_DEAL_PROPERTY_DOUBLE

Identifier	Description	Type
DEAL_VOLUME	Deal volume	double
DEAL_PRICE	Deal price	double
DEAL_COMMISSION	Deal commission	double
DEAL_SWAP	Cumulative swap on close	double
DEAL_PROFIT	Deal profit	double
DEAL_FEE	Fee for making a deal charged immediately after performing a deal	double

Identifier	Description	Type
DEAL_SL	Stop Loss level • Entry and reversal deals use the Stop Loss values from the original order based on which the position was opened or reversed • Exit deals use the Stop Loss of a position as at the time of position closing	double
DEAL_TP	Take Profit level • Entry and reversal deals use the Take Profit values from the original order based on which the position was opened or reversed • Exit deals use the Take Profit value of a position as at the time of position closing	double

For the function HistoryDealGetString()

ENUM_DEAL_PROPERTY_STRING

Identifier	Description	Type
DEAL_SYMBOL	Deal symbol	string
DEAL_COMMENT	Deal comment	string
DEAL_EXTERNAL_ID	Deal identifier in an external trading system (on the Exchange)	string

Each deal is characterized by a type, allowed values are enumerated in ENUM_DEAL_TYPE. In order to obtain information about the deal type, use the HistoryDealGetInteger() function with the DEAL_TYPE modifier.

ENUM_DEAL_TYPE

Identifier	Description
DEAL_TYPE_BUY	Buy
DEAL_TYPE_SELL	Sell
DEAL_TYPE_BALANCE	Balance
DEAL_TYPE_CREDIT	Credit

Identifier	Description
DEAL_TYPE_CHARGE	Additional charge
DEAL_TYPE_CORRECTION	Correction
DEAL_TYPE_BONUS	Bonus
DEAL_TYPE_COMMISSION	Additional commission
DEAL_TYPE_COMMISSION_DAILY	Daily commission
DEAL_TYPE_COMMISSION_MONTHLY	Monthly commission
DEAL_TYPE_COMMISSION_AGENT_DAILY	Daily agent commission
DEAL_TYPE_COMMISSION_AGENT_MONTHLY	Monthly agent commission
DEAL_TYPE_INTEREST	Interest rate
DEAL_TYPE_BUY_CANCELED	Canceled buy deal. There can be a situation when a previously executed buy deal is canceled. In this case, the type of the previously executed deal (DEAL_TYPE_BUY) is changed to DEAL_TYPE_BUY_CANCELED, and its profit/loss is zeroized. Previously obtained profit/loss is charged/withdrawn using a separated balance operation
DEAL_TYPE_SELL_CANCELED	Canceled sell deal. There can be a situation when a previously executed sell deal is canceled. In this case, the type of the previously executed deal (DEAL_TYPE_SELL) is changed to DEAL_TYPE_SELL_CANCELED, and its profit/loss is zeroized. Previously obtained profit/loss is charged/withdrawn using a separated balance operation
DEAL_DIVIDEND	Dividend operations
DEAL_DIVIDEND_FRANKED	Franked (non-taxable) dividend operations
DEAL_TAX	Tax charges

Deals differ not only in their types set in ENUM_DEAL_TYPE, but also in the way they change positions. This can be a simple position opening, or accumulation of a previously opened position (market entering), position closing by an opposite deal of a corresponding volume (market exiting), or position reversing, if the opposite-direction deal covers the volume of the previously opened position.

All these situations are described by values from the ENUM_DEAL_ENTRY enumeration. In order to receive this information about a deal, use the HistoryDealGetInteger() function with the DEAL_ENTRY modifier.

ENUM_DEAL_ENTRY

Identifier	Description
DEAL_ENTRY_IN	Entry in
DEAL_ENTRY_OUT	Entry out
DEAL_ENTRY_INOUT	Reverse
DEAL_ENTRY_OUT_BY	Close a position by an opposite one

The reason for deal execution is contained in the DEAL_REASON property. A deal can be executed as a result of triggering of an order placed from a mobile application or an MQL5 program, as well as as a result of the StopOut event, variation margin calculation, etc. Possible values of DEAL_REASON are described in the ENUM_DEAL_REASON enumeration. For non-trading deals resulting from balance, credit, commission and other operations, DEAL_REASON_CLIENT is indicated as the reason.

ENUM_DEAL_REASON

Identifier	Description
DEAL_REASON_CLIENT	The deal was executed as a result of activation of an order placed from a desktop terminal
DEAL_REASON_MOBILE	The deal was executed as a result of activation of an order placed from a mobile application
DEAL_REASON_WEB	The deal was executed as a result of activation of an order placed from the web platform
DEAL_REASON_EXPERT	The deal was executed as a result of activation of an order placed from an MQL5 program, i.e. an Expert Advisor or a script
DEAL_REASON_SL	The deal was executed as a result of Stop Loss activation
DEAL_REASON_TP	The deal was executed as a result of Take Profit activation
DEAL_REASON_SO	The deal was executed as a result of the Stop Out event
DEAL_REASON_ROLLOVER	The deal was executed due to a rollover
DEAL_REASON_VMARGIN	The deal was executed after charging the variation margin
DEAL_REASON_SPLIT	The deal was executed after the split (price reduction) of an instrument, which had an open position during split announcement

Trade Operation Types

Trading is done by sending orders to open positions using the OrderSend() function, as well as to place, modify or delete pending orders. Each trade order refers to the type of the requested operation. Trading operations are described in the ENUM_TRADE_REQUEST_ACTIONS enumeration.

ENUM_TRADE_REQUEST_ACTIONS

Identifier	Description
TRADE_ACTION_DEAL	Place a trade order for an immediate execution with the specified parameters (market order)
TRADE_ACTION_PENDING	Place a trade order for the execution under specified conditions (pending order)
TRADE_ACTION_SLTP	Modify Stop Loss and Take Profit values of an opened position
TRADE_ACTION_MODIFY	Modify the parameters of the order placed previously
TRADE_ACTION_REMOVE	Delete the pending order placed previously
TRADE_ACTION_CLOSE_BY	Close a position by an opposite one

Example of the TRADE_ACTION_DEAL trade operation for opening a Buy position:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Opening Buy position                                             |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request={};
   MqlTradeResult  result={};
//--- parameters of request
   request.action   =TRADE_ACTION_DEAL;                     // type of trade operatio
   request.symbol   =Symbol();                              // symbol
   request.volume   =0.1;                                   // volume of 0.1 lot
   request.type     =ORDER_TYPE_BUY;                        // order type
   request.price    =SymbolInfoDouble(Symbol(),SYMBOL_ASK); // price for opening
   request.deviation=5;                                     // allowed deviation from
   request.magic    =EXPERT_MAGIC;                          // MagicNumber of the orde
//--- send the request
   if(!OrderSend(request,result))
      PrintFormat("OrderSend error %d",GetLastError());     // if unable to send the r
//--- information about the operation
   PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,result
  }
//+------------------------------------------------------------------+
```

Example of the TRADE_ACTION_DEAL trade operation for opening a Sell position:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Opening Sell position                                            |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request={};
   MqlTradeResult  result={};
//--- parameters of request
   request.action   =TRADE_ACTION_DEAL;                     // type of trade operatio
   request.symbol   =Symbol();                              // symbol
   request.volume   =0.2;                                   // volume of 0.2 lot
   request.type     =ORDER_TYPE_SELL;                       // order type
   request.price    =SymbolInfoDouble(Symbol(),SYMBOL_BID); // price for opening
   request.deviation=5;                                     // allowed deviation from
   request.magic    =EXPERT_MAGIC;                          // MagicNumber of the orde
//--- send the request
   if(!OrderSend(request,result))
      PrintFormat("OrderSend error %d",GetLastError());     // if unable to send the r
//--- information about the operation
   PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,result
  }
//+------------------------------------------------------------------+
```

Example of the TRADE_ACTION_DEAL trade operation for closing positions:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Closing all positions                                            |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request;
   MqlTradeResult  result;
   int total=PositionsTotal(); // number of open positions
//--- iterate over all open positions
   for(int i=total-1; i>=0; i--)
     {
      //--- parameters of the order
      ulong  position_ticket=PositionGetTicket(i);
      string position_symbol=PositionGetString(POSITION_SYMBOL);
      int    digits=(int)SymbolInfoInteger(position_symbol,SYMBOL_DIGITS);
      ulong  magic=PositionGetInteger(POSITION_MAGIC);
      double volume=PositionGetDouble(POSITION_VOLUME);
      ENUM_POSITION_TYPE type=(ENUM_POSITION_TYPE)PositionGetInteger(POSITION_TYPE);
      //--- output information about the position
      PrintFormat("#%I64u %s  %s  %.2f  %s [%I64d]",
                  position_ticket,
                  position_symbol,
                  EnumToString(type),
                  volume,
                  DoubleToString(PositionGetDouble(POSITION_PRICE_OPEN),digits),
                  magic);
      //--- if the MagicNumber matches
      if(magic==EXPERT_MAGIC)
        {
         //--- zeroing the request and result values
         ZeroMemory(request);
         ZeroMemory(result);
         //--- setting the operation parameters
         request.action   =TRADE_ACTION_DEAL;        // type of trade operation
         request.position =position_ticket;          // ticket of the position
         request.symbol   =position_symbol;          // symbol
         request.volume   =volume;                   // volume of the position
         request.deviation=5;                        // allowed deviation from the pri
         request.magic    =EXPERT_MAGIC;             // MagicNumber of the position
         //--- set the price and order type depending on the position type
         if(type==POSITION_TYPE_BUY)
           {
            request.price=SymbolInfoDouble(position_symbol,SYMBOL_BID);
            request.type =ORDER_TYPE_SELL;
           }
         else
           {
            request.price=SymbolInfoDouble(position_symbol,SYMBOL_ASK);
            request.type =ORDER_TYPE_BUY;
           }
         //--- output information about the closure
         PrintFormat("Close #%I64d %s %s",position_ticket,position_symbol,EnumToStrin
         //--- send the request
         if(!OrderSend(request,result))
            PrintFormat("OrderSend error %d",GetLastError());  // if unable to send th
         //--- information about the operation
         PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,
         //---
        }
```

```
      }
   }
//+------------------------------------------------------------------+
```

Example of the TRADE_ACTION_PENDING trade operation for placing a pending order:

```
#property description "Example of placing pending orders"
#property script_show_inputs
#define EXPERT_MAGIC 123456                                  // MagicNumber of the expert
input ENUM_ORDER_TYPE orderType=ORDER_TYPE_BUY_LIMIT;   // order type
//+------------------------------------------------------------------+
//| Placing pending orders                                           |
//+------------------------------------------------------------------+
void OnStart()

//+------------------------------------------------------------------+
```

Trade Transaction Types

When performing some definite actions on a trade account, its state changes. Such actions include:

- Sending a trade request from any MQL5 application in the client terminal using OrderSend and OrderSendAsync functions and its further execution;
- Sending a trade request via the terminal graphical interface and its further execution;
- Pending orders and stop orders activation on the server;
- Performing operations on a trade server side.

The following trade transactions are performed as a result of these actions:

- handling a trade request;
- changing open orders;
- changing orders history;
- changing deals history;
- changing positions.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. All these actions are trade transactions.

To let a programmer to track the actions performed in relation to a trade account, OnTradeTransaction function has been provided. This handler allows to get trade transactions applied to an account in MQL5 application. Trade transaction description is submitted in OnTradeTransaction first parameter using MqlTradeTransaction structure.

Trade transaction type is submitted in the type parameter of MqlTradeTransaction structure. Possible types of trade transactions are described by the following enumeration:

ENUM_TRADE_TRANSACTION_TYPE

Identifier	Description
TRADE_TRANSACTION_ORDER_ADD	Adding a new open order.
TRADE_TRANSACTION_ORDER_UPDATE	Updating an open order. The updates include not only evident changes from the client terminal or a trade server sides but also changes of an order state when setting it (for example, transition from ORDER_STATE_STARTED to ORDER_STATE_PLACED or from ORDER_STATE_PLACED to ORDER_STATE_PARTIAL, etc.).
TRADE_TRANSACTION_ORDER_DELETE	Removing an order from the list of the open ones. An order can be deleted from the open ones as a result of setting an appropriate request or execution (filling) and moving to the history.
TRADE_TRANSACTION_DEAL_ADD	Adding a deal to the history. The action is performed as a result of an order execution or performing

Identifier	Description
	operations with an account balance.
TRADE_TRANSACTION_DEAL_UPDATE	Updating a deal in the history. There may be cases when a previously executed deal is changed on a server. For example, a deal has been changed in an external trading system (exchange) where it was previously transferred by a broker.
TRADE_TRANSACTION_DEAL_DELETE	Deleting a deal from the history. There may be cases when a previously executed deal is deleted from a server. For example, a deal has been deleted in an external trading system (exchange) where it was previously transferred by a broker.
TRADE_TRANSACTION_HISTORY_ADD	Adding an order to the history as a result of execution or cancellation.
TRADE_TRANSACTION_HISTORY_UPDATE	Changing an order located in the orders history. This type is provided for enhancing functionality on a trade server side.
TRADE_TRANSACTION_HISTORY_DELETE	Deleting an order from the orders history. This type is provided for enhancing functionality on a trade server side.
TRADE_TRANSACTION_POSITION	Changing a position not related to a deal execution. This type of transaction shows that a position has been changed on a trade server side. Position volume, open price, Stop Loss and Take Profit levels can be changed. Data on changes are submitted in MqlTradeTransaction structure via OnTradeTransaction handler. Position change (adding, changing or closing), as a result of a deal execution, does not lead to the occurrence of TRADE_TRANSACTION_POSITION transaction.
TRADE_TRANSACTION_REQUEST	Notification of the fact that a trade request has been processed by a server and processing result has been received. Only type field (trade transaction type) must be analyzed for such transactions in MqlTradeTransaction structure. The second and third parameters of OnTradeTransaction (request and result) must be analyzed for additional data.

Depending on a trade transaction type, various parameters are filled in MqlTradeTransaction structure describing it. A detailed description of submitted data is shown in "Structure of a Trade Transaction".

Trade Orders in Depth Of Market

For equity securities, the Depth of Market window is available, where you can see the current Buy and Sell orders. Desired direction of a trade operation, required amount and requested price are specified for each order.

To obtain information about the current state of the DOM by MQL5 means, the MarketBookGet() function is used, which places the DOM "screen shot" into the MqlBookInfo array of structures. Each element of the array in the *type* field contains information about the direction of the order - the value of the ENUM_BOOK_TYPE enumeration.

ENUM_BOOK_TYPE

Identifier	Description
BOOK_TYPE_SELL	Sell order (Offer)
BOOK_TYPE_BUY	Buy order (Bid)
BOOK_TYPE_SELL_MARKET	Sell order by Market
BOOK_TYPE_BUY_MARKET	Buy order by Market

Signal Properties

The following enumerations are used when working with trading signals and signal copy settings.

Enumeration of double type properties of the trading signal:

ENUM_SIGNAL_BASE_DOUBLE

ID	Description
SIGNAL_BASE_BALANCE	Account balance
SIGNAL_BASE_EQUITY	Account equity
SIGNAL_BASE_GAIN	Account gain
SIGNAL_BASE_MAX_DRAWDOWN	Account maximum drawdown
SIGNAL_BASE_PRICE	Signal subscription price
SIGNAL_BASE_ROI	Return on Investment (%)

Enumeration of integer type properties of the trading signal:

ENUM_SIGNAL_BASE_INTEGER

ID	Description
SIGNAL_BASE_DATE_PUBLISHED	Publication date (date when it become available for subscription)
SIGNAL_BASE_DATE_STARTED	Monitoring starting date
SIGNAL_BASE_DATE_UPDATED	The date of the last update of the signal's trading statistics
SIGNAL_BASE_ID	Signal ID
SIGNAL_BASE_LEVERAGE	Account leverage
SIGNAL_BASE_PIPS	Profit in pips
SIGNAL_BASE_RATING	Position in rating
SIGNAL_BASE_SUBSCRIBERS	Number of subscribers
SIGNAL_BASE_TRADES	Number of trades
SIGNAL_BASE_TRADE_MODE	Account type (0-real, 1-demo, 2-contest)

Enumeration of string type properties of the trading signal:

ENUM_SIGNAL_BASE_STRING

ID	Description
SIGNAL_BASE_AUTHOR_LOGIN	Author login
SIGNAL_BASE_BROKER	Broker name (company)

ID	Description
SIGNAL_BASE_BROKER_SERVER	Broker server
SIGNAL_BASE_NAME	Signal name
SIGNAL_BASE_CURRENCY	Signal base currency

Enumeration of double type properties of the signal copy settings:

ENUM_SIGNAL_INFO_DOUBLE

ID	Description
SIGNAL_INFO_EQUITY_LIMIT	Equity limit
SIGNAL_INFO_SLIPPAGE	Slippage (used when placing market orders in synchronization of positions and copying of trades)
SIGNAL_INFO_VOLUME_PERCENT	Maximum percent of deposit used (%), r/o

Enumeration of integer type properties of the signal copy settings:

ENUM_SIGNAL_INFO_INTEGER

ID	Description
SIGNAL_INFO_CONFIRMATIONS_DISABLED	The flag enables synchronization without confirmation dialog
SIGNAL_INFO_COPY_SLTP	Copy Stop Loss and Take Profit flag
SIGNAL_INFO_DEPOSIT_PERCENT	Deposit percent (%)
SIGNAL_INFO_ID	Signal id, r/o
SIGNAL_INFO_SUBSCRIPTION_ENABLED	"Copy trades by subscription" permission flag
SIGNAL_INFO_TERMS_AGREE	"Agree to terms of use of Signals service" flag, r/o

Enumeration of string type properties of the signal copy settings:

ENUM_SIGNAL_INFO_STRING

ID	Description
SIGNAL_INFO_NAME	Signal name, r/o

Trade signals

Named Constants

All constants used in MQL5 can be divided into the following groups:

- Predefined macro substitutions - values are substituted during compilation;
- Mathematical constants - values of some mathematical expressions;
- Numerical type constants - some of the simple type restrictions;
- Uninitialization reason codes - description of uninitialization reasons;
- Checking Object Pointer - enumeration of types of pointers returned by the CheckPointer() function;
- Other constants - all other constants.

Predefined Macro Substitutions

To simplify the debugging process and obtain information about operation of a mql5-program, there are special macro constant, values of which are set at the moment of compilation. The easiest way to use these constants is outputting values by the Print() function, as it's shown in the example.

Constant	Description
__CPU_ARCHITECTURE__	Name of architecture (set of commands) EX5 file compiled for
__DATE__	File compilation date without time (hours, minutes and seconds are equal to 0)
__DATETIME__	File compilation date and time
__LINE__	Line number in the source code, in which the macro is located
__FILE__	Name of the currently compiled file
__PATH__	An absolute path to the file that is currently being compiled
__FUNCTION__	Name of the function, in whose body the macro is located
__FUNCSIG__	Signature of the function in whose body the macro is located. Logging of the full description of functions can be useful in the identification of overloaded functions
__MQLBUILD__,__MQL5BUILD__	Compiler build number
__COUNTER__	The compiler for each encountered __COUNTER__ declaration substitutes the counter value from 0 to N-1 where N is a number of uses in the code. The __COUNTER__ order is guaranteed when recompiling the source code with no changes. The __COUNTER__ value is calculated the following way: • the initial counter value is 0, • after each counter usage, its value is increased by 1, • first, the compiler expands all macros and templates into source code on-site, • a separate code is created for each template function specialization, • a separate code is created for each template class/structure specialization, • next, the compiler passes through the obtained source code in the defined order and replaces each detected __COUNTER__ usage with the current counter value. The example below shows how the compiler handles the source code and replaces all instances of __COUNTER__ it meets with sequentially increasing values.

Constant	Description
__RANDOM__	The compiler inserts a random ulong value for each __RANDOM__ declaration.

Example:

```
#property copyright "Copyright © 2009, MetaQuotes Software Corp."
#property link      "https://www.metaquotes.net"
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- an example of information output at Expert Advisor initialization
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__);
//--- set the interval between the timer events
   EventSetTimer(5);
//---
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- an example of information output at Expert Advisor deinitialization
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__);
//---
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//--- information output at tick receipt
   Print(" __MQLBUILD__ = ",__MQLBUILD__,"  __FILE__ = ",__FILE__);
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__);
   test1(__FUNCTION__);
   test2();
//---
  }
//+------------------------------------------------------------------+
//| test1                                                            |
//+------------------------------------------------------------------+
void test1(string par)
  {
//--- information output inside the function
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__," par=",par);
  }
```

```
//+------------------------------------------------------------------+
//| test2                                                            |
//+------------------------------------------------------------------+
void test2()
  {
//--- information output inside the function
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__);
  }
//+------------------------------------------------------------------+
//| OnTimer event handler                                            |
//+------------------------------------------------------------------+
void OnTimer()
  {
//---
   Print(" __FUNCTION__ = ",__FUNCTION__,"  __LINE__ = ",__LINE__);
   test1(__FUNCTION__);
  }
```

The example for learning how to work with the __COUNTER__ macro

```
//--- create a macro for a quick display of the expression and its value in the journa
#define print(expr) Print(#expr,"=",expr)

//--- define the MACRO_COUNTER custom macro via the predefined __COUNTER__ macro
#define MACRO_COUNTER __COUNTER__

//--- set the input value of the variable using the __COUNTER__ macro
input int InpVariable = __COUNTER__;

//--- set the value of the global variable using the __COUNTER__ macro before defining
int ExtVariable = __COUNTER__;

//+------------------------------------------------------------------+
//| the function returns the __COUNTER__ value                       |
//+------------------------------------------------------------------+
int GlobalFunc(void)
  {
   return(__COUNTER__);
  }
//+------------------------------------------------------------------+
//| the template function returns the __COUNTER__ value              |
//+------------------------------------------------------------------+
template<typename T>
int GlobalTemplateFunc(void)
  {
   return(__COUNTER__);
  }
//+------------------------------------------------------------------+
```

```
//| the structure with the method returning __COUNTER__              |
//+------------------------------------------------------------------+
struct A
  {
   int               dummy;  // not used

   int               Method(void)
     {
      return(__COUNTER__);
     }
  };
//+------------------------------------------------------------------+
//| the template structure with the method returning __COUNTER__     |
//+------------------------------------------------------------------+
template<typename T>
struct B
  {
   int               dummy;  // not used

   int               Method(void)
     {
      return(__COUNTER__);
     }
  };
//+------------------------------------------------------------------+
//| the structure with the template method returning __COUNTER__     |
//+------------------------------------------------------------------+
struct C
  {
   int               dummy;  // not used

   template<typename T>
   int               Method(void)
     {
      return(__COUNTER__);
     }
  };
//+------------------------------------------------------------------+
//| the function #2, which returns the __COUNTER__ value             |
//+------------------------------------------------------------------+
int GlobalFunc2(void)
  {
   return(__COUNTER__);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
```

```
// __COUNTER__ in the macro and the variables
   print(MACRO_COUNTER);
   print(InpVariable);
   print(ExtVariable);

//--- __COUNTER__ in the functions
   print(GlobalFunc());
   print(GlobalFunc());                // the value is not changed
   print(GlobalTemplateFunc<int>());
   print(GlobalTemplateFunc<int>());   // the value is not changed
   print(GlobalTemplateFunc<double>());// the value has changed
   print(GlobalFunc2());
   print(GlobalFunc2());               // the value is not changed

// __COUNTER__ in the structure
   A a1, a2;
   print(a1.Method());
   print(a2.Method());                 // the value is not changed

// __COUNTER__ in the template structure
   B<int> b1, b2;
   B<double> b3;
   print(b1.Method());
   print(b2.Method());                 // the value is not changed
   print(b3.Method());                 // the value has changed

// __COUNTER__ in the structure with the template function
   C c1, c2;
   print(c1.Method<int>());
   print(c1.Method<double>());         // the value has changed
   print(c2.Method<int>());            // the same value as during the first c1.Metho

//--- let's have another look at __COUNTER__ in the macro and the global variable
   print(MACRO_COUNTER);  // the value has changed
   print(ExtGlobal2);
  }
//--- set the value of the global variable using the __COUNTER__ macro after defining
int ExtGlobal2 = __COUNTER__;
//+------------------------------------------------------------------+

/* Result
   __COUNTER__=3
   InpVariable=0
   ExtVariable=1
   GlobalFunc()=5
   GlobalFunc()=5
   GlobalTemplateFunc<int>()=8
   GlobalTemplateFunc<int>()=8
   GlobalTemplateFunc<double>()=9
```

```

*/
```

Mathematical Constants

Special constants containing values are reserved for some mathematical expressions. These constants can be used in any place of the program instead of calculating their values using mathematical functions.

Constant	Description	Value
M_E	e	2.71828182845904523536
M_LOG2E	log2(e)	1.44269504088896340736
M_LOG10E	log10(e)	0.43429448190325182765 1
M_LN2	ln(2)	0.69314718055994530941 7
M_LN10	ln(10)	2.30258509299404568402
M_PI	pi	3.14159265358979323846
M_PI_2	pi/2	1.57079632679489661923
M_PI_4	pi/4	0.78539816339744830962
M_1_PI	1/pi	0.31830988618379067153 8
M_2_PI	2/pi	0.63661977236758134307 6
M_2_SQRTPI	2/sqrt(pi)	1.12837916709551257390
M_SQRT2	sqrt(2)	1.41421356237309504880
M_SQRT1_2	1/sqrt(2)	0.70710678118654752440 1

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the values of constants
   Print("M_E = ",DoubleToString(M_E,16));
   Print("M_LOG2E = ",DoubleToString(M_LOG2E,16));
   Print("M_LOG10E = ",DoubleToString(M_LOG10E,16));
   Print("M_LN2 = ",DoubleToString(M_LN2,16));
   Print("M_LN10 = ",DoubleToString(M_LN10,16));
   Print("M_PI = ",DoubleToString(M_PI,16));
   Print("M_PI_2 = ",DoubleToString(M_PI_2,16));
   Print("M_PI_4 = ",DoubleToString(M_PI_4,16));
   Print("M_1_PI = ",DoubleToString(M_1_PI,16));
   Print("M_2_PI = ",DoubleToString(M_2_PI,16));
   Print("M_2_SQRTPI = ",DoubleToString(M_2_SQRTPI,16));
   Print("M_SQRT2 = ",DoubleToString(M_SQRT2,16));
   Print("M_SQRT1_2 = ",DoubleToString(M_SQRT1_2,16));
```

```
}
```

Numerical Type Constants

Each simple numerical type is intended for a certain type of tasks and allows optimizing the operation of a mql5-program when used correctly. For a better code readability and correct handling of calculation results, there are constants which allow to receive information about restrictions set to a certain type of simple data.

Constant	Description	Value
CHAR_MIN	Minimal value, which can be represented by char type	-128
CHAR_MAX	Maximal value, which can be represented by char type	127
UCHAR_MAX	Maximal value, which can be represented by uchar type	255
SHORT_MIN	Minimal value, which can be represented by short type	-32768
SHORT_MAX	Maximal value, which can be represented by short type	32767
USHORT_MAX	Maximal value, which can be represented by ushort type	65535
INT_MIN	Minimal value, which can be represented by int type	-2147483648
INT_MAX	Maximal value, which can be represented by int type	2147483647
UINT_MAX	Maximal value, which can be represented by uint type	4294967295
LONG_MIN	Minimal value, which can be represented by long type	-9223372036854775808
LONG_MAX	Maximal value, which can be represented by long type	9223372036854775807
ULONG_MAX	Maximal value, which can be represented by ulong type	18446744073709551615
DBL_MIN	Minimal positive value, which can be represented by double type	2.2250738585072014e-308
DBL_MAX	Maximal value, which can be represented by double type	1.7976931348623158e+308
DBL_EPSILON	Minimal value, which satisfies the condition: 1.0+DBL_EPSILON != 1.0 (for double type)	2.2204460492503131e-016
DBL_DIG	Number of significant decimal digits for double type	15

Constant	Description	Value
DBL_MANT_DIG	Number of bits in a mantissa for double type	53
DBL_MAX_10_EXP	Maximal decimal value of exponent degree for double type	308
DBL_MAX_EXP	Maximal binary value of exponent degree for double type	1024
DBL_MIN_10_EXP	Minimal decimal value of exponent degree for double type	(-307)
DBL_MIN_EXP	Minimal binary value of exponent degree for double type	(-1021)
FLT_MIN	Minimal positive value, which can be represented by float type	1.175494351e-38
FLT_MAX	Maximal value, which can be represented by float type	3.402823466e+38
FLT_EPSILON	Minimal value, which satisfies the condition: 1.0+DBL_EPSILON != 1.0 (for float type)	1.192092896e-07
FLT_DIG	Number of significant decimal digits for float type	6
FLT_MANT_DIG	Number of bits in a mantissa for float type	24
FLT_MAX_10_EXP	Maximal decimal value of exponent degree for float type	38
FLT_MAX_EXP	Maximal binary value of exponent degree for float type	128
FLT_MIN_10_EXP	Minimal decimal value of exponent degree for float type	-37
FLT_MIN_EXP	Minimal binary value of exponent degree for float type	(-125)

Example:

```
void OnStart()
  {
//--- print the constant values
   printf("CHAR_MIN = %d",CHAR_MIN);
   printf("CHAR_MAX = %d",CHAR_MAX);
   printf("UCHAR_MAX = %d",UCHAR_MAX);
   printf("SHORT_MIN = %d",SHORT_MIN);
   printf("SHORT_MAX = %d",SHORT_MAX);
   printf("USHORT_MAX = %d",USHORT_MAX);
   printf("INT_MIN = %d",INT_MIN);
```

```
   printf("INT_MAX = %d",INT_MAX);
   printf("UINT_MAX = %u",UINT_MAX);
   printf("LONG_MIN = %I64d",LONG_MIN);
   printf("LONG_MAX = %I64d",LONG_MAX);
   printf("ULONG_MAX = %I64u",ULONG_MAX);
   printf("EMPTY_VALUE = %.16e",EMPTY_VALUE);
   printf("DBL_MIN = %.16e",DBL_MIN);
   printf("DBL_MAX = %.16e",DBL_MAX);
   printf("DBL_EPSILON = %.16e",DBL_EPSILON);
   printf("DBL_DIG = %d",DBL_DIG);
   printf("DBL_MANT_DIG = %d",DBL_MANT_DIG);
   printf("DBL_MAX_10_EXP =  %d",DBL_MAX_10_EXP);
   printf("DBL_MAX_EXP = %d",DBL_MAX_EXP);
   printf("DBL_MIN_10_EXP = %d",DBL_MIN_10_EXP);
   printf("DBL_MIN_EXP = %d",DBL_MIN_EXP);
   printf("FLT_MIN = %.8e",FLT_MIN);
   printf("FLT_MAX = %.8e",FLT_MAX);
   printf("FLT_EPSILON = %.8e",FLT_EPSILON);
/*
   CHAR_MIN = -128
   CHAR_MAX = 127
   UCHAR_MAX = 255
   SHORT_MIN = -32768
   SHORT_MAX = 32767
   USHORT_MAX = 65535
   INT_MIN = -2147483648
   INT_MAX = 2147483647
   UINT_MAX = 4294967295
   LONG_MIN = -9223372036854775808
   LONG_MAX = 9223372036854775807
   ULONG_MAX = 18446744073709551615
   EMPTY_VALUE = 1.7976931348623157e+308
   DBL_MIN = 2.2250738585072014e-308
   DBL_MAX = 1.7976931348623157e+308
   DBL_EPSILON = 2.2204460492503131e-16
   DBL_DIG = 15
   DBL_MANT_DIG = 53
   DBL_MAX_10_EXP =  308
   DBL_MAX_EXP = 1024
   DBL_MIN_10_EXP = -307
   DBL_MIN_EXP = -1021
   FLT_MIN = 1.17549435e-38
   FLT_MAX = 3.40282347e+38
   FLT_EPSILON = 1.19209290e-07
*/
  }
```

Uninitialization Reason Codes

Uninitialization reason codes are returned by the UninitializeReason() function. The possible values are the following:

Constant	Value	Description
REASON_PROGRAM	0	Expert Advisor terminated its operation by calling the ExpertRemove() function
REASON_REMOVE	1	Program has been deleted from the chart
REASON_RECOMPILE	2	Program has been recompiled
REASON_CHARTCHANGE	3	Symbol or chart period has been changed
REASON_CHARTCLOSE	4	Chart has been closed
REASON_PARAMETERS	5	Input parameters have been changed by a user
REASON_ACCOUNT	6	Another account has been activated or reconnection to the trade server has occurred due to changes in the account settings
REASON_TEMPLATE	7	A new template has been applied
REASON_INITFAILED	8	This value means that OnInit() handler has returned a nonzero value
REASON_CLOSE	9	Terminal has been closed

The uninitialization reason code is also passed as a parameter of the predetermined function OnDeinit(const int reason).

Example:

```
//+------------------------------------------------------------------+
//| get text description                                             |
//+------------------------------------------------------------------+
string getUninitReasonText(int reasonCode)
  {
   string text="";
//---
   switch(reasonCode)
     {
      case REASON_ACCOUNT:
         text="Account was changed";break;
      case REASON_CHARTCHANGE:
         text="Symbol or timeframe was changed";break;
      case REASON_CHARTCLOSE:
         text="Chart was closed";break;
      case REASON_PARAMETERS:
         text="Input-parameter was changed";break;
      case REASON_RECOMPILE:
```

```
         text="Program "+__FILE__+" was recompiled";break;
      case REASON_REMOVE:
         text="Program "+__FILE__+" was removed from chart";break;
      case REASON_TEMPLATE:
         text="New template was applied to chart";break;
      default:text="Another reason";
     }
//---
   return text;
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- The first way to get the uninitialization reason code
   Print(__FUNCTION__,"_Uninitalization reason code = ",reason);
    //--- The second way to get the uninitialization reason code
   Print(__FUNCTION__,"_UninitReason = ",getUninitReasonText(_UninitReason));
  }
```

Checking Object Pointer

The CheckPointer() function is used for checking the type of the object pointer. The function returns a value of the ENUM_POINTER_TYPE enumeration. If an incorrect pointer is used, the program execution will be immediately terminated.

Objects created by the new() operator are of POINTER_DYNAMIC type. The delete() operator can and should be used only for such pointers.

All other pointers are of POINTER_AUTOMATIC type, which means that this object has been created automatically by the mql5 program environment. Such objects are deleted automatically after being used.

ENUM_POINTER_TYPE

Constant	Description
POINTER_INVALID	Incorrect pointer
POINTER_DYNAMIC	Pointer of the object created by the new() operator
POINTER_AUTOMATIC	Pointer of any objects created automatically (not using new())

Runtime errors, Object Delete Operator delete, CheckPointer

Other Constants

The CLR_NONE constant is used to outline the absence of color, it means that the graphical object or graphical series of an indicator will not be plotted. This constant was not included into the Web-color constants list, but it can be applied everywhere where the color arguments are required.

The INVALID_HANDLE constant can be used for checking file handles (see FileOpen() and FileFindFirst()).

Constant	Description	Value
CHARTS_MAX	The maximum possible number of simultaneously open charts in the terminal	100
clrNONE	Absence of color	-1
EMPTY_VALUE	Empty value in an indicator buffer	DBL_MAX
INVALID_HANDLE	Incorrect handle	-1
IS_DEBUG_MODE	Flag that a mq5-program operates in debug mode	non zero in debug mode, otherwise zero
IS_PROFILE_MODE	Flag that a mq5-program operates in profiling mode	non zero in profiling mode, otherwise zero
NULL	Zero for any types	0
WHOLE_ARRAY	Means the number of items remaining until the end of the array, i.e., the entire array will be processed	-1
WRONG_VALUE	The constant can be implicitly cast to any enumeration type	-1

The EMPTY_VALUE constant usually corresponds to the values of indicators that are not shown in the chart. For example, for built-in indicator Standard Deviation with a period of 20, the line for the first 19 bars in the history is not shown in the chart. If you create a handle of this indicator with the iStdDev() function and copy it to an array of indicator values for these bars through CopyBuffer(), then these values will be equal to EMPTY_VALUE.

You can choose to specify for a custom indicator your own empty value of the indicator, when the indicator shouldn't be drawn in the chart. Use the PlotIndexSetDouble() function with the PLOT_EMPTY_VALUE modifier.

The NULL constant can be assigned to a variable of any simple type or to an object structure or class pointer. The NULL assignment for a string variable means the full deinitialization of this variable.

The WRONG_VALUE constant is intended for cases, when it is necessary to return value of an enumeration, and this must be a wrong value. For example, when we need to inform that a return value is a value from this enumeration. Let's consider as an example some function CheckLineStyle(), which returns the line style for an object, specified by its name. If at style check by

ObjectGetInteger() the result is true, a value from ENUM_LINE_STYLE is returned; otherwise WRONG_VALUE is returned.

```
void OnStart()
  {
   if(CheckLineStyle("MyChartObject")==WRONG_VALUE)
      printf("Error line style getting.");
  }
//+------------------------------------------------------------------+
//| returns the line style for an object specified by its name       |
//+------------------------------------------------------------------+
ENUM_LINE_STYLE CheckLineStyle(string name)
  {
   long style;
//---
   if(ObjectGetInteger(0,name,OBJPROP_STYLE,0,style))
      return((ENUM_LINE_STYLE)style);
   else
      return(WRONG_VALUE);
  }
```

The WHOLE_ARRAY constant is intended for functions that require specifying the number of elements in processed arrays:

- ArrayCopy();
- ArrayMinimum();
- ArrayMaximum();
- FileReadArray();
- FileWriteArray().

If you want to specify that all the array values from a specified position till the end must be processed, you should specify just the WHOLE_ARRAY value.

IS_PROFILE_MODE constant allows changing a program operation for correct data collection in the profiling mode. Profiling allows measuring the execution time of the individual program fragments (usually comprising functions), as well as calculating the number of such calls. Sleep() function calls can be disabled to determine the execution time in the profiling mode, like in this example:

```
//--- Sleep can greatly affect (change) profiling result
if(!IS_PROFILE_MODE) Sleep(100); // disabling Sleep() call in the profiling mode
```

IS_PROFILE_MODE constant value is set by the compiler during the compilation, while it is set to zero in conventional mode. When launching a program in the profiling mode, a special compilation is performed and IS_PROFILE_MODE is replaced with a non-zero value.

The IS_DEBUG_MODE constant can be useful when you need to slightly change the operation of a mql5 program in the debugging mode. For example, in debug mode you may need to display additional debugging information in the terminal log or create additional graphical objects in a chart.

The following example creates a Label object and sets its description and color depending on the script running mode. In order to run a script in the debug mode from MetaEditor, press F5. If you run the script from the browser window in the terminal, then the color and text of the object Label will be different.

Example:

```
//+------------------------------------------------------------------+
//|                                              Check_DEBUG_MODE.mq5 |
//|                        Copyright © 2009, MetaQuotes Software Corp. |
//|                                             https://www.metaquotes.net |
//+------------------------------------------------------------------+
#property copyright "Copyright © 2009, MetaQuotes Software Corp."
#property link      "https://www.metaquotes.net"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   string label_name="invisible_label";
   if(ObjectFind(0,label_name)<0)
     {
      Print("Object",label_name,"not found. Error code = ",GetLastError());
      //--- create Label
      ObjectCreate(0,label_name,OBJ_LABEL,0,0,0);
      //--- set X coordinate
      ObjectSetInteger(0,label_name,OBJPROP_XDISTANCE,200);
      //--- set Y coordinate
      ObjectSetInteger(0,label_name,OBJPROP_YDISTANCE,300);
      ResetLastError();
      if(IS_DEBUG_MODE) // debug mode
        {
         //--- show message about the script execution mode
         ObjectSetString(0,label_name,OBJPROP_TEXT,"DEBUG MODE");
         //--- set text color to red
         if(!ObjectSetInteger(0,label_name,OBJPROP_COLOR,clrRed))
            Print("Unable to set the color. Error",GetLastError());
        }
      else              // operation mode
        {
         ObjectSetString(0,label_name,OBJPROP_TEXT,"RELEASE MODE");
         //--- set text color to invisible
         if(!ObjectSetInteger(0,label_name,OBJPROP_COLOR,CLR_NONE))
            Print("Unable to set the color. Error ",GetLastError());
        }
      ChartRedraw();
      DebugBreak();     // here termination will occur, if we are in debug mode
     }
```

```
}
```

Crypt Methods

The ENUM_CRYPT_METHOD enumeration is used to specify the data transformation method, used in CryptEncode() and CryptDecode() functions.

ENUM_CRYPT_METHOD

Constant	Description
CRYPT_BASE64	BASE64
CRYPT_AES128	AES encryption with 128 bit key (16 bytes)
CRYPT_AES256	AES encryption with 256 bit key (32 bytes)
CRYPT_DES	DES encryption with 56 bit key (7 bytes)
CRYPT_HASH_SHA1	SHA1 HASH calculation
CRYPT_HASH_SHA256	SHA256 HASH calculation
CRYPT_HASH_MD5	MD5 HASH calculation
CRYPT_ARCH_ZIP	ZIP archives

Data Structures

MQL5 Language offers 12 predefined structures:

- MqlDateTime is intended for working with date and time;
- MqlParam can send input parameters when creating a handle of the indicator using the IndicatorCreate() function;
- MqlRates is intended for manipulating the historical data, it contains information about the price, volume and spread;
- MqlBookInfo is intended for obtaining information about the Depth of Market;
- MqlTradeRequest is used for creating a trade request for trade operations;
- MqlTradeCheckResult is intended for checking the prepared trade request before sending it;
- MqlTradeResult contains a trade server reply to a trade request, sent by OrderSend() function;
- MqlTradeTransaction contains description of a trade transaction;
- MqlTick is designed for fast retrieval of the most requested information about current prices.
- Economic calendar structures are used to obtain data on the economic calendar events sent to the MetaTrader 5 platform in real time. Economic calendar functions allow analyzing macroeconomic parameters immediately after new reports are released, since relevant values are broadcast directly from the source with no delay.

MqlDateTime

The date type structure contains eight fields of the int type:

```
struct MqlDateTime
  {
   int year;            // Year
   int mon;             // Month
   int day;             // Day
   int hour;            // Hour
   int min;             // Minutes
   int sec;             // Seconds
   int day_of_week;     // Day of week (0-Sunday, 1-Monday, ... ,6-Saturday)
   int day_of_year;     // Day number of the year (January 1st is assigned the number v
  };
```

Note

The day number of the year day_of_year for the leap year, since March, will differ from a number of the corresponding day for a non-leap year.

Example:

```
void OnStart()
  {
//---
   datetime date1=D'2008.03.01';
   datetime date2=D'2009.03.01';

   MqlDateTime str1,str2;
   TimeToStruct(date1,str1);
   TimeToStruct(date2,str2);
   printf("%02d.%02d.%4d, day of year = %d",str1.day,str1.mon,
          str1.year,str1.day_of_year);
   printf("%02d.%02d.%4d, day of year = %d",str2.day,str2.mon,
          str2.year,str2.day_of_year);
  }
/*  Result:
   01.03.2008, day of year = 60
   01.03.2009, day of year = 59
*/
```

TimeToStruct, Structures and Classes

The Structure of Input Parameters of Indicators (MqlParam)

The MqlParam structure has been specially designed to provide input parameters when creating the handle of a technical indicator using the IndicatorCreate() function.

```
struct MqlParam
  {
   ENUM_DATATYPE     type;                // type of the input parameter, value o
   long              integer_value;       // field to store an integer type
   double            double_value;        // field to store a double type
   string            string_value;        // field to store a string type
  };
```

All input parameters of an indicator are transmitted in the form of an array of the MqlParam type, the *type* field of each element of this array specifies the type of data transmitted by the element. The indicator values must be first placed in the appropriate fields for each element (in *integer_value*, in *double_value* or *string_value*) depending on what value of ENUM_DATATYPE enumeration is specified in the *type* field.

If the IND_CUSTOM value is passed third as the indicator type to the IndicatorCreate() function, the first element of the array of input parameters must have the *type* field with the value of TYPE_STRING from the ENUM_DATATYPE enumeration, and the *string_value* field must contain the name of the custom indicator.

MqlRates

This structure stores information about the prices, volumes and spread.

```
struct MqlRates
  {
   datetime time;         // Period start time
   double   open;         // Open price
   double   high;         // The highest price of the period
   double   low;          // The lowest price of the period
   double   close;        // Close price
   long     tick_volume;  // Tick volume
   int      spread;       // Spread
   long     real_volume;  // Trade volume
  };
```

Example:

```
void OnStart()
  {
   MqlRates rates[];
   int copied=CopyRates(NULL,0,0,100,rates);
   if(copied<=0)
      Print("Error copying price data ",GetLastError());
   else Print("Copied ",ArraySize(rates)," bars");
  }
```

See also

CopyRates, Access to timeseries

MqlBookInfo

It provides information about the market depth data.

```
struct MqlBookInfo
  {
   ENUM_BOOK_TYPE    type;           // Order type from ENUM_BOOK_TYPE enumeration
   double            price;          // Price
   long              volume;         // Volume
   double            volume_real;    // Volume with greater accuracy
  };
```

Note

The MqlBookInfo structure is predefined, thus it doesn't require any declaration and description. To use the structure, just declare a variable of this type.

The DOM is available only for some symbols.

Example:

```
   MqlBookInfo priceArray[];
   bool getBook=MarketBookGet(NULL,priceArray);
   if(getBook)
     {
      int size=ArraySize(priceArray);
      Print("MarketBookInfo about ",Symbol());
     }
   else
     {
      Print("Failed to receive DOM for the symbol ",Symbol());
     }
```

The Trade Request Structure (MqlTradeRequest)

Interaction between the client terminal and a trade server for executing the order placing operation is performed by using trade requests. The trade request is represented by the special predefined structure of MqlTradeRequest type, which contain all the fields necessary to perform trade deals. The request processing result is represented by the structure of MqlTradeResult type.

```
struct MqlTradeRequest
  {
   ENUM_TRADE_REQUEST_ACTIONS    action;           // Trade operation type
   ulong                         magic;            // Expert Advisor ID (magic number)
   ulong                         order;            // Order ticket
   string                        symbol;           // Trade symbol
   double                        volume;           // Requested volume for a deal in l
   double                        price;            // Price
   double                        stoplimit;        // StopLimit level of the order
   double                        sl;               // Stop Loss level of the order
   double                        tp;               // Take Profit level of the order
   ulong                         deviation;        // Maximal possible deviation from
   ENUM_ORDER_TYPE               type;             // Order type
   ENUM_ORDER_TYPE_FILLING       type_filling;     // Order execution type
   ENUM_ORDER_TYPE_TIME          type_time;        // Order expiration type
   datetime                      expiration;       // Order expiration time (for the o
   string                        comment;          // Order comment
   ulong                         position;         // Position ticket
   ulong                         position_by;      // The ticket of an opposite positi
  };
```

Fields description

Field	Description
action	Trade operation type. Can be one of the ENUM_TRADE_REQUEST_ACTIONS enumeration values.
magic	Expert Advisor ID. It allows organizing analytical processing of trade orders. Each Expert Advisor can set its own unique ID when sending a trade request.
order	Order ticket. It is used for modifying pending orders.
symbol	Symbol of the order. It is not necessary for order modification and position close operations.
volume	Requested order volume in lots. Note that the real volume of a deal will depend on the order execution type.
price	Price, reaching which the order must be executed. Market orders of symbols, whose execution type is "Market Execution" (SYMBOL_TRADE_EXECUTION_MARKET), of TRADE_ACTION_DEAL type, do not require specification of price.

Field	Description
stoplimit	The price value, at which the Limit pending order will be placed, when price reaches the *price* value (this condition is obligatory). Until then the pending order is not placed.
sl	Stop Loss price in case of the unfavorable price movement
tp	Take Profit price in the case of the favorable price movement
deviation	The maximal price deviation, specified in points
type	Order type. Can be one of the ENUM_ORDER_TYPE enumeration values.
type_filling	Order execution type. Can be one of the enumeration ENUM_ORDER_TYPE_FILLING values.
type_time	Order expiration type. Can be one of the enumeration ENUM_ORDER_TYPE_TIME values.
expiration	Order expiration time (for orders of ORDER_TIME_SPECIFIED type)
comment	Order comment
position	Ticket of a position. Should be filled in when a position is modified or closed to identify the position. As a rule it is equal to the ticket of the order, based on which the position was opened.
position_by	Ticket of an opposite position. Used when a position is closed by an opposite one open for the same symbol in the opposite direction.

When modifying or closing a position in the hedging system, make sure to specify its ticket (MqlTradeRequest::position). The ticket can also be specified in the netting system, though a position is identified by the symbol name.

For sending orders to perform trade operations it is necessary to use the OrderSend() function. For each trade operation it is necessary to specify obligatory fields; optional fields also may be filled. There are seven possible cases to send a trade order:

Request Execution

This is a trade order to open a position in the Request Execution mode (trade upon requested prices). It requires to specify the following 9 fields:

- action
- symbol
- volume
- price
- sl
- tp
- deviation
- type
- type_filling

Also it is possible to specify the "magic" and "comment" field values.

Instant Execution

This is a trade order to open a position in the Instant Execution mode (trade by current prices). It requires specification of the following 9 fields:

- action
- symbol
- volume
- price
- sl
- tp
- deviation
- type
- type_filling

Also it is possible to specify the "magic" and "comment" field values.

Market Execution

This is a trade order to open a position in the Market Execution mode. It requires to specify the following 5 fields:

- action
- symbol
- volume
- type
- type_filling

Also it is possible to specify the "magic" and "comment" field values.

Exchange Execution

This is a trade order to open a position in the Exchange Execution mode. It requires to specify the following 5 fields:

- action
- symbol
- volume
- type
- type_filling

Also it is possible to specify the "magic" and "comment" field values.

Example of the TRADE_ACTION_DEAL trade operation for opening a Buy position:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Opening Buy position                                             |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request={};
   MqlTradeResult  result={};
//--- parameters of request
   request.action   =TRADE_ACTION_DEAL;                    // type of trade operatio
   request.symbol   =Symbol();                             // symbol
   request.volume   =0.1;                                  // volume of 0.1 lot
   request.type     =ORDER_TYPE_BUY;                       // order type
   request.price    =SymbolInfoDouble(Symbol(),SYMBOL_ASK); // price for opening
   request.deviation=5;                                    // allowed deviation from
   request.magic    =EXPERT_MAGIC;                         // MagicNumber of the orde
//--- send the request
   if(!OrderSend(request,result))
      PrintFormat("OrderSend error %d",GetLastError());     // if unable to send the
//--- information about the operation
   PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,result
  }
//+------------------------------------------------------------------+
```

Example of the TRADE_ACTION_DEAL trade operation for opening a Sell position:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Opening Sell position                                            |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request={};
   MqlTradeResult  result={};
//--- parameters of request
   request.action   =TRADE_ACTION_DEAL;                    // type of trade operatio
   request.symbol   =Symbol();                             // symbol
   request.volume   =0.2;                                  // volume of 0.2 lot
   request.type     =ORDER_TYPE_SELL;                      // order type
   request.price    =SymbolInfoDouble(Symbol(),SYMBOL_BID); // price for opening
   request.deviation=5;                                    // allowed deviation from
   request.magic    =EXPERT_MAGIC;                         // MagicNumber of the orde
//--- send the request
   if(!OrderSend(request,result))
      PrintFormat("OrderSend error %d",GetLastError());     // if unable to send the
//--- information about the operation
   PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,result
  }
//+------------------------------------------------------------------+
```

Example of the TRADE_ACTION_DEAL trade operation for closing positions:

```
#define EXPERT_MAGIC 123456   // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Closing all positions                                            |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request;
   MqlTradeResult  result;
   int total=PositionsTotal(); // number of open positions
//--- iterate over all open positions
   for(int i=total-1; i>=0; i--)
     {
      //--- parameters of the order
      ulong  position_ticket=PositionGetTicket(i);
      string position_symbol=PositionGetString(POSITION_SYMBOL);
      int    digits=(int)SymbolInfoInteger(position_symbol,SYMBOL_DIGITS);
      ulong  magic=PositionGetInteger(POSITION_MAGIC);
      double volume=PositionGetDouble(POSITION_VOLUME);
      ENUM_POSITION_TYPE type=(ENUM_POSITION_TYPE)PositionGetInteger(POSITION_TYPE);
      //--- output information about the position
      PrintFormat("#%I64u %s  %s  %.2f  %s [%I64d]",
                  position_ticket,
                  position_symbol,
                  EnumToString(type),
                  volume,
                  DoubleToString(PositionGetDouble(POSITION_PRICE_OPEN),digits),
                  magic);
      //--- if the MagicNumber matches
      if(magic==EXPERT_MAGIC)
        {
         //--- zeroing the request and result values
         ZeroMemory(request);
         ZeroMemory(result);
         //--- setting the operation parameters
         request.action   =TRADE_ACTION_DEAL;        // type of trade operation
         request.position =position_ticket;          // ticket of the position
         request.symbol   =position_symbol;          // symbol
         request.volume   =volume;                   // volume of the position
         request.deviation=5;                        // allowed deviation from the pri
         request.magic    =EXPERT_MAGIC;             // MagicNumber of the position
         //--- set the price and order type depending on the position type
         if(type==POSITION_TYPE_BUY)
           {
            request.price=SymbolInfoDouble(position_symbol,SYMBOL_BID);
            request.type =ORDER_TYPE_SELL;
           }
         else
           {
            request.price=SymbolInfoDouble(position_symbol,SYMBOL_ASK);
            request.type =ORDER_TYPE_BUY;
           }
         //--- output information about the closure
         PrintFormat("Close #%I64d %s %s",position_ticket,position_symbol,EnumToStrin
         //--- send the request
         if(!OrderSend(request,result))
            PrintFormat("OrderSend error %d",GetLastError());  // if unable to send th
         //--- information about the operation
         PrintFormat("retcode=%u  deal=%I64u  order=%I64u",result.retcode,result.deal,
         //---
        }
```

```
      }
   }
//+------------------------------------------------------------------+
```

SL & TP Modification

Trade order to modify the StopLoss and/or TakeProfit price levels. It requires to specify the following 4 fields:

- action
- symbol
- sl
- tp
- position

Example of the TRADE_ACTION_SLTP trade operation for modifying the Stop Loss and Take Profit values of an open position:

```
#define EXPERT_MAGIC 123456  // MagicNumber of the expert
//+------------------------------------------------------------------+
//| Modification of Stop Loss and Take Profit of position            |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request;
   MqlTradeResult  result;
   int total=PositionsTotal(); // number of open positions
//--- iterate over all open positions
   for(int i=0; i<total; i++)
     {
      //--- parameters of the order
      ulong  position_ticket=PositionGetTicket(i);// ticket of the position
      string position_symbol=PositionGetString(POSITION_SYMBOL); // symbol
      int    digits=(int)SymbolInfoInteger(position_symbol,SYMBOL_DIGITS); // number o
      ulong  magic=PositionGetInteger(POSITION_MAGIC); // MagicNumber of the position
      double volume=PositionGetDouble(POSITION_VOLUME);    // volume of the position
      double sl=PositionGetDouble(POSITION_SL);  // Stop Loss of the position
      double tp=PositionGetDouble(POSITION_TP);  // Take Profit of the position
      ENUM_POSITION_TYPE type=(ENUM_POSITION_TYPE)PositionGetInteger(POSITION_TYPE);
      //--- output information about the position
      PrintFormat("#%I64u %s  %s  %.2f  %s  sl: %s  tp: %s  [%I64d]",
                  position_ticket,
                  position_symbol,
                  EnumToString(type),
                  volume,
                  DoubleToString(PositionGetDouble(POSITION_PRICE_OPEN),digits),
                  DoubleToString(sl,digits),
                  DoubleToString(tp,digits),
                  magic);
      //--- if the MagicNumber matches, Stop Loss and Take Profit are not defined
      if(magic==EXPERT_MAGIC && sl==0 && tp==0)
        {
```

```
         //--- calculate the current price levels
         double price=PositionGetDouble(POSITION_PRICE_OPEN);
         double bid=SymbolInfoDouble(position_symbol,SYMBOL_BID);
         double ask=SymbolInfoDouble(position_symbol,SYMBOL_ASK);

        }
     }
  }
//+------------------------------------------------------------------+
```

Pending Order

Trade order to place a pending order. It requires to specify the following 11 fields:

- action
- symbol
- volume
- price
- stoplimit
- sl
- tp
- type

- type_filling
- type_time
- expiration

Also it is possible to specify the "magic" and "comment" field values.

Example of the TRADE_ACTION_PENDING trade operation for placing a pending order:

```
#property description "Example of placing pending orders"
#property script_show_inputs
#define EXPERT_MAGIC 123456                                  // MagicNumber of the expert
input ENUM_ORDER_TYPE orderType=ORDER_TYPE_BUY_LIMIT;   // order type
//+------------------------------------------------------------------+
//| Placing pending orders                                           |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the trade request and result of trade request
   MqlTradeRequest request={};
   MqlTradeResult  result={};
//--- parameters to place a pending order
   request.action   =TRADE_ACTION_PENDING;                                  // type of trad
   request.symbol   =Symbol();                                              // symbol
   request.volume   =0.1;                                                   // volume of 0.
   request.deviation=2;                                                     // allowed devi
   request.magic    =EXPERT_MAGIC;                                          // MagicNumber
   int offset = 50;                                                         // offset from

Structures and Classes, Trade Functions, Order Properties

The Structure of Results of a Trade Request Check (MqlTradeCheckResult)

Before sending a request for a trade operation to a trade server, it is recommended to check it. The check is performed using the OrderCheck() function, to which the checked request and a variable of the MqlTradeCheckResult structure type are passed. The check result will be written to this variable.

```
struct MqlTradeCheckResult
  {
   uint          retcode;             // Reply code
   double        balance;             // Balance after the execution of the deal
   double        equity;              // Equity after the execution of the deal
   double        profit;              // Floating profit
   double        margin;              // Margin requirements
   double        margin_free;         // Free margin
   double        margin_level;        // Margin level
   string        comment;             // Comment to the reply code (description of the
  };
```

Description of Fields

Field	Description
retcode	Return code
balance	Balance value that will be after the execution of the trade operation
equity	Equity value that will be after the execution of the trade operation
profit	Value of the floating profit that will be after the execution of the trade operation
margin	Margin required for the trade operation
margin_free	Free margin that will be left after the execution of the trade operation
margin_level	Margin level that will be set after the execution of the trade operation
comment	Comment to the reply code, error description

Trade Request Structure, Structure for Current Prices, OrderSend, OrderCheck

The Structure of a Trade Request Result (MqlTradeResult)

As result of a trade request, a trade server returns data about the trade request processing result as a special predefined structure of MqlTradeResult type.

```
struct MqlTradeResult
  {
   uint     retcode;          // Operation return code
   ulong    deal;             // Deal ticket, if it is performed
   ulong    order;            // Order ticket, if it is placed
   double   volume;           // Deal volume, confirmed by broker
   double   price;            // Deal price, confirmed by broker
   double   bid;              // Current Bid price
   double   ask;              // Current Ask price
   string   comment;          // Broker comment to operation (by default it is filled
   uint     request_id;       // Request ID set by the terminal during the dispatch
   int      retcode_external; // Return code of an external trading system
  };
```

Fields description

Field	Description
retcode	Return code of a trade server
deal	Deal ticket, if a deal has been performed. It is available for a trade operation of TRADE_ACTION_DEAL type
order	Order ticket, if a ticket has been placed. It is available for a trade operation of TRADE_ACTION_PENDING type
volume	Deal volume, confirmed by broker. It depends on the order filling type
price	Deal price, confirmed by broker. It depends on the *deviation* field of the trade request and/or on the trade operation
bid	The current market Bid price (requote price)
ask	The current market Ask price (requote price)
comment	The broker comment to operation (by default it is filled by description of trade server return code)
request_id	Request ID set by the terminal when sending to the trade server
retcode_external	The code of the error returned by an external trading system. The use and types of these errors depend on the broker and the external trading system, to which trading operations are sent.

The trade operation result is returned to a variable of the MqlTradeResult type, which is passed as the second parameter to OrderSend() to perform trade operations.

The terminal fixes request ID in request_id field when sending it to the trade server using OrdersSend() and OrderSendAsync() functions. The terminal receives messages about performed

transactions from the trade server and submits them for processing by OnTradeTransaction() function containing the following components as parameters:

- description of the trade transaction in MqlTradeTransaction structure;
- description of the trade request sent from OrderSend() or OrdersSendAsync() function. Request ID is sent by the terminal to the trade server, while the request itself and its request_id are stored in the terminal memory;
- the trade request execution result as MqlTradeResult structure with request_id field containing ID of this request.

OnTradeTransaction() function receives three input parameters but the last two should be analyzed only for transactions having TRADE_TRANSACTION_REQUEST type. In all other cases, data on the trade request and its execution result are not filled. Example of parameters analysis can be found at Structure of a Trade Request.

Setting request_id by the terminal for the trade request when sending it to the server is mainly introduced for working with OrderSendAsync() asynchronous function. This identifier allows to associate the performed action (OrderSend or OrderSendAsync functions call) with the result of this action sent to OnTradeTransaction().

Example:

```
//+------------------------------------------------------------------+
//| Sending a trade request with the result processing               |
//+------------------------------------------------------------------+
bool MyOrderSend(MqlTradeRequest request,MqlTradeResult result)
  {
//--- reset the last error code to zero
   ResetLastError();
//--- send request
   bool success=OrderSend(request,result);
//--- if the result fails - try to find out why
   if(!success)
     {
      int answer=result.retcode;
      Print("TradeLog: Trade request failed. Error = ",GetLastError());
      switch(answer)
        {
         //--- requote
         case 10004:
           {
            Print("TRADE_RETCODE_REQUOTE");
            Print("request.price = ",request.price,"   result.ask = ",
                  result.ask," result.bid = ",result.bid);
            break;
           }
         //--- order is not accepted by the server
         case 10006:
           {
            Print("TRADE_RETCODE_REJECT");
```

```
            Print("request.price = ",request.price,"   result.ask = ",
                  result.ask," result.bid = ",result.bid);
            break;
           }
         //--- invalid price
         case 10015:
           {
            Print("TRADE_RETCODE_INVALID_PRICE");
            Print("request.price = ",request.price,"   result.ask = ",
                  result.ask," result.bid = ",result.bid);
            break;
           }
         //--- invalid SL and/or TP
         case 10016:
           {
            Print("TRADE_RETCODE_INVALID_STOPS");
            Print("request.sl = ",request.sl," request.tp = ",request.tp);
            Print("result.ask = ",result.ask," result.bid = ",result.bid);
            break;
           }
         //--- invalid volume
         case 10014:
           {
            Print("TRADE_RETCODE_INVALID_VOLUME");
            Print("request.volume = ",request.volume,"   result.volume = ",
                  result.volume);
            break;
           }
         //--- not enough money for a trade operation
         case 10019:
           {

      return(false);
     }
//--- OrderSend() returns true - repeat the answer
   return(true);
  }
```

Structure of a Trade Transaction (MqlTradeTransaction)

When performing some definite actions on a trade account, its state changes. Such actions include:

- Sending a trade request from any MQL5 application in the client terminal using OrderSend and OrderSendAsync functions and its further execution;
- Sending a trade request via the terminal graphical interface and its further execution;
- Pending orders and stop orders activation on the server;
- Performing operations on a trade server side.

The following trade transactions are performed as a result of these actions:

- handling a trade request;
- changing open orders;
- changing orders history;
- changing deals history;
- changing positions.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. All these actions are trade transactions.

Special OnTradeTransaction() handler is provided in MQL5 to get trade transactions applied to an account. The first parameter of the handler gets MqlTradeTransaction structure describing trade transactions.

```
struct MqlTradeTransaction
  {
   ulong                     deal;             // Deal ticket
   ulong                     order;            // Order ticket
   string                    symbol;           // Trade symbol name
   ENUM_TRADE_TRANSACTION_TYPE type;           // Trade transaction type
   ENUM_ORDER_TYPE           order_type;       // Order type
   ENUM_ORDER_STATE          order_state;      // Order state
   ENUM_DEAL_TYPE            deal_type;        // Deal type
   ENUM_ORDER_TYPE_TIME      time_type;        // Order type by action period
   datetime                  time_expiration;  // Order expiration time
   double                    price;            // Price
   double                    price_trigger;    // Stop limit order activation pric
   double                    price_sl;         // Stop Loss level
   double                    price_tp;         // Take Profit level
   double                    volume;           // Volume in lots
   ulong                     position;         // Position ticket
   ulong                     position_by;      // Ticket of an opposite position
  };
```

Fields Description

Field	Description
deal	Deal ticket.
order	Order ticket.
symbol	The name of the trading symbol, for which transaction is performed.
type	Trade transaction type. The value can be one of ENUM_TRADE_TRANSACTION_TYPE enumeration values.
order_type	Trade order type. The value can be one of ENUM_ORDER_TYPE enumeration values.
order_state	Trade order state. The value can be one of ENUM_ORDER_STATE enumeration values.
deal_type	Deal type. The value can be one of ENUM_DEAL_TYPE enumeration values.
time_type	Order type upon expiration. The value can be one of ENUM_ORDER_TYPE_TIME values.
time_expiration	Pending order expiration term (for orders of ORDER_TIME_SPECIFIED and ORDER_TIME_SPECIFIED_DAY types).
price	Price. Depending on a trade transaction type, it may be a price of an order, a deal or a position.
price_trigger	Stop limit order stop (activation) price (ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT).
price_sl	Stop Loss price. Depending on a trade transaction type, it may relate to an order, a deal or a position.
price_tp	Take Profit price. Depending on a trade transaction type, it may relate to an order, a deal or a position.
volume	Volume in lots. Depending on a trade transaction type, it may indicate the current volume of an order, a deal or a position.
position	The ticket of the position affected by the transaction.
position_by	The ticket of the opposite position. Used when closing a position by an opposite one, i.e. by a position of the same symbol that was opened in the opposite direction.

The essential parameter for received transaction analysis is its type specified in **type** field. For example, if a transaction is of TRADE_TRANSACTION_REQUEST type (a result of handling a trade request by the server has been received), the structure has only only one field that is filled completely - **type**. Other fields are not analyzed. In this case, we may analyze two additional **request** and **result** parameters submitted to OnTradeTransaction() handler, as shown below.

Having data on a trading operation type, you can decide on the analysis of the current state of orders, positions and deals on a trading account. Remember that one trade request sent to the server from the terminal can generate several new transactions. The priority of their arrival at the terminal is not guaranteed.

MqlTradeTransaction structure is filled in different ways depending on a trade transaction type (ENUM_TRADE_TRANSACTION_TYPE):

TRADE_TRANSACTION_ORDER_* and TRADE_TRANSACTION_HISTORY_*

The following fields in MqlTradeTransaction structure are filled for trade transactions related to open orders handling (TRADE_TRANSACTION_ORDER_ADD, TRADE_TRANSACTION_ORDER_UPDATE and TRADE_TRANSACTION_ORDER_DELETE) and orders history (TRADE_TRANSACTION_HISTORY_ADD, TRADE_TRANSACTION_HISTORY_UPDATE, TRADE_TRANSACTION_HISTORY_DELETE):

- order - order ticket;
- symbol - order symbol name;
- type - trade transaction type;
- order_type - order type;
- orders_state - order current state;
- time_type - order expiration type;
- time_expiration - order expiration time (for orders having ORDER_TIME_SPECIFIED and ORDER_TIME_SPECIFIED_DAY expiration types);
- price - order price specified by a client;
- price_trigger - stop limit order stop price (only for ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT);
- price_sl - Stop Loss order price (filled, if specified in the order);
- price_tp - Take Profit order price (filled, if specified in the order);
- volume - order current volume (unfilled). Initial order volume can be found in the orders history using HistoryOrders* function.
- position - the ticket of the position that was opened, modified or closed as a result of order execution. It is only filled for market orders, not filled for TRADE_TRANSACTION_ORDER_ADD.
- position_by - the ticket of the opposite position. It is only filled for the close by orders (to close a position by an opposite one).

TRADE_TRANSACTION_DEAL_*

The following fields in MqlTradeTransaction structure are filled for trade transactions related to deals handling (TRADE_TRANSACTION_DEAL_ADD, TRADE_TRANSACTION_DEAL_UPDATE and TRADE_TRANSACTION_DEAL_DELETE):

- deal - deal ticket;
- order - order ticket, based on which a deal has been performed;
- symbol - deal symbol name;
- type - trade transaction type;
- deal_type - deal type;
- price - deal price;
- price_sl - Stop Loss price (filled, if specified in the order, based on which a deal has been performed);
- price_tp - Take Profit price (filled, if specified in the order, based on which a deal has been performed);
- volume - deal volume in lots.
- position - the ticket of the position that was opened, modified or closed as a result of deal execution.

- position_by - the ticket of the opposite position. It is only filled for the out by deals (closing a position by an opposite one).

TRADE_TRANSACTION_POSITION

The following fields in MqlTradeTransaction structure are filled for trade transactions related to changing the positions not connected with deals execution (TRADE_TRANSACTION_POSITION):

- symbol - position symbol name;
- type - trade transaction type;
- deal_type - position type (DEAL_TYPE_BUY or DEAL_TYPE_SELL);
- price - weighted average position open price;
- price_sl - Stop Loss price;
- price_tp - Take Profit price;
- volume - position volume in lots, if it has been changed.

> Position change (adding, changing or closing), as a result of a deal execution, does not lead to the occurrence of TRADE_TRANSACTION_POSITION transaction.

TRADE_TRANSACTION_REQUEST

Only one field in MqlTradeTransaction structure is filled for trade transactions describing the fact that a trade request has been processed by a server and processing result has been received (TRADE_TRANSACTION_REQUEST):

- type - trade transaction type;

> Only type field (trade transaction type) must be analyzed for such transactions. The second and third parameters of OnTradeTransaction function (request and result) must be analyzed for additional data.

Example:

```
input int MagicNumber=1234567;

//--- enable CTrade trading class and declare the variable of this class
#include <Trade\Trade.mqh>
CTrade trade;
//--- flags for installing and deleting the pending order
bool pending_done=false;
bool pending_deleted=false;
//--- pending order ticket will be stored here
ulong order_ticket;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- set MagicNumber to mark all our orders
   trade.SetExpertMagicNumber(MagicNumber);
//--- trade requests will be sent in asynchronous mode using OrderSendAsync() functio
   trade.SetAsyncMode(true);
//--- initialize the variable by zero
```

```
   order_ticket=0;
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//---installing a pending order
   if(!pending_done)
     {
      double ask=SymbolInfoDouble(_Symbol,SYMBOL_ASK);
      double buy_stop_price=NormalizeDouble(ask+1000*_Point,(int)SymbolInfoInteger(_Sy
      bool res=trade.BuyStop(0.1,buy_stop_price,_Symbol);
      //--- if BuyStop() function performed successfully
      if(res)
        {
         pending_done=true;
         //--- get a result of the request sending from ctrade
         MqlTradeResult trade_result;
         trade.Result(trade_result);
         //--- get request_id for the sent request
         uint request_id=trade_result.request_id;
         Print("Request has been sent to set a pending order. Request_ID=",request_id)
         //--- storing the order ticket (will be zero if using the asynchronous mode o
         order_ticket=trade_result.order;

The Structure for Returning Current Prices (MqlTick)

This is a structure for storing the latest prices of the symbol. It is designed for fast retrieval of the most requested information about current prices.

```
struct MqlTick
  {
   datetime     time;          // Time of the last prices update
   double       bid;           // Current Bid price
   double       ask;           // Current Ask price
   double       last;          // Price of the last deal (Last)
   ulong        volume;        // Volume for the current Last price
   long         time_msc;      // Time of a price last update in milliseconds
   uint         flags;         // Tick flags
   double       volume_real;   // Volume for the current Last price with greater accu
  };
```

The variable of the MqlTick type allows obtaining values of Ask, Bid, Last and Volume within a single call of the SymbolInfoTick() function.

The parameters of each tick are filled in regardless of whether there are changes compared to the previous tick. Thus, it is possible to find out a correct price for any moment in the past without the need to search for previous values at the tick history. For example, even if only a Bid price changes during a tick arrival, the structure still contains other parameters as well, including the previous Ask price, volume, etc.

You can analyze the tick flags to find out what data have been changed exactly:

- TICK_FLAG_BID - tick has changed a Bid price
- TICK_FLAG_ASK - a tick has changed an Ask price
- TICK_FLAG_LAST - a tick has changed the last deal price
- TICK_FLAG_VOLUME - a tick has changed a volume
- TICK_FLAG_BUY - a tick is a result of a buy deal
- TICK_FLAG_SELL - a tick is a result of a sell deal

Example:

```
void OnTick()
  {
   MqlTick last_tick;
//---
   if(SymbolInfoTick(Symbol(),last_tick))
     {
      Print(last_tick.time,": Bid = ",last_tick.bid,
            " Ask = ",last_tick.ask,"  Volume = ",last_tick.volume);
     }
   else Print("SymbolInfoTick() failed, error = ",GetLastError());
//---
  }
```

Economic Calendar structures

This section describes the structures for working with the economic calendar available directly in the MetaTrader platform. The economic calendar is a ready-made encyclopedia featuring descriptions of macroeconomic indicators, their release dates and degrees of importance. Relevant values of macroeconomic indicators are sent to the MetaTrader platform right at the moment of publication and are displayed on a chart as tags allowing you to visually track the required indicators by countries, currencies and importance.

Economic calendar functions allow conducting the auto analysis of incoming events according to custom importance criteria from a perspective of necessary countries/currency pairs.

Country descriptions are set by the MqlCalendarCountry structure. It is used in the CalendarCountryById() and CalendarCountries() functions

```
struct MqlCalendarCountry
  {
   ulong                                id;                  // country ID (ISO 3166-
   string                               name;                // country text name (ir
   string                               code;                // country code name (IS
   string                               currency;            // country currency code
   string                               currency_symbol;     // country currency symb
   string                               url_name;            // country name used in
  };
```

Event descriptions are set by the MqlCalendarEvent structure. It is used in the CalendarEventById(), CalendarEventByCountry() and CalendarEventByCurrency() functions

```
struct MqlCalendarEvent
  {
   ulong                                id;                  // event ID
   ENUM_CALENDAR_EVENT_TYPE             type;                // event type from the E
   ENUM_CALENDAR_EVENT_SECTOR           sector;              // sector an event is re
   ENUM_CALENDAR_EVENT_FREQUENCY        frequency;           // event frequency
   ENUM_CALENDAR_EVENT_TIMEMODE         time_mode;           // event time mode
   ulong                                country_id;          // country ID
   ENUM_CALENDAR_EVENT_UNIT             unit;                // economic indicator va
   ENUM_CALENDAR_EVENT_IMPORTANCE       importance;          // event importance
   ENUM_CALENDAR_EVENT_MULTIPLIER       multiplier;          // economic indicator va
   uint                                 digits;              // number of decimal pla
   string                               source_url;          // URL of a source where
   string                               event_code;          // event code
   string                               name;                // event text name in th
  };
```

Event values are set by the MqlCalendarValue structure. It is used in the CalendarValueById(), CalendarValueHistoryByEvent(), CalendarValueHistory(), CalendarValueLastByEvent() and CalendarValueLast() functions

```
struct MqlCalendarValue
  {
   ulong                             id;                // value ID
   ulong                             event_id;          // event ID
   datetime                          time;              // event date and time
   datetime                          period;            // event reporting perio
   int                               revision;          // revision of the publi
   long                              actual_value;      // actual value multipli
   long                              prev_value;        // previous value multip
   long                              revised_prev_value; // revised previous valu
   long                              forecast_value;    // forecast value multip
   ENUM_CALENDAR_EVENT_IMPACT        impact_type;       // potential impact on t
  //--- functions checking the values
   bool                         HasActualValue(void) const;   // returns true if actua
   bool                         HasPreviousValue(void) const; // returns true if prev_
   bool                         HasRevisedValue(void) const;  // returns true if revis
   bool                         HasForecastValue(void) const; // returns true if forec
  //--- functions receiving the values
   double                       GetActualValue(void) const;   // returns actual_value
   double                       GetPreviousValue(void) const; // returns prev_value or
   double                       GetRevisedValue(void) const;  // returns revised_prev_
   double                       GetForecastValue(void) const; // returns forecast_valu
  };
```

The MqlCalendarValue structure provides methods for checking and setting values from the *actual_value*, *forecast_value*, *prev_value* and *revised_prev_value* fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in the field, then you should divide the value by 1,000,000 in order to get the desired value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

An example of handling calendar events:

```
//--- Create a structure to store calendar events with real values instead of integers
struct AdjustedCalendarValue
  {
   ulong                             id;                // value ID
   ulong                             event_id;          // event ID
   datetime                          time;              // event date and time
   datetime                          period;            // event reporting perio
   int                               revision;          // revision of the publi
   double                            actual_value;      // actual value
```

```
   double                            prev_value;            // previous value
   double                            revised_prev_value;    // revised previous valu
   double                            forecast_value;        // forecast value
   ENUM_CALENDAR_EVENT_IMPACT        impact_type;           // potential impact on t
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()

Event frequency is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_FREQUENCY**

ID	Description
CALENDAR_FREQUENCY_NONE	Release frequency is not set
CALENDAR_FREQUENCY_WEEK	Released once a week
CALENDAR_FREQUENCY_MONTH	Released once a month
CALENDAR_FREQUENCY_QUARTER	Released once a quarter
CALENDAR_FREQUENCY_YEAR	Released once a year
CALENDAR_FREQUENCY_DAY	Released once a day

Event type is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_TYPE**

ID	Description
CALENDAR_TYPE_EVENT	Event (meeting, speech, etc.)
CALENDAR_TYPE_INDICATOR	Indicator
CALENDAR_TYPE_HOLIDAY	Holiday

A sector of the economy an event is related to is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_SECTOR**

ID	Description
CALENDAR_SECTOR_NONE	Sector is not set

ID	Description
CALENDAR_SECTOR_MARKET	Market, exchange
CALENDAR_SECTOR_GDP	Gross Domestic Product (GDP)
CALENDAR_SECTOR_JOBS	Labor market
CALENDAR_SECTOR_PRICES	Prices
CALENDAR_SECTOR_MONEY	Money
CALENDAR_SECTOR_TRADE	Trading
CALENDAR_SECTOR_GOVERNMENT	Government
CALENDAR_SECTOR_BUSINESS	Business
CALENDAR_SECTOR_CONSUMER	Consumption
CALENDAR_SECTOR_HOUSING	Housing
CALENDAR_SECTOR_TAXES	Taxes
CALENDAR_SECTOR_HOLIDAYS	Holidays

Event importance is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_IMPORTANCE**

ID	Description
CALENDAR_IMPORTANCE_NONE	Importance is not set
CALENDAR_IMPORTANCE_LOW	Low importance
CALENDAR_IMPORTANCE_MODERATE	Medium importance
CALENDAR_IMPORTANCE_HIGH	High importance

Measurement unit type used in displaying event values is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_UNIT**

ID	Description
CALENDAR_UNIT_NONE	Measurement unit is not set
CALENDAR_UNIT_PERCENT	Percentage
CALENDAR_UNIT_CURRENCY	National currency
CALENDAR_UNIT_HOUR	Hours
CALENDAR_UNIT_JOB	Jobs
CALENDAR_UNIT_RIG	Drilling rigs

ID	Description
CALENDAR_UNIT_USD	USD
CALENDAR_UNIT_PEOPLE	People
CALENDAR_UNIT_MORTGAGE	Mortgage loans
CALENDAR_UNIT_VOTE	Votes
CALENDAR_UNIT_BARREL	Barrels
CALENDAR_UNIT_CUBICFEET	Cubic feet
CALENDAR_UNIT_POSITION	Non-commercial net positions
CALENDAR_UNIT_BUILDING	Buildings

In some cases, economic parameter values require a multiplier set in the MqlCalendarEvent structure. Possible multiplier values are set in the listing **ENUM_CALENDAR_EVENT_MULTIPLIER**

ID	Description
CALENDAR_MULTIPLIER_NONE	Multiplier is not set
CALENDAR_MULTIPLIER_THOUSANDS	Thousands
CALENDAR_MULTIPLIER_MILLIONS	Millions
CALENDAR_MULTIPLIER_BILLIONS	Billions
CALENDAR_MULTIPLIER_TRILLIONS	Trillions

Event's potential impact on a national currency rate is indicated in the MqlCalendarValue structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_IMPACT**

ID	Description
CALENDAR_IMPACT_NA	Impact is not set
CALENDAR_IMPACT_POSITIVE	Positive impact
CALENDAR_IMPACT_NEGATIVE	Negative impact

Event time is specified in the MqlCalendarEvent structure. Possible values are set in the listing **ENUM_CALENDAR_EVENT_TIMEMODE**

ID	Description
CALENDAR_TIMEMODE_DATETIME	Source publishes an exact time of an event
CALENDAR_TIMEMODE_DATE	Event takes all day

ID	Description
CALENDAR_TIMEMODE_NOTIME	Source publishes no time of an event
CALENDAR_TIMEMODE_TENTATIVE	Source publishes a day of an event rather than its exact time. The time is specified upon the occurrence of the event.

Codes of Errors and Warnings

This section contains the following descriptions:

- Return codes of the trade server - analyzing results of the trade request sent by function OrderSend();
- Compiler warnings - codes of warning messages that appear at compilation (not errors);
- Compilation errors - codes of error messages at an unsuccessful attempt to compile;
- Runtime errors - error codes in the execution of mql5-programs, which can be obtained using the GetLastError() function.

Return Codes of the Trade Server

All requests to execute trade operations are sent as a structure of a trade request MqlTradeRequest using function OrderSend(). The function execution result is placed to structure MqlTradeResult, whose *retcode* field contains the trade server return code.

Code	Constant	Description
10004	TRADE_RETCODE_REQUOTE	Requote
10006	TRADE_RETCODE_REJECT	Request rejected
10007	TRADE_RETCODE_CANCEL	Request canceled by trader
10008	TRADE_RETCODE_PLACED	Order placed
10009	TRADE_RETCODE_DONE	Request completed
10010	TRADE_RETCODE_DONE_PARTIAL	Only part of the request was completed
10011	TRADE_RETCODE_ERROR	Request processing error
10012	TRADE_RETCODE_TIMEOUT	Request canceled by timeout
10013	TRADE_RETCODE_INVALID	Invalid request
10014	TRADE_RETCODE_INVALID_VOLUME	Invalid volume in the request
10015	TRADE_RETCODE_INVALID_PRICE	Invalid price in the request
10016	TRADE_RETCODE_INVALID_STOPS	Invalid stops in the request
10017	TRADE_RETCODE_TRADE_DISABLED	Trade is disabled
10018	TRADE_RETCODE_MARKET_CLOSED	Market is closed
10019	TRADE_RETCODE_NO_MONEY	There is not enough money to complete the request
10020	TRADE_RETCODE_PRICE_CHANGED	Prices changed
10021	TRADE_RETCODE_PRICE_OFF	There are no quotes to process the request
10022	TRADE_RETCODE_INVALID_EXPIRATION	Invalid order expiration date in the request
10023	TRADE_RETCODE_ORDER_CHANGED	Order state changed
10024	TRADE_RETCODE_TOO_MANY_REQUESTS	Too frequent requests
10025	TRADE_RETCODE_NO_CHANGES	No changes in request
10026	TRADE_RETCODE_SERVER_DISABLES_AT	Autotrading disabled by server
10027	TRADE_RETCODE_CLIENT_DISABLES_AT	Autotrading disabled by client terminal
10028	TRADE_RETCODE_LOCKED	Request locked for processing
10029	TRADE_RETCODE_FROZEN	Order or position frozen
10030	TRADE_RETCODE_INVALID_FILL	Invalid order filling type

Code	Constant	Description
10031	TRADE_RETCODE_CONNECTION	No connection with the trade server
10032	TRADE_RETCODE_ONLY_REAL	Operation is allowed only for live accounts
10033	TRADE_RETCODE_LIMIT_ORDERS	The number of pending orders has reached the limit
10034	TRADE_RETCODE_LIMIT_VOLUME	The volume of orders and positions for the symbol has reached the limit
10035	TRADE_RETCODE_INVALID_ORDER	Incorrect or prohibited order type
10036	TRADE_RETCODE_POSITION_CLOSED	Position with the specified POSITION_IDENTIFIER has already been closed
10038	TRADE_RETCODE_INVALID_CLOSE_VOLUME	A close volume exceeds the current position volume
10039	TRADE_RETCODE_CLOSE_ORDER_EXIST	A close order already exists for a specified position. This may happen when working in the hedging system: • when attempting to close a position with an opposite one, while close orders for the position already exist • when attempting to fully or partially close a position if the total volume of the already present close orders and the newly placed one exceeds the current position volume
10040	TRADE_RETCODE_LIMIT_POSITIONS	The number of open positions simultaneously present on an account can be limited by the server settings. After a limit is reached, the server returns the TRADE_RETCODE_LIMIT_POSITIONS error when attempting to place an order. The limitation operates differently depending on the position accounting type: • Netting — number of open positions is considered. When a limit is reached, the platform does not let placing new orders whose execution may increase the number of open positions. In fact, the platform allows placing orders only for the symbols that already have open positions. The current pending orders are not considered since their execution may lead to changes in the current positions but it cannot increase their number.

Code	Constant	Description
		• Hedging — pending orders are considered together with open positions, since a pending order activation always leads to opening a new position. When a limit is reached, the platform does not allow placing both new market orders for opening positions and pending orders.
10041	TRADE_RETCODE_REJECT_CANCEL	The pending order activation request is rejected, the order is canceled
10042	TRADE_RETCODE_LONG_ONLY	The request is rejected, because the "**Only long positions are allowed**" rule is set for the symbol (POSITION_TYPE_BUY)
10043	TRADE_RETCODE_SHORT_ONLY	The request is rejected, because the "**Only short positions are allowed**" rule is set for the symbol (POSITION_TYPE_SELL)
10044	TRADE_RETCODE_CLOSE_ONLY	The request is rejected, because the "**Only position closing is allowed**" rule is set for the symbol
10045	TRADE_RETCODE_FIFO_CLOSE	The request is rejected, because "**Position closing is allowed only by FIFO rule**" flag is set for the trading account (ACCOUNT_FIFO_CLOSE=true)
10046	TRADE_RETCODE_HEDGE_PROHIBITED	The request is rejected, because the "**Opposite positions on a single symbol are disabled**" rule is set for the trading account. For example, if the account has a Buy position, then a user cannot open a Sell position or place a pending sell order. The rule is only applied to accounts with hedging accounting system (ACCOUNT_MARGIN_MODE=ACCOUNT_MARGIN_MODE_RETAIL_HEDGING).

Compiler Warnings

Compiler warnings are shown for informational purposes only and are not error messages.

Code	Description
21	Incomplete record of a date in the datetime string
22	Wrong number in the datetime string for the date. Requirements: Year 1970 <= X <= 3000 Month 0 <X <= 12 Day 0 <X <= 31/30/28 (29)....
23	Wrong number of datetime string for time. Requirements: Hour 0 <= X <24 Minute 0 <= X <60
24	Invalid color in RGB format: one of RGB components is less than 0 or greater than 255
25	Unknown character of the escape sequences. Known: \n \r \t \\ \" \' \X \x
26	Too large volume of local variables (> 512Kb) of the function, reduce the number
29	Enumeration already defined (duplication) - members will be added to the first definition
30	Overriding macro
31	The variable is declared but is not used anywhere
32	Constructor must be of void type
33	Destructor must be of void type
34	Constant does not fit in the range of integers (X> _UI64_MAX | | X <_I64_MIN) and will be converted to the double type
35	Too long HEX - more than 16 significant characters (senior nibbles are cut)
36	No nibbles in HEX string "0x"
37	No function - nothing to be performed
38	A non-initialized variable is used
41	Function has no body, and is not called
43	Possible loss of data at typecasting. Example: int x = (double) z;
44	Loss of accuracy (of data) when converting a constant. Example: int x = M_PI
45	Difference between the signs of operands in the operations of comparison. Example: (char) c1> (uchar) c2
46	Problems with function importing - declaration of #import is required or import of functions is closed

Code	Description
47	Too large description - extra characters will not be included in the executable file
48	The number of indicator buffers declared is less than required
49	No color to plot a graphical series in the indicator
50	No graphical series to draw the indicator
51	'OnStart' handler function not found in the script
52	'OnStart' handler function is defined with wrong parameters
53	'OnStart' function can be defined only in a script
54	'OnInit' function is defined with wrong parameters
55	'OnInit' function is not used in scripts
56	'OnDeinit' function is defined with wrong parameters
57	'OnDeinit' function is not used in scripts
58	Two 'OnCalculate' functions are defined. OnCalculate () at one price array will be used
59	Overfilling detected when calculating a complex integer constant
60	Probably, the variable is not initialized.
61	This declaration makes it impossible to refer to the local variable declared on the specified line
62	This declaration makes it impossible to refer to the global variable declared on the specified line
63	Cannot be used for static allocated array
64	This variable declaration hides predefined variable
65	The value of the expression is always true/false
66	Using a variable or bool type expression in mathematical operations is unsafe
67	The result of applying the unary minus operator to an unsigned ulong type is undefined
68	The version specified in the #property version property is unacceptable for the Market section; the correct format of #property version id "XXX.YYY"
69	Empty controlled statement found
70	Invalid function return type or incorrect parameters during declaration of the event handler function
71	An implicit cast of structures to one type is required
72	This declaration makes direct access to the member of a class declared in the specified string impossible. Access will be possible only with the scope resolution operation ::

Code	Description
73	Binary constant is too big, high-order digits will be truncated
74	Parameter in the method of the inherited class has a different const modifier, the derived function has overloaded the parent function
75	Negative or too large shift value in shift bitwise operation, execution result is undefined
76	Function must return a value
77	void function returns a value
78	Not all control paths return a value
79	Expressions are not allowed on a global scope
80	Check operator precedence for possible error; use parentheses to clarify precedence
81	Two OnCalCulate() are defined. OHLC version will be used
82	Struct has no members, size assigned to 1 byte
83	Return value of the function should be checked
84	Resource indicator is compiled for debugging. That slows down the performance. Please recompile the indicator to increase performance
85	Too great character code in the string, must be in the range 0 to 65535
86	Unrecognized character in the string
87	No indicator window property (setting the display in the main window or a subwindow) is defined. Property #property indicator_chart_window is applied

Compilation Errors

MetaEdtior 5 shows error messages about the program errors detected by the built-in compiler during compilation. The list of these errors is given below in table. To compile a source code into an executable one, press **F7**. Programs that contain errors cannot be compiled until the errors identified by the compiler are eliminated.

Code	Description
100	File reading error
101	Error of opening an *. EX5 for writing
103	Not enough free memory to complete compilation
104	Empty syntactic unit unrecognized by compiler
105	Incorrect file name in #include
106	Error accessing a file in #include (probably the file does not exist)
108	Inappropriate name for #define
109	Unknown command of preprocessor (valid #include, #define, #property, #import)
110	Symbol unknown to compiler
111	Function not implemented (description is present, but no body)
112	Double quote (") omitted
113	Opening angle bracket (<) or double quote (") omitted
114	Single quote (') omitted
115	Closing angle bracket ">" omitted
116	Type not specified in declaration
117	No return operator or return is found not in all branches of the implementation
118	Opening bracket of call parameters was expected
119	Error writing EX5
120	Invalid access to an array
121	The function is not of void type and the return operator must return a value
122	Incorrect declaration of the destructor
123	Colon ":" is missing
124	Variable is already declared
125	Variable with such identifier already declared
126	Variable name is too long (> 250 characters)
127	Structure with such identifier already defined

Code	Description
128	Structure is not defined
129	Structure member with the same name already defined
130	No such structure member
131	Breached pairing of brackets
132	Opening parenthesis "(" expected
133	Unbalanced braces (no "}")
134	Difficult to compile (too much branching, internal stack levels are overfilled)
135	Error of file opening for reading
136	Not enough memory to download the source file into memory
137	Variable is expected
138	Reference cannot be initialized
140	Assignment expected (appears at declaration)
141	Opening brace "{" expected
142	Parameter can be a dynamic array only
143	Use of "void" type is unacceptable
144	No pair for ")" or "]", i.e. "(or" [" is absent
145	No pair for "(or" [", i.e. ") "or"] " is absent
146	Incorrect array size
147	Too many parameters (> 64)
149	This token is not expected here
150	Invalid use of operation (invalid operands)
151	Expression of void type not allowed
152	Operator is expected
153	Misuse of break
154	Semicolon ";" expected
155	Comma "," expected
156	Must be a class type, not struct
157	Expression is expected
158	"non HEX character" found in HEX or too long number (number of digits> 511)
159	String-constant has more than 65534 characters

Code	Description
160	Function definition is unacceptable here
161	Unexpected end of program
162	Forward declaration is prohibited for structures
163	Function with this name is already defined and has another return type
164	Function with this name is already defined and has a different set of parameters
165	Function with this name is already defined and implemented
166	Function overload for this call was not found
167	Function with a return value of void type cannot return a value
168	Function is not defined
170	Value is expected
171	In *case* expression only integer constants are valid
172	The value of *case* in this *switch* is already used
173	Integer is expected
174	In #import expression file name is expected
175	Expressions are not allowed on global level
176	Omitted parenthesis ")" before ";"
177	To the left of equality sign a variable is expected
178	The result of expression is not used
179	Declaring of variables is not allowed in *case*
180	Implicit conversion from a string to a number
181	Implicit conversion of a number to a string
182	Ambiguous call of an overloaded function (several overloads fit)
183	Illegal *else* without proper *if*
184	Invalid *case* or *default* without a *switch*
185	Inappropriate use of ellipsis
186	The initializing sequence has more elements than the initialized variable
187	A constant for *case* expected
188	A constant expression required
189	A constant variable cannot be changed
190	Closing bracket or a comma is expected (declaring array member)

Code	Description
191	Enumerator identifier already defined
192	Enumeration cannot have access modifiers (const, extern, static)
193	Enumeration member already declared with a different value
194	There is a variable defined with the same name
195	There is a structure defined with the same name
196	Name of enumeration member expected
197	Integer expression expected
198	Division by zero in constant expression
199	Wrong number of parameters in the function
200	Parameter by reference must be a variable
201	Variable of the same type to pass by reference expected
202	A constant variable cannot be passed by a non-constant reference
203	Requires a positive integer constant
204	Failed to access protected class member
205	Import already defined in another way
208	Executable file not created
209	'OnCalculate' entry point not found for the indicator
210	The continue operation can be used only inside a loop
211	Error accessing private (closed) class member
213	Method of structure or class is not declared
214	Error accessing private (closed) class method
216	Copying of structures with objects is not allowed
218	Index out of array range
219	Array initialization in structure or class declaration not allowed
220	Class constructor cannot have parameters
221	Class destructor can not have parameters
222	Class method or structure with the same name and parameters have already been declared
223	Operand expected
224	Class method or structure with the same name exists, but with different parameters (declaration!=implementation)

Code	Description
225	Imported function is not described
226	ZeroMemory() is not allowed for objects with protected members or inheritance
227	Ambiguous call of the overloaded function (exact match of parameters for several overloads)
228	Variable name expected
229	A reference cannot be declared in this place
230	Already used as the enumeration name
232	Class or structure expected
235	Cannot call 'delete' operator to delete the array
236	Operator ' while' expected
237	Operator 'delete' must have a pointer
238	There is 'default' for this 'switch' already
239	Syntax error
240	Escape-sequence can occur only in strings (starts with '\')
241	Array required - square bracket '[' does not apply to an array, or non arrays are passed as array parameters
242	Can not be initialized through the initialization sequence
243	Import is not defined
244	Optimizer error on the syntactic tree
245	Declared too many structures (try to simplify the program)
246	Conversion of the parameter is not allowed
247	Incorrect use of the 'delete' operator
248	It's not allowed to declare a pointer to a reference
249	It's not allowed to declare a reference to a reference
250	It's not allowed to declare a pointer to a pointer
251	Structure declaration in the list of parameter is not allowed
252	Invalid operation of typecasting
253	A pointer can be declared only for a class or structure
256	Undeclared identifier
257	Executable code optimizer error
258	Executable code generation error

Code	Description
260	Invalid expression for the 'switch' operator
261	Pool of string constants overfilled, simplify program
262	Cannot convert to enumeration
263	Do not use 'virtual' for data (members of a class or structure)
264	Cannot call protected method of class
265	Overridden virtual functions return a different type
266	Class cannot be inherited from a structure
267	Structure cannot be inherited from a class
268	Constructor cannot be virtual (*virtual* specifier is not allowed)
269	Method of structure cannot be virtual
270	Function must have a body
271	Overloading of system functions (terminal functions) is prohibited
272	*Const* specifier is invalid for functions that are not members of a class or structure
274	Not allowed to change class members in constant method
276	Inappropriate initialization sequence
277	Missed default value for the parameter (specific declaration of default parameters)
278	Overriding the default parameter (different values in declaration and implementation)
279	Not allowed to call non-constant method for a constant object
280	An object is necessary for accessing members (a dot for a non class/structure is specified)
281	The name of an already declared structure cannot be used in declaration
284	Unauthorized conversion (at closed inheritance)
285	Structures and arrays cannot be used as input variables
286	*Const* specifier is not valid for constructor/destructor
287	Incorrect string expression for a datetime
288	Unknown property (#property)
289	Incorrect value of a property
290	Invalid index for a property in #property
291	Call parameter omitted - <func (x,)>
293	Object must be passed by reference

Code	Description
294	Array must be passed by reference
295	Function was declared as exportable
296	Function was not declared as exportable
297	It is prohibited to export imported function
298	Imported function cannot have this parameter (prohibited to pass a pointer, class or structure containing a dynamic array, pointer, class, etc.)
299	Must be a class
300	#import was not closed
302	Type mismatch
303	Extern variable is already initialized
304	No exported function or entry point found
305	Explicit constructor call is not allowed
306	Method was declared as constant
307	Method was not declared as constant
308	Incorrect size of the resource file
309	Incorrect resource name
310	Resource file opening error
311	Resource file reading error
312	Unknown resource type
313	Incorrect path to the resource file
314	The specified resource name is already used
315	Argument expected for the function-like macro
316	Unexpected symbol in macro definition
317	Error in formal parameters of the macro
318	Invalid number of parameters for a macro
319	Too many parameters for a macro
320	Too complex, simplify the macro
321	Parameter for EnumToString() can be only an enumeration
322	The resource name is too long
323	Unsupported image format (only BMP with 24 or 32 bit color depth is supported)
324	An array cannot be declared in operator

Code	Description
325	The function can be declared only in the global scope
326	The declaration is not allowed for the current scope
327	Initialization of static variables with the values of local variables is not allowed
328	Illegal declaration of an array of objects that do not have a default constructor
329	Initialization list allowed only for constructors
330	No function definition after initialization list
331	Initialization list is empty
332	Array initialization in a constructor is not allowed
333	Initializing members of a parent class in the initialization list is not allowed
334	Expression of the integer type expected
335	Memory required for the array exceeds the maximum value
336	Memory required for the structure exceeds the maximum value
337	Memory required for the variables declared on the global level exceeds the maximum value
338	Memory required for local variables exceeds the maximum value
339	Constructor not defined
340	Invalid name of the icon file
341	Could not open the icon file at the specified path
342	The icon file is incorrect and is not of the ICO format
343	Reinitialization of a member in a class/structure constructor using the initialization list
344	Initialization of static members in the constructor initialization list is not allowed
345	Initialization of a non-static member of a class/structure on a global level is not allowed
346	The name of the class/structure method matches the name of an earlier declared member
347	The name of the class/structure member matches the name of an earlier declared method
348	Virtual function cannot be declared as static
349	The const modifier is not allowed for static functions
350	Constructor or destructor cannot be static
351	Non-static member/method of a class or a structure cannot be accessed from a static function

Code	Description
352	An overload operation (+,-,[],++,-- etc.) is expected after the operator keyword
353	Not all operations can be overloaded in MQL5
354	Definition does not match declaration
355	An invalid number of parameters is specified for the operator
356	Event handling function not found
357	Method cannot be exported
358	A pointer to the constant object cannot be normalized by a non-constant object
359	Class templates are not supported yet
360	Function template overload is not supported yet
361	Function template cannot be applied
362	Ambiguous parameter in function template (several parameter types can be applied)
363	Unable to determine the parameter type, by which the function template argument should be normalized
364	Incorrect number of parameters in the function template
365	Function template cannot be virtual
366	Function templates cannot be exported
367	Function templates cannot be imported
368	Structures containing the objects are not allowed
369	String arrays and structures containing the objects are not allowed
370	A static class/structure member must be explicitly initialized
371	Compiler limitation: the string cannot contain more than 65 535 characters
372	Inconsistent #ifdef/#endif
373	Object of class cannot be returned, copy constructor not found
374	Non-static members and methods cannot be used
375	OnTesterInit() impossible to use without OnTesterDeinit()
376	Redefinition of formal parameter '%s'
377	Macro __FUNCSIG__ and __FUNCTION__ cannot appear outside of a function body
378	Invalid returned type. For example, this error will be produced for functions imported from DLL that return structure or pointer.
379	Template usage error
380	Not used

Code	Description
381	Illegal syntax when declaring pure virtual function, only "=NULL" or "=0" are allowed
382	Only virtual functions can be declared with the pure-specifier ("=NULL" or "=0")
383	Abstract class cannot be instantiated
384	A pointer to a user-defined type should be applied as a target type for dynamic casting using the dynamic_cast operator
385	"Pointer to function" type is expected
386	Pointers to methods are not supported
387	Error - cannot define the type of a pointer to function
388	Type cast is not available due to private inheritance
389	A variable with const modifier should be initialized during declaration
393	Only methods with public access can be declared in an interface
394	Invalid nesting of an interface inside of another interface
395	An interface can only be derived from another interface
396	An interface is expected
397	Interfaces only support public inheritance
398	An interface cannot contain members
399	Interface objects cannot be created directly, only use inheritance
400	A specifier cannot be used in a forward declaration
401	Inheritance from the class is impossible, since it is declared with the final specifier
402	Cannot redefine a method declared with the final specifier
403	The final specifier can be applied only to virtual functions
404	The method marked by the override specifier actually does not override any base class function
405	A specifier is not allowed in defining a function, but only in declaring
406	Cannot cast the type to the specified one
407	The type cannot be used for a resource variable
408	Error in the project file
409	Cannot be used as a union member
410	Ambiguous choice for the name, the usage context should be explicitly defined
411	The structure cannot be used from DLL
412	Cannot call a function marked by the delete specifier

Code	Description
413	MQL4 is not supported. To compile this program, use MetaEditor from your MetaTrader 4 installation folder

Runtime Errors

GetLastError() is the function that returns the last error code that is stored in the predefined variable _LastError. This value can be reset to zero by the ResetLastError() function.

Constant	Code	Description
ERR_SUCCESS	0	The operation completed successfully
ERR_INTERNAL_ERROR	4001	Unexpected internal error
ERR_WRONG_INTERNAL_PARAMETER	4002	Wrong parameter in the inner call of the client terminal function
ERR_INVALID_PARAMETER	4003	Wrong parameter when calling the system function
ERR_NOT_ENOUGH_MEMORY	4004	Not enough memory to perform the system function
ERR_STRUCT_WITHOBJECTS_ORCLASS	4005	The structure contains objects of strings and/or dynamic arrays and/or structure of such objects and/or classes
ERR_INVALID_ARRAY	4006	Array of a wrong type, wrong size, or a damaged object of a dynamic array
ERR_ARRAY_RESIZE_ERROR	4007	Not enough memory for the relocation of an array, or an attempt to change the size of a static array
ERR_STRING_RESIZE_ERROR	4008	Not enough memory for the relocation of string
ERR_NOTINITIALIZED_STRING	4009	Not initialized string
ERR_INVALID_DATETIME	4010	Invalid date and/or time
ERR_ARRAY_BAD_SIZE	4011	Total amount of elements in the array cannot exceed 2147483647
ERR_INVALID_POINTER	4012	Wrong pointer
ERR_INVALID_POINTER_TYPE	4013	Wrong type of pointer
ERR_FUNCTION_NOT_ALLOWED	4014	Function is not allowed for call
ERR_RESOURCE_NAME_DUPLICATED	4015	The names of the dynamic and the static resource match
ERR_RESOURCE_NOT_FOUND	4016	Resource with this name has not been found in EX5

Constant	Code	Description
ERR_RESOURCE_UNSUPPORTED_TYPE	4017	Unsupported resource type or its size exceeds 16 Mb
ERR_RESOURCE_NAME_IS_TOO_LONG	4018	The resource name exceeds 63 characters
ERR_MATH_OVERFLOW	4019	Overflow occurred when calculating math function
ERR_SLEEP_ERROR	4020	Out of test end date after calling Sleep()
ERR_PROGRAM_STOPPED	4022	Test forcibly stopped from the outside. For example, optimization interrupted, visual testing window closed or testing agent stopped
ERR_INVALID_TYPE	4023	Invalid type
ERR_INVALID_HANDLE	4024	Invalid handle
ERR_TOO_MANY_OBJECTS	4025	Object pool filled out
Charts		
ERR_CHART_WRONG_ID	4101	Wrong chart ID
ERR_CHART_NO_REPLY	4102	Chart does not respond
ERR_CHART_NOT_FOUND	4103	Chart not found
ERR_CHART_NO_EXPERT	4104	No Expert Advisor in the chart that could handle the event
ERR_CHART_CANNOT_OPEN	4105	Chart opening error
ERR_CHART_CANNOT_CHANGE	4106	Failed to change chart symbol and period
ERR_CHART_WRONG_PARAMETER	4107	Error value of the parameter for the function of working with charts
ERR_CHART_CANNOT_CREATE_TIMER	4108	Failed to create timer
ERR_CHART_WRONG_PROPERTY	4109	Wrong chart property ID
ERR_CHART_SCREENSHOT_FAILED	4110	Error creating screenshots
ERR_CHART_NAVIGATE_FAILED	4111	Error navigating through chart
ERR_CHART_TEMPLATE_FAILED	4112	Error applying template
ERR_CHART_WINDOW_NOT_FOUND	4113	Subwindow containing the indicator was not found

Constant	Code	Description
ERR_CHART_INDICATOR_CANNOT_ADD	4114	Error adding an indicator to chart
ERR_CHART_INDICATOR_CANNOT_DEL	4115	Error deleting an indicator from the chart
ERR_CHART_INDICATOR_NOT_FOUND	4116	Indicator not found on the specified chart
Graphical Objects		
ERR_OBJECT_ERROR	4201	Error working with a graphical object
ERR_OBJECT_NOT_FOUND	4202	Graphical object was not found
ERR_OBJECT_WRONG_PROPERTY	4203	Wrong ID of a graphical object property
ERR_OBJECT_GETDATE_FAILED	4204	Unable to get date corresponding to the value
ERR_OBJECT_GETVALUE_FAILED	4205	Unable to get value corresponding to the date
MarketInfo		
ERR_MARKET_UNKNOWN_SYMBOL	4301	Unknown symbol
ERR_MARKET_NOT_SELECTED	4302	Symbol is not selected in MarketWatch
ERR_MARKET_WRONG_PROPERTY	4303	Wrong identifier of a symbol property
ERR_MARKET_LASTTIME_UNKNOWN	4304	Time of the last tick is not known (no ticks)
ERR_MARKET_SELECT_ERROR	4305	Error adding or deleting a symbol in MarketWatch
History Access		
ERR_HISTORY_NOT_FOUND	4401	Requested history not found
ERR_HISTORY_WRONG_PROPERTY	4402	Wrong ID of the history property
ERR_HISTORY_TIMEOUT	4403	Exceeded history request timeout
ERR_HISTORY_BARS_LIMIT	4404	Number of requested bars limited by terminal settings
ERR_HISTORY_LOAD_ERRORS	4405	Multiple errors when loading history
ERR_HISTORY_SMALL_BUFFER	4407	Receiving array is too small to store all requested data

Constant	Code	Description
Global_Variables		
ERR_GLOBALVARIABLE_NOT_FOUND	4501	Global variable of the client terminal is not found
ERR_GLOBALVARIABLE_EXISTS	4502	Global variable of the client terminal with the same name already exists
ERR_GLOBALVARIABLE_NOT_MODIFIED	4503	Global variables were not modified
ERR_GLOBALVARIABLE_CANNOTREAD	4504	Cannot read file with global variable values
ERR_GLOBALVARIABLE_CANNOTWRITE	4505	Cannot write file with global variable values
ERR_MAIL_SEND_FAILED	4510	Email sending failed
ERR_PLAY_SOUND_FAILED	4511	Sound playing failed
ERR_MQL5_WRONG_PROPERTY	4512	Wrong identifier of the program property
ERR_TERMINAL_WRONG_PROPERTY	4513	Wrong identifier of the terminal property
ERR_FTP_SEND_FAILED	4514	File sending via ftp failed
ERR_NOTIFICATION_SEND_FAILED	4515	Failed to send a notification
ERR_NOTIFICATION_WRONG_PARAMETER	4516	Invalid parameter for sending a notification - an empty string or NULL has been passed to the SendNotification() function
ERR_NOTIFICATION_WRONG_SETTINGS	4517	Wrong settings of notifications in the terminal (ID is not specified or permission is not set)
ERR_NOTIFICATION_TOO_FREQUENT	4518	Too frequent sending of notifications
ERR_FTP_NOSERVER	4519	FTP server is not specified
ERR_FTP_NOLOGIN	4520	FTP login is not specified
ERR_FTP_FILE_ERROR	4521	File not found in the MQL5\Files directory to send on FTP server
ERR_FTP_CONNECT_FAILED	4522	FTP connection failed
ERR_FTP_CHANGEDIR	4523	FTP path not found on server
Custom Indicator Buffers		

Constant	Code	Description
ERR_BUFFERS_NO_MEMORY	4601	Not enough memory for the distribution of indicator buffers
ERR_BUFFERS_WRONG_INDEX	4602	Wrong indicator buffer index
Custom Indicator Properties		
ERR_CUSTOM_WRONG_PROPERTY	4603	Wrong ID of the custom indicator property
Account		
ERR_ACCOUNT_WRONG_PROPERTY	4701	Wrong account property ID
ERR_TRADE_WRONG_PROPERTY	4751	Wrong trade property ID
ERR_TRADE_DISABLED	4752	Trading by Expert Advisors prohibited
ERR_TRADE_POSITION_NOT_FOUND	4753	Position not found
ERR_TRADE_ORDER_NOT_FOUND	4754	Order not found
ERR_TRADE_DEAL_NOT_FOUND	4755	Deal not found
ERR_TRADE_SEND_FAILED	4756	Trade request sending failed
ERR_TRADE_CALC_FAILED	4758	Failed to calculate profit or margin
Indicators		
ERR_INDICATOR_UNKNOWN_SYMBOL	4801	Unknown symbol
ERR_INDICATOR_CANNOT_CREATE	4802	Indicator cannot be created
ERR_INDICATOR_NO_MEMORY	4803	Not enough memory to add the indicator
ERR_INDICATOR_CANNOT_APPLY	4804	The indicator cannot be applied to another indicator
ERR_INDICATOR_CANNOT_ADD	4805	Error applying an indicator to chart
ERR_INDICATOR_DATA_NOT_FOUND	4806	Requested data not found
ERR_INDICATOR_WRONG_HANDLE	4807	Wrong indicator handle
ERR_INDICATOR_WRONG_PARAMETERS	4808	Wrong number of parameters when creating an indicator
ERR_INDICATOR_PARAMETERS_MISSING	4809	No parameters when creating an indicator
ERR_INDICATOR_CUSTOM_NAME	4810	The first parameter in the array must be the name of the custom indicator

Constant	Code	Description
ERR_INDICATOR_PARAMETER_TYPE	4811	Invalid parameter type in the array when creating an indicator
ERR_INDICATOR_WRONG_INDEX	4812	Wrong index of the requested indicator buffer
Depth of Market		
ERR_BOOKS_CANNOT_ADD	4901	Depth Of Market can not be added
ERR_BOOKS_CANNOT_DELETE	4902	Depth Of Market can not be removed
ERR_BOOKS_CANNOT_GET	4903	The data from Depth Of Market can not be obtained
ERR_BOOKS_CANNOT_SUBSCRIBE	4904	Error in subscribing to receive new data from Depth Of Market
File Operations		
ERR_TOO_MANY_FILES	5001	More than 64 files cannot be opened at the same time
ERR_WRONG_FILENAME	5002	Invalid file name
ERR_TOO_LONG_FILENAME	5003	Too long file name
ERR_CANNOT_OPEN_FILE	5004	File opening error
ERR_FILE_CACHEBUFFER_ERROR	5005	Not enough memory for cache to read
ERR_CANNOT_DELETE_FILE	5006	File deleting error
ERR_INVALID_FILEHANDLE	5007	A file with this handle was closed, or was not opening at all
ERR_WRONG_FILEHANDLE	5008	Wrong file handle
ERR_FILE_NOTTOWRITE	5009	The file must be opened for writing
ERR_FILE_NOTTOREAD	5010	The file must be opened for reading
ERR_FILE_NOTBIN	5011	The file must be opened as a binary one
ERR_FILE_NOTTXT	5012	The file must be opened as a text
ERR_FILE_NOTTXTORCSV	5013	The file must be opened as a text or CSV
ERR_FILE_NOTCSV	5014	The file must be opened as CSV
ERR_FILE_READERROR	5015	File reading error

Constant	Code	Description
ERR_FILE_BINSTRINGSIZE	5016	String size must be specified, because the file is opened as binary
ERR_INCOMPATIBLE_FILE	5017	A text file must be for string arrays, for other arrays - binary
ERR_FILE_IS_DIRECTORY	5018	This is not a file, this is a directory
ERR_FILE_NOT_EXIST	5019	File does not exist
ERR_FILE_CANNOT_REWRITE	5020	File can not be rewritten
ERR_WRONG_DIRECTORYNAME	5021	Wrong directory name
ERR_DIRECTORY_NOT_EXIST	5022	Directory does not exist
ERR_FILE_ISNOT_DIRECTORY	5023	This is a file, not a directory
ERR_CANNOT_DELETE_DIRECTORY	5024	The directory cannot be removed
ERR_CANNOT_CLEAN_DIRECTORY	5025	Failed to clear the directory (probably one or more files are blocked and removal operation failed)
ERR_FILE_WRITEERROR	5026	Failed to write a resource to a file
ERR_FILE_ENDOFFILE	5027	Unable to read the next piece of data from a CSV file (FileReadString, FileReadNumber, FileReadDatetime, FileReadBool), since the end of file is reached
String Casting		
ERR_NO_STRING_DATE	5030	No date in the string
ERR_WRONG_STRING_DATE	5031	Wrong date in the string
ERR_WRONG_STRING_TIME	5032	Wrong time in the string
ERR_STRING_TIME_ERROR	5033	Error converting string to date
ERR_STRING_OUT_OF_MEMORY	5034	Not enough memory for the string
ERR_STRING_SMALL_LEN	5035	The string length is less than expected
ERR_STRING_TOO_BIGNUMBER	5036	Too large number, more than ULONG_MAX
ERR_WRONG_FORMATSTRING	5037	Invalid format string
ERR_TOO_MANY_FORMATTERS	5038	Amount of format specifiers more than the parameters

Constant	Code	Description
ERR_TOO_MANY_PARAMETERS	5039	Amount of parameters more than the format specifiers
ERR_WRONG_STRING_PARAMETER	5040	Damaged parameter of string type
ERR_STRINGPOS_OUTOFRANGE	5041	Position outside the string
ERR_STRING_ZEROADDED	5042	0 added to the string end, a useless operation
ERR_STRING_UNKNOWNTYPE	5043	Unknown data type when converting to a string
ERR_WRONG_STRING_OBJECT	5044	Damaged string object
Operations with Arrays		
ERR_INCOMPATIBLE_ARRAYS	5050	Copying incompatible arrays. String array can be copied only to a string array, and a numeric array - in numeric array only
ERR_SMALL_ASSERIES_ARRAY	5051	The receiving array is declared as AS_SERIES, and it is of insufficient size
ERR_SMALL_ARRAY	5052	Too small array, the starting position is outside the array
ERR_ZEROSIZE_ARRAY	5053	An array of zero length
ERR_NUMBER_ARRAYS_ONLY	5054	Must be a numeric array
ERR_ONEDIM_ARRAYS_ONLY	5055	Must be a one-dimensional array
ERR_SERIES_ARRAY	5056	Timeseries cannot be used
ERR_DOUBLE_ARRAY_ONLY	5057	Must be an array of type double
ERR_FLOAT_ARRAY_ONLY	5058	Must be an array of type float
ERR_LONG_ARRAY_ONLY	5059	Must be an array of type long
ERR_INT_ARRAY_ONLY	5060	Must be an array of type int
ERR_SHORT_ARRAY_ONLY	5061	Must be an array of type short
ERR_CHAR_ARRAY_ONLY	5062	Must be an array of type char
ERR_STRING_ARRAY_ONLY	5063	String array only
Operations with OpenCL		
ERR_OPENCL_NOT_SUPPORTED	5100	OpenCL functions are not supported on this computer
ERR_OPENCL_INTERNAL	5101	Internal error occurred when running OpenCL

Constant	Code	Description
ERR_OPENCL_INVALID_HANDLE	5102	Invalid OpenCL handle
ERR_OPENCL_CONTEXT_CREATE	5103	Error creating the OpenCL context
ERR_OPENCL_QUEUE_CREATE	5104	Failed to create a run queue in OpenCL
ERR_OPENCL_PROGRAM_CREATE	5105	Error occurred when compiling an OpenCL program
ERR_OPENCL_TOO_LONG_KERNEL_NAME	5106	Too long kernel name (OpenCL kernel)
ERR_OPENCL_KERNEL_CREATE	5107	Error creating an OpenCL kernel
ERR_OPENCL_SET_KERNEL_PARAMETER	5108	Error occurred when setting parameters for the OpenCL kernel
ERR_OPENCL_EXECUTE	5109	OpenCL program runtime error
ERR_OPENCL_WRONG_BUFFER_SIZE	5110	Invalid size of the OpenCL buffer
ERR_OPENCL_WRONG_BUFFER_OFFSET	5111	Invalid offset in the OpenCL buffer
ERR_OPENCL_BUFFER_CREATE	5112	Failed to create an OpenCL buffer
ERR_OPENCL_TOO_MANY_OBJECTS	5113	Too many OpenCL objects
ERR_OPENCL_SELECTDEVICE	5114	OpenCL device selection error
Working with databases		
ERR_DATABASE_INTERNAL	5120	Internal database error
ERR_DATABASE_INVALID_HANDLE	5121	Invalid database handle
ERR_DATABASE_TOO_MANY_OBJECTS	5122	Exceeded the maximum acceptable number of Database objects
ERR_DATABASE_CONNECT	5123	Database connection error
ERR_DATABASE_EXECUTE	5124	Request execution error
ERR_DATABASE_PREPARE	5125	Request generation error
ERR_DATABASE_NO_MORE_DATA	5126	No more data to read
ERR_DATABASE_STEP	5127	Failed to move to the next request entry
ERR_DATABASE_NOT_READY	5128	Data for reading request results are not ready yet
ERR_DATABASE_BIND_PARAMETERS	5129	Failed to auto substitute parameters to an SQL request

Constant	Code	Description
Operations with WebRequest		
ERR_WEBREQUEST_INVALID_ADDRESS	5200	Invalid URL
ERR_WEBREQUEST_CONNECT_FAILED	5201	Failed to connect to specified URL
ERR_WEBREQUEST_TIMEOUT	5202	Timeout exceeded
ERR_WEBREQUEST_REQUEST_FAILED	5203	HTTP request failed
Operations with network (sockets)		
ERR_NETSOCKET_INVALIDHANDLE	5270	Invalid socket handle passed to function
ERR_NETSOCKET_TOO_MANY_OPENED	5271	Too many open sockets (max 128)
ERR_NETSOCKET_CANNOT_CONNECT	5272	Failed to connect to remote host
ERR_NETSOCKET_IO_ERROR	5273	Failed to send/receive data from socket
ERR_NETSOCKET_HANDSHAKE_FAILED	5274	Failed to establish secure connection (TLS Handshake)
ERR_NETSOCKET_NO_CERTIFICATE	5275	No data on certificate protecting the connection
Custom Symbols		
ERR_NOT_CUSTOM_SYMBOL	5300	A custom symbol must be specified
ERR_CUSTOM_SYMBOL_WRONG_NAME	5301	The name of the custom symbol is invalid. The symbol name can only contain Latin letters without punctuation, spaces or special characters (may only contain ".", "_", "&" and "#"). It is not recommended to use characters <, >, :, ", /,\, |, ?, *.
ERR_CUSTOM_SYMBOL_NAME_LONG	5302	The name of the custom symbol is too long. The length of the symbol name must not exceed 32 characters including the ending 0 character
ERR_CUSTOM_SYMBOL_PATH_LONG	5303	The path of the custom symbol is too long. The path length should not exceed 128 characters including "Custom\\", the symbol name, group separators and the ending 0

Constant	Code	Description
ERR_CUSTOM_SYMBOL_EXIST	5304	A custom symbol with the same name already exists
ERR_CUSTOM_SYMBOL_ERROR	5305	Error occurred while creating, deleting or changing the custom symbol
ERR_CUSTOM_SYMBOL_SELECTED	5306	You are trying to delete a custom symbol selected in Market Watch
ERR_CUSTOM_SYMBOL_PROPERTY_WRONG	5307	An invalid custom symbol property
ERR_CUSTOM_SYMBOL_PARAMETER_ERROR	5308	A wrong parameter while setting the property of a custom symbol
ERR_CUSTOM_SYMBOL_PARAMETER_LONG	5309	A too long string parameter while setting the property of a custom symbol
ERR_CUSTOM_TICKS_WRONG_ORDER	5310	Ticks in the array are not arranged in the order of time
Economic Calendar		
ERR_CALENDAR_MORE_DATA	5400	Array size is insufficient for receiving descriptions of all values
ERR_CALENDAR_TIMEOUT	5401	Request time limit exceeded
ERR_CALENDAR_NO_DATA	5402	Country is not found
Working with databases		
ERR_DATABASE_ERROR	5601	Generic error
ERR_DATABASE_LOGIC	5602	SQLite internal logic error
ERR_DATABASE_PERM	5603	Access denied
ERR_DATABASE_ABORT	5604	Callback routine requested abort
ERR_DATABASE_BUSY	5605	Database file locked
ERR_DATABASE_LOCKED	5606	Database table locked
ERR_DATABASE_NOMEM	5607	Insufficient memory for completing operation
ERR_DATABASE_READONLY	5608	Attempt to write to readonly database
ERR_DATABASE_INTERRUPT	5609	Operation terminated by sqlite3_interrupt()
ERR_DATABASE_IOERR	5610	Disk I/O error

Constant	Code	Description
ERR_DATABASE_CORRUPT	5611	Database disk image corrupted
ERR_DATABASE_NOTFOUND	5612	Unknown operation code in sqlite3_file_control()
ERR_DATABASE_FULL	5613	Insertion failed because database is full
ERR_DATABASE_CANTOPEN	5614	Unable to open the database file
ERR_DATABASE_PROTOCOL	5615	Database lock protocol error
ERR_DATABASE_EMPTY	5616	Internal use only
ERR_DATABASE_SCHEMA	5617	Database schema changed
ERR_DATABASE_TOOBIG	5618	String or BLOB exceeds size limit
ERR_DATABASE_CONSTRAINT	5619	Abort due to constraint violation
ERR_DATABASE_MISMATCH	5620	Data type mismatch
ERR_DATABASE_MISUSE	5621	Library used incorrectly
ERR_DATABASE_NOLFS	5622	Uses OS features not supported on host
ERR_DATABASE_AUTH	5623	Authorization denied
ERR_DATABASE_FORMAT	5624	Not used
ERR_DATABASE_RANGE	5625	Bind parameter error, incorrect index
ERR_DATABASE_NOTADB	5626	File opened that is not database file
Matrix and Vector Methods		
ERR_MATRIX_INTERNAL	5700	Internal error of the matrix/vector executing subsystem
ERR_MATRIX_NOT_INITIALIZED	5701	Matrix/vector not initialized
ERR_MATRIX_INCONSISTENT	5702	Inconsistent size of matrices/vectors in operation
ERR_MATRIX_INVALID_SIZE	5703	Invalid matrix/vector size
ERR_MATRIX_INVALID_TYPE	5704	Invalid matrix/vector type
ERR_MATRIX_FUNC_NOT_ALLOWED	5705	Function not available for this matrix/vector
ERR_MATRIX_CONTAINS_NAN	5706	Matrix/vector contains non-numbers (Nan/Inf)

Constant	Code	Description
ONNX models		
ERR_ONNX_INTERNAL	5800	ONNX internal error
ERR_ONNX_NOT_INITIALIZED	5801	ONNX Runtime API initialization error
ERR_ONNX_NOT_SUPPORTED	5802	Property or value not supported by MQL5
ERR_ONNX_RUN_FAILED	5803	ONNX runtime API run error
ERR_ONNX_INVALID_PARAMETERS_COUNT	5804	Invalid number of parameters passed to OnnxRun
ERR_ONNX_INVALID_PARAMETER	5805	Invalid parameter value
ERR_ONNX_INVALID_PARAMETER_TYPE	5806	Invalid parameter type
ERR_ONNX_INVALID_PARAMETER_SIZE	5807	Invalid parameter size
ERR_ONNX_WRONG_DIMENSION	5808	Tensor dimension not set or invalid
User errors		
ERR_USER_ERROR_FIRST	65536	User defined errors start with this code

Input and Output Constants

Constants:

- File opening flags
- File properties
- Positioning inside a file
- Code page usage
- MessageBox

File Opening Flags

File opening flag values specify the file access mode. Flags are defined as follows:

Identifier	Value	Description
FILE_READ	1	File is opened for reading. Flag is used in FileOpen(). When opening a file specification of FILE_WRITE and/or FILE_READ is required.
FILE_WRITE	2	File is opened for writing. Flag is used in FileOpen(). When opening a file specification of FILE_WRITE and/or FILE_READ is required.
FILE_BIN	4	Binary read/write mode (without string to string conversion). Flag is used in FileOpen().
FILE_CSV	8	CSV file (all its elements are converted to strings of the appropriate type, Unicode or ANSI, and separated by separator). Flag is used in FileOpen().
FILE_TXT	16	Simple text file (the same as csv file, but without taking into account the separators). Flag is used in FileOpen().
FILE_ANSI	32	Strings of ANSI type (one byte symbols). Flag is used in FileOpen().
FILE_UNICODE	64	Strings of UNICODE type (two byte symbols). Flag is used in FileOpen().
FILE_SHARE_READ	128	Shared access for reading from several programs. Flag is used in FileOpen(), but it does not replace the necessity to indicate FILE_WRITE and/or the FILE_READ flag when opening a file.
FILE_SHARE_WRITE	256	Shared access for writing from several programs. Flag is used in FileOpen(), but it does not replace the necessity to indicate FILE_WRITE and/or the FILE_READ flag when opening a file.
FILE_REWRITE	512	Possibility for the file rewrite using functions FileCopy() and FileMove(). The file should exist or should be opened for writing, otherwise the file will not be opened.
FILE_COMMON	4096	The file path in the common folder of all client terminals \Terminal\Common\Files. Flag is used in FileOpen(), FileCopy(), FileMove() and in FileIsExist() functions.

One or several flags can be specified when opening a file. This is a combination of flags. The combination of flags is written using the sign of logical OR (|), which is positioned between enumerated flags. For example, to open a file in CSV format for reading and writing at the same time, specify the combination FILE_READ|FILE_WRITE|FILE_CSV.

Example:

```
int filehandle=FileOpen(filename,FILE_READ|FILE_WRITE|FILE_CSV);
```

There are some specific features of work when you specify read and write flags:

- If FILE_READ is specified, an attempt is made to open an existing file. If a file does not exist, file opening fails, a new file is not created.
- FILE_READ|FILE_WRITE – a new file is created if the file with the specified name does not exist.
- FILE_WRITE – the file is created again with a zero size.

When opening a file, specification of FILE_WRITE and/or FILE_READ is required.

Flags that define the type of reading of an open file possess priority. The highest flag is FILE_CSV, then goes FILE_BIN, and FILE_TXT is of lowest priority. Thus, if several flags are specified at the same time, (FILE_TXT|FILE_CSV or FILE_TXT|FILE_BIN or FILE_BIN|FILE_CSV), the flag with the highest priority will be used.

Flags that define the type of encoding also have priority. FILE_UNICODE is of a higher priority than FILE_ANSI. So if you specify combination FILE_UNICODE|FILE_ANSI, flag FILE_UNICODE will be used.

If neither FILE_UNICODE nor FILE_ANSI is indicated, FILE_UNICODE is implied. If neither FILE_CSV, nor FILE_BIN, nor FILE_TXT is specified, FILE_CSV is implied.

If a file is opened for reading as a text file (FILE_TXT or FILE_CSV), and at the file beginning a special two-byte indication 0xff,0xfe is found, the encoding flag will be FILE_UNICODE, even if FILE_ANSI is specified.

File Functions

File Properties

The FileGetInteger() function is used for obtaining file properties. The identifier of the required property from the ENUM_FILE_PROPERTY_INTEGER enumeration is passed to it during call.

ENUM_FILE_PROPERTY_INTEGER

ID	ID description
FILE_EXISTS	Check the existence
FILE_CREATE_DATE	Date of creation
FILE_MODIFY_DATE	Date of the last modification
FILE_ACCESS_DATE	Date of the last access to the file
FILE_SIZE	File size in bytes
FILE_POSITION	Position of a pointer in the file
FILE_END	Get the end of file sign
FILE_LINE_END	Get the end of line sign
FILE_IS_COMMON	The file is opened in a shared folder of all terminals (see FILE_COMMON)
FILE_IS_TEXT	The file is opened as a text file (see FILE_TXT)
FILE_IS_BINARY	The file is opened as a binary file (see FILE_BIN)
FILE_IS_CSV	The file is opened as CSV (see FILE_CSV)
FILE_IS_ANSI	The file is opened as ANSI (see FILE_ANSI)
FILE_IS_READABLE	The opened file is readable (see FILE_READ)
FILE_IS_WRITABLE	The opened file is writable (see FILE_WRITE)

The FileGetInteger() function has two different options of call. In the first option, for getting properties of a file, its handle is specified, which is obtained while opening the file using the FileOpen() function. This option allows getting all properties of a file.

The second option of the FileGetInteger() function returns values of file properties by the file name. Using this option, only the following general properties can be obtained:

- FILE_EXISTS - existence of a file with a specified name
- FILE_CREATE_DATE - date of creation of the file with the specified name
- FILE_MODIFY_DATE - date of modification of the file with the specified name
- FILE_ACCESS_DATE - date of the last access to the file with the specified name
- FILE_SIZE - size of the file with the specified name

When trying to get properties other than specified above, the second option of FileGetInteger() call will return an error.

Positioning Inside a File

Most of file functions are associated with data read/write operations. At the same time, using the FileSeek() you can specify the position of a file pointer to a position inside the file, from which the next read or write operation will be performed. The ENUM_FILE_POSITION enumeration contains valid pointer positions, relative to which you can specify the shift in bytes for the next operation.

ENUM_FILE_POSITION

Identifier	Description
SEEK_SET	File beginning
SEEK_CUR	Current position of a file pointer
SEEK_END	File end

FileIsEnding, FileIsLineEnding

Using a Codepage in String Conversion Operations

When converting string variables into arrays of char type and back, the encoding that by default corresponds to the current ANSI of Windows operating system (CP_ACP) is used in MQL5. If you want to specify a different type of encoding, it can be set as additional parameter for the CharArrayToString(), StringToCharArray() and FileOpen() functions.

The table lists the built-in constants for some of the most popular code pages. Not mentioned code pages can be specified by a code corresponding to the page.

Built-in Constants of Codepages

Constant	Value	Description
CP_ACP	0	The current Windows ANSI code page.
CP_OEMCP	1	The current system OEM code page.
CP_MACCP	2	The current system Macintosh code page. **Note:** This value is mostly used in earlier created program codes and is of no use now, since modern Macintosh computers use Unicode for encoding.
CP_THREAD_ACP	3	The Windows ANSI code page for the current thread.
CP_SYMBOL	42	Symbol code page
CP_UTF7	65000	UTF-7 code page.
CP_UTF8	65001	UTF-8 code page.

Client Terminal Properties

Constants of the MessageBox Dialog Window

This section contains return codes of the MessageBox() function. If a message window has a Cancel button, the function returns IDCANCEL, in case if the ESC key or the Cancel button is pressed. If there is no Cancel button in the message window, the pressing of ESC does not give any effect.

Constant	Value	Description
IDOK	1	"OK" button has been pressed
IDCANCEL	2	"Cancel" button has been pressed
IDABORT	3	"Abort" button has been pressed
IDRETRY	4	"Retry" button has been pressed
IDIGNORE	5	"Ignore" button has been pressed
IDYES	6	"Yes" button has been pressed
IDNO	7	"No" button has been pressed
IDTRYAGAIN	10	"Try Again" button has been pressed
IDCONTINUE	11	"Continue" button has been pressed

The main flags of the MessageBox() function define contents and behavior of the dialog window. This value can be a combination of the following flag groups:

Constant	Value	Description
MB_OK	0x00000000	Message window contains only one button: OK. Default
MB_OKCANCEL	0x00000001	Message window contains two buttons: OK and Cancel
MB_ABORTRETRYIGNORE	0x00000002	Message window contains three buttons: Abort, Retry and Ignore
MB_YESNOCANCEL	0x00000003	Message window contains three buttons: Yes, No and Cancel
MB_YESNO	0x00000004	Message window contains two buttons: Yes and No
MB_RETRYCANCEL	0x00000005	Message window contains two buttons: Retry and Cancel
MB_CANCELTRYCONTINUE	0x00000006	Message window contains three buttons: Cancel, Try Again, Continue

To display an icon in the message window it is necessary to specify additional flags:

Constant	Value	Description
MB_ICONSTOP, MB_ICONERROR, MB_ICONHAND	0x00000010	The STOP sign icon
MB_ICONQUESTION	0x00000020	The question sign icon
MB_ICONEXCLAMATION, MB_ICONWARNING	0x00000030	The exclamation/warning sign icon
MB_ICONINFORMATION, MB_ICONASTERISK	0x00000040	The encircled i sign

Default buttons are defined by the following flags:

Constant	Value	Description
MB_DEFBUTTON1	0x00000000	The first button MB_DEFBUTTON1 - is default, if the other buttons MB_DEFBUTTON2, MB_DEFBUTTON3, or MB_DEFBUTTON4 are not specified
MB_DEFBUTTON2	0x00000100	The second button is default
MB_DEFBUTTON3	0x00000200	The third button is default
MB_DEFBUTTON4	0x00000300	The fourth button is default

MQL5 Programs

For the mql5-program to operate, it must be compiled (Compile button or F7 key). Compilation should pass without errors (some warnings are possible; they should be analyzed). At this process, an executable file with the same name and with EX5 extension must be created in the corresponding directory, terminal_dir\MQL5\Experts, terminal_dir\MQL5\indicators or terminal_dir\MQL5\scripts. This file can be run.

Operating features of MQL5 programs are described in the following sections:

- Program running – order of calling predefined event-handlers.
- Testing trading strategies – operating features of MQL5 programs in the Strategy Tester.
- Client terminal events – description of events, which can be processed in programs.
- Call of imported functions – description order, allowed parameters, search details and call agreement for imported functions.
- Runtime errors – getting information about runtime and critical errors.

Expert Advisors, custom indicators and scripts are attached to one of opened charts by Drag'n'Drop method from the Navigator window.

For an expert Advisor to stop operating, it should be removed from a chart. To do it select "Expert list" in chart context menu, then select an Expert Advisor from list and click "Remove" button. Operation of Expert Advisors is also affected by the state of the "AutoTrading" button.

In order to stop a custom indicator, it should be removed from a chart.

Custom indicators and Expert Advisors work until they are explicitly removed from a chart; information about attached Expert Advisors and Indicators is saved between client terminal sessions.

Scripts are executed once and are deleted automatically upon operation completion or change of the current chart state, or upon client terminal shutdown. After the restart of the client terminal scripts are not started, because the information about them is not saved.

Maximum one Expert Advisor, one script and unlimited number of indicators can operate in one chart.

Services do not require to be bound to a chart to work and are designed to perform auxiliary functions. For example, in a service, you can create a custom symbol, open its chart, receive data for it in an endless loop using the network functions and constantly update it.

Program Running

Each script, each service and each Expert Advisor runs in its own separate thread. All indicators calculated on one symbol, even if they are attached to different charts, work in the same thread. Thus, all indicators on one symbol share the resources of one thread.

All other actions associated with a symbol, like processing of ticks and history synchronization, are also consistently performed in the same thread with indicators. This means that if an infinite action is performed in an indicator, all other events associated with its symbol will never be performed.

When running an Expert Advisor, make sure that it has an actual trading environment and can access the history of the required symbol and period, and synchronize data between the terminal and the server. For all these procedures, the terminal provides a start delay of no more than 5 seconds, after which the Expert Advisor will be started with available data. Therefore, in case there is no connection to the server, this may lead to a delay in the start of an Expert Advisor.

The below table contains a brief summary of MQL5 programs:

Program	Running	Note
Service	A separate thread, the number of threads for services is equal to the number of services	A looped service cannot break running of other programs
Script	A separate thread, the number of threads for scripts is equal to the number of scripts	A looped script cannot break running of other programs
Expert Advisor	A separate thread, the number of threads for Expert Advisors is equal to the number of Expert Advisors	A looped Expert Advisor cannot break running of other programs
Indicator	One thread for all indicators on a symbol. The number of threads is equal to the number of symbols with indicators	An infinite loop in one indicator will stop all other indicators on this symbol

Right after a program is attached to a chart, it is uploaded to the client terminal memory, as well as global variable are initialized. If some global variable of the class type has a constructor, this constructor will be called during initialization of global variables.

After that the program is waiting for an event from the client terminal. Each mql5-program should have at least one event-handler, otherwise the loaded program will not be executed. Event handlers have predefined names, parameters and return types.

Type	Function name	Parameters	Application	Comment
int	OnInit	none	Expert Advisors and indicators	Init event handler. It allows to use the void return type.

Type	Function name	Parameters	Application	Comment
void	OnDeinit	const int reason	Expert Advisors and indicators	Deinit event handler.
void	OnStart	none	scripts and services	Start event handler.
int	OnCalculate	const int rates_total, const int prev_calculated, const datetime &Time[], const double &Open[], const double &High[], const double &Low[], const double &Close[], const long &TickVolume[], const long &Volume[], const int &Spread[]	indicators	Calculate event handler for all prices.
int	OnCalculate	const int rates_total, const int prev_calculated, const int begin, const double &price[]	indicators	Calculate event handler on the single data array. Indicator cannot have two event handlers simultaneously. In this case the only one event handler will work on the data array.
void	OnTick	none	Expert Advisors	NewTick event handler. While the event of a new tick receipt is being processed, no other events of this type are received.
void	OnTimer	none	Expert Advisors and indicators	Timer event handler.
void	OnTrade	none	Expert Advisors	Trade event handler.
double	OnTester	none	Expert Advisors	Tester event handler.
void	OnChartEvent	const int id, const long &lparam, const double &dparam, const string &sparam	Expert Advisors and indicators	ChartEvent event handler.
void	OnBookEvent	const string &symbol_name	Expert Advisors and indicators	BookEvent event handler.

A client terminal sends new events to the corresponding open charts. Events can also be generated by charts (chart events) or mql5-programs (custom events). Generation of events of creation or deletion of graphical objects on a chart can be enabled or disabled by setting CHART_EVENT_OBJECT_CREATE and CHART_EVENT_OBJECT_DELETE chart properties. Each MQL5 program and each chart has its own queue of events, where all new incoming events are added.

A program receives only events from the chart it runs on. All events are processed one after another in the order they are received. If a queue already has a NewTick event, or this event is currently being processed, then the new NewTick event is not placed in the queue of the MQL5 program. Similarly, if ChartEvent is already enqueued, or this event is being processed, no new event of this kind is enqueued. The timer events are handled the same way – if the Timer event is in the queue or being handled, the new timer event is not enqueued.

Event queues have a limited but sufficient size, so that the queue overflow for well written programs is unlikely. In case of queue overflow, new events are discarded without queuing.

It is strongly recommended not to use infinite loops to handle events. Possible exceptions are scripts and services handling a single Start event.

Libraries do not handle any events.

Functions prohibited in Indicators and Expert Advisors

Indicators, scripts and Expert Advisors are executable programs written in MQL5. They are designed for different types of tasks. Therefore there are some restrictions on the use of certain functions, depending on the type of program. The following functions are prohibited in indicators:

- OrderCalcMargin();
- OrderCalcProfit();
- OrderCheck();
- OrderSend();
- SendFTP();
- Sleep();
- ExpertRemove();
- MessageBox().

All functions designed for indicators are prohibited in Expert Advisors and scripts:

- SetIndexBuffer();
- IndicatorSetDouble();
- IndicatorSetInteger();
- IndicatorSetString();
- PlotIndexSetDouble();
- PlotIndexSetInteger();
- PlotIndexSetString();

- PlotIndexGetInteger.

The library is not an independent program and is executed in the context of the MQL5 program that has called it: script, indicator or Expert Advisor. Accordingly, the above restrictions apply to the called library.

Functions prohibited in services

Services do not accept any events, as they are not bound to a chart. The following functions are prohibited in services:

ExpertRemove();

EventSetMillisecondTimer();

EventSetTimer();

EventKillTimer();

SetIndexBuffer();

IndicatorSetDouble();

IndicatorSetInteger();

IndicatorSetString();

PlotIndexSetDouble();

PlotIndexSetInteger();

PlotIndexSetString();

PlotIndexGetInteger();

Loading and Unloading of Indicators

Indicators are loaded in the following cases:

- an indicator is attached to a chart;
- terminal start (if the indicator was attached to the chart prior to the shutdown of the terminal);
- loading of a template (if the indicator attached to a chart is specified in the template);
- change of a profile (if the indicator is attached to one of the profile charts);
- change of a symbol and/or timeframe of a chart, to which the indicator is attached;
- change of the account to which the terminal is connected;
- after the successful recompilation of an indicator (if the indicator was attached to a chart);
- change of input parameters of the indicator.

Indicators are unloaded in the following cases:

- when detaching an indicator from a chart;
- terminal shutdown (if the indicator was attached to a chart);
- loading of a template (if an indicator is attached to a chart);

- closing of a chart, to which the indicator was attached;
- change of a profile (if the indicator is attached to one of charts of the changed profile);
- change of a symbol and/or timeframe of a chart, to which the indicator is attached;
- change of the account to which the terminal is connected;
- change of input parameters of the indicator.

Loading and Unloading of Expert Advisors

Expert Advisors are loaded in the following cases:

- when attaching an Expert Advisor to a chart;
- terminal start (if the Expert Advisor was attached to the chart prior to the shutdown of the terminal);
- loading of a template (if the Expert Advisor attached to the chart is specified in the template);
- change of a profile (if the Expert Advisor is attached to the one of the profile charts);
- connection to an account, even if the account number is the same (if the Expert Advisor was attached to the chart before the authorization of the terminal on the server).

Expert Advisors are unloaded in the following cases:

- when detaching an Expert Advisor from a chart;
- if a new Expert Advisor is attached to a chart, if another Expert Advisor has been attached already, this Expert Advisor is unloaded.
- terminal shutdown (if the Expert Advisor was attached to a chart);
- loading of a template (if an Expert Advisor is attached to the chart);
- close of a chart, to which the Expert Advisor is attached.
- change of a profile (if the Expert Advisor is attached to one of charts of the changed profile);
- change of the account to which the terminal is connected (if the Expert Advisor was attached to the chart before the authorization of the terminal on the server);
- calling the ExpertRemove() function.

In case the symbol or timeframe of a chart, to which the Expert Advisor is attached, changes, Expert Advisors are not loaded or unloaded. In this case client terminal subsequently calls OnDeinit() handlers on the old symbol/timeframe and OnInit() on the new symbol/timeframe (if they are such), values of global variables and static variables are not reset. All events, which have been received for the Expert Advisor before the initialization is completed (OnInit() function) are skipped.

Loading and Unloading of Scripts

Scripts are loaded immediately after they are attached to a chart and unloaded immediately after they complete their operation. OnInit() and OnDeinit() are not called for scripts.

When a program is unloaded (deleted from a chart) the client terminal performs deinitialization of global variables and deletes the events queue. In this case deinitialization means reset of all the

string-type variables, deallocation of dynamical array objects and call of their destructors if they are available.

Loading and Unloading services

Services are loaded right after starting the terminal if they were launched at the moment of the terminal shutdown. Services are unloaded immediately after completing their work.

Services have a single OnStart() handler, in which you can implement an endless data receiving and handling loop, for example creating and updating custom symbols using the network functions.

Unlike Expert Advisors, indicators and scripts, services are not bound to a specific chart, therefore a separate mechanism is provided to launch them. A new service instance is created in the Navigator using the "Add Service" command. A service instance can be launched, stopped and removed using the appropriate instance menu. To manage all instances, use the service menu.

For a better understanding of the Expert Advisor operation we recommend to compile the code of the following Expert Advisor and perform actions of load/unload, template change, symbol change, timeframe change etc:

Example:

```
//+------------------------------------------------------------------+
//|                                                   TestExpert.mq5 |
//|                        Copyright 2009, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "2009, MetaQuotes Software Corp."
#property link      "https://www.mql5.com"
#property version   "1.00"

class CTestClass
  {
public:
   CTestClass() { Print("CTestClass constructor"); }
   ~CTestClass() { Print("CTestClass destructor"); }
  };
CTestClass global;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//---
   Print("Initialization");
//---
   return(INIT_SUCCEEDED);
```

```
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//---
   Print("Deinitialization with reason",reason);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//---

  }
//+------------------------------------------------------------------+
```

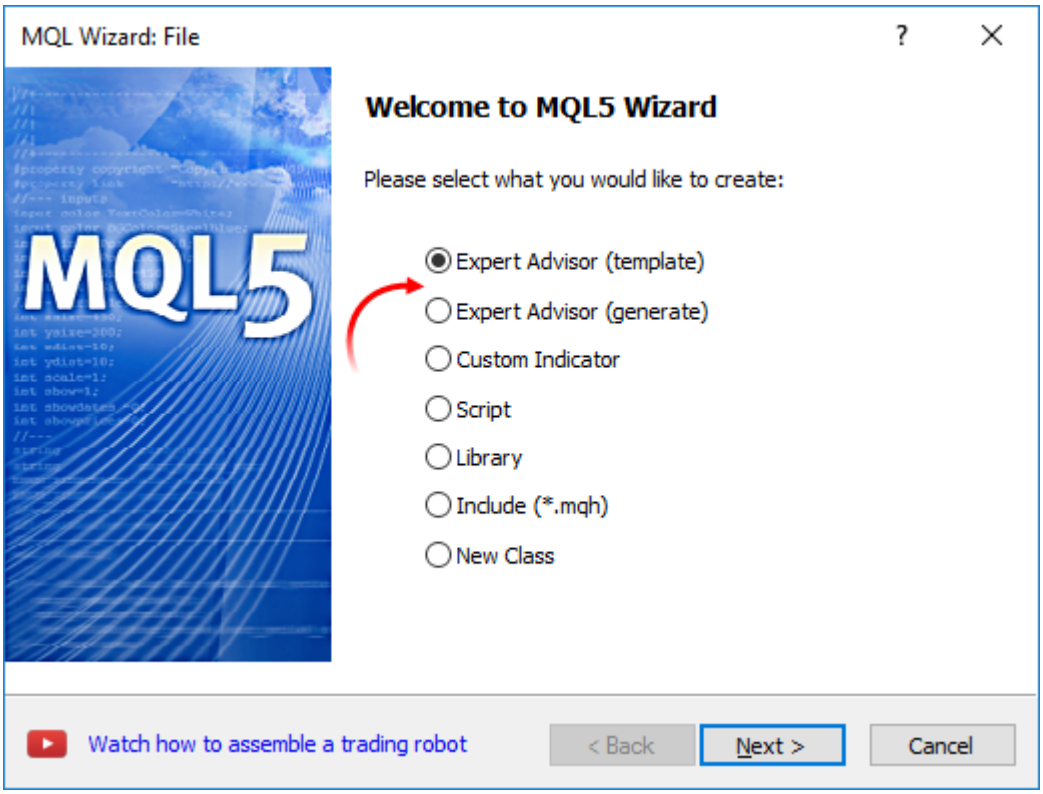
Trade Permission

Trade Automation

MQL5 language provides a special group of trade functions designed for developing automated trading systems. Programs developed for automated trading with no human intervention are called Expert Advisors or trading robots. In order to create an Expert Advisor in MetaEditor, launch MQL5 Wizard and select one of the two options:

- Expert Advisor (template) – allows you to create a template with ready-made event handling functions that should be supplemented with all necessary functionality by means of programming.
- Expert Advisor (generate) – allows you to develop a full-fledged trading robot simply by selecting the necessary modules: trading signals module, money management module and trailing stop module.



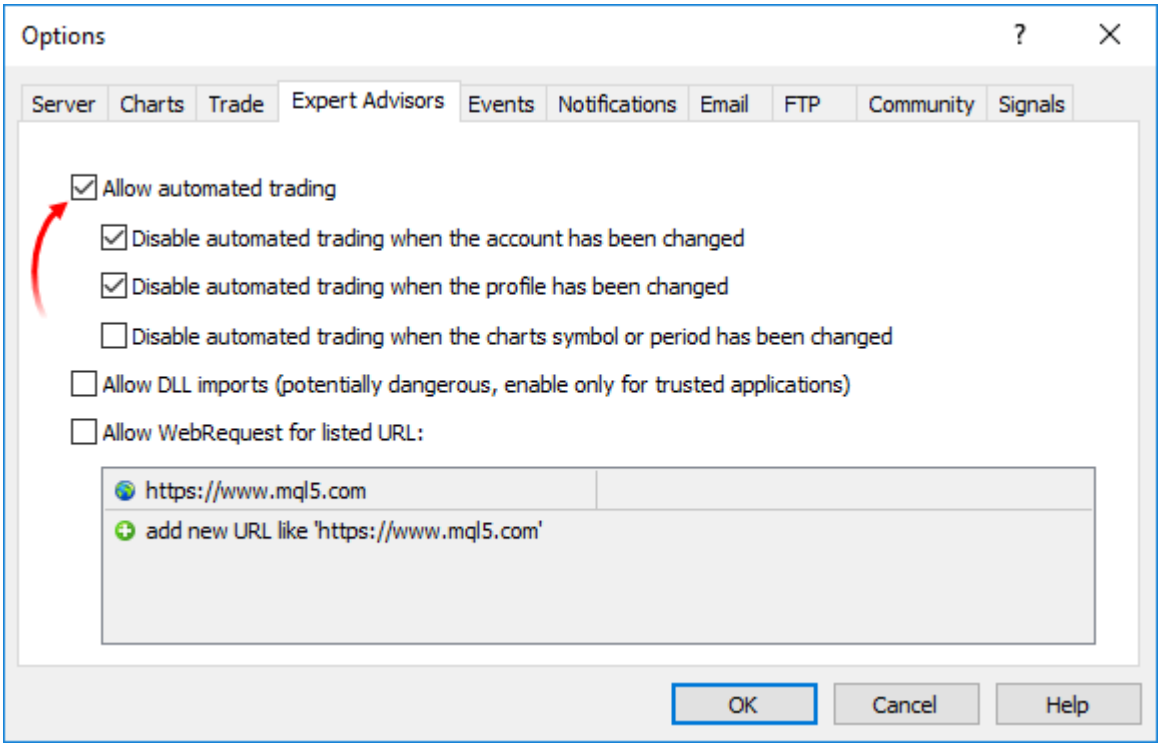
Trading functions can work only in Expert Advisors and scripts. Trading is not allowed for indicators.

Checking for Permission to Perform Automated Trading

In order to develop a reliable Expert Advisor capable of working without human intervention, it is necessary to arrange a set of important checks. First, we should programmatically check if trading is allowed at all. This is a basic check that is indispensable when developing any automated system.

Checking for permission to perform automated trading in the terminal

The terminal settings provide you with an ability to allow or forbid automated trading for all programs.



You can switch automated trading option right on the terminal's Standard panel:

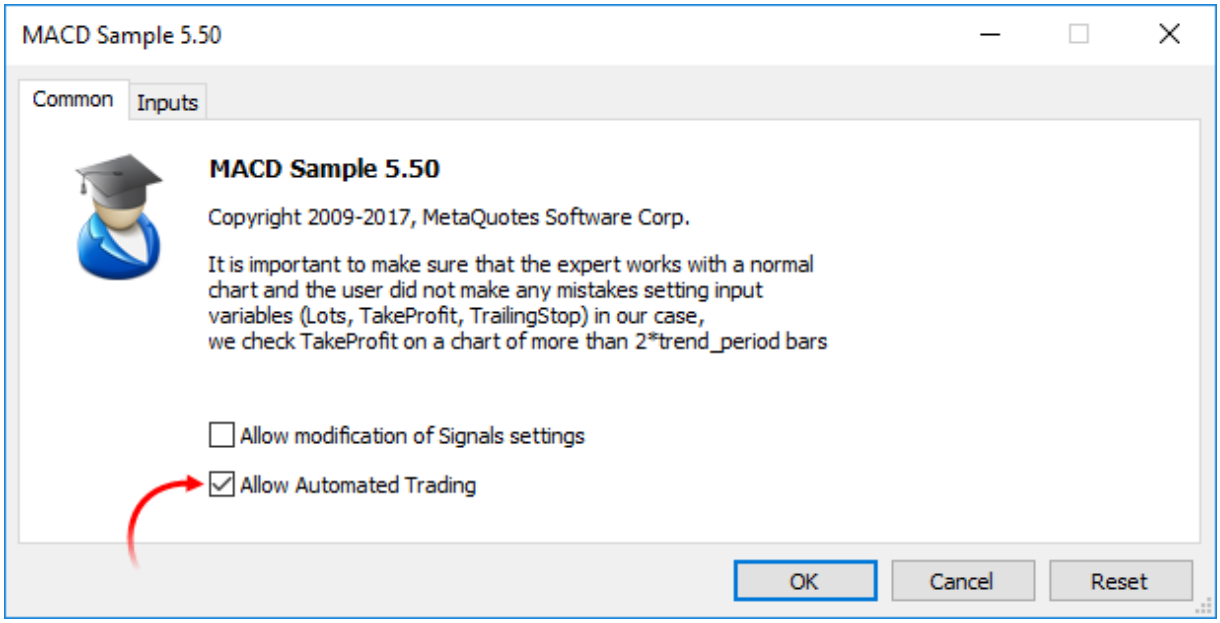
- 
- automated trading enabled, trading functions in launched applications are allowed for use.
- 
- automated trading disabled, running applications are unable to execute trading functions.

Sample check:

```
if (!TerminalInfoInteger(TERMINAL_TRADE_ALLOWED))
   Alert("Check if automated trading is allowed in the terminal settings!");
```

Checking if trading is allowed for a certain running Expert Advisor/script

You can allow or forbid automated trading for a certain program when launching it. To do this, use the special check box in the program properties.



Sample check:

```
if(!TerminalInfoInteger(TERMINAL_TRADE_ALLOWED))
   Alert("Check if automated trading is allowed in the terminal settings!");
else
  {
   if(!MQLInfoInteger(MQL_TRADE_ALLOWED))
      Alert("Automated trading is forbidden in the program settings for ",__FILE__)
  }
```

Checking if trading is allowed for any Expert Advisors/scripts for the current account

Automated trading can be disabled at the trade server side. Sample check:

```
if(!AccountInfoInteger(ACCOUNT_TRADE_EXPERT))
   Alert("Automated trading is forbidden for the account ",AccountInfoInteger(ACCOU
   " at the trade server side");
```

If automated trading is disabled for a trading account, trading operations of Expert Advisors/scripts are not executed.

Checking if trading is allowed for the current account

In some cases, any trading operations are disabled for a certain trading account - neither manual nor automated trading can be performed. Sample check when an investor password has been used to connect to a trading account:

```
if(!AccountInfoInteger(ACCOUNT_TRADE_ALLOWED))
   Comment("Trading is forbidden for the account ",AccountInfoInteger(ACCOUNT_LOGIN
         ".\n Perhaps an investor password has been used to connect to the trading
         "\n Check the terminal journal for the following entry:",
```

```
            "\n\'",AccountInfoInteger(ACCOUNT_LOGIN),"\': trading has been disabled -
```

AccountInfoInteger(ACCOUNT_TRADE_ALLOWED) may return **false** in the following cases:

- no connection to the trade server. That can be checked using TerminalInfoInteger(TERMINAL_CONNECTED);
- trading account switched to read-only mode (sent to the archive);
- trading on the account is disabled at the trade server side;
- connection to a trading account has been performed in Investor mode.

Client Terminal Events

Init

Immediately after the client terminal loads a program (an Expert Advisor or custom indicator) and starts the process of initialization of global variables, the Init event will be sent, which will be processed by OnInit() event handler, if there is such. This event is also generated after a financial instrument and/or chart timeframe is changed, after a program is recompiled in MetaEditor, after input parameters are changed from the setup window of an Expert Advisor or a custom indicator. An Expert Advisor is also initialized after the account is changed. The Init event is not generated for scripts.

Deinit

Before global variables are deinitialized and the program (Expert Advisor or custom indicator) is unloaded, the client terminal sends the Deinit event to the program. Deinit is also generated when the client terminal is closed, when a chart is closed, right before the security and/or timeframe is changed, at a successful program re-compilation, when input parameters are changed, and when account is changed.

The deinitialization reason can be obtained from the parameter, passed to the OnDeinit() function. The OnDeinit() function run is restricted to 2.5 seconds. If during this time the function hasn't been completed, then it is forcibly terminated. The Deinit event is not generated for scripts.

Start

Start is a special event for launching a script or a service after loading it. It is handled by the OnStart function. The Start event is not passed to EAs and custom indicators.

NewTick

The NewTick event is generated if there are new quotes, it is processed by OnTick() of Expert Advisors attached. In case when OnTick function for the previous quote is being processed when a new quote is received, the new quote will be ignored by an Expert Advisor, because the corresponding event will not enqueued.

All new quotes that are received while the program is running are ignored until the OnTick() is completed. After that the function will run only after a new quote is received. The NewTick event is generated irrespective of whether automated trade is allowed or not ("Allow/prohibit Auto trading" button). The prohibition of automated trading denotes only that sending of trade requests from an Expert Advisor is not allowed, while the Expert Advisor keeps working.

The prohibition of automated trading by pressing the appropriate button will not stop the current execution of the OnTick() function.

Calculate

The Calculate event is generated only for indicators right after the Init event is sent and at any change of price data. It is processed by the OnCalculate function.

Timer

The Timer event is periodically generated by the client terminal for the Expert Advisor that has activated the timer by the EventSetTimer function. Usually, this function is called by OnInit. Timer event processing is performed by the OnTimer function. After the operation of the Expert Advisor is completed, it is necessary to destroy the timer using the EventKillTimer function, which is usually called in the OnDeinit function.

Trade

The Trade event is generated when a trade operation is completed on a trade server. The Trade event is handled by the OnTrade() function for the following trade operations:

- sending, modifying or removing of a pending order;
- cancellation of a pending order with not enough of money or expiration;
- activation of a pending order;
- opening, adding or closing a position (or part of the position);
- modifying of the open position (change stops – Stop Loss and/or Take Profit).

TradeTransaction

When performing some definite actions on a trade account, its state changes. Such actions include:

- Sending a trade request from any MQL5 application in the client terminal using OrderSend and OrderSendAsync functions and its further execution;
- Sending a trade request via the terminal graphical interface and its further execution;
- Pending orders and stop orders activation on the server;
- Performing operations on a trade server side.

The following trade transactions are performed as a result of these actions:

- handling a trade request;
- changing open orders;
- changing orders history;
- changing deals history;
- changing positions.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. All these actions are trade transactions. Arrival of such a transaction at the terminal is a TradeTransaction event. This event is handled by OnTradeTransaction function.

Tester

The Tester event is generated after testing of an Expert Advisor on history data is over. The event is handled by the OnTester() function.

TesterInit

The TesterInit event is generated with the start of optimization in the strategy tester before the first optimization pass. The TesterInit event is handled by the OnTesterInit() function.

TesterPass

The TesterPass event is generated when a new data frame is received. The TesterPass event is handled by the OnTesterPass() function.

TesterDeinit

The TesterDeinit event is generated after the end of optimization of an Expert Advisor in the strategy tester. The TesterDeinit event is handled by the OnTesterDeinit() function.

ChartEvent

The ChartEvent event is generated by the client terminal when a user is working with a chart:

- keystroke, when the chart window is in focus;
- graphical object created
- graphical object deleted
- mouse press on the graphical object of the chart
- move of the graphical object using the mouse
- end of text editing in LabelEdit.

Also there is a custom event ChartEvent, which can be sent to an Expert Advisor by any mql5 program by using the EventChartCustom function. The event is processed by the OnChartEvent function.

BookEvent

The BookEvent event is generated by the client terminal after the Depth Of Market is changed; it is processed by the OnBookEvent function. To start generation of BookEvent for the specified symbol, it is necessary to subscribe the symbol to this event by using the MarketBookAdd function.

To unsubscribe from BookEvent for a specified symbol, it is necessary to call the MarketBookRelease function. The BookEvent event is a broadcasting-type event - it means that it is sufficient to subscribe just one Expert Advisor for this event, and all other Expert Advisors that have the OnBookEvent event handler, will receive it. That's why it is necessary to analyze the symbol name, which is passed to a handler as a parameter.

Resources

Using graphics and sound in MQL5 programs

Programs in MQL5 allow working with sound and graphic files:

- PlaySound() plays a sound file;
- ObjectCreate() allows creating user interfaces using graphical objects OBJ_BITMAP and OBJ_BITMAP_LABEL.

PlaySound()

Example of call of the PlaySound() function:

```
//+------------------------------------------------------------------+
//| Calls standard OrderSend() and plays a sound                     |
//+------------------------------------------------------------------+
void OrderSendWithAudio(MqlTradeRequest  &request, MqlTradeResult &result)
  {
  //--- send a request to a server
   OrderSend(request,result);
   //--- if a request is accepted, play sound Ok.wav
   if(result.retcode==TRADE_RETCODE_PLACED) PlaySound("Ok.wav");
   //--- if fails, play alarm from file timeout.wav
   else PlaySound("timeout.wav");
  }
```

The example shows how to play sounds from files 'Ok.wav' and 'timeout.wav', which are included into the standard terminal package. These files are located in the folder **terminal_directory\Sounds**. Here **terminal_directory** is a folder, from which the MetaTrader 5 Client Terminal is started. The location of the terminal directory can be found out from an mql5 program in the following way:

```
//--- Folder, in which terminal data are stored
   string terminal_path=TerminalInfoString(TERMINAL_PATH);
```

You can use sound files not only from the folder **terminal_directory\Sounds**, but also from any subfolder located in **terminal_data_directory\MQL5.** You can find out the location of the terminal data directory from the terminal menu "File" -> "Open Data Folder" or using program method:

```
//--- Folder, in which terminal data are stored
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
```

For example, if the Demo.wav sound file is located in terminal_data_directory\MQL5\Files, then call of PlaySound() should be written the following way:

```
//--- play Demo.wav from the folder terminal_directory_data\MQL5\Files\
   PlaySound("\\Files\\Demo.wav");
```

Please note that in the comment the path to the file is written using backslash "\", and in the function "\\" is used.

When specifying the path, always use only the double backslash as a separator, because a single backslash is a control symbol for the compiler when dealing with constant strings and character constants in the program source code.

Call PlaySound() function with NULL parameter to stop playback:

```
//--- call of PlaySound() with NULL parameter stops playback
   PlaySound(NULL);
```

ObjectCreate()

Example of an Expert Advisor, which creates a graphical label (OBJ_BITMAP_LABEL) using the ObjectCreate() function.

```
string label_name="currency_label";         // name of the OBJ_BITMAP_LABEL object
string euro      ="\\Images\\euro.bmp";     // path to the file terminal_data_directory
string dollar    ="\\Images\\dollar.bmp";   // path to the file terminal_data_directory
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- create a button OBJ_BITMAP_LABEL, if it hasn't been created yet
   if(ObjectFind(0,label_name)<0)
     {
      //--- trying to create object OBJ_BITMAP_LABEL
      bool created=ObjectCreate(0,label_name,OBJ_BITMAP_LABEL,0,0,0);
      if(created)
        {
         //--- link the button to the left upper corner of the chart
         ObjectSetInteger(0,label_name,OBJPROP_CORNER,CORNER_RIGHT_UPPER);
         //--- now set up the object properties
         ObjectSetInteger(0,label_name,OBJPROP_XDISTANCE,100);
         ObjectSetInteger(0,label_name,OBJPROP_YDISTANCE,50);
         //--- reset the code of the last error to 0
         ResetLastError();
         //--- download a picture to indicate the "Pressed" state of the button
         bool set=ObjectSetString(0,label_name,OBJPROP_BMPFILE,0,euro);
         //--- test the result
         if(!set)
           {
            PrintFormat("Failed to download image from file %s. Error code %d",euro,Ge
           }
         ResetLastError();
         //--- download a picture to indicate the "Unpressed" state of the button
         set=ObjectSetString(0,label_name,OBJPROP_BMPFILE,1,dollar);

         if(!set)
```

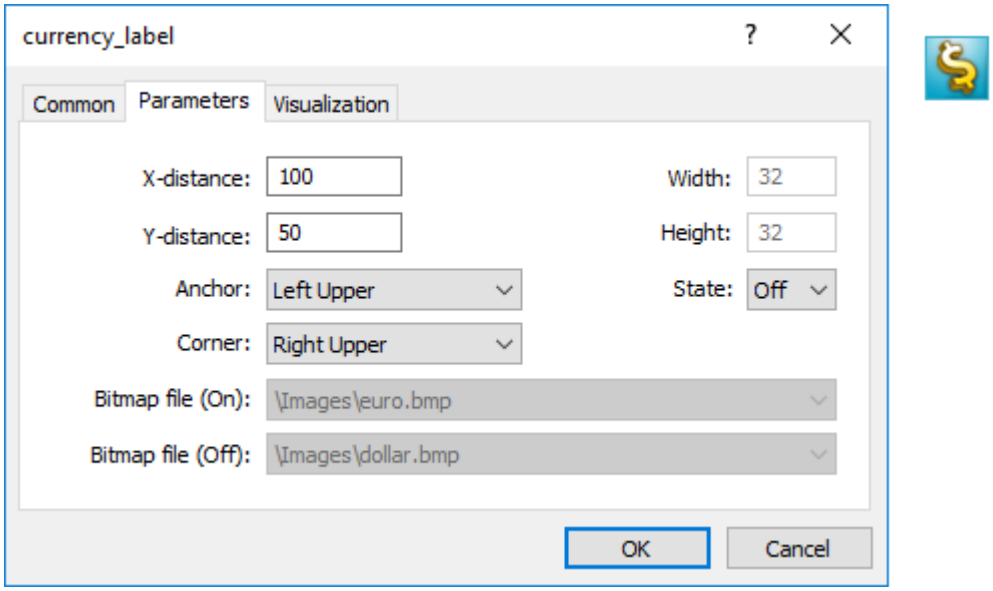
```
            {
             PrintFormat("Failed to download image from file %s. Error code %d",dollar,
            }
          //--- send a command for a chart to refresh so that the button appears immedi
          ChartRedraw(0);
         }
       else
         {
          //--- failed to create an object, notify
          PrintFormat("Failed to create object OBJ_BITMAP_LABEL. Error code %d",GetLast
         }
      }
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- delete an object from a chart
   ObjectDelete(0,label_name);
  }
```

Creation and setup of the graphical object named currency_label are carried out in the OnInit() function. The paths to the graphical files are set in global variables **euro** and **dollar**, a double backlash is used for a separator:

```
string euro      ="\\Images\\euro.bmp";    // path to the file terminal_dara_directory
string dollar    ="\\Images\\dollar.bmp";  // path to the file terminal_dara_directory
```

The files are located in the folder **terminal_data_directory**\MQL5\Images.

Object OBJ_BITMAP_LABEL is actually a button, which displays one of the two images, depending on the button state (pressed or unpressed): euro.bmp or dollar.bmp.



The size of the button with a graphical interface is automatically adjusted to the size of the picture. The image is changed by a left mouse button click on the OBJ_BITMAP_LABEL object (**"Disable selection" option must be checked in the properties**). The OBJ_BITMAP object is created the same way - it is used for creating the background with a necessary image.

The value of the OBJPROP_BMPFILE property, which is responsible for the appearance of the objects OBJ_BITMAP and OBJ_BITMAP_LABEL, can be changed dynamically. This allows creating various interactive user interfaces for mql5 programs.

Including resources to executable files during compilation of mql5 programs

An mql5 program may need a lot of different downloadable resources in the form of image and sound files. In order to eliminate the need to transfer all these files when moving an executable file in MQL5, the compiler's directive #resource should be used:

```
#resource path_to_resource_file
```

The #resource command tells the compiler that the resource at the specified path **path_to_resource_file** should be included into the executable EX5 file. Thus all the necessary images and sounds can be located directly in an EX5 file, so that there is no need to transfer separately the files used in it, if you want to run the program on a different terminal. Any EX5 file can contain resources, and any EX5 program can use resources from another EX5 program.

The files in format BMP and WAV are automatically compressed before including them to an EX5 file. This denotes that in addition to the creation of complete programs in MQL5, using resources also allows to reduce the total size of necessary files when using graphics and sounds, as compared to the usual way of MQL5 program writing.

The resource file size must not exceed 128 Mb.

Search for specified resources by a compiler

A resource is inserted using the command #resource "<path to the resource file>"

```
#resource "<path_to_resource_file>"
```

The length of the constant string <path_to_resource_file> must not exceed 63 characters.

The compiler searches for a resource at the specified path in the following order:

- if the backslash "\" separator (written as "\\") is placed at the beginning of the path, it searches for the resource relative to the directory **terminal_data_directory**\MQL5\,
- if there is no backslash, it searches for the resource relative to the location of the source file, in which the resource is written.

The resource path cannot contain the substrings "..\\" and ":\\".

Examples of resource inclusion:

```
//--- correct specification of resources
#resource "\\Images\\euro.bmp" // euro.bmp is located in terminal_data_directory\MQL5\
#resource "picture.bmp"        // picture.bmp is located in the same directory as the
#resource "Resource\\map.bmp"  // the resource is located in source_file_directory\Res

//--- incorrect specification of resources
#resource ":picture_2.bmp"     // must not contain ":"
#resource "..\\picture_3.bmp"  // must not contain ".."
#resource "\\Files\\Images\\Folder_First\\My_panel\\Labels\\too_long_path.bmp" //more
```

Use of Resources

Resource name

After a resource is declared using the #resource directive, it can be used in any part of a program. The name of the resource is its path without a backslash at the beginning of the line, which sets the path to the resource. To use your own resource in the code, the special sign "::" should be added before the resource name.

Examples:

```
//--- examples of resource specification and their names in comments
#resource "\\Images\\euro.bmp"          // resource name - Images\euro.bmp
#resource "picture.bmp"                 // resource name - picture.bmp
#resource "Resource\\map.bmp"           // resource name - Resource\map.bmp
#resource "\\Files\\Pictures\\good.bmp" // resource name - Files\Pictures\good.bmp
#resource "\\Files\\Demo.wav";          // resource name - Files\Demo.wav"
#resource "\\Sounds\\thrill.wav";       // resource name - Sounds\thrill.wav"
...

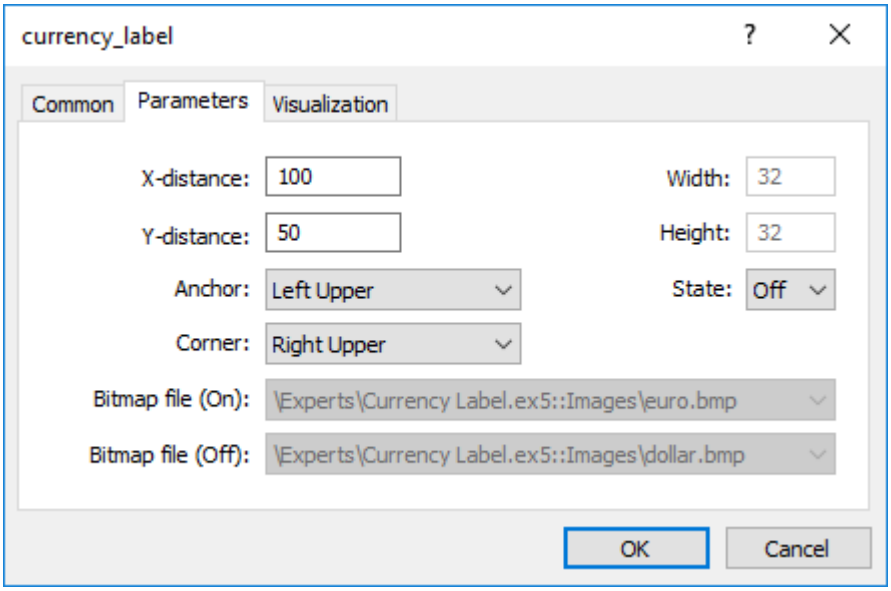
//--- utilization of resources
```

```
ObjectSetString(0,bitmap_name,OBJPROP_BMPFILE,0,"::Images\\euro.bmp");
...
ObjectSetString(0,my_bitmap,OBJPROP_BMPFILE,0,"::picture.bmp");
...
set=ObjectSetString(0,bitmap_label,OBJPROP_BMPFILE,1,"::Files\\Pictures\\good.bmp");
...
PlaySound("::Files\\Demo.wav");
...
PlaySound("::Sounds\\thrill.wav");
```

It should be noted that when setting images from a resource to the OBJ_BITMAP and OBJ_BITMAP_LABEL objects, the value of the OBJPROP_BMPFILE property cannot be modified manually. For example, for creating OBJ_BITMAP_LABEL we use resources euro.bmp and dollar.bmp.

```
#resource "\\Images\\euro.bmp";    // euro.bmp is located in terminal_data_directory\M
#resource "\\Images\\dollar.bmp";  // dollar.bmp is located in terminal_data_directory
```

When viewing the properties of this object, we'll see that the properties BitMap File (On) and BitMap File (Off) are dimmed and cannot be change manually:



Using the resources of other mql5 programs

There is another advantage of using resources - in any MQL5 program, resources of another EX5 file can be used. Thus the resources from one EX5 file can be used in many other mql5 programs.

In order to use a resource name from another file, it should be specified as <path_EX5_file_name>::<resource_name>. For example, suppose the Draw_Triangles_Script.mq5 script contains a resource to an image in the file triangle.bmp:

```
#resource "\\Files\\triangle.bmp"
```

Then its name, for using in the script itself, will look like "Files\triangle.bmp", and in order to use it, "::" should be added to the resource name.

```
//--- using the resource in the script
ObjectSetString(0,my_bitmap_name,OBJPROP_BMPFILE,0,"::Files\\triangle.bmp");
```

In order to use the same resource from another program, e.g. from an Expert Advisor, we need to add to the resource name the path to the EX5 file relative to **terminal_data_directory\MQL5** and the name of the script's EX5 file - **Draw_Triangles_Script.ex5**. Suppose the script is located in the standard folder **terminal_data_directory\MQL5**Scripts\, then the call should be written the following way:

```
//--- using a resource from a script in an EA
ObjectSetString(0,my_bitmap_name,OBJPROP_BMPFILE,0,"\\Scripts\\Draw_Triangles_Script.e
```

If the path to the executable file is not specified when calling the resource from another EX5, the executable file is searched for in the same folder that contains the program that calls the resource. This means that if an Expert Advisor calls a resource from Draw_Triangles_Script.ex5 without specification of the path, like this:

```
//--- call script resource in an EA without specifying the path
ObjectSetString(0,my_bitmap_name,OBJPROP_BMPFILE,0,"Draw_Triangles_Script.ex5::Files\\
```

then the file will be searched for in the folder **terminal_data_directory\MQL5**Experts\, if the Expert Advisor is located in **terminal_data_directory\MQL5**Experts\.

Working with custom indicators included as resources

One or several custom indicators may be necessary for the operation of MQL5 applications. All of them can be included into the code of an executable MQL5 program. Inclusion of indicators as resources simplifies the distribution of applications.

Below is an example of including and using SampleIndicator.ex5 custom indicator located in **terminal_data_folder**\MQL5\Indicators\ directory:

```
//+------------------------------------------------------------------+
//|                                                     SampleEA.mq5 |
//|                        Copyright 2013, MetaQuotes Software Corp. |
//|                                             https://www.mql5.com |
//+------------------------------------------------------------------+
#resource "\\Indicators\\SampleIndicator.ex5"
int handle_ind;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//---
   handle_ind=iCustom(_Symbol,_Period,"::Indicators\\SampleIndicator.ex5");
   if(handle_ind==INVALID_HANDLE)
     {
      Print("Expert: iCustom call: Error code=",GetLastError());
      return(INIT_FAILED);
```

```
      }
//--- ...
   return(INIT_SUCCEEDED);
  }
```

The case when a custom indicator in OnInit() function creates one or more copies of itself requires special consideration. Please keep in mind that the resource should be specified in the following way: **<path_EX5_file_name>::<resource_name>**.

For example, if SampleIndicator.ex5 indicator is included to SampleEA.ex5 Expert Advisor as a resource, the path to itself specified when calling iCustom() in the custom indicator's initialization function looks the following way: "\\Experts\\SampleEA.ex5::Indicators\\SampleIndicator.ex5". When this path is set explicitly, SampleIndicator.ex5 custom indicator is rigidly connected to SampleEA.ex5 Expert Advisor losing ability to work independently.

The path to itself can be received using GetRelativeProgramPath() function. The example of its usage is provided below:

```
//+------------------------------------------------------------------+
//|                                                SampleIndicator.mq5 |

  }
```

Resource variables

Resources can be declared using the resource variables and treated as if they are variables of the appropriate type. Declaration format:

```
#resource path_to_the_resource_file as resource_variable_type resource_variable_name
```

Sample declarations:

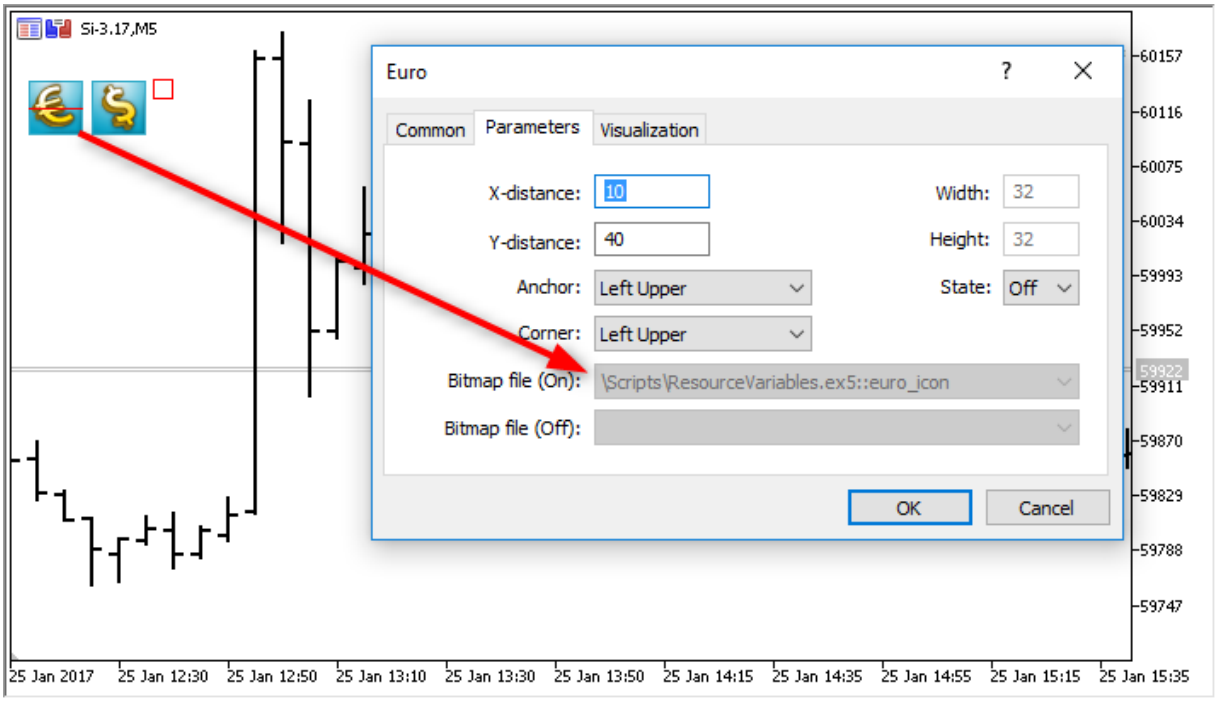
```
#resource "data.bin" as int ExtData[]              // declare the numeric array contai
```

```
#resource "data.bin" as MqlRates ExtData[]        // declare the simple structures ar
//--- strings
#resource "data.txt" as string ExtCode            // declare the string containing the
//--- graphical resources
#resource "image.bmp" as bitmap ExtBitmap[]       // declare the one-dimensional array
#resource "image.bmp" as bitmap ExtBitmap2[][]    // declare the two-dimensional array
```

In case of such declaration, the resource data can be addressed only via the variable, auto addressing via "::<rsource name>" does not work.

```
#resource "\\Images\\euro.bmp" as bitmap euro[][]
#resource "\\Images\\dollar.bmp"
//+------------------------------------------------------------------+
//|  OBJ_BITMAP_LABEL object creation function using the resource    |
//+------------------------------------------------------------------+
void Image(string name,string rc,int x,int y)
  {
   ObjectCreate(0,name,OBJ_BITMAP_LABEL,0,0,0);
   ObjectSetInteger(0,name,OBJPROP_XDISTANCE,x);
   ObjectSetInteger(0,name,OBJPROP_YDISTANCE,y);
   ObjectSetString(0,name,OBJPROP_BMPFILE,rc);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- output the size of the image [width, height] stored in euro resource variable
   Print(ArrayRange(euro,1),", ",ArrayRange(euro,0));
//--- change the image in euro - draw the red horizontal stripe in the middle
   for(int x=0;x<ArrayRange(euro,1);x++)
      euro[ArrayRange(euro,1)/2][x]=0xFFFF0000;
//--- create the graphical resource using the resource variable
   ResourceCreate("euro_icon",euro,ArrayRange(euro,1),ArrayRange(euro,0),0,0,ArrayRang
//--- create the Euro graphical label object, to which the image from the euro_icon re
   Image("Euro","::euro_icon",10,40);
//--- another method of applying the resource, we cannot draw do it
   Image("USD","::Images\\dollar.bmp",15+ArrayRange(euro,1),40);
//--- direct method of addressing the euro.bmp resource is unavailable since it has al
   Image("E2","::Images\\euro.bmp",20+ArrayRange(euro,1)*2,40); // execution time erro
  }
```

Script execution result - only two OBJ_BITMAP_LABEL objects out of three ones are created. The image of the first object has the red stripe in the middle.



An important advantage of applying the resources is that the resource files are automatically compressed before they are included into an executable EX5 file prior to compilation. Thus, using the resource variables allows you to put all necessary data directly into the executable EX5 file as well as reduce the number and total size of the files compared to the conventional way of writing MQL5 programs.

Using the resource variables is particularly convenient for publishing products in the Market.

Features

- The special *bitmap* resource variable type informs the compiler that the resource is an image. Such variables receive the uint type.
- The *bitmap* type array resource variable may have two dimensions. In this case, the array size is defined as [image_height][image_width]. If an array of one dimension is specified, the number of elements is equal to image_height*image_width.
- When downloading a 24-bit image, the alpha channel component is set to 255 for all the image pixels.
- When downloading a 32-bit image without the alpha channel, the alpha channel component is also set to 255 for all the image pixels.
- When downloading a 32-bit image with the alpha channel, the pixels are not processed in any way.
- The resource file size cannot exceed 128 Mb.
- The automatic encoding detection by BOM (header) presence is performed for string files. If BOM is absent, the encoding is defined by the file contents. The files in the ANSI, UTF-8 and UTF-16 encodings are supported. All strings are converted to Unicode when reading data from the files.

OpenCL programs

Using the resource string variables may greatly facilitate the development of some programs. For example, you are able to write a code of an OpenCL program in a separate CL file and then include it as a string into your MQL5 program resources.

```
#resource "seascape.cl" as string cl_program
...
int context;
if((cl_program=CLProgramCreate(context,cl_program)!=INVALID_HANDLE)
  {
   //--- perform further actions with an OpenCL program
  }
```

In this example, you would have had to write the entire code as a single big string if no *cl_program* resource variable had been used.

Call of Imported Functions

To import functions during the execution of a mql5-program, the client terminal uses early binding. This means that if a program has call of an imported function, the corresponding module (ex5 or dll) is loaded during the program load. MQL5 and DLL libraries are executed in the thread of a calling module.

It is not recommended to use the fully specified name of the module to be loaded like *Drive:\Directory\FileName.Ext*. The MQL5 libraries are loaded from the *terminal_dir\MQL5\Libraries* folder. If the library hasn't been found, then the client terminal performs an attempt to load it from *terminal_dir\experts* folder.

The system libraries (DLL) are loaded by the operating system rules. If the library is already loaded (for example, another Expert Advisor, and even from another client terminal, running in parallel), then it uses requests to the library already loaded. Otherwise, it performs a search in the following sequence:

1. Directory, from which the module importing dll was started. The module here is an Expert Advisor, a script, an indicator or EX5 library;
2. Directory terminal_data_directory\MQL5\Libraries (TERMINAL_DATA_PATH\MQL5\Libraries);
3. Directory, from which the MetaTrader 5 client terminal was started;
4. System directory;
5. Windows directory;
6. Current directory;
7. Directories listed in the PATH system variable.

If the DLL library uses another DLL in its work, the first one cannot be loaded in case when there is no second DLL.

Before an Expert Advisor (script, indicator) is loaded, a common list of all EX5 library modules is formed. It's going to be used both from a loaded Expert Advisor (script, indicator) and from libraries of this list. Thus the one-time loading of many times used EX5 library modules is needed. Libraries use predefined variables of the Expert Advisor (script, indicator) they were called by.

The imported library EX5 is searched for in the following sequence:

1. Directory, path to which is set relative to the directory of the Expert Advisor (script, indicator) that imports EX5;
2. Directory terminal_directory\MQL5\Libraries;
3. Directory MQL5\Libraries in the common directory of all MetaTrader 5 client terminals (Common\MQL5\Libraries).

Functions imported DLL into a mql5-program must ensure the Windows API calls agreement. To ensure such an agreement, in the source text of programs written in C or C++, use the keyword __stdcall, which is specific to the Microsoft(r) compilers. This agreement is characterized by the following:

- caller (in our case it is a mq5-program) should "see" a prototype of a function called (imported from the DLL), in order to properly combine parameters to a stack;
- caller (in our case it is a mql5-program) puts parameters to the stack in a reverse order, from right to left - in this order an imported function reads parameters passed to it;
- parameters are passed by value, except those explicitly passed by reference (in our case strings)

- an imported function cleans the stack independently by reading parameters passed to it.

When describing the prototype of an imported function, default parameters can be used.

If the corresponding library is unable to load, or there is a prohibition on the DLL use, or the imported function is not found - the Expert Advisor stops its operation with the appropriate message "Expert Advisor stopped" in the Journal (log file). In this case the Expert Advisor will not run until it is reinitialized. An Expert Advisor can be reinitialized as a result of recompilation or after the table of its properties is opened and OK is pressed.

Passing Parameters

All parameters of simple types are passed by values unless it is explicitly indicated that they are passed by reference. When a string is passed, the address of the buffer of the copied string is passed; if a string is passed by reference, the address of the buffer of this string without copying it is passed to the function imported from DLL.

Structures that contain dynamic arrays, strings, classes, other complex structures, as well as static or dynamic arrays of the enumerated objects, can't be passed as a parameter to an imported function.

When passing an array to DLL, the address of the beginning of the data buffer is always passed (irrespective of the AS_SERIES flag). A function inside a DLL knows nothing about the AS_SERIES flag, the passed array is a static array of an undefined length; an additional parameter should be used for specifying the array size.

Runtime Errors

The executing subsystem of the client terminal has an opportunity to save the error code in case it occurs during a MQL5 program run. There is a predefined variable _LastError for each executable MQL5 program.

Before starting the OnInit function, the _LastError variable is reset. In case an erroneous situation occurs during calculations or in the process of internal function calls, the _LastError variable accepts a corresponding error code. The value stored in this variable can be obtained using the GetLastError() function.

There are several critical errors in case of which a program is terminated immediately:

- division by zero
- going beyond array boundary
- using an incorrect object pointer

Testing Trading Strategies

The idea of automated trading is appealing by the fact that the trading robot can work non-stop for 24 hours a day, seven days a week. The robot does not get tired, doubtful or scared, it's is totally free from any psychological problems. It is sufficient enough to clearly formalize the trading rules and implement them in the algorithms, and the robot is ready to work tirelessly. But first, you must make sure that the following two important conditions are met:

- The Expert Advisor performs trading operations in accordance with the rules of the trading system;
- The trading strategy, implemented in the EA, demonstrates a profit on the history.

To get answers to these questions, we turn to the Strategy Tester, included in the MetaTrader 5 client terminal.

This section covers the features of program testing and optimization in the strategy tester:

- Function Limitations in the Strategy Tester
- Tick Generation Modes
- Simulation of spread
- Using real ticks during a test
- The Global Variables of the Client Terminal
- The Calculation of Indicators During Testing
- Loading History during Testing
- Multi-Currency Testing
- Simulation of Time in the Strategy Tester
- Graphical Objects in Testing
- The OnTimer() Function in the Strategy Tester
- The Sleep() Function in the Strategy Tester
- Using the Strategy Tester for Optimization Problems in Mathematical Calculations
- The Synchronization of Bars in the "Open prices only" mode
- The IndicatorRelease() function in the Tester
- Event Handling in the Tester
- Testing Agents
- The Data Exchange between the Terminal and the Agent
- Using the Shared Folder of All of the Client Terminals
- Using DLLs

Memory and disk space limits in MQL5 Cloud Network

The following limitation applies to optimizations run in the MQL5 Cloud Network: the Expert Advisor must not write to disk more than 4GB of information or use more than 4GB of RAM. If the limit is exceeded, the network agent will not be able to complete the calculation correctly, and you will not receive the result. However, you will be charged for all the time spent on the calculations.

If you need to get information from each optimization pass, send frames without writing to disk. To avoid using file operations in Expert Advisors during calculations in the MQL5 Cloud Network, you can use the following check:

```
int handle=INVALID_HANDLE;
bool file_operations_allowed=true;
if(MQLInfoInteger(MQL_OPTIMIZATION) || MQLInfoInteger(MQL_FORWARD))
   file_operations_allowed=false;

if(file_operations_allowed)
  {
   ...
   handle=FileOpen(...);
   ...
  }
```

Function Limitations in the Strategy Tester

There are operation limitations for some functions in the client terminal's Strategy Tester.

The Comment(), Print() and PrintFormat() Functions

To increase performance Comment(), Print() and PrintFormat() functions are not executed when optimizing the trading robot's parameters. The exception is the use of these functions inside the OnInit() handler. This allows you to easily find the cause of errors when they occur.

The Alert(), MessageBox(), PlaySound(), SendFTP, SendMail(), SendNotification(), WebRequest() Functions

The Alert(), MessageBox(), PlaySound(), SendFTP(), SendMail(), SendNotification() and WebRequest() functions designed for interaction with the "outside world" are not executed in the Strategy Tester.

Tick Generation Modes

An Expert Advisor is a program, written in MQL5, that is run each time in response to some external event. The EA has a corresponding function (event handler) for each pre-defined event.

The NewTick event (price change) is the main event for the EA and, therefore, we need to generate a tick sequence to test the EA. There are 3 modes of tick generation implemented in the Strategy Tester of MetaTrader 5 client terminal:

- Every tick
- 1 Minute OHLC (OHLC prices with minute bars)
- Open prices only

The basic and the most detailed is the "Every tick" mode, the other two modes are the simplifications of the basic one, and will be described in comparison to the "Every tick" mode. Consider all three modes in order to understand the differences between them.

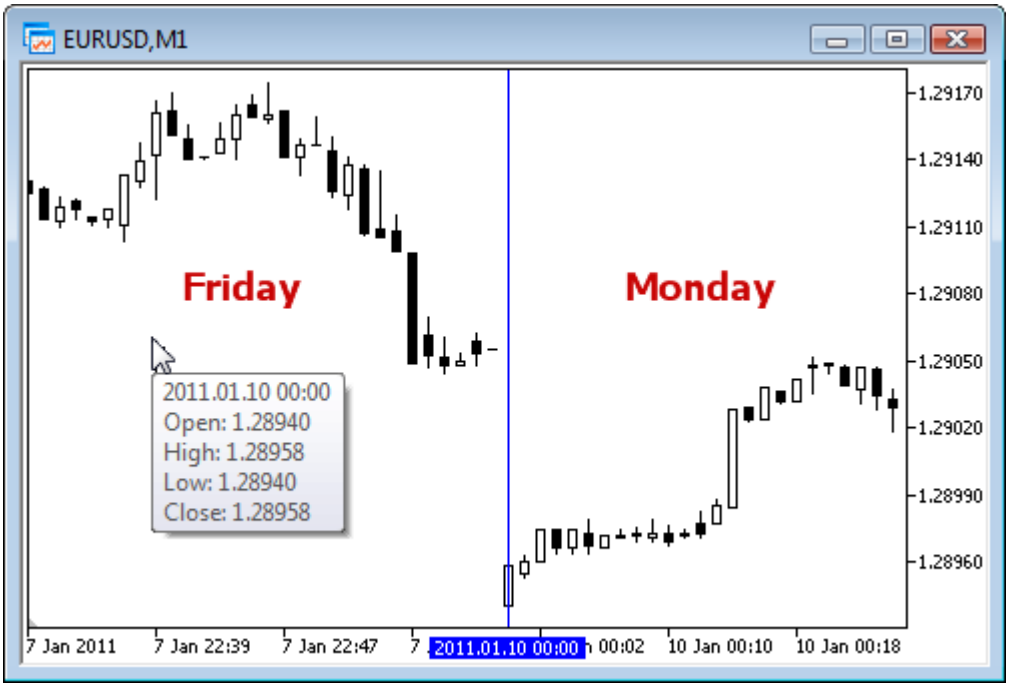
"Every Tick"

The historical quotes data for financial instruments is transferred from the trading server to the MetaTrader 5 client terminal in the form of packed minute bars. Detailed information on the occurrence of requests and the construction of the required time-frames can be obtained from the Organizing Data Access chapter of MQL5 Reference.

The minimal element of the price history is the minute bar, from which you can obtain information on the four values of the price:

- Open - the price at which the minute bar was opened;
- High - the maximum that was achieved during this minute bar;
- Low - the minimum that was achieved during this minute bar;
- Close - the closing price of the bar.

The new minute bar is not opened at the moment when the new minute begins (number of seconds becomes equal to 0), but when a tick occurs - a price change by at least one point. The figure shows the first minute bar of the new trading week, which has the opening time of 2011.01.10 00:00. The price gap between Friday and Monday, which we see on the chart, is common, since currency rates fluctuates even on weekends in response to incoming news.



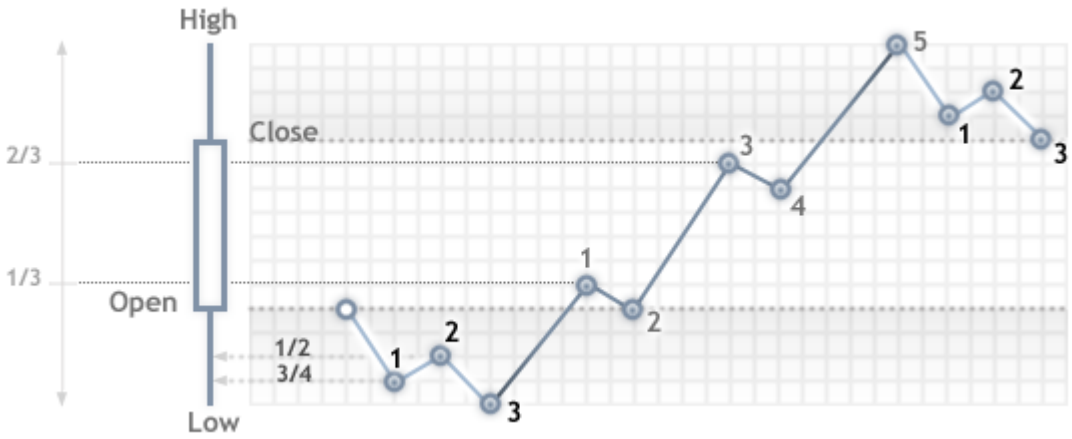
For this bar, we only know that the minute bar was opened on January 10th 2011 at 00 hours 00 minutes, but we know nothing about the seconds. It could have been opened at 00:00:12 or 00:00:36 (12 or 36 seconds after the start of a new day) or any other time within that minute. But we do know that the Open price of EURUSD was at 1.28940 at the opening time of the new minute bar.

We also don't know (accurate within a second) when we received the tick corresponding to the closing price of the considered minute bar. We known only one thing - the last Close price of the minute bar.

For this minute, the price was 1.28958. The time of the appearance of High and Low prices is also unknown, but we know that the maximum and minimum prices were on the levels of 1.28958 and 1.28940, respectively.

To test the trading strategy, we need a sequence of ticks, on which the work of the Expert Advisor will be simulated. Thus, for every minute bar, we know the **4 control points**, where the price has definitely been. If a bar has only 4 ticks, then this is enough information to perform a testing, but usually the tick volume is greater than 4.

Hence, there is a need to generate additional control points for ticks, which occurred between the Open, High, Low, and Close prices. The principle of the "Every tick" ticks generation mode is described in the The Algorithm of Ticks' Generation within the Strategy Tester of the MetaTrader 5 Terminal a figure from which is presented below.



When testing in the "Every tick" mode, the OnTick() function of the EA will be called at every control point. Each control point is a tick from a generated sequence. The EA will receive the time and price of the simulated tick, just as it would when working online.

> **Important:** the "Every tick" testing mode is the most accurate, but at the same time, the most time consuming. For an initial testing of the majority of trading strategies, it is usually sufficient to use one of the other two testing modes.

"1 Minute OHLC"

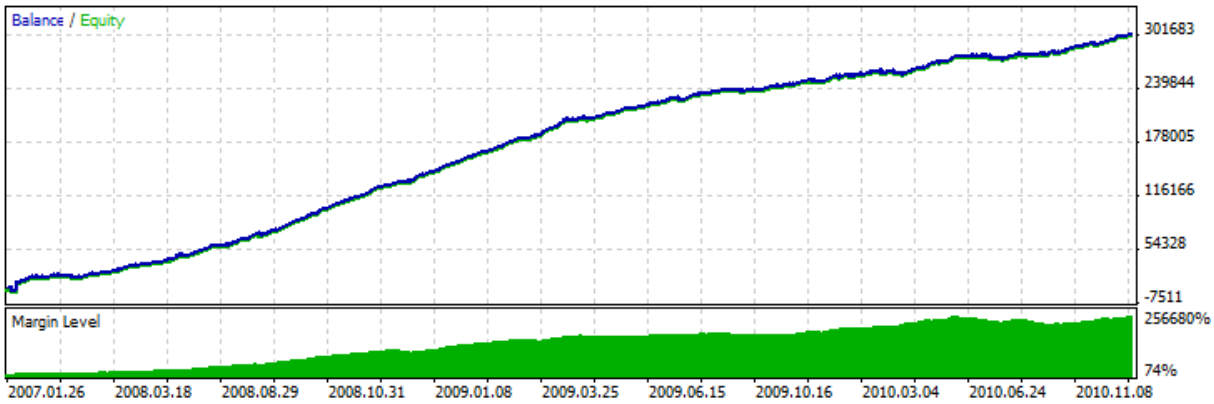
The "Every tick" mode is the most accurate of the three modes, but at the same time, is the slowest. The running of the OnTick() handler occurs at every tick, while tick volume can be quite large. For a strategy, in which the tick sequence of price movement throughout the bar, does not matter, there is a faster and rougher simulation mode - "1 minute OHLC".

In the "1 minute OHLC" mode, the tick sequence is constructed only by the **OHLC prices of the minute bars**, the number of the generated control points is significantly reduced - hence, so is the testing time. The launch of the OnTick () function is performed on all control points, which are constructed by the prices of OHLC minute bars.

The refusal to generate additional intermediate ticks between the Open, High, Low, and Close prices, leads to an appearance of rigid determinism in the development of prices, from the moment that the

Open price is determined. This makes it possible to create a "Testing Grail", which shows a nice upward graph of the testing balance.

An example of such Grail is presented in the CodeBase - Grr-al.



The figure shows a very attractive graph of this EA testing. How was it obtained? We know 4 prices for a minute bar, and we also know that the first is the Open price, and the last is the Close price. We have the High and Low prices between them, and the sequence of their occurrence is unknown, but it is known, that the High price is greater than or equal to the Open price (and the Low price is less than or equal to the Open price).

It is sufficient enough to determine the moment of receiving the Open price, and then analyze the next tick in order to determine what price we have at the moment - either the High or the Low. If the price is below the Open price, then we have a Low price and buy at this tick, the next tick will correspond to the High price, at which we will close the buy and open for sell. The next tick is the last one, this is the Close price, and we close the sale on it.

If after the price, we receive a tick with a price greater than the opening price, then the sequence of deals is reversed. Process a minute bar in this "cheat" mode, and wait for the next one.

When testing such EA on the history, everything goes smoothly, but once we launch it online, the truth begins to get revealed - the balance line remains steady, but heads downwards. To expose this trick, we simply need to run the EA in the "Every tick" mode.

> **Note:** If the test results of the EA in the rough testing modes ("1 minute OHLC" and "Open Prices only") seem too good, make sure to test it in the "Every tick" mode.

"Open Prices Only"

In this mode ticks are generated based on the OHLC prices of the timeframe selected for testing. The OnTick() function of the Expert Advisor runs only at the beginning of the bar at the Open price. Due to this feature, stop levels and pending may trigger at a price that differs from the specified one (especially when testing on higher timeframes). Instead, we have an opportunity to quickly run an evaluation test of the Expert Advisor.

W1 and MN1 periods are the exceptions in the "Open Price Only" ticks generation mode: for these timeframes ticks are generated for the OHLC prices of each day, not OHLC prices of the week or month.

Suppose we test an Expert Advisor on EURUSD H1 in the "Open Prices Only" mode. In this case the total number of ticks (control points) will be no more than 4*number of one-hour bars within the tested interval. But the **OnTick() handler is called only at the opening of the one-hour bar**. The checks required for a correct testing occur on the rest of the ticks (that are "hidden" from the EA).

- The calculation of margin requirements;
- The triggering of Stop Loss and Take Profit levels;
- The triggering of pending orders;
- The removal of expired pending orders.

If there are no open positions or pending orders, we don't need to perform these checks on hidden ticks, and the increase of speed may be quite substantial. This "Open prices only" mode is well suited for testing strategies, which process deals only at the opening of the bar and do not use pending orders, as well as StopLoss and TakeProfit orders. For the class of such strategies, the necessary accuracy of testing is preserved.

Let's use the Moving Average Expert Advisor from the standard package as an example of an EA, which can be tested in any mode. The logic of this EA is built in such a way that all of the decisions are made at the opening of the bar, and deals are carried out immediately, without the use of pending orders.

Run a testing of the EA on EURUSD H1 on an interval from 2010.09.01 to 2010.12.31, and compare the graphs. The figure shows the balance graph from the test report for all of the three modes.

As you can see, the graphs on different testing modes are exactly the same for the Moving Average EA from the standard package.

There are some limitations on the "Open Prices Only" mode:

- You cannot use the Random Delay execution mode.
- In the tested Expert Advisor, you cannot access data of the timeframe lower than that used for testing/optimization. For example, if you run testing/optimization on the H1 period, you can access

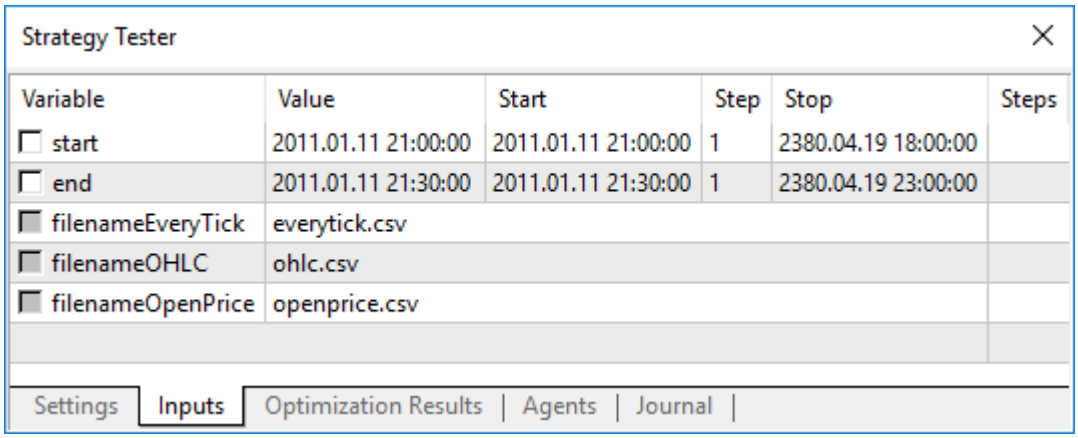
data of H2, H3, H4 etc., but not M30, M20, M10 etc. In addition, the higher timeframes that are accessed must be multiple of the testing timeframe. For example, if you run testing in M20, you cannot access data of M30, but it is possible to access H1. These limitations are connected with the impossibility to obtain data of lower or non-multiple timeframes out of the bars generated during testing/optimization.

- Limitations on accessing data of other timeframes also apply to other symbols whose data are used by the Expert Advisor. In this case the limitation for each symbol depends on the first timeframe accessed during testing/optimization. Suppose, during testing on EURUSD H1, an Expert Advisor accesses data of GBPUSD M20. In this case the Expert Advisor will be able to further use data of EURUSD H1, H2, etc., as well as GBPUSD M20, H1, H2 etc.

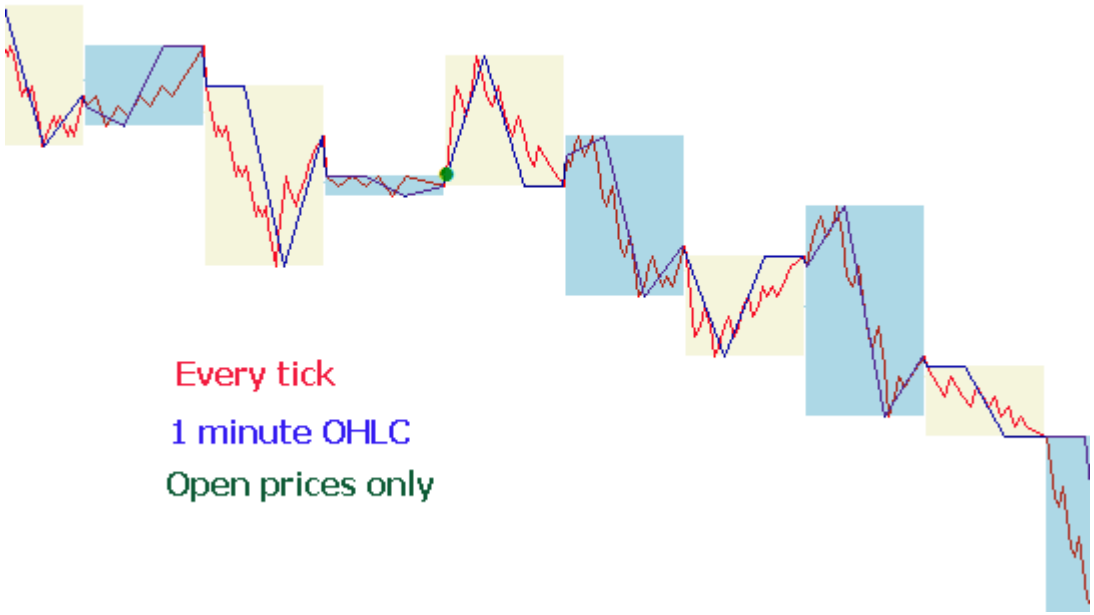
Note: The "Open prices only" mode has the fastest testing time, but it is not suitable for all of the trading strategies. Select the desired test mode based on the characteristics of the trading system.

To conclude the section on the tick generation modes, let's consider a visual comparison of the different tick generation modes for EURUSD, for two M15 bars on an interval from 2011.01.11 21:00:00 - 2011.01.11 21:30:00.

The ticks were saved into different files using the WriteTicksFromTester.mq5 EA and the ending of these files names are specified in filenameEveryTick, filenameOHLC and filenameOpenPrice input-parameters.



To obtain three files with three tick sequences (for each of the following modes "Every tick", "1 minute OHLC" and "Open prices only), the EA was launched three times in the corresponding modes, in single runs. Then, the data from these three files were displayed on the chart using the TicksFromTester.mq5 indicator. The indicator code is attached to this article.



By default, all of the file operations in the MQL5 language are made within the "file sandbox", and during testing the EA has access only to its own "file sandbox". In order for the indicator and the EA to work with files from one folder during testing, we used the flag FILE_COMMON. An example of code from the EA:

```
//--- open the file
   file=FileOpen(filename,FILE_WRITE|FILE_CSV|FILE_COMMON,";");
//--- check file handle
   if(file==INVALID_HANDLE)
     {
      PrintFormat("Error in opening of file %s for writing. Error code=%d",filename,Ge
      return;
     }
   else
     {
      PrintFormat("The file will be created in %s folder",TerminalInfoString(TERMINAL_
     }
```

For reading the data in the indicator, we also used the flag FILE_COMMON. This allowed us to avoid manually transferring the necessary files from one folder to another.

```
//--- open the file
   int file=FileOpen(fname,FILE_READ|FILE_CSV|FILE_COMMON,";");
//--- check file handle
   if(file==INVALID_HANDLE)
     {
      PrintFormat("Error in open of file %s for reading. Error code=%d",fname,GetLastE
      return;
     }
   else
     {
```

```
      PrintFormat("File will be opened from %s",TerminalInfoString(TERMINAL_COMMONDATA
     }
```

Simulation of spread

The price difference between the Bid and the Ask prices is called the spread. During testing, the spread is not modeled but is taken from historical data. If the spread is less than or equal to zero in the historical data, then the last known (at the moment of generation) spread is used by testing agent.

In the Strategy Tester, the spread is always considered floating. That is, SymbolInfoInteger(symbol, SYMBOL_SPREAD_FLOAT) always returns true.

In addition, the historical data contains tick values and trading volumes. For the storage and retrieval of data we use a special MqlRates structure:

```
struct MqlRates
  {
   datetime time;         // Period start time
   double   open;         // Open price
   double   high;         // The highest price of the period
   double   low;          // The lowest price of the period
   double   close;        // Close price
   long     tick_volume;  // Tick volume
   int      spread;       // Spread
   long     real_volume;  // Trade volume
  };
```

Using real ticks during a test

Testing and optimization on real ticks are as close to real conditions as possible. Instead of generated ticks based on minute data, it is possible to use real ticks accumulated by a broker. These are ticks from exchanges and liquidity providers.

To ensure the greatest test accuracy, minute bars are also used in the real ticks mode. The bars are applied to check and correct tick data. This also allows you to avoid the divergence of charts in the tester and the client terminal.

The tester compares the tick data to the minute bar parameters: a tick should not exceed the bar's High/Low levels, also initial and final ticks should coincide with the bar's Open/Close prices. The volume is compared as well. If a mismatch is detected, all ticks corresponding to this minute bar are discarded. Generated ticks are used instead (like in the "Every tick" mode).

If a symbol history has a minute bar with no tick data for it, the tester generates ticks in the "Every tick" mode. This allows plotting a correct chart in the tester in case a broker's tick data is insufficient.

If a symbol history has no minute bar but the appropriate tick data for the minute is present, the data can be used in the tester. For example, exchange symbol pairs are formed using Last prices. If only ticks with Bid/Ask prices without the Last price arrive from the server, the bar is not generated. The tester uses these tick data since they do not contradict the minute ones.

Tick data may not coincide with minute bars for various reasons, for example because of connection losses or other failures when transmitting data from a source to the client terminal. The minute data is considered more reliable during tests.

Keep in mind the following features when testing on real ticks:

- When launching a test, the minute data on a symbol is synchronized along with the tick one.
- Ticks are stored in the symbol cache of the strategy tester. The cache size does not exceed 128 000 ticks. When new ticks arrive, the oldest data is removed from the cache. However, the CopyTicks function allows receiving ticks outside the cache (only when testing on real ticks). In that case, the data is requested from the tester tick database that is completely similar to the corresponding client terminal database. No minute bar corrections are implemented to this base. Therefore, the ticks there may differ from the ones stored in the cache.

The Global Variables of the Client Terminal

During testing, the global variables of the client terminal are also emulated, but they are not related to the current global variables of the terminal, which can be seen in the terminal using the F3 button. It means that all operations with the global variables of the terminal, during testing, take place outside of the client terminal (in the testing agent).

The Calculation of Indicators During Testing

In the real-time mode, the indicator values are calculated at every tick.

In the Strategy Tester, indicators are calculated only when they are accessed for data, i.e. when indicator buffer values are requested. The only exceptions are custom indicators with the specified #property tester_everytick_calculate. In this case, recalculation is done on each tick.

In the visual testing mode, all indicators are unconditionally recalculated when a new tick arrives in order to be correctly displayed on the visual testing chart.

The indicator is calculated once per tick. All subsequent requests for indicator data do not lead to recalculation until a new tick arrives. Therefore, if the timer is enabled in an EA via the EventSetTimer() function, the indicator data is requested from the last tick before each call of the OnTimer() handler. If the indicator has not been calculated on the last tick yet, the calculations of the indicator values are launched. If the data has already been prepared, it is provided without a new recalculation.

Thus, all indicator calculations are performed in the most resource-saving manner — if the indicator has already been calculated at a given tick, its data is provided 'as is'. No recalculation is launched.

Loading History during Testing

The history of a symbol to be tested is synchronized and loaded by the terminal from the trade server before starting the testing process. During the first time, the terminal loads all available history of a symbol in order not to request it later. Further only the new data are loaded.

A testing agent receives the history of a symbol to be tested from the client terminal right after the start of testing. If data of other instruments are used in the process of testing (for example, it is a multicurrency Expert Advisor), the testing agent requests the required history from the client terminal

during the first call to such data. If historical data are available in the terminal, they are immediately passed to the testing agent. If data are not available, the terminal requests and downloads them from the server, and then passes to the testing agent.

Data of additional instruments is also required for calculating cross-rates for trade operations. For example, when testing a strategy on EURCHF with the deposit currency in USD, prior to processing the first trading operation, the testing agent requests the history data of EURUSD and USDCHF from the client terminal, though the strategy does not contain direct use call of these symbols.

Before testing a multi-currency strategy, it is recommended to download all the necessary historical data to the client terminal. This will help to avoid delays in testing/optimization associated with download of the required data. You can download history, for example, by opening the appropriate charts and scrolling them to the history beginning. An example of forced loading of history into the terminal is available in the Organizing Access to Data section of the MQL5 Reference.

Testing agents, in turn, receive history from the terminal in the packed form. During the next testing, the tester does not load history from the terminal, because the required data is available since the previous run of the tester.

- The terminal loads history from a trade server only once, the first time the agent requests the history of a symbol to be tested from the terminal. The history is loaded in a packed form to reduce the traffic.
- Ticks are not sent over the network, they are generated on testing agents.

Multi-Currency Testing

The Strategy Tester allows us to perform a testing of strategies, trading on multiple symbols. Such EAs are conventionally referred to as multi-currency Expert Advisors, since originally, in the previous platforms, testing was performed only for a single symbol. In the Strategy Tester of the MetaTrader 5 terminal, we can model trading for all of the available symbols.

The tester loads the history of the used symbols from the **client terminal** (not from the trade server!) automatically during the first call of the symbol data.

The testing agent downloads only the missing history, with a small margin to provide the necessary data on the history, for the calculation of the indicators at the starting time of testing. For the time-frames D1 and less, the minimum volume of the downloaded history is one year.

Thus, if we run a testing on an interval 2010.11.01-2010.12.01 (testing for an interval of one month) with a period of M15 (each bar is equal to 15 minutes), then the terminal will be requested the history for the instrument for the entire year of 2010. For the weekly time-frame, we will request a history of 100 bars, which is about two years (a year has 52 weeks). For testing on a monthly time-frame the agent will request the history of 8 years (12 months x 8 years = 96 months).

If there isn't necessary bars, the **starting date of testing will be automatically shifted** from past to present to provide the necessary reserve of bars before the testing.

During testing, the "Market Watch" is emulated as well, from which one can obtain information on symbols.

By default, at the beginning of testing, there is only one symbol in the "Market Watch" of the Strategy Tester - the symbol that the testing is running on. All of the necessary symbols are connected to the "Market Watch" of the Strategy Tester (not terminal!) automatically when referred to.

> Prior to starting testing of a multi-currency Expert Advisor, it is necessary to select symbols required for testing in the "Market Watch" of the terminal and load the required data. During the first call of a "foreign" symbol, its history will be automatically synchronized between the testing agent and the client terminal. A "foreign" symbol is the symbol other than that on which testing is running.

Referral to the data of an "other" symbol occurs in the following cases:

- When using the technical indicators function and IndicatorCreate() on the symbol/timeframe;
- The request to the "Market Watch" data for the other symbol:
  1. SeriesInfoInteger
  2. Bars
  3. SymbolSelect
  4. SymbolIsSynchronized
  5. SymbolInfoDouble
  6. SymbolInfoInteger
  7. SymbolInfoString
  8. SymbolInfoTick
  9. SymbolInfoSessionQuote
  10. SymbolInfoSessionTrade
  11. MarketBookAdd
  12. MarketBookGet
- Request of the time-series for a symbol/timeframe by using the following functions:
  1. CopyBuffer
  2. CopyRates
  3. CopyTime
  4. CopyOpen
  5. CopyHigh
  6. CopyLow
  7. CopyClose
  8. CopyTickVolume
  9. CopyRealVolume
  10. CopySpread

At the moment of the first call to an "other" symbol, the testing process is stopped and the history is downloaded for the symbol/timeframe, from the terminal to the testing agent. At the same time, the generation of tick sequence for this symbol is made.

An individual tick sequence is generated for each symbol, according to the selected tick generation mode. You can also request the history explicitly for the desired symbols by calling the SymbolSelect() in the OnInit() handler - the downloading of the history will be made immediately prior to the testing of the Expert Advisor.

Thus, it does not require any extra effort to perform multi-currency testing in the MetaTrader 5 client terminal. Just open the charts of the appropriate symbols in the client terminal. The history will be automatically uploaded from the trading server for all the required symbols, provided that it contains this data.

Simulation of Time in the Strategy Tester

During testing, the local time TimeLocal() is always equal to the server time TimeTradeServer(). In turn, the server time is always equal to the time corresponding to the GMT time - TimeGMT(). This way, all of these functions display the same time during testing.

The lack of a difference between the GMT, the Local, and the server time in the Strategy Tester is done deliberately in case there is no connection to the server. The test results should always be the same, regardless of whether or not there is a connection. Information about the server time is not stored locally, and is taken from the server.

Graphical Objects in Testing

During testing/optimization graphical objects are not plotted. Thus, when referring to the properties of a created object during testing/optimization, an Expert Advisor will receive zero values.

> This limitation does not apply to testing in visual mode.

The OnTimer() Function in the Strategy Tester

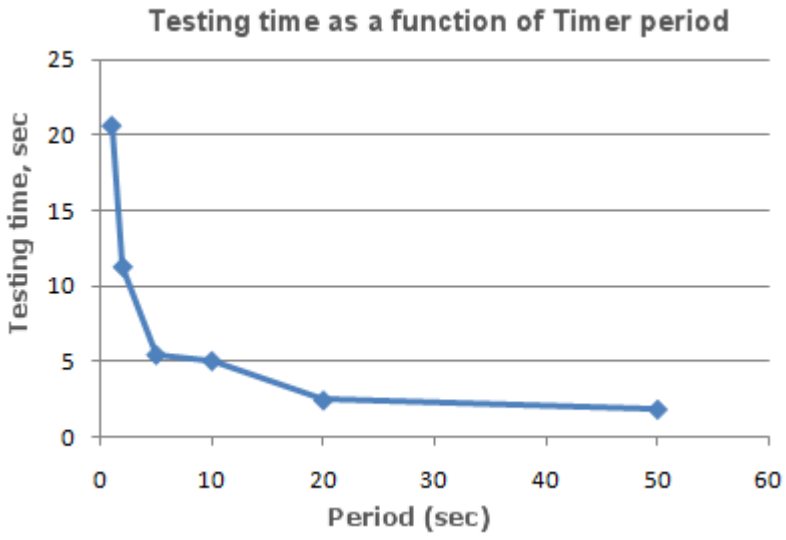
MQL5 provides the opportunity for handling timer events. The call of the OnTimer() handler is done regardless of the test mode. This means that if a test is running in the "Opening prices only" mode for the period H4, and the EA has a timer set to a call per second, then at the opening of each H4 bar, the OnTick() handler will be called one time, and the OnTimer() handler will be called 14400 times (3600 seconds * 4 hours). The amount by which the testing time of the EA will be increased depends on the logic of the EA.

To check the dependence of the testing time from the given frequency of the timer, we have created a simple EA without any trading operations.

```
//--- input parameters
input int      timer=1;              // timer value, sec
input bool     timer_switch_on=true; // timer on
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- run the timer if  timer_switch_on==true
   if(timer_switch_on)
```

```
      {
       EventSetTimer(timer);
      }
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- stop the timer
   EventKillTimer();
  }
//+------------------------------------------------------------------+
//| Timer function                                                   |
//+------------------------------------------------------------------+
void OnTimer()
  {
//---
// take no actions, the body of the handler is empty
  }
//+------------------------------------------------------------------+
```

Testing time measurements were taken at different values of the timer parameter (periodicity of the Timer event). On the obtained data, we plot a testing time as function of Timer period.



It can be clearly seen that the smaller is the parameter timer, during the initialization of the EventSetTimer(Timer) function, the smaller is the period (Period) between the calls of the OnTimer() handler, and the larger is the testing time T, under the same other conditions.

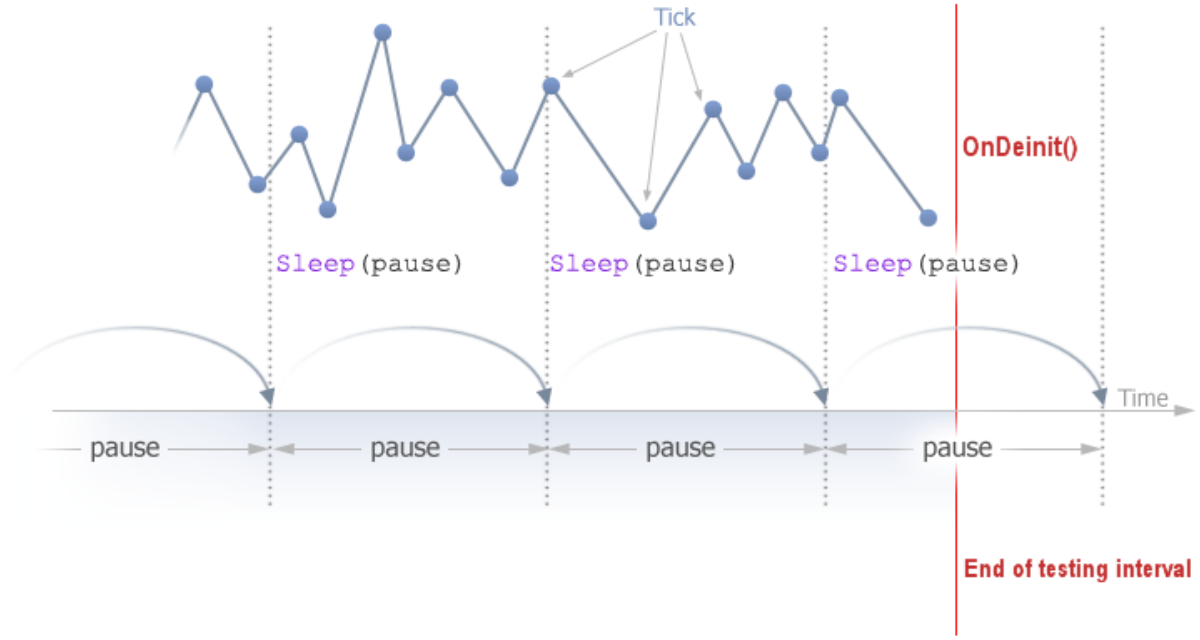
The Sleep() Function in the Strategy Tester

The Sleep() function allows the EA or script to suspend the execution of the mql5-program for a while, when working on the graph. This can be useful when requesting data, which is not ready at the time of the request and you need to wait until it is ready. A detailed example of using the Sleep() function can be found in the section Organizing Data Access.

The testing process is not lingered by the Sleep() calls.When you call the Sleep(), the generated ticks are "played" within a specified delay, which may result in the triggering of pending orders, stops, etc. After a Sleep() call, the simulated time in the Strategy Tester increases by an interval, specified in the parameter of the Sleep function.

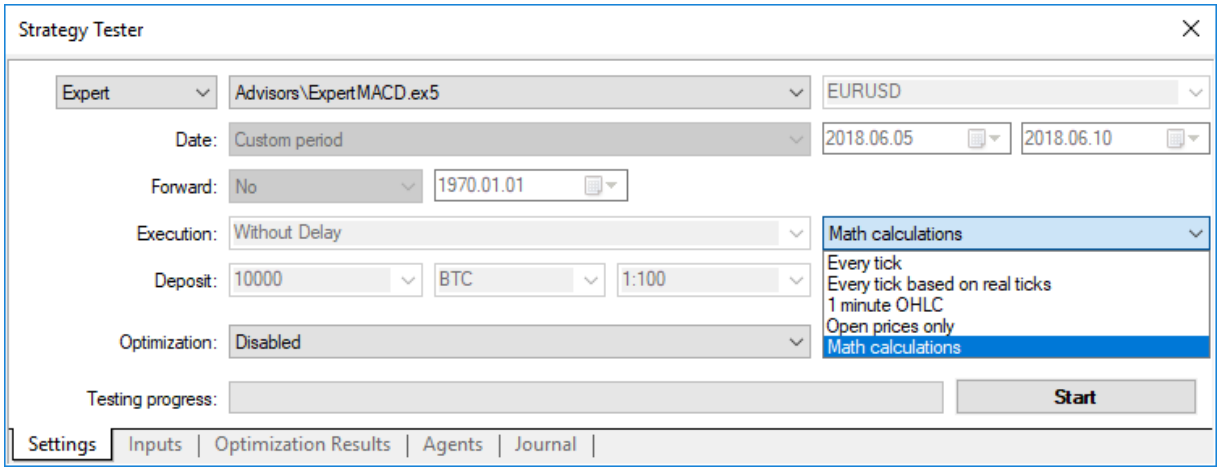
If as a result of the execution of the Sleep() function, the current time in the Strategy Tester went over the testing period, then you will receive an error "Infinite Sleep loop detected while testing". If you receive this error, the test results are not rejected, all of the computations are performed in their full volume (the number of deals, subsidence, etc.), and the results of this testing are passed on to the terminal.

The Sleep() function will not work in OnDeinit(), since after it is called, the testing time will be guaranteed to surpass the range of the testing interval.



Using the Strategy Tester for Optimization Problems in Mathematical Calculations

The tester in the MetaTrader 5 terminal can be used, not only to testing trading strategies, but also for mathematical calculations. To use it, it's necessary to select the "Math calculations" mode:



In this case, only three functions will be called: OnInit(), OnTester(), OnDeinit(). In "Math calculations" mode the Strategy Tester doesn't generate any ticks and download the history.

The Strategy Tester works in "Math calculations" mode also if you specify the starting date greater than ending date.

When using the tester to solve mathematical problems, the uploading of the history and the generation of ticks does not occur.

A typical mathematical problem for solving in the MetaTrader 5 Strategy Tester - searching for an extremum of a function with many variables.

To solve it we need to:

- The calculation of function value should be located in OnTester() function;
- The function parameters must be defined as input-variables of the Expert Advisor;

Compile the EA, open the "Strategy Tester" window. In the "Input parameters" tab, select the required input variables, and define the set of parameter values by specifying the start, stop and step values for each of the function variables.

Select the optimization type - "Slow complete algorithm" (full search of parameters space) or "Fast genetic based algorithm". For a simple search of the extremum of the function, it is better to choose a fast optimization, but if you want to calculate the values for the entire set of variables, then it is best to use the slow optimization.

Select "Math calculation" mode and using the "Start" button, run the optimization procedure. Note that during the optimization the Strategy Tester will search for the maximum values of the OnTester function. To find a local minimum, return the inverse of the computed function value from the OnTester function:

```
return(1/function_value);
```

It is necessary to check that the function_value is not equal to zero, since otherwise we can obtain a critical error of dividing by zero.

There is another way, it is more convenient and does not distort the results of optimization, it was suggested by the readers of this article:

```
return(-function_value);
```

This option does not require the checking of the function_value for being equal to zero, and the surface of the optimization results in a 3D-representation has the same shape. The only difference is that it is mirrored comparing to the original.

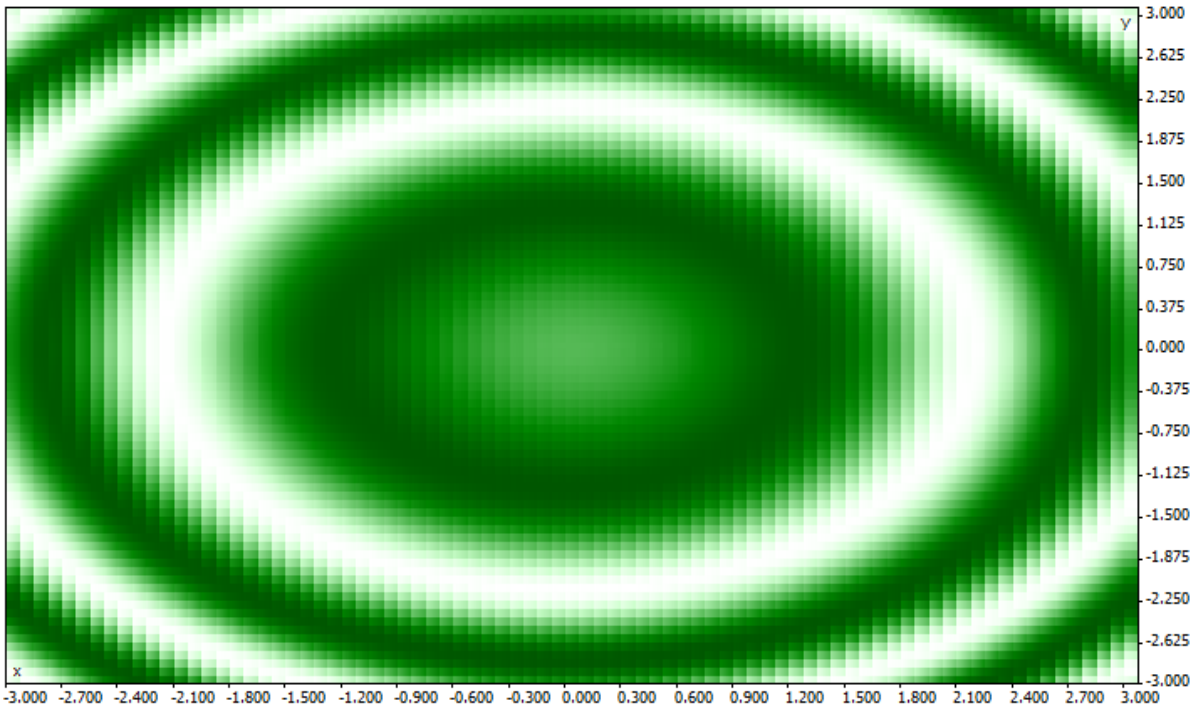
As an example, we provide the sink() function:

$$sink(x,y) = \sin(x^2 + y^2)$$

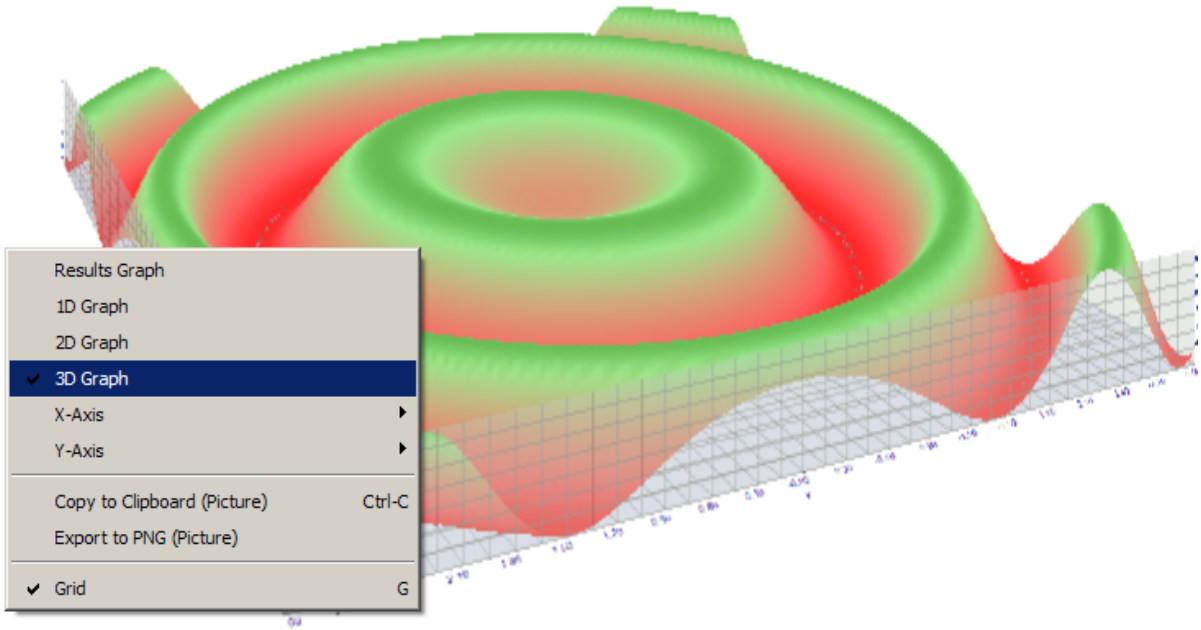
The code of the EA for finding the extremum of this function is placed into the OnTester():

```
//+------------------------------------------------------------------+
//|                                                         Sink.mq5 |
//|                        Copyright 2011, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "Copyright 2000-2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com"
#property version   "1.00"
//--- input parameters
input double   x=-3.0; // start=-3, step=0.05, stop=3
input double   y=-3.0; // start=-3, step=0.05, stop=3
//+------------------------------------------------------------------+
//| Tester function                                                  |
//+------------------------------------------------------------------+
double OnTester()
  {
//---
   double sink=MathSin(x*x+y*y);
//---
   return(sink);
  }
//+------------------------------------------------------------------+
```

Perform an optimization and see the optimization results in the form of a 2D graph.



The better the value is for a given pair of parameters (x, y), the more saturated the color is. As was expected from the view of the form of the sink() formula, its values forms concentric circles with a center at (0,0). One can see in the 3D-graph, that the sink() function has no single global extremum:



The Synchronization of Bars in the "Open prices only" mode

The tester in the MetaTrader 5 client terminal allows us to check the so-called "multi-currency" EAs. A multi-currency EA - is an EA that trades on two or more symbols.

The testing of strategies, that are trading on multiple symbols, imposes a few additional technical requirements on the tester:

- The generation of ticks for these symbols;
- The calculation of indicator values for these symbols;
- The calculation of margin requirements for these symbols;
- Synchronization of generated tick sequences for all trading symbols.

The Strategy Tester generates and plays a tick sequence for each instrument in accordance with the selected trading mode. At the same time, a new bar for each symbol is opened, regardless of how the bar opened on another symbol. This means that when testing a multi-currency EA, a situation may occur (and often does), when for one instrument a new bar has already opened, and for the other it has not. Thus, in testing, everything happens just like in reality.

This authentic simulation of the history in the tester does not cause any problems as long as the "Every tick" and "1 minute OHLC" testing modes are used. For these modes, enough ticks are generated for one candlestick, to be able to wait until the synchronization of bars from different symbols takes place. But how do we test multi-currency strategies in the "Open prices only" mode, if the synchronization of bars on trading instruments is mandatory? In this mode, the EA is called only on one tick, which corresponds to the time of the opening of the bars.

We'll illustrate it on an example: we are testing an EA on the EURUSD, and a new H1 candlestick has been opened on EURUSD. We can easily recognize this fact - while testing in the "Open prices only" mode, the NewTick event corresponds to the moment of a bar opening on the tested period. But there is no guarantee that the new candlestick was opened on the USDJPY symbol, which is used in the EA.

Under normal circumstances, it is sufficient enough to complete the work of the OnTick() function and to check for the emergence of a new bar on USDJPY at the next tick. But when testing in the "Open prices only" mode, there will be no other tick, and so it may seem that this mode is not fit for testing multi-currency EAs. But this is not so - do not forget that the tester in MetaTrader 5 behaves just as it would in real life. You can wait until a new bar is opened on another symbols using the function Sleep()!

The code of the EA Synchronize_Bars_Use_Sleep.mq5, which shows an example of the synchronization of bars in the "Open prices only" mode:

```
//+------------------------------------------------------------------+
//|                                  Synchronize_Bars_Use_Sleep.mq5 |
//|                        Copyright 2011, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "Copyright 2000-2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com"
#property version   "1.00"
//--- input parameters
input string   other_symbol="USDJPY";
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- check symbol
   if(_Symbol==other_symbol)
     {
```

```
      PrintFormat("You have to specify the other symbol in input parameters or select
      //--- forced stop testing
      return(INIT_PARAMETERS_INCORRECT);
     }
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//--- static variable, used for storage of last bar time
   static datetime last_bar_time=0;
//--- sync flag
   static bool synchonized=false;
//--- if static variable isn't initialized
   if(last_bar_time==0)
     {
      //--- it's first call, save bar time and exit
      last_bar_time=(datetime)SeriesInfoInteger(_Symbol,Period(),SERIES_LASTBAR_DATE);
      PrintFormat("The last_bar_time variable is initialized with value %s",TimeToStri
     }
//--- get open time of the last bar of chart symbol
   datetime curr_time=(datetime)SeriesInfoInteger(Symbol(),Period(),SERIES_LASTBAR_DAT
//--- if times aren't equal
   if(curr_time!=last_bar_time)
     {
      //--- save open bar time to the static variable
      last_bar_time=curr_time;
      //--- not synchronized
      synchonized=false;
      //--- print message
      PrintFormat("A new bar has appeared on symbol %s at %s",_Symbol,TimeToString(Tir
     }
//--- open time of the other symbol's bar
   datetime other_time;
//--- loop until the open time of other symbol become equal to curr_time
   while(!(curr_time==(other_time=(datetime)SeriesInfoInteger(other_symbol,Period(),SE
     {
      PrintFormat("Waiting 5 seconds..");
      //--- wait 5 seconds and call SeriesInfoInteger(other_symbol,Period(),SERIES_LAS
      Sleep(5000);
     }
//--- bars are synchronized
   synchonized=true;
   PrintFormat("Open bar time of the chart symbol %s: is %s",_Symbol,TimeToString(last
   PrintFormat("Open bar time of the symbol %s: is %s",other_symbol,TimeToString(other
//--- TimeCurrent() is not useful, use TimeTradeServer()
```

```
    Print("The bars are synchronized at ",TimeToString(TimeTradeServer(),TIME_SECONDS))
  }
//+------------------------------------------------------------------+
```

Notice the last line in the EA, which displays the current time when the fact of synchronization was established:

```
    Print("The bars synchronized at ",TimeToString(TimeTradeServer(),TIME_SECONDS));
```

To display the current time we used the TimeTradeServer() function rather than TimeCurrent(). The TimeCurrent() function returns the time of the last tick, which does not change after using Sleep(). Run the EA in the "Open prices only" mode, and you will see a message about the synchronization of the bars.

Core 1	2010.12.01 20:00:05	The bars are synchronized at 2010.12.01 20:00:05
Core 1	2010.12.01 20:00:05	Open bar time of the chart symbol USDJPY: 2010.12.01 20:00
Core 1	2010.12.01 20:00:05	A new bar has appeared on symbol EURUSD: 2010.12.01 20:00
Core 1	2010.12.01 20:00:00	Waiting 5 seconds..
Core 1	2010.12.01 20:00:05	A new bar has appeared on symbol EURUSD: 2010.12.01 20:00
Core 1	2010.12.01 16:00:05	The bars are synchronized at 2010.12.01 16:00:05

Use the TimeTradeServer() function instead of the TimeCurrent(), if you need to obtain the current server time, and not the time of the last tick arrival.

There is another way to synchronize bars - using a timer. An example of such an EA is Synchronize_Bars_Use_OnTimer.mq5, which is attached to this article.

The IndicatorRelease() function in the Tester

After completing a single testing, a chart of the instrument is automatically opened, which displays the completed deals and the indicators used in the EA. This helps to visually check the entry and exit points, and compare them with the values of the indicators.

> **Note:** indicators, displayed on the chart, which automatically opens after the completion of the testing, are calculated anew after the completion of testing. Even if these indicators were used in the tested EA.

But in some cases, the programmer may want to hide the information on which indicators were involved in the trading algorithms. For example, the code of the EA is rented or sold as an executable file, without the provision of the source code. For this purpose, the IndicatorRelease() function is suitable.

If the terminal sets a template with the name tester.tpl in the directory/profiles/templates of the client terminal, then it will be applied to the opened chart. In its absence, the default template is applied. (default.tpl).

The IndicatorRelease() function is originally intended for releasing the calculating portion of the indicator, if it is no longer needed. This allows you to save both the memory and the CPU resources, because each tick calls for an indicator calculation. Its second purpose is to prohibit the showing of an indicator on the testing chart, after a single test run.

To prohibit the showing of the indicator on the chart after testing, call the IndicatorRelease() with the handle of the indicator in the handler OnDeinit(). The OnDeinit() function is always called after the completion and before the showing of the testing chart.

```
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//---
   bool hidden=IndicatorRelease(handle_ind);
   if(hidden) Print("IndicatorRelease() successfully completed");
   else Print("IndicatorRelease() returned false. Error code ",GetLastError());
  }
```

In order to prohibit the showing of the indicator on the chart, after the completion of a single test, use the function IndicatorRelease() in the handler OnDeinit().

Event Handling in the Tester

The presence of the OnTick() handler in the EA is not mandatory in order for it to be subjected to testing on historical data in the MetaTrader 5 tester. It is sufficient enough for the EA ti contain at least one of the following function-handlers:

- OnTick() - Event handler of a new tick arrival;
- OnTrade() - Trading event handler;
- OnTimer() - Event handler of a signal arrival from the timer;
- OnChartEvent() - a handler for client events.

When testing in an EA, we can handle custom events using the OnChartEvent() function, but in the indicators, this function can not be called in the tester. Even if the indicator has the OnChartEvent() event handler and this indicator is used in the tested EA, the indicator itself will not receive any custom events.

During testing, an Indicator can generate custom events using the EventChartCustom() function, and the EA can process this event in the OnChartEvent().

In addition to these events, special events associated with the process of testing and optimization are generated in the strategy tester:

- Tester - this event is generated after completion of Expert Advisor testing on history data. The Tester event is handled using the OnTester() function. This function can be used only when testing Expert Advisor and is intended primarily for the calculation of a value that is used as a Custom max criterion for genetic optimization of input parameters.
- TesterInit - this event is generated during the start of optimization in the strategy tester before the very first pass. The TesterInit event is handled using the OnTesterInit() function. During the start of optimization, an Expert Advisor with this handler is automatically loaded on a separate terminal chart with the symbol and period specified in the tester, and receives the TesterInit event. The function is used to initiate an Expert Advisor before start of optimization for further processing of optimization results.

- TesterPass - this event is generated when a new data frame is received. The TesterPass event is handled using the OnTesterPass() function. An Expert Advisor with this handler is automatically loaded on a separate terminal chart with the symbol/period specified for testing, and receives the TesterPass event when a frame is received during optimization. The function is used for dynamic handling of optimization results "on the spot" without waiting for its completion. Frames are added using the FrameAdd() function, which can be called after the end of a single pass in the OnTester() handler.
- TesterDeinit - this event is generated after the end of Expert Advisor optimization in the strategy tester. The TesterDeinit event is handles using the OnTesterDeinit() function. An Expert Advisor with this handler is automatically loaded on a chart at the start of optimization, and receives TesterDeinit after its completion. The function is used for final processing of all optimization results.

Testing Agents

Testing in the MetaTrader 5 client terminal is carried out using test agents. Local agents are created and enabled automatically. The default number of local agents corresponds to the number of cores in a computer.

Each testing agent has its own copy of the global variables, which is not related to the client terminal. The terminal itself is the dispatcher, which distributes the tasks to the local and remote agents. After executing a task on the testing of an EA, with the given parameters, the agent returns the results to the terminal. With a single test, only one agent is used.

The agent stores the history, received from the terminal, in separate folders, by the name of the instrument, so the history for EURUSD is stored in a folder named EURUSD. In addition, the history of the instruments is separated by their sources. The structure for storing the history looks the following way:

```
tester_catalog\Agent-IPaddress-Port\bases\name_source\history\symbol_name
```

For example, the history for EURUSD from the server MetaQuotes-Demo can be stored in the folder tester_catalog\Agent-127.0.0.1-3000\bases\MetaQuotes-Demo\EURUSD.

A local agent, after the completion of testing, goes into a standby mode, awaiting for the next task for another 5 minutes, so as not to waste time on launching for the next call. Only after the waiting period is over, the local agent shuts down and unloads from the CPU memory.

In case of an early completion of the testing, from the user's side (the "Cancel" button), as well as with the closing of the client terminal, all local agents immediately stop their work and are unloaded from the memory.

The Data Exchange between the Terminal and the Agent

When you run a test, the client terminal prepares to send an agent a number of parameter blocks:

- Input parameters for testing (simulation mode, the interval of testing, instruments, optimization criterion, etc.)
- The list of the selected symbols in the "Market Watch"
- The specification of the testing symbol (the contract size, the allowable margins from the market for setting a StopLoss and Takeprofit, etc)

- The Expert Advisor to be tested and the values of its input parameters
- Information about additional files (libraries, indicators, data files - # property tester_ ...)

tester_indicator	string	Name of a custom indicator in the format of "indicator_name.ex5". Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter that sets the indicator name) this property is required
tester_file	string	File name for a tester with the indication of extension, in double quotes (as a constant string). The specified file will be passed to tester. Input files to be tested, if there are necessary ones, must always be specified.
tester_library	string	Library name with the extension, in double quotes. A library can have extension dll or ex5. Libraries that require testing are defined automatically. However, if any of libraries is used by a custom indicator, this property is required

For each block of parameters, a digital fingerprint in the form of MD5-hash is created, which is sent to the agent. MD5-hash is unique for each set, its volume is many more times smaller than the amount of information on which it is calculated.

The agent receives a hash of blocks and compares them with those that it already has. If the fingerprint of the given parameter block is not present in the agent, or the received hash is different from the existing one, the agent requests this block of parameters. This reduces the traffic between the terminal and the agent.

After the testing, the agent returns to the terminal all of the results of the run, which are shown in the tabs "Test Results" and "Optimization Results": the received profit, the number of deals, the Sharpe coefficient, the result of the OnTester() function, etc.

During optimizing, the terminal hands out testing tasks to the agents in small packages, each package contains several tasks (each task means single testing with a set of input parameters). This reduces the exchange time between the terminal and the agent.

The agents never record to the hard disk the EX5-files, obtained from the terminal (EA, indicators, libraries, etc.) for security reasons, so that a computer with a running agent could not use the sent data. All other files, including DLL, are recorded in the sandbox. In remote agents you can not test EAs using DLL.

The testing results are added up by the terminal into a special cache of results (the result cache), for a quick access to them when they are needed. For each set of parameters, the terminal searches the result cache for already available results from the previous runs, in order to avoid re-runs. If the result with such a set of parameters is not found, the agent is given the task to conduct the testing.

All traffic between the terminal and the agent is encrypted.

> Ticks are not sent over the network, they are generated on testing agents.

Using the Shared Folder of All of the Client Terminals

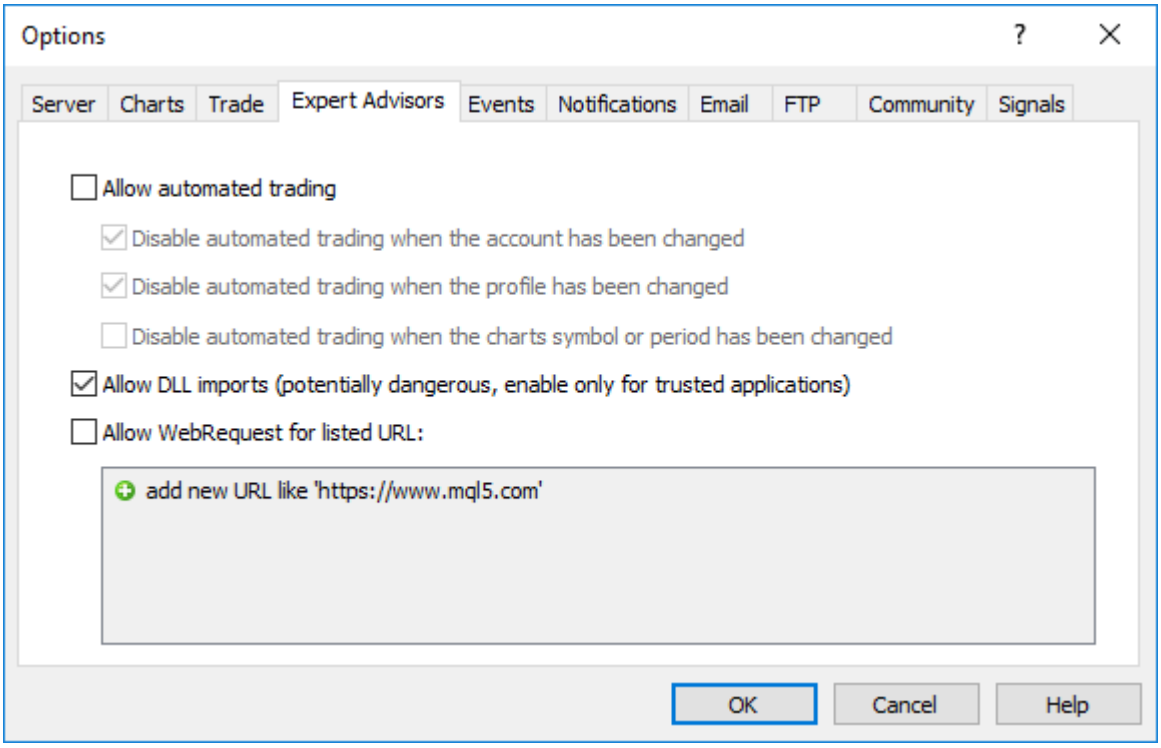
All testing agents are isolated from each other and from the client terminal: each agent has its own folder in which its logs are recorded. In addition, all file operations during the testing of the agent occur in the folder **agent_name/MQL5/Files**. However, we can implement the interaction between the local agents and the client terminal through a shared folder for all of the client terminals, if during the file opening you specify the flag FILE_COMMON:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- the shared folder for all of the client terminals
   common_folder=TerminalInfoString(TERMINAL_COMMONDATA_PATH);
//--- draw out the name of this folder
   PrintFormat("Open the file in the shared folder of the client terminals %s", commor
//--- open a file in the shared folder (indicated by FILE_COMMON flag)
   handle=FileOpen(filename,FILE_WRITE|FILE_READ|FILE_COMMON);
   ... further actions
//---
   return(INIT_SUCCEEDED);
  }
```

Using DLLs

To speed up the optimization we can use not only local, but also remote agents. In this case, there are some limitations for remote agents. First of all, remote agents do not display in their logs the results of the execution of the Print() function, messages about the opening and closing of positions. A minimum of information is displayed in the log to prevent incorrectly written EAs from trashing up the computer, on which the remote agent is working, with messages.

A second limitation - the prohibition on the use of DLL when testing EAs. DLL calls are absolutely forbidden on remote agents for security reasons. On local agent, DLL calls in tested EAs are allowed only with the appropriate permission "Allow import DLL".



Note: When using 3rd party EAs (scripts, indicators) that require allowed DLL calls, you should be aware of the risks which you assume when allowing this option in the settings of the terminal. Regardless of how the EA will be used - for testing or for running on a chart.

The predefined Variables

For each executable mql5-program a set of predefined variables is supported, which reflect the state of the current price chart by the moment a mql5-program (Expert Advisor, script or custom indicator) is started.

Values of predefined variables are set by the client terminal before a mql5-program is started. Predefined variables are constant and cannot be changed from a mql5-program. As exception, there is a special variable _LastError, which can be reset to 0 by the ResetLastError function.

Variable	Value
_AppliedTo	The _AppliedTo variable allows finding out the type of data, used for indicator calculation
_Digits	Number of decimal places
_Point	Size of the current symbol point in the quote currency
_LastError	The last error code
_Period	Timeframe of the current chart
_RandomSeed	Current status of the generator of pseudo-random integers
_StopFlag	Program stop flag
_Symbol	Symbol name of the current chart
_UninitReason	Uninitialization reason code
_IsX64	The _IsX64 variable allows finding out the bit version of the terminal, in which an MQL5 application is running

Predefined variables cannot be defined in a library. A library uses such variables that are defined in program from which this library is called.

int _AppliedTo

The _AppliedTo variable allows finding out the type of data, used for indicator calculation:

Data type	Meaning	Description of data used for indicator calculation.
—	0	The indicator uses the second OnCalculate() call form - the data for calculation are not specified by a certain buffer or data array
Close	1	Close prices
Open	2	Open prices
High	3	High prices
Low	4	Low prices
Median Price (HL/2)	5	Median price = (High+Low)/2
Typical Price (HLC/3)	6	Typical price = (High+Low+Close)/3
Weighted Price (HLCC/4)	7	Weighted price = (Open+High+Low+Close)/4
Previous Indicator's Data	8	Data of the indicator, which was launched on the chart before this indicator
First Indicator's Data	9	Data of the indicator, which was launched first on the chart
Indicator handle	10+	Data of the indicator, which was passed to the iCustom() function using the indicator handle. The _AppliedTo value contains the indicator handle

Example:

```
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,Label1Buffer,INDICATOR_DATA);
// Getting the type of data used for indicator calculation
   Print("_AppliedTo=",_AppliedTo);
   Print(getIndicatorDataDescription(_AppliedTo));
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
```

```
//| Description of data used for indicator calculation                |
//+------------------------------------------------------------------+
string getIndicatorDataDescription(int data_id)
  {
   string descr="";
   switch(data_id)
     {
      case(0):descr="It's first type of OnCalculate() - no data buffer";
         break;
      case(1):descr="Indicator calculates on Close price";
         break;
      case(2):descr="Indicator calculates on Open price";
         break;
      case(3):descr="Indicator calculates on High price";
         break;
      case(4):descr="Indicator calculates on Low price";
         break;
      case(5):descr="Indicator calculates on Median Price (HL/2)";
         break;
      case(6):descr="Indicator calculates on Typical Price (HLC/3)";
         break;
      case(7):descr="Indicator calculates on Weighted Price (HLCC/4)";
         break;
      case(8):descr="Indicator calculates Previous Indicator's data";
         break;
      case(9):descr="Indicator calculates on First Indicator's data";
         break;
      default: descr="Indicator calculates on data of indicator with handle="+string(d
         break;
     }
//---
   return descr;
  }
```

See also

ENUM_APPLIED_PRICE

int _Digits

The _Digits variable stores number of digits after a decimal point, which defines the price accuracy of the symbol of the current chart.

You may also use the Digits() function.

double _Point

The _Point variable contains the point size of the current symbol in the quote currency.

You may also use the Point() function.

int _LastError

The _LastError variable contains code of the last error, that occurred during the mql5-program run. Its value can be reset to zero by ResetLastError().

To obtain the code of the last error, you may also use the GetLastError() function.

ENUM_TIMEFRAMES _Period

The _Period variable contains the value of the timeframe of the current chart.

Also you may use the Period() function.

See also

PeriodSeconds, Chart timeframes, Date and Time, Visibility of objects

_RandomSeed

Variable for storing the current state when generating pseudo-random integers. _RandomSeed changes its value when calling MathRand(). Use MathSrand() to set the required initial condition.

x random number received by MathRand() function is calculated in the following way at each call:

```
x=_RandomSeed*214013+2531011;
_RandomSeed=x;
x=(x>>16)&0x7FFF;
```

See also

MathRand(), MathSrand(), Integer types

bool _StopFlag

The _StopFlag variable contains the flag of the mql5-program stop. When the client terminal is trying to stop the program, it sets the _StopFlag variable to true.

To check the state of the _StopFlag you may also use the IsStopped() function.

string _Symbol

The _Symbol variable contains the symbol name of the current chart.

You may also use the Symbol() function.

int _UninitReason

The _UninitReason variable contains the code of the program uninitialization reason.

Usually, this code is obtained by UninitializeReason()the function.

int _IsX64

The _IsX64 variable allows finding out the bit version of the terminal, in which an MQL5 application is running: _IsX64=0 for the 32-bit terminal and _IsX64!=0 for the 64-bit terminal.

Also, function TerminalInfoInteger(TERMINAL_X64) can be used.

Example:

```
// Checking the terminal, in which the program is running
   Print("_IsX64=",_IsX64);
   if(_IsX64)
      Print("Program ",__FILE__," is running in the 64-bit terminal");
   else
      Print("Program ",__FILE__," is running in the 32-bit terminal");
   Print("TerminalInfoInteger(TERMINAL_X64)=",TerminalInfoInteger(TERMINAL_X64));
```

MQLInfoInteger, Importing functions (#import)

Common Functions

General-purpose functions not included into any specialized group are listed here.

Function	Action
Alert	Displays a message in a separate window
CheckPointer	Returns the type of the object pointer
Comment	Outputs a comment in the left top corner of the chart
CryptEncode	Transforms the data from array with the specified method
CryptDecode	Performs the inverse transformation of the data from array
DebugBreak	Program breakpoint in debugging
ExpertRemove	Stops Expert Advisor and unloads it from the chart
GetPointer	Returns the object pointer
GetTickCount	Returns the number of milliseconds that have elapsed since the system was started
GetTickCount64	Returns the number of milliseconds that have elapsed since the system was started
GetMicrosecondCount	Returns the number of microseconds that have elapsed since the start of MQL5 program
MessageBox	Creates, displays a message box and manages it
PeriodSeconds	Returns the number of seconds in the period
PlaySound	Plays a sound file
Print	Displays a message in the log
PrintFormat	Formats and prints the sets of symbols and values in a log file in accordance with a preset format
ResetLastError	Sets the value of a predetermined variable _LastError to zero
ResourceCreate	Creates an image resource based on a data set
ResourceFree	Deletes dynamically created resource (freeing the memory allocated for it)
ResourceReadImage	Reads data from the graphical resource created by ResourceCreate() function or saved in EX5 file during compilation
ResourceSave	Saves a resource into the specified file
SetUserError	Sets the predefined variable _LastError into the value equal to ERR_USER_ERROR_FIRST + user_error
SetReturnError	Sets the code that returns the terminal process when completing the operation.

Function	Action
Sleep	Suspends execution of the current Expert Advisor or script within a specified interval
TerminalClose	Commands the terminal to complete operation
TesterHideIndicators	Sets the mode of displaying/hiding indicators used in an EA
TesterStatistics	It returns the value of a specified statistic calculated based on testing results
TesterStop	Gives program operation completion command when testing
TesterDeposit	Emulates depositing funds during a test. It can be used in some money management systems
TesterWithdrawal	Emulates the operation of money withdrawal in the process of testing
TranslateKey	Returns a Unicode character by a virtual key code
ZeroMemory	Resets a variable passed to it by reference. The variable can be of any type, except for classes and structures that have constructors.

Alert

Displays a message in a separate window.

```
void  Alert(
   argument,      // first value
   ...            // other values
   );
```

Parameters

argument

[in] Any values separated by commas. To split the information output in several lines you can use the line feed character "\n" or "\r\n". The number of parameters can not exceed 64.

Return Value

No return value.

Note

Arrays can't be passed to the Alert() function. Arrays should be output elementwise. Data of the double type are output with 8 digits after the decimal point, data of the float type are displayed with 5 digits after the decimal point. To output the real numbers with a different precision or in a scientific format, use the DoubleToString() function.

Data of the bool type is output as "true" or "false" strings. Dates are output as YYYY.MM.DD HH:MI:SS. To display a date in another format use the TimeToString() function. Data of the color type are output either as an R,G,B string or as a color name, if the color is present in a color set.

Alert() function does not work in the Strategy Tester.

CheckPointer

The function returns the type of the object pointer.

```
ENUM_POINTER_TYPE  CheckPointer(
   object* anyobject      // object pointer
   );
```

Parameters

anyobject

[in] Object pointer.

Return value

Returns a value from the ENUM_POINTER_TYPE enumeration.

Note

An attempt to call an incorrect pointer results in the critical termination of a program. That's why it's necessary to call the CheckPointer function before using a pointer. A pointer can be incorrect in the following cases:

- the pointer is equal to NULL;
- the object has been deleted using the delete operator.

This function can be used for checking pointer validity. A non-zero value warranties that the pointer can be used for accessing.

To quickly validate the pointer, you can also use operator "!" (example) which checks it via an implicit call of the CheckPointer function.

Example:

```
//+------------------------------------------------------------------+
//| Deletes list by deleting its elements                            |
//+------------------------------------------------------------------+
void CMyList::Destroy()
  {
//--- service pointer for working in the loop
   CItem* item;
//--- go through loop and try to delete dynamic pointers
   while(CheckPointer(m_items)!=POINTER_INVALID)
     {
      item=m_items;
      m_items=m_items.Next();
      if(CheckPointer(item)==POINTER_DYNAMIC)
        {
         Print("Dynamic object ",item.Identifier()," to be deleted");
         delete (item);
        }
      else Print("Non-dynamic object ",item.Identifier()," cannot be deleted");
     }
```

```
//---
  }
```

See also

Object Pointers, Checking the Object Pointer, Object Delete Operator delete

Comment

This function outputs a comment defined by a user in the top left corner of a chart.

```
void  Comment(
   argument,      // first value
   ...            // next values
   );
```

Parameters

...

[in] Any values, separated by commas. To delimit output information into several lines, a line break symbol "\n" or "\r\n" is used. Number of parameters cannot exceed 64. Total length of the input comment (including invisible symbols) cannot exceed 2045 characters (excess symbols will be cut out during output).

Return Value

No return value

Note

Arrays can't be passed to the Comment() function. Arrays must be entered element-by-element.

Data of double type are output with the accuracy of up to 16 digits after a decimal point, and can be output either in traditional or in scientific format, depending on what notation will be more compact. Data of float type are output with 5 digits after a decimal point. To output real numbers with another accuracy or in a predefined format, use the DoubleToString() function.

Data of bool type are output as "true" or "false" strings. Dates are shown as YYYY.MM.DD HH:MI:SS. To show dates in another format, use the TimeToString() function. Data of color type are output either as R,G,B string or as a color name, if this color is present in the color set.

Comment() function does not work during optimization in the Strategy Tester.

Example:

```
void OnTick()
  {
//---
   double Ask,Bid;
   int Spread;
   Ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   Bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   Spread=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD);
//--- Output values in three lines
   Comment(StringFormat("Show prices\nAsk = %G\nBid = %G\nSpread = %d",Ask,Bid,Spread)
  }
```

See also

ChartSetString, ChartGetString

CryptEncode

Transforms the data from array with the specified method.

```
int  CryptEncode(
   ENUM_CRYPT_METHOD   method,         // method
   const uchar&        data[],         // source array
   const uchar&        key[],          // key
   uchar&              result[]        // destination array
   );
```

Parameters

method

[in] Data transformation method. Can be one of the values of ENUM_CRYPT_METHOD enumeration.

data[]

[in] Source array.

key[]

[in] Key array.

result[]

[out] Destination array.

Return Value

Amount of bytes in the destination array or 0 in case of error. To obtain information about the error call the GetLastError() function.

Example:

```
//+------------------------------------------------------------------+
//| ArrayToHex                                                       |
//+------------------------------------------------------------------+
string ArrayToHex(uchar &arr[],int count=-1)
  {
   string res="";
//--- check
   if(count<0 || count>ArraySize(arr))
      count=ArraySize(arr);
//--- transform to HEX string
   for(int i=0; i<count; i++)
      res+=StringFormat("%.2X",arr[i]);
//---
   return(res);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

```
  {
   string text="The quick brown fox jumps over the lazy dog";
   string keystr="ABCDEFG";
   uchar src[],dst[],key[];
//--- prepare key
   StringToCharArray(keystr,key);
//--- copy text to source array src[]
   StringToCharArray(text,src);
//--- print initial data
   PrintFormat("Initial data: size=%d, string='%s'",ArraySize(src),CharArrayToString(s
//--- encrypt src[] with DES 56-bit key in key[]
   int res=CryptEncode(CRYPT_DES,src,key,dst);
//--- check error
   if(res>0)
     {
      //--- print encrypted data
      PrintFormat("Encoded data: size=%d %s",res,ArrayToHex(dst));
      //--- decode dst[] to src[]
      res=CryptDecode(CRYPT_DES,dst,key,src);
      //--- check error
      if(res>0)
        {
         //--- print decoded data
         PrintFormat("Decoded data: size=%d, string='%s'",ArraySize(src),CharArrayToSt
        }
      else
         Print("Error in CryptDecode. Error code=",GetLastError());
     }
   else
      Print("Error in CryptEncode. Error code=",GetLastError());
  }
```

See also

Array Functions, CryptDecode()

CryptDecode

Performs the inverse transformation of the data from array, tranformed by CryptEncode().

```
int  CryptEncode(
   ENUM_CRYPT_METHOD   method,         // method
   const uchar&        data[],         // source array
   const uchar&        key[],          // key
   uchar&              result[]        // destination array
   );
```

Parameters

method

[in] Data transformation method. Can be one of the values of ENUM_CRYPT_METHOD enumeration.

data[]

[in] Source array.

key[]

[in] Key array.

result[]

[out] Destination array.

Return Value

Amount of bytes in the destination array or 0 in case of error. To obtain information about the error call the GetLastError() function.

See also

Array Functions, CryptEncode()

DebugBreak

It is a program breakpoint in debugging.

```
void  DebugBreak();
```

Return Value

No return value.

Note

Execution of an MQL5 program is interrupted only if a program is started in a debugging mode. The function can be used for viewing values of variables and/or for further step-by-step execution.

ExpertRemove

The function stops an Expert Advisor and unloads it from a chart.

```
void  ExpertRemove();
```

Return Value

No return value.

Note

The Expert Advisor is not stopped immediately as you call ExpertRemove(); just a flag to stop the EA operation is set. That is, any next event won't be processed, OnDeinit() will be called and the Expert Advisor will be unloaded and removed from the chart.

Calling ExpertRemove() in the strategy tester inside the OnInit() handler cancels testing on the current set of parameters. Such completion is considered an initialization error.

When calling ExpertRemove() in the strategy tester after successful initialization of an EA, a test is completed normally with the call of OnDeinit() and OnTester(). In this case, the entire trading statistics and an optimization criterion value are obtained.

Example:

```
//+------------------------------------------------------------------+
//|                                              Test_ExpertRemove.mq5 |
//|                        Copyright 2009, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "2009, MetaQuotes Software Corp."
#property link      "https://www.mql5.com"
#property version   "1.00"
input int ticks_to_close=20;// number of ticks before EA unload
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//---
   Print(TimeCurrent(),": " ,__FUNCTION__," reason code = ",reason);
//--- "clear" comment
   Comment("");
//---
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
   static int tick_counter=0;
//---
```

```
   tick_counter++;
   Comment("\nBefore unloading expert advisor ",__FILE__," left",
           (ticks_to_close-tick_counter)," ticks");
//--- before
   if(tick_counter>=ticks_to_close)
     {
      ExpertRemove();
      Print(TimeCurrent(),": ",__FUNCTION__," expert advisor will be unloaded");
     }
   Print("tick_counter =",tick_counter);
//---
  }
//+------------------------------------------------------------------+
```

See also

Program running, Client terminal events

GetPointer

The function returns the object pointer.

```
void*  GetPointer(
   any_class anyobject      // object of any class
   );
```

Parameters

anyobject

[in] Object of any class.

Return Value

The function returns the object pointer.

Note

Only class objects have pointers. Instances of structures and simple-type variables can't have pointers. The class object not created using the new() operator, but, e.g., automatically created in the array of objects, still has a pointer. But this pointer will be of the automatic type POINTER_AUTOMATIC, therefore the delete() operator can't be applied to it. Aside from that, the type pointer doesn't differ from dynamic pointers of the POINTER_DYNAMIC type.

Since variables of structure types and simple types do not have pointers, it's prohibited to apply the GetPointer() function to them. It's also prohibited to pass the pointer as a function argument. In all these cases the compiler will notify an error.

An attempt to call an incorrect pointer causes the critical termination of a program. That's why the CheckPointer() function should be called prior to using a pointer. A pointer can be incorrect in the following cases:

- the pointer is equal to NULL;
- the object has been deleted using the delete operator.

This function can be used to check the validity of a pointer. A non-zero value guarantees, that the pointer can be used for accessing.

Example:

```
//+------------------------------------------------------------------+
//|                                              Check_GetPointer.mq5 |
//|                        Copyright 2009, MetaQuotes Software Corp. |
//|                                              https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "2009, MetaQuotes Software Corp."
#property link      "https://www.mql5.com"
#property version   "1.00"

//+------------------------------------------------------------------+
//| Class implementing the list element                              |
//+------------------------------------------------------------------+
```

```
class CItem
  {
   int               m_id;
   string            m_comment;
   CItem*            m_next;
public:
                     CItem() { m_id=0; m_comment=NULL; m_next=NULL; }
                    ~CItem() { Print("Destructor of ",m_id,

GetTickCount

The GetTickCount() function returns the number of milliseconds that elapsed since the system start.

```
uint  GetTickCount();
```

Return Value

Value of uint type.

Note

Counter is limited by the restrictions of the system timer. Time is stored as an unsigned integer, so it's overfilled every 49.7 days if a computer works uninterruptedly.

Example:

```
#define MAX_SIZE 40
//+------------------------------------------------------------------+
//| Script for measuring computation time of 40 Fibonacci numbers    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Remember the initial value
   uint start=GetTickCount();
//--- A variable for getting the next number in the Fibonacci series
   long fib=0;
//--- In loop calculate the specified amount of numbers from Fibonacci series
   for(int i=0;i<MAX_SIZE;i++) fib=TestFibo(i);
//--- Get the spent time in milliseconds
   uint time=GetTickCount()-start;
//--- Output a message to the Experts journal
   PrintFormat("Calculating %d first Fibonacci numbers took %d ms",MAX_SIZE,time);
//--- Script completed
   return;
  }
//+------------------------------------------------------------------+
//| Function for getting Fibonacci number by its serial number       |
//+------------------------------------------------------------------+
long TestFibo(long n)
  {
//--- The first member of the Fibonacci series
   if(n<2) return(1);
//--- All other members are calculated by the following formula
   return(TestFibo(n-2)+TestFibo(n-1));
  }
```

Date and Time, EventSetMillisecondTimer, GetTickCount64, GetMicrosecondCount

GetTickCount64

The GetTickCount64() function returns the number of milliseconds that have elapsed since the system was launched.

```
ulong  GetTickCount64();
```

Return Value

A ulong type value.

Note

The counter is limited to the accuracy of the system timer, which usually returns a result with the 10-16 millisecond precision. Unlike GetTickCount, which is of uint type and the contents of which overflow every 49.7 days in the case of continued computer operation, GetTickCount64() can be used for the unlimited computer operation time and is not subject to overflow.

See also

Date and Time, EventSetMillisecondTimer, GetTickCount, GetMicrosecondCount

GetMicrosecondCount

The GetMicrosecondCount() function returns the number of microseconds that have elapsed since the start of MQL5-program.

```
ulong  GetMicrosecondCount();
```

Return Value

Value of ulong type.

Example:

```
//+------------------------------------------------------------------+
//| Test function                                                    |
//+------------------------------------------------------------------+
void Test()
  {
   int    res_int=0;
   double res_double=0;
//---
   for(int i=0;i<10000;i++)
     {
      res_int+=i*i;
      res_int++;
      res_double+=i*i;
      res_double++;
     }
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   uint   ui=0,ui_max=0,ui_min=INT_MAX;
   ulong  ul=0,ul_max=0,ul_min=INT_MAX;
//--- number of measurements
   for(int count=0;count<1000;count++)
     {
      uint  ui_res=0;
      ulong ul_res=0;
      //---
      for(int n=0;n<2;n++)
        {
         //--- select measurement type
         if(n==0) ui=GetTickCount();
         else     ul=GetMicrosecondCount();
         //--- execute code
         Test();
         //--- add measurement result (depending on type)
```

```
         if(n==0) ui_res+=GetTickCount()-ui;
         else     ul_res+=GetMicrosecondCount()-ul;
        }
      //--- calculate minimum and maximum time for both measurements
      if(ui_min>ui_res) ui_min=ui_res;
      if(ui_max<ui_res) ui_max=ui_res;
      if(ul_min>ul_res) ul_min=ul_res;
      if(ul_max<ul_res) ul_max=ul_res;
     }
//---
   Print("GetTickCount error(msec): ",ui_max-ui_min);
   Print("GetMicrosecondCount error(msec): ",DoubleToString((ul_max-ul_min)/1000.0,2))
  }
```

Date and Time, GetTickCount, GetTickCount64

MessageBox

It creates and shows a message box and manages it. A message box contains a message and header, any combination of predefined signs and command buttons.

```
int  MessageBox(
   string  text,              // message text
   string  caption=NULL,      // box header
   int     flags=0            // defines set of buttons in the box
   );
```

Parameters

text

[in] Text, containing message to output.

caption=NULL

[in] Optional text to be displayed in the box header. If the parameter is empty, Expert Advisor name is shown in the box header.

flags=0

[in] Optional flags defining appearance and behavior of a message box. Flags can be a combination of a special group of flags.

Return Value

If the function is successfully performed, the returned value is one of values of MessageBox() return codes.

Note

The function cannot be used in custom indicators since calling MessageBox() suspends the thread of execution for the whole time while waiting for the user's response. Since all indicators for each symbol are executed in a single thread, such suspension makes the operation of all charts on all timeframes for this symbol impossible.

MessageBox() function does not work in the Strategy Tester.

PeriodSeconds

This function returns number of seconds in a period.

```
int  PeriodSeconds(
   ENUM_TIMEFRAMES  period=PERIOD_CURRENT      // chart period
   );
```

Parameters

period=PERIOD_CURRENT

[in] Value of a chart period from the enumeration ENUM_TIMEFRAMES. If the parameter isn't specified, it returns the number of seconds of the current chart period, at which the program runs.

Return Value

Number of seconds in a selected period.

See also

_Period, Chart timeframes, Date and Time, Visibility of objects

PlaySound

It plays a sound file.

```
bool  PlaySound(
   string  filename      // file name
   );
```

Parameters

filename

[in] Path to a sound file. If filename=NULL, the playback is stopped.

Return Value

true - if the file is found, otherwise - false.

Note

The file must be located in terminal_directory\Sounds or its sub-directory. Only WAV files are played.

Call of PlaySound() with NULL parameter stops playback.

PlaySound() function does not work in the Strategy Tester.

See also

Resources

Print

It enters a message in the Expert Advisor log. Parameters can be of any type.

```
void  Print(
   argument,      // first value
   ...            // next values
   );
```

Parameters

...

[in] Any values separated by commas. The number of parameters cannot exceed 64.

Note

Arrays cannot be passed to the Print() function. Arrays must be input element-by-element.

Data of double type are shown with the accuracy of up to 16 digits after a decimal point, and can be output either in traditional or in scientific format, depending on what entry will be more compact. Data of float type are output with 5 digits after a decimal point. To output real numbers with another accuracy or in a predefined format, use the PrintFormat() function.

Data of bool type are output as "true" or "false" lines. Dates are shown as YYYY.MM.DD HH:MI:SS. To show data in another format, use TimeToString(). Data of color type are returned either as R,G,B line or as a color name, if this color is present in the color set.

Print() function does not work during optimization in the Strategy Tester.

Example:

```
void OnStart()
  {
//--- Output DBL_MAX using Print(), this is equivalent to PrintFormat(%%.16G,DBL_MAX)
   Print("---- how DBL_MAX looks like -----");
   Print("Print(DBL_MAX)=",DBL_MAX);
//--- Now output a DBL_MAX number using PrintFormat()
   PrintFormat("PrintFormat(%%.16G,DBL_MAX)=%.16G",DBL_MAX);
//--- Output to the Experts journal
// Print(DBL_MAX)=1.797693134862316e+308
// PrintFormat(%.16G,DBL_MAX)=1.797693134862316E+308

//--- See how float is output
   float c=(float)M_PI; // We should explicitly cast to the target type
   Print("c=",c, "    Pi=",M_PI, "    (float)M_PI=",(float)M_PI);
// c=3.14159    Pi=3.141592653589793    (float)M_PI=3.14159

//--- Show what can happen with arithmetic operations with real types
   double a=7,b=200;
   Print("---- Before arithmetic operations");
   Print("a=",a,"   b=",b);
   Print("Print(DoubleToString(b,16))=",DoubleToString(b,16));
//--- Divide a by b (7/200)
```

```
   a=a/b;
//--- Now emulate restoring a value in the b variable
   b=7.0/a; // It is expected that b=7.0/(7.0/200.0)=>7.0/7.0*200.0=200 - but it diffe
//--- Output the newly calculated value of b
   Print("----- After arithmetic operations");
   Print("Print(b)=",b);
   Print("Print(DoubleToString(b,16))=",DoubleToString(b,16));
//--- Output to the Experts journal
// Print(b)=200.0
// Print(DoubleToString(b,16))=199.9999999999999716 (see that b is no more equal to 20

//--- Create a very small value epsilon=1E-013
   double epsilon=1e-13;
   Print("---- Create a very small value");
   Print("epsilon=",epsilon); // Get epsilon=1E-013
//--- Now subtract epsilon from b and again output the value to the Experts journal
   b=b-epsilon;
//--- Use two ways
   Print("---- After subtracting epsilon from the b variable");
   Print("Print(b)=",b);
   Print("Print(DoubleToString(b,16))=",DoubleToString(b,16));
//--- Output to the Experts journal
// Print(b)=199.9999999999999  (now the value of b after subtracting epsilon cannot be
// Print(DoubleToString(b,16))=199.9999999999998578
//    (now the value of b after subtracting epsilon cannot be rounded to 200)
  }
```

See also

DoubleToString, StringFormat

PrintFormat

It formats and enters sets of symbols and values in the Expert Advisor log in accordance with a preset format.

```
void  PrintFormat(
   string format_string,   // format string
   ...                     // values of simple types
   );
```

Parameters

format_string

[in] A format string consists of simple symbols, and if the format string is followed by arguments, it also contains format specifications.

...

[in] Any values of simple types separated by commas. Total number of parameters can't exceed 64 including the format string.

Return Value

String.

Note

PrintFormat() function does not work during optimization in the Strategy Tester.

The number, order and type of parameters must exactly match the set of qualifiers, otherwise the print result is undefined. Instead of PrintFormat() you can use printf().

If the format string is followed by parameters, this string must contain format specifications that denote output format of these parameters. Specification of format always starts with the percent sign (%).

A format string is read from left to right. When the first format specification is met (if there is any), the value of the first parameter after the format string is transformed and output according to the preset specification. The second format specification calls transformation and output of the second parameter, and so on till the format string end.

The format specification has the following form:

%[flags][width][.precision][{h | l | ll | I32 | I64}]type

Each field of the format specification is either a simple symbol, or a number denoting a simple format option. The simplest format specification contains only the percent sign (%) and a symbol defining the type of the output parameter (for example, %s). If you need to output the percent sign in the format string, use the format specification %%.

flags

Flag	Description	Default Behavior
- (minus)	Left justification within the set width	Right justification
+ (plus)	Output of the + or - sign for values of sign types	The sign is shown only if the value is negative
0 (zero)	Zeroes are added before an output value within the preset width. If **0** flag is specified with an integer format (**i**, **u**, **x**, **X**, **o**, **d**) and accuracy specification is set (for example, %04.d), then 0 is ignored.	Nothing is added
space	A space is shown before an output value, if it is a sign and positive value	Spaces aren't inserted
#	If used together with the format **o**, **x** or **X**, then before the output value 0, 0x or 0X is added respectively.	Nothing is added
	If used together with the format **e**, **E**, **a** or **A**, value is always shown with a decimal point.	Decimal point is shown only if there is a non-zero fractional part.
	If used together with the format **g** or **G**, flag defines presence of a decimal point in the output value and prevents the cutting off of leading zeroes. Flag # is ignored when used together with formats **c**, **d**, **i**, **u**, **s**.	Decimal point is shown only if there is a non-zero fractional part. Leading zeroes are cut off.

width

A non-negative decimal number that sets the minimal number of output symbols of the formatted value. If the number of output symbols is less than the specified width, the corresponding number of spaces is added from the left or right depending on the alignment (flag -). If there is flag zero (0), the corresponding number of zeroes is added before the output value. If the number of output symbols is greater than the specified width, the output value is never cut off.

If an asterisk (*) is specified as width, value of int type must be indicated in the corresponding place of the list of passed parameters. It will be used for specifying width of the output value.

precision

A non-negative decimal number that sets the output precision - number of digits after a decimal point. As distinct from width specification, precision specification can cut off the part of fractional type with or without rounding.

The use of precision specification is different for different format types.

Types	Description	Default Behavior
a, A	Precision specification sets the number of digits after a decimal point.	Default precision - 6.
c, C	Not used	
d, i, u, o, x, X	Sets minimal number of output digits. If number of digits in a corresponding parameter is less than this precision, zeroes are added to the left of the output value. The output value isn't cut off, if the number of output digits is larger than the specified precision.	Default precision - 1.
e, E, f	Sets number of output digits after a decimal point. The last digit is rounded off.	Default precision - 6. If set precision is 0 or decimal part is absent, the decimal point is not shown.
g, G	Sets maximal number of meaningful numbers.	6 meaningful numbers are output.
s	Sets number of output symbols of a string. If the string length exceeds the precision, the string is cut off.	The whole string is output.

```
PrintFormat("1. %s", _Symbol);
PrintFormat("2. %.3s", _Symbol);
int length=4;
PrintFormat("3. %.*s", length, _Symbol);
/*
1. EURUSD
2. EUR
3. EURU
/
```

h | l | ll | I32 | I64

Specification of data sizes, passed as a parameter.

Parameter Type	Used Prefix	Joint Specifier of Type
int	l (lower case L)	d, i, o, x, or X
uint	l (lower case L)	o, u, x, or X
long	ll (two lower case L)	d, i, o, x, or X

Parameter Type	Used Prefix	Joint Specifier of Type
short	h	d, i, o, x, or X
ushort	h	o, u, x, or X
int	I32	d, i, o, x, or X
uint	I32	o, u, x, or X
long	I64	d, i, o, x, or X
ulong	I64	o, u, x, or X

type

Type specifier is the only obligatory field for formatted output.

Symbol	Type	Output Format
c	int	Symbol of short type (Unicode)
C	int	Symbol of char type (ANSI)
d	int	Signed decimal integer
i	int	Signed decimal integer
o	int	Unsigned octal integer
u	int	Unsigned decimal integer
x	int	Unsigned hexadecimal integer, using "abcdef"
X	int	Unsigned hexadecimal integer, using "ABCDEF"
e	double	A real value in the format [-] d.ddde[sign] ddd, where d - one decimal digit, dddd - one or more decimal digits, ddd - a three-digit number that determines the size of the exponent, sign - plus or minus
E	double	Similar to the format of e, except that the sign of exponent is output by upper case letter (**E** instead of e)
f	double	A real value in the format [-] dddd.dddd, where dddd - one or more decimal digits. Number of displayed digits before the decimal point depends on the size of number value. Number of digits after the decimal point depends on the required accuracy.
g	double	A real value output in **f** or **e** format depending on what output is more compact.
G	double	A real value output in **F** or **E** format depending on what output is more compact.

Symbol	Type	Output Format
a	double	A real number in format [-]0xh.hhhh **p**±dd, where h.hhhh - mantissa in the form of hexadecimal digits, using "abcdef", dd - One or more digits of exponent. Number of decimal places is determined by the accuracy specification
A	double	A real number in format [-]0xh.hhhh **P**±dd, where h.hhhh - mantissa in the form of hexadecimal digits, using "ABCDEF", dd - One or more digits of exponent. Number of decimal places is determined by the accuracy specification
s	string	String output

Instead of PrintFormat() you can use printf().

Example:

```
void OnStart()
  {
//--- trade server name
   string server=AccountInfoString(ACCOUNT_SERVER);
//--- account number
   int login=(int)AccountInfoInteger(ACCOUNT_LOGIN);
//--- long value output
   long leverage=AccountInfoInteger(ACCOUNT_LEVERAGE);
   PrintFormat("%s %d: leverage = 1:%I64d",
               server,login,leverage);
//--- account currency
   string currency=AccountInfoString(ACCOUNT_CURRENCY);
//--- double value output with 2 digits after the decimal point
   double equity=AccountInfoDouble(ACCOUNT_EQUITY);
   PrintFormat("%s %d: account equity = %.2f %s",
               server,login,equity,currency);
//--- double value output with mandatory output of the +/- sign
   double profit=AccountInfoDouble(ACCOUNT_PROFIT);
   PrintFormat("%s %d: current result for open positions = %+.2f %s",
               server,login,profit,currency);
//--- double value output with variable number of digits after the decimal point
   double point_value=SymbolInfoDouble(_Symbol,SYMBOL_POINT);
   string format_string=StringFormat("%%s: point value  = %%.%df",_Digits);
   PrintFormat(format_string,_Symbol,point_value);
//--- int value output
   int spread=(int)SymbolInfoInteger(_Symbol,SYMBOL_SPREAD);
   PrintFormat("%s: current spread in points = %d ",
               _Symbol,spread);
//--- double value output in the scientific (floating point) format with 17 meaningful
   PrintFormat("DBL_MAX = %.17e",DBL_MAX);
//--- double value output in the scientific (floating point) format with 17 meaningful
   PrintFormat("EMPTY_VALUE = %.17e",EMPTY_VALUE);
//--- output using PrintFormat() with default accuracy
   PrintFormat("PrintFormat(EMPTY_VALUE) = %e",EMPTY_VALUE);
//--- simple output using Print()
   Print("Print(EMPTY_VALUE) = ",EMPTY_VALUE);
/* execution result
   MetaQuotes-Demo 1889998: leverage = 1:100
   MetaQuotes-Demo 1889998: account equity = 22139.86 USD
   MetaQuotes-Demo 1889998: current result for open positions = +174.00 USD
   EURUSD: point value  = 0.00001
   EURUSD: current spread in points = 12
   DBL_MAX = 1.79769313486231570e+308
   EMPTY_VALUE = 1.79769313486231570e+308
   PrintFormat(EMPTY_VALUE) = 1.797693e+308
   Print(EMPTY_VALUE) = 1.797693134862316e+308
*/
  }
```

StringFormat, DoubleToString, Real types (double, float)

ResetLastError

Sets the value of the predefined variable _LastError into zero.

```
void  ResetLastError();
```

Return Value

No return value.

Note

It should be noted that the GetLastError() function doesn't zero the _LastError variable. Usually the ResetLastError() function is called before calling a function, after which an error appearance is checked.

ResourceCreate

Creates an image resource based on a data set. There are two variants of the function:

Creating a resource based on a file

```
bool  ResourceCreate(
   const string      resource_name,       // Resource name
   const string      path                 // A relative path to the file
   );
```

Creating a resource based on the array of pixels

```
bool  ResourceCreate(
   const string      resource_name,       // Resource name
   const uint&       data[],              // Data set as an array
   uint              img_width,           // The width of the image resource
   uint              img_height,          // The height of the image resource
   uint              data_xoffset,        // The horizontal rightward offset of the up
   uint              data_yoffset,        // The vertical downward offset of the upper
   uint              data_width,          // The total width of the image based on the
   ENUM_COLOR_FORMAT color_format         // Color processing method
   );
```

Parameters

resource_name

[in] Resource name.

data[][]

[in] A one-dimensional or two-dimensional array for creating a complete image.

img_width

[in] The width of the rectangular image area in pixels to be placed in the resource in the form of an image. It cannot be greater than the *data_width* value.

img_height

[in] The height of the rectangular image area in pixels to be placed in the resource in the form of an image.

data_xoffset

[in] The horizontal rightward offset of the rectangular area of the image.

data_yoffset

[in] The vertical downward offset of the rectangular area of the image.

data_width

[in] Required only for one-dimensional arrays. It denotes the full width of the image from the data set. If *data_width*=0, it is assumed to be equal to *img_width*. For two-dimensional arrays the parameter is ignored and is assumed to be equal to the second dimension of the *data[]* array.

color_format

[in] Color processing method, from a value from the ENUM_COLOR_FORMAT enumeration.

Return Value

Returns true if successful, otherwise false. To get information about the error call the GetLastError() function. The following errors may occur:

- 4015 - ERR_RESOURCE_NAME_DUPLICATED (identical names of the dynamic and the static resource)
- 4016 - ERR_RESOURCE_NOT_FOUND (the resource is not found)
- 4017 - ERR_RESOURCE_UNSUPPORTED_TYPE (this type of resource is not supported)
- 4018 - ERR_RESOURCE_NAME_IS_TOO_LONG (the name of the resource is too long)

Note

If the second version of the function is called for creating the same resource with different width, height and shift parameters, it does not create a new resource, but simply updates the existing one.

The first version of the function is used for uploading images and sounds from files, and the second version is used only for the dynamic creation of images.

Images must be in the BMP format with a color depth of 24 or 32 bits. Sounds can only be in the WAV format. The size of the resource should not exceed 16 Mb.

ENUM_COLOR_FORMAT

Identifier	Description
COLOR_FORMAT_XRGB_NOALPHA	The component of the alpha channel is ignored
COLOR_FORMAT_ARGB_RAW	Color components are not handled by the terminal (must be correctly set by the user)
COLOR_FORMAT_ARGB_NORMALIZE	Color components are handled by the terminal

See also

Resources, ObjectCreate(), ObjectSetString(), OBJPROP_BMPFILE

ResourceFree

The function deletes dynamically created resource (freeing the memory allocated for it).

```
bool  ResourceFree(
   const string  resource_name      // resource name
   );
```

Parameters

resource_name

[in] Resource name should start with "::".

Return Value

True if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

ResourceFree() allows mql5 application developers to manage memory consumption when actively working with resources. Graphical objects bound to the resource being deleted from the memory will be displayed correctly after its deletion. However, newly created graphical objects (OBJ_BITMAP and OBJ_BITMAP_LABEL) will not be able to use the deleted resource.

The function deletes only dynamic resources created by the program.

See also

Resources, ObjectCreate(), PlaySound(), ObjectSetString(), OBJPROP_BMPFILE

ResourceReadImage

The function reads data from the graphical resource created by ResourceCreate() function or saved in EX5 file during compilation.

```
bool  ResourceReadImage(
   const string      resource_name,       // graphical resource name for reading
   uint&             data[],              // array for receiving data from the resourc
   uint&             width,               // for receiving the image width in the resc
   uint&             height,              // for receiving the image height in the res
   );
```

Parameters

resource_name

[in] Name of the graphical resource containing an image. To gain access to its own resources, the name is used in brief form "::resourcename". If we download a resource from a compiled EX5 file, the full name should be used with the path relative to MQL5 directory, file and resource names - "path\\filename.ex5::resourcename".

data[][]

[in] One- or two-dimensional array for receiving data from the graphical resource.

img_width

[out] Graphical resource image width in pixels.

img_height

[out] Graphical resource image height in pixels.

Return Value

true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

If *data[]* array is then to be used for creating a graphical resource, _COLOR_FORMAT_ARGB_NORMALIZE or COLOR_FORMAT_XRGB_NOALPHA color formats should be used.

If *data[]* array is two-dimensional and its second dimension is less than X(width) graphical resource size, ResourceReadImage() function returns false and reading is not performed. But if the resource exists, actual image size is returned to width and height parameters. This will allow making another attempt to receive data from the resource.

See also

Resource, ObjectCreate(), ObjectSetString(), OBJPROP_BMPFILE

ResourceSave

Saves a resource into the specified file.

```
bool  ResourceSave(
   const string  resource_name      // Resource name
   const string  file_name          // File name
   );
```

Parameters

resource_name

[in] The name of the resource, must start with "::".

file_name

[in] The name of the file relative to MQL5\Files.

Return Value

true - in case of success, otherwise false. For the error information call GetLastError().

Note

The function always overwrites a file and creates all the required intermediate directories in the file name if necessary.

See also

Resources, ObjectCreate(), PlaySound(), ObjectSetString(), OBJPROP_BMPFILE

SetReturnError

Sets the code that returns the terminal process when completing the operation.

```
void  SetReturnError(
   int ret_code      // client terminal completion code
   );
```

Parameters

ret_code

[in] The code to be returned by the client terminal process when completing the operation.

Return Value

No return value.

Note

Setting the specified *ret_code* return code using the SetReturnError() function is useful for analyzing reasons of the programmatic operation completion when launching the terminal via the command line.

Unlike TerminalClose(), the SetReturnError() function does not complete the terminal operation. Instead, it only sets the code that returns the terminal process upon its completion.

If the SetReturnError() function is called multiple times and/or from different MQL5 programs, the terminal returns the last set return code.

The set code is returned upon the terminal process completion except for the following cases:

- a critical error has occurred during execution;
- the TerminalClose(int ret_code) function issuing the terminal operation completion command with a specified code has been called.

See also

Program Running, Runtime Errors, Uninitialization Reason Codes, TerminalClose

SetUserError

Sets the predefined variable _LastError into the value equal to ERR_USER_ERROR_FIRST + user_error

```
void  SetUserError(
   ushort user_error,    // error number
   );
```

Parameters

user_error

[in] Error number set by a user.

Return Value

No return value.

Note

After an error has been set using the SetUserError(user_error) function, GetLastError() returns value equal to ERR_USER_ERROR_FIRST + user_error.

Example:

```
void OnStart()
  {
//--- set error number 65537=(ERR_USER_ERROR_FIRST +1)
   SetUserError(1);
//--- get last error code
   Print("GetLastError = ",GetLastError());
/*
   Result
   GetLastError = 65537
*/
  }
```

Sleep

The function suspends execution of the current Expert Advisor or script within a specified interval.

```
void  Sleep(
   int  milliseconds      // interval
   );
```

Parameters

milliseconds

[in] Delay interval in milliseconds.

Return Value

No return value.

Note

The Sleep() function can't be called for custom indicators, because indicators are executed in the interface thread and must not slow down it. The function has the built-in check of EA halt flag every 0.1 seconds.

TerminalClose

The function commands the terminal to complete operation.

```
bool  TerminalClose(
   int ret_code      // closing code of the client terminal
   );
```

Parameters

ret_code

[in] Return code, returned by the process of the client terminal at the operation completion.

Return Value

The function returns true on success, otherwise - false.

Note

The TerminalClose() function does not stop the terminal immediately, it just commands the terminal to complete its operation.

The code of an Expert Advisor that called TerminalClose() must have all arrangements for the immediate completion (e.g. all previously opened files must be closed in the normal mode). Call of this function must be followed by the return operator.

The *ret_code* parameter allows indicating the necessary return code for analyzing reasons of the program termination of the terminal operation when starting it from the command prompt.

Example:

```
//--- input parameters
input int  tiks_before=500; // number of ticks till termination
input int  pips_to_go=15;   // distance in pips
input int  seconds_st=50;   // number of seconds given to the Expert Advisor
//--- globals
datetime   launch_time;
int        tick_counter=0;
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//---
   Print(__FUNCTION__," reason code = ",reason);
   Comment("");
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
   static double first_bid=0.0;
```

```
   MqlTick       tick;
   double        distance;
//---
   SymbolInfoTick(_Symbol,tick);
   tick_counter++;
   if(first_bid==0.0)
     {
      launch_time=tick.time;
      first_bid=tick.bid;
      Print("first_bid =",first_bid);
      return;
     }
//--- price distance in pips
   distance=(tick.bid-first_bid)/_Point;
//--- show a notification to track the EA operation
   string comm="From the moment of start:\r\n\x25CF elapsed seconds: "+
               IntegerToString(tick.time-launch_time)+" ;"+
               "\r\n\x25CF ticks received: "+(string)tick_counter+" ;"+
               "\r\n\x25CF price went in points: "+StringFormat("%G",distance);
   Comment(comm);
//--- section for checking condition to close the terminal
   if(tick_counter>=tiks_before)
      TerminalClose(0);    // exit by tick counter
   if(distance>pips_to_go)
      TerminalClose(1);    // go up by the number of pips equal to pips_to_go
   if(distance<-pips_to_go)
      TerminalClose(-1);   // go down by the number of pips equal to pips_to_go
   if(tick.time-launch_time>seconds_st)
      TerminalClose(100);  // termination by timeout
//---
  }
```

Program running, Execution errors, Reasons for deinitialization

TesterHideIndicators

Sets the mode of displaying/hiding indicators used in an EA. The function is intended for managing the visibility of used indicators only during testing.

```
void  TesterHideIndicators(
   bool      hide     // flag
   );
```

Parameters

hide

[in] Flag for hiding indicators when testing. Set true to hide created indicators, otherwise false.

Return Value

None.

Note

By default, all indicators created in a tested EA are displayed on the visual testing chart. Besides, these indicators are displayed on the chart that is automatically opened when testing is complete. The TesterHideIndicators() function allows developers to implement the ability to disable the display of used indicators.

To disable the display of an applied indicator when testing an EA, call TesterHideIndicators() equal to true before creating the EA's handle - all indicators created after that are marked with the hide flag. These indicators are not displayed during a visual test and on the chart that is automatically opened upon completion of the test.

To disable the hide mode of the newly created indicators, call TesterHideIndicators() equal to false. Only indicators generated directly from the tested EA can be displayed on the testing chart. This rule applies only to cases where there is not a single template in <data_folder>MQL5\Profiles\Templates.

If the <data_folder>MQL5\Profiles\Templates directory contains a special template <EA_name>.tpl, only the indicators from this template are displayed during a visual testing and on the testing chart. In this case, no indicators applied in the tested EA are displayed. This behavior remains even if TesterHideIndicators() equal to true is called in the EA code.

If the <data_folder>MQL5\Profiles\Templates directory contains no special <EA_name>.tpl template having tester.tpl instead, indicators from the tester.tpl and the ones from the EA not disabled by the TesterHideIndicators() function are displayed during a visual testing and on the testing chart. If there is no tester.tpl template, indicators from the default.tpl template are used instead.

If the strategy tester finds no suitable template (<EA_name>.tpl, tester.tpl or default.tpl), display of the indicators applied in the EA is fully managed by the TesterHideIndicators() function.

Example:

```
bool CSampleExpert::InitIndicators(void)
  {
   TesterHideIndicators(true);
//--- create MACD indicator
   if(m_handle_macd==INVALID_HANDLE)
      if((m_handle_macd=iMACD(NULL,0,12,26,9,PRICE_CLOSE))==INVALID_HANDLE)
```

```
         {
          printf("Error creating MACD indicator");
          return(false);
         }
   TesterHideIndicators(false);
//--- create EMA indicator and add it to collection
   if(m_handle_ema==INVALID_HANDLE)
      if((m_handle_ema=iMA(NULL,0,InpMATrendPeriod,0,MODE_EMA,PRICE_CLOSE))==INVALID_H
         {
          printf("Error creating EMA indicator");
          return(false);
         }
//--- succeed
   return(true);
  }
```

IndicatorRelease

TesterStatistics

The function returns the value of the specified statistical parameter calculated based on testing results.

```
double  TesterStatistics(
   ENUM_STATISTICS statistic_id      // ID
   );
```

Parameters

statistic_id

[in] The ID of the statistical parameter from the ENUM_STATISTICS enumeration.

Return Value

The value of the statistical parameter from testing results.

Note

The function can be called inside OnTester() or OnDeinit() in the tester. In other cases the result is undefined.

TesterStop

Gives program operation completion command when testing.

```
void  TesterStop();
```

Return Value

No return value.

Note

The TesterStop() function is designed for a routine early shutdown of an EA on a test agent - for example, when reaching a specified number of losing trades or a preset drawdown level.

TesterStop() call is considered a normal completion of a test, therefore the OnTester() function is called, and the entire accumulated trading statistics and optimization criterion value are submitted to the strategy tester.

Calling ExpertRemove() in the strategy tester also means normal test completion and allows for obtaining trading statistics, but the EA is unloaded from the agent's memory. In this case, performing a pass on the next set of parameters requires time in order to reload the program. Therefore, TesterStop() is a preferred option for an early routine completion of a test.

See also

Program Running, Testing Trading Strategies, ExpertRemove, SetReturnError

TesterDeposit

The special function that emulates depositing funds during a test. It can be used in some money management systems.

```
bool  TesterDeposit(
   double money      // deposited sum
   );
```

Parameters

money

[in] Money to be deposited to an account in the deposit currency.

Return Value

Returns true if successful, otherwise - false.

See also

TesterWithdrawal

TesterWithdrawal

The special function to emulate the operation of money withdrawal in the process of testing. Can be used in some asset management systems.

```
bool  TesterWithdrawal(
   double money      // the sum to withdraw
   );
```

Parameters

money

[in] The sum of money that we need to withdraw (in the deposit currency).

Return Value

If successful, returns true, otherwise - false.

See also

TesterDeposit

TranslateKey

Returns a Unicode character by a virtual key code considering the current input language and the status of control keys.

```
short  TranslateKey(
   int  key_code      // key code for receiving a Unicode character
   );
```

Parameters

key_code

[in] Key code.

Return Value

Unicode character in case of a successful conversion. The function returns -1 in case of an error.

Note

The function uses ToUnicodeEx to convert keys pressed by a user into Unicode characters. An error may occur in case ToUnicodeEx is not triggered - for example, when trying to receive the SHIFT key character.

Example:

```
void OnChartEvent(const int id,const long& lparam,const double& dparam,const string& s
  {
   if(id==CHARTEVENT_KEYDOWN)
     {
      short sym=TranslateKey((int)lparam);
      //--- if the entered character is successfully converted to Unicode
      if(sym>0)
         Print(sym,"'",ShortToString(sym),"'");
      else
         Print("Error in TranslateKey for key=",lparam);
     }
  }
```

See also

Client terminal events, OnChartEvent

ZeroMemory

The function resets a variable passed to it by reference.

```
void  ZeroMemory(
   void & variable      // reset variable
   );
```

Parameters

variable

[in] [out] Variable passed by reference, you want to reset (initialize by zero values).

Return Value

No return value.

Note

If the function parameter is a string, the call will be equivalent to indicating NULL as its value.
For simple types and their arrays, as well as for structures/classes consisting of such types, this is a simple reset.
For objects containing strings and dynamic arrays, ZeroMemory() is called for each element.
For any arrays not protected by the const modifier, this is the zeroing of all elements.
For arrays of complex objects, ZeroMemory() is called for each element.

ZeroMemory() can't be applied to classes with protected members or inheritance.

Group of Functions for Working with Arrays

Arrays are allowed to be maximum four-dimensional. Each dimension is indexed from 0 to *dimension_size-1*. In a particular case of a one-dimensional array of 50 elements, calling of the first element will appear as array[0], of the last one - as array[49].

Function	Action
ArrayBsearch	Returns index of the first found element in the first array dimension
ArrayCopy	Copies one array into another
ArrayCompare	Returns the result of comparing two arrays of simple types or custom structures without complex objects
ArrayFree	Frees up buffer of any dynamic array and sets the size of the zero dimension in 0.
ArrayGetAsSeries	Checks direction of array indexing
ArrayInitialize	Sets all elements of a numeric array into a single value
ArrayFill	Fills an array with the specified value
ArrayIsSeries	Checks whether an array is a timeseries
ArrayIsDynamic	Checks whether an array is dynamic
ArrayMaximum	Search for an element with the maximal value
ArrayMinimum	Search for an element with the minimal value
ArrayPrint	Prints an array of a simple type or a simple structure into journal
ArrayRange	Returns the number of elements in the specified dimension of the array
ArrayResize	Sets the new size in the first dimension of the array
ArrayInsert	Inserts the specified number of elements from a source array to a receiving one starting from a specified index
ArrayRemove	Removes the specified number of elements from the array starting with a specified index
ArrayReverse	Reverses the specified number of elements in the array starting with a specified index
ArraySetAsSeries	Sets the direction of array indexing
ArraySize	Returns the number of elements in the array
ArraySort	Sorting of numeric arrays by the first dimension
ArraySwap	Swaps the contents of two dynamic arrays of the same type

ArrayBsearch

Searches for a specified value in a multidimensional numeric array sorted ascending. Search is performed through the elements of the first dimension.

For searching in an array of double type

```
int  ArrayBsearch(
   const double&    array[],   // array for search
   double           value      // what is searched for
   );
```

For searching in an array of float type

```
int  ArrayBsearch(
   const float&    array[],   // array for search
   float           value      // what is searched for
   );
```

For searching in an array of long type

```
int  ArrayBsearch(
   const long&    array[],   // array for search
   long           value      // what is searched for
   );
```

For searching in an array of int type

```
int  ArrayBsearch(
   const int&    array[],   // array for search
   int           value      // what is searched for
   );
```

For searching in an array of short type

```
int  ArrayBsearch(
   const short&    array[],   // array for search
   short           value      // what is searched for
   );
```

For searching in an array of char type

```
int  ArrayBsearch(
   const char&    array[],   // array for search
   char           value      // what is searched for
   );
```

Parameters

array[]

[in] Numeric array for search.

value

[in] Value for search.

Return Value

The function returns index of a found element. If the wanted value isn't found, the function returns the index of an element nearest in value.

Note

Binary search processes only sorted arrays. To sort numeric arrays use the ArraySort() function.

Example:

```
#property description "Script based on RSI indicator data displays"
#property description "how often the market was in"
#property description "overbought and oversold areas in the specified time interval."
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input int                InpMAPeriod=14;                  // Moving average period
input ENUM_APPLIED_PRICE InpAppliedPrice=PRICE_CLOSE;     // Price type
input double             InpOversoldValue=30.0;           // Oversold level
input double             InpOverboughtValue=70.0;         // Overbought level
input datetime           InpDateStart=D'2012.01.01 00:00'; // Analysis start date
input datetime           InpDateFinish=D'2013.01.01 00:00'; // Analysis finish date
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   double rsi_buff[]; // array of the indicator values
   int    size=0;     // array size
//--- receive RSI indicator handle
   ResetLastError();
   int rsi_handle=iRSI(Symbol(),Period(),InpMAPeriod,InpAppliedPrice);
   if(rsi_handle==INVALID_HANDLE)
     {
      //--- failed to receive the indicator handle
      PrintFormat("Indicator handle receiving error. Error code = %d",GetLastError());
      return;
     }
//--- being in the loop, until the indicator calculates all its values
   while(BarsCalculated(rsi_handle)==-1)
     {
      //--- exit if the indicator has forcedly completed the script's operation
      if(IsStopped())
         return;
      //--- a pause to allow the indicator to calculate all its values
      Sleep(10);
     }
//--- copy the indicator values for a certain period of time
```

```
   ResetLastError();
   if(CopyBuffer(rsi_handle,0,InpDateStart,InpDateFinish,rsi_buff)==-1)
     {
      PrintFormat("Failed to copy the indicator values. Error code = %d",GetLastError
      return;
     }
//--- receive the array size
   size=ArraySize(rsi_buff);
//--- sort out the array
   ArraySort(rsi_buff);
//--- find out the time (in percentage terms) the market was in the oversold area
   double ovs=(double)ArrayBsearch(rsi_buff,InpOversoldValue)*100/(double)size;
//--- find out the time (in percentage terms) the market was in the overbought area
   double ovb=(double)(size-ArrayBsearch(rsi_buff,InpOverboughtValue))*100/(double)siz
//--- form the strings for displaying the data
   string str="From "+TimeToString(InpDateStart,TIME_DATE)+" to "
              +TimeToString(InpDateFinish,TIME_DATE)+" the market was:";
   string str_ovb="in overbought area "+DoubleToString(ovb,2)+"% of time";
   string str_ovs="in oversold area "+DoubleToString(ovs,2)+"% of time";
//--- display the data on the chart
   CreateLabel("top",5,60,str,clrDodgerBlue);
   CreateLabel("overbought",5,35,str_ovb,clrDodgerBlue);
   CreateLabel("oversold",5,10,str_ovs,clrDodgerBlue);
//--- redraw the chart
   ChartRedraw(0);
//--- pause
   Sleep(10000);
  }
//+------------------------------------------------------------------+
//| Display comment in the bottom left corner of the chart           |
//+------------------------------------------------------------------+
void CreateLabel(const string name,const int x,const int y,
                 const string str,const color clr)
  {
//--- create the label
   ObjectCreate(0,name,OBJ_LABEL,0,0,0);
//--- bind the label to the bottom left corner
   ObjectSetInteger(0,name,OBJPROP_CORNER,CORNER_LEFT_LOWER);
//--- change position of the anchor point
   ObjectSetInteger(0,name,OBJPROP_ANCHOR,ANCHOR_LEFT_LOWER);
//--- distance from the anchor point in X-direction
   ObjectSetInteger(0,name,OBJPROP_XDISTANCE,x);
//--- distance from the anchor point in Y-direction
   ObjectSetInteger(0,name,OBJPROP_YDISTANCE,y);
//--- label text
   ObjectSetString(0,name,OBJPROP_TEXT,str);
//--- text color
   ObjectSetInteger(0,name,OBJPROP_COLOR,clr);
//--- text size
```

```
   ObjectSetInteger(0,name,OBJPROP_FONTSIZE,12);
  }
```

ArrayCopy

It copies an array into another one.

```
int  ArrayCopy(
   void&        dst_array[],          // destination array
   const void&  src_array[],          // source array
   int          dst_start=0,          // index starting from which write into destinati
   int          src_start=0,          // first index of a source array
   int          count=WHOLE_ARRAY     // number of elements
   );
```

Parameters

dst_array[]

[out] Destination array

src_array[]

[in] Source array

dst_start=0

[in] Starting index from the destination array. By default, start index is 0.

src_start=0

[in] Starting index for the source array. By default, start index is 0.

count=WHOLE_ARRAY

[in] Number of elements that should be copied. By default, the whole array is copied (count=WHOLE_ARRAY).

Return Value

It returns the number of copied elements.

Note

If count<0 or count>src_size-src_start, all the remaining array part is copied. Arrays are copied from left to right. For series arrays, the starting position is correctly defined adjusted for copying from left to right.

If arrays are of different types, during copying it tries to transform each element of a source array into the type of the destination array. A string array can be copied into a string array only. Array of classes and structures containing objects that require initialization aren't copied. An array of structures can be copied into an array of the same type only.

For dynamic arrays with indexing as in timeseries, the size of a destination array is automatically increased to the amount of copied data (if the latter exceeds the array size). The destination array size is not decreased automatically.

Example:

```

  }
```

ArrayCompare

The function returns the result of comparing two arrays of the same type. It can be used to compare arrays of simple types or custom structures without complex objects, that is the custom structures that do not contain strings, dynamic arrays, classes and other structures with complex objects.

```
int  ArrayCompare(
   const void&  array1[],           // first array
   const void&  array2[],           // second array
   int          start1=0,           // initial offset in the first array
   int          start2=0,           // initial offset in the second array
   int          count=WHOLE_ARRAY   // number of elements for comparison
   );
```

Parameters

array1[]

[in] First array.

array2[]

[in] Second array.

start1=0

[in] The element's initial index in the first array, from which comparison starts. The default start index - 0.

start2=0

[in] The element's initial index in the second array, from which comparison starts. The default start index - 0.

count=WHOLE_ARRAY

[in] Number of elements to be compared. All elements of both arrays participate in comparison by default (count=WHOLE_ARRAY).

Return Value

- -1, if array1[] less than array2[]
- 0, if array1[] equal to array2[]
- 1, if array1[] more than array2[]
- -2, if an error occurs due to incompatibility of the types of compared arrays or if start1, start2 or count values lead to falling outside the array.

Note

The function will not return 0 (the arrays will not be considered equal) if the arrays differ in size and count=WHOLE_ARRAY for the case when one array is a faithful subset of another one. In this case, the result of comparing the sizes of that arrays will be returned: -1, if the size of array1[] is less than the size of array2[] , otherwise 1.

ArrayFree

It frees up a buffer of any dynamic array and sets the size of the zero dimension to 0.

```
void  ArrayFree(
   void&  array[]      // array
   );
```

Parameters

array[]

[in] Dynamic array.

Return Value

No return value.

Note

The need for using ArrayFree() function may not appear too often considering that all used memory is freed at once and main work with the arrays comprises the access to the indicator buffers. The sizes of the buffers are automatically managed by the terminal's executive subsystem.

In case it is necessary to manually manage the memory in complex dynamic environment of the application, ArrayFree() function allows users to free the memory occupied by the already unnecessary dynamic array explicitly and immediately.

Example:

```
#include <Controls\Dialog.mqh>

                  const string &sparam)
  {
   ExtDialog.ChartEvent(id,lparam,dparam,sparam);
  }
```

ArrayGetAsSeries

It checks direction of an array index.

```
bool  ArrayGetAsSeries(
   const void&  array[]    // array for checking
   );
```

Parameters

array

[in] Checked array.

Return Value

Returns true, if the specified array has the AS_SERIES flag set, i.e. access to the array is performed back to front as in timeseries. A timeseries differs from a usual array in that the indexing of timeseries elements is performed from its end to beginning (from the newest data to old).

Note

To check whether an array belongs to timeseries, use the ArrayIsSeries() function. Arrays of price data passed as input parameters into the OnCalculate() function do not obligatorily have the indexing direction the same as in timeseries. The necessary indexing direction can be set using the ArraySetAsSeries() function.

Example:

```
#property description "Indicator calculates absolute values of the difference between"
#property description "Open and Close or High and Low prices displaying them in a sepa
#property description "as a histrogram."
//--- indicator settings
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot
#property indicator_type1   DRAW_HISTOGRAM
#property indicator_style1  STYLE_SOLID
#property indicator_width1  3
//--- input parameters
input bool InpAsSeries=true; // Indexing direction in the indicator buffer
input bool InpPrices=true;   // Calculation prices (true - Open,Close; false - High,Lo
//--- indicator buffer
double ExtBuffer[];
//+------------------------------------------------------------------+
//| Calculating indicator values                                     |
//+------------------------------------------------------------------+
void CandleSizeOnBuffer(const int rates_total,const int prev_calculated,
                        const double &first[],const double &second[],double &buffer[])
  {
//--- start variable for calculation of bars
   int start=prev_calculated;
```

```
//--- work at the last bar if the indicator values have already been calculated at the
   if(prev_calculated>0)
      start--;
//--- define indexing direction in arrays
   bool as_series_first=ArrayGetAsSeries(first);
   bool as_series_second=ArrayGetAsSeries(second);
   bool as_series_buffer=ArrayGetAsSeries(buffer);
//--- replace indexing direction with direct one if necessary
   if(as_series_first)
      ArraySetAsSeries(first,false);
   if(as_series_second)
      ArraySetAsSeries(second,false);
   if(as_series_buffer)
      ArraySetAsSeries(buffer,false);
//--- calculate indicator values
   for(int i=start;i<rates_total;i++)
      buffer[i]=MathAbs(first[i]-second[i]);
  }
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- bind indicator buffers
   SetIndexBuffer(0,ExtBuffer);
//--- set indexing element in the indicator buffer
   ArraySetAsSeries(ExtBuffer,InpAsSeries);
//--- check for what prices the indicator is calculated
   if(InpPrices)
     {
      //--- Open and Close prices
      PlotIndexSetString(0,PLOT_LABEL,"BodySize");

Access to timeseries, ArraySetAsSeries

ArrayInitialize

The function initializes a numeric array by a preset value.

For initialization of an array of char type

```
int  ArrayInitialize(
   char    array[],     // initialized array
   char    value        // value that will be set
   );
```

For initialization of an array of short type

```
int  ArrayInitialize(
   short   array[],     // initialized array
   short   value        // value that will be set
   );
```

For initialization of an array of int type

```
int  ArrayInitialize(
   int     array[],     // initialized array
   int     value        // value that will be set
   );
```

For initialization of an array of long type

```
int  ArrayInitialize(
   long    array[],     // initialized array
   long    value        // value that will be set
   );
```

For initialization of an array of float type

```
int  ArrayInitialize(
   float   array[],     // initialized array
   float   value        // value that will be set
   );
```

For initialization of an array of double type

```
int  ArrayInitialize(
   double  array[],     // initialized array
   double  value        // value that will be set
   );
```

For initialization of an array of bool type

```
int  ArrayInitialize(
   bool    array[],     // initialized array
   bool    value        // value that will be set
   );
```

For initialization of an array of uint type

```
int  ArrayInitialize(
   uint    array[],     // initialized array
   uint    value        // value that will be set
   );
```

Parameters

array[]

[out] Numeric array that should be initialized.

value

[in] New value that should be set to all array elements.

Return Value

Number of initialized elements.

Note

The ArrayResize() function allows to set size of an array with a reserve for further expansion without the physical relocation of memory. It is implemented for the better performance, because the operations of memory relocation are reasonably slow.

Initialization of the array using ArrayInitialize(array, init_val) doesn't mean the initialization with the same value of reserve elements allocated for this array. At further expanding of the *array* using the ArrayResize() function, the elements will be added at the end of the array, their values will be undefined and in most cases will not be equal to *init_value*.

Example:

```
void OnStart()
  {
//--- dynamic array
   double array[];
//--- let's set the array size for 100 elements and reserve a buffer for another 10 el
   ArrayResize(array,100,10);
//--- initialize the array elements with EMPTY_VALUE=DBL_MAX value
   ArrayInitialize(array,EMPTY_VALUE);
   Print("Values of 10 last elements after initialization");
   for(int i=90;i<100;i++) printf("array[%d] = %G",i,array[i]);
//--- expand the array by 5 elements
   ArrayResize(array,105);
   Print("Values of 10 last elements after ArrayResize(array,105)");
//--- values of 5 last elements are obtained from reserve buffer
   for(int i=95;i<105;i++) printf("array[%d] = %G",i,array[i]);
  }
```

ArrayFill

The function fills an array with the specified value.

```
void  ArrayFill(
   void&  array[],      // array
   int    start,         // starting index
   int    count,         // number of elements to fill
   void   value          // value
   );
```

Parameters

array[]

[out] Array of simple type (char, uchar, short, ushort, int, uint, long, ulong, bool, color, datetime, float, double).

start

[in] Starting index. In such a case, specified AS_SERIES flag is ignored.

count

[in] Number of elements to fill.

value

[in] Value to fill the array with.

Return Value

No return value.

Note

When ArrayFill() function is called, normal indexation direction (from left to right) is always implied. It means that the change of the order of access to the array elements using ArraySetAsSeries() function is ignored.

A multidimensional array is shown as one-dimensional when processed by ArrayFill() function. For example, array[2][4] is processed as array[8]. Therefore, you may specify the initial element's index to be equal to 5 when working with this array. Thus, the call of ArrayFill(array, 5, 2, 3.14) for array[2][4] fills array[1][1] and array[1][2] elements with 3.14.

Example:

```
void OnStart()
  {
//--- declare dynamic array
   int a[];
//--- set size
   ArrayResize(a,10);
//--- fill first 5 elements with 123
   ArrayFill(a,0,5,123);
//--- fill next 5 elements with 456
   ArrayFill(a,5,5,456);
```

```
//--- show values
   for(int i=0;i<ArraySize(a);i++) printf("a[%d] = %d",i,a[i]);
  }
```

ArrayIsDynamic

The function checks whether an array is dynamic.

```
bool  ArrayIsDynamic(
   const void&  array[]    // checked array
   );
```

Parameters

array[]

[in] Checked array.

Return Value

It returns true if the selected array is dynamic, otherwise it returns false.

Example:

```
#property description "This indicator does not calculate values. It makes a single att
#property description "apply the call of ArrayFree() function to three arrays: dynamic
#property description "an indicator buffer. Results are shown in Experts journal."
//--- indicator settings
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//--- global variables

double ExtStatic[100]; // static array
bool   ExtFlag=true;   // flag
double ExtBuff[];      // indicator buffer
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- allocate memory for the array
   ArrayResize(ExtDynamic,100);
//--- indicator buffers mapping
   SetIndexBuffer(0,ExtBuff);
   PlotIndexSetDouble(0,PLOT_EMPTY_VALUE,0);
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
```

```
  {
//--- perform a single analysis
   if(ExtFlag)
     {
      //--- attempt to free memory for arrays
      //--- 1. Dynamic array
      Print("+============================+");
      Print("1. Check dynamic array:");
      Print("Size before memory is freed = ",ArraySize(ExtDynamic));
      Print("Is this a dynamic array = ",ArrayIsDynamic(ExtDynamic) ? "Yes" : "No");
      //--- attempt to free array memory
      ArrayFree(ExtDynamic);
      Print("Size after memory is freed = ",ArraySize(ExtDynamic));
      //--- 2. Static array
      Print("2. Check static array:");
      Print("Size before memory is freed = ",ArraySize(ExtStatic));
      Print("Is this a dynamic array = ",ArrayIsDynamic(ExtStatic) ? "Yes" : "No");
      //--- attempt to free array memory
      ArrayFree(ExtStatic);
      Print("Size after memory is freed = ",ArraySize(ExtStatic));
      //--- 3. Indicator buffer
      Print("3. Check indicator buffer:");
      Print("Size before memory is freed = ",ArraySize(ExtBuff));
      Print("Is this a dynamic array = ",ArrayIsDynamic(ExtBuff) ? "Yes" : "No");
      //--- attempt to free array memory
      ArrayFree(ExtBuff);
      Print("Size after memory is freed = ",ArraySize(ExtBuff));
      //--- change the flag value
      ExtFlag=false;
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Access to timeseries and indicators

ArrayIsSeries

The function checks whether an array is a timeseries.

```
bool  ArrayIsSeries(
   const void&  array[]    // checked array
   );
```

Parameters

array[]

[in] Checked array.

Return Value

It returns true, if a checked array is an array timeseries, otherwise it returns false. Arrays passed as a parameter to the OnCalculate() function must be checked for the order of accessing the array elements by ArrayGetAsSeries().

Example:

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot Label1
#property indicator_label1  "Label1"
#property indicator_type1   DRAW_LINE
#property indicator_color1  clrRed
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- indicator buffers
double         Label1Buffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,Label1Buffer,INDICATOR_DATA);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
```

```
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//---
   if(ArrayIsSeries(open))
      Print("open[] is timeseries");
   else
      Print("open[] is not timeseries!!!");
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Access to timeseries and indicators

ArrayMaximum

Searches for the largest element in the first dimension of a multidimensional numeric array.

```
int  ArrayMaximum(
   const void&   array[],             // array for search
   int           start=0,             // index to start checking with
   int           count=WHOLE_ARRAY    // number of checked elements
   );
```

Parameters

array[]

[in] A numeric array, in which search is made.

start=0

[in] Index to start checking with.

count=WHOLE_ARRAY

[in] Number of elements for search. By default, searches in the entire array (count=WHOLE_ARRAY).

Return Value

The function returns an index of a found element taking into account the array serial. In case of failure it returns -1.

Note

The AS_SERIES flag value is taken into account while searching for a maximum.

Functions ArrayMaximum and ArrayMinimum accept any-dimensional arrays as a parameter. However, searching is always applied to the first (zero) dimension.

Example:

```
#property description "The indicator displays larger timeframe's candlesticks on the c
//--- indicator settings
#property indicator_chart_window
#property indicator_buffers 16
#property indicator_plots   8
//---- plot 1

```

ArrayMinimum

Searches for the lowest element in the first dimension of a multidimensional numeric array.

```
int  ArrayMinimum(
   const void&   array[],             // array for search
   int           start=0,             // index to start checking with
   int           count=WHOLE_ARRAY    // number of checked elements
   );
```

Parameters

array[]

[in] A numeric array, in which search is made.

start=0

[in] Index to start checking with.

count=WHOLE_ARRAY

[in] Number of elements for search. By default, searches in the entire array (count=WHOLE_ARRAY).

Return Value

The function returns an index of a found element taking into account the array serial. In case of failure it returns -1.

Note

The AS_SERIES flag value is taken into account while searching for a minimum.

Functions ArrayMaximum and ArrayMinimum accept any-dimensional arrays as a parameter. However, searching is always applied to the first (zero) dimension.

Example:

```
#property description "The indicator displays larger timeframe's candlesticks on the c
//--- indicator settings
#property indicator_chart_window
#property indicator_buffers 16

   const string  separator=NULL,      // separator of the structure field values
   ulong         start=0,             // first printed element index
   ulong         count=WHOLE_ARRAY,   // number of printed elements
   ulong         flags=ARRAYPRINT_HEADER|ARRAYPRINT_INDEX|ARRAYPRINT_LIMIT|ARRAYPRINT_
   );
```

Parameters

array[]

[in] Array of a simple type or a simple structure.

digits=_Digits

[in] The number of decimal places for real types. The default value is _Digits.

separator=NULL

[in] Separator of the structure element field values. The default value NULL means an empty line. A space is used as a separator in that case.

start=0

[in] The index of the first printed array element. It is printed from the zero index by default.

count=WHOLE_ARRAY

[in] Number of the array elements to be printed. The entire array is displayed by default (count=WHOLE_ARRAY).

flags=ARRAYPRINT_HEADER|ARRAYPRINT_INDEX|ARRAYPRINT_LIMIT|ARRAYPRINT_ALIGN

[in] Combination of flags setting the output mode. All flags are enabled by default:

- ARRAYPRINT_HEADER - print headers for the structure array
- ARRAYPRINT_INDEX - print index at the left side
- ARRAYPRINT_LIMIT - print only the first 100 and the last 100 array elements. Use if you want to print only a part of a large array.
- ARRAYPRINT_ALIGN - enable alignment of the printed values - numbers are aligned to the right, while lines to the left.
- ARRAYPRINT_DATE - when printing datetime, print the date in the dd.mm.yyyy format
- ARRAYPRINT_MINUTES - when printing datetime, print the time in the HH:MM format
- ARRAYPRINT_SECONDS - when printing datetime, print the time in the HH:MM:SS format

Return Value

No

Note

ArrayPrint() does not print all structure array fields into journal - array and object pointer fields are skipped. These columns are simply not printed for more convenient presentation. If you need to

print all structure fields, you need to write your own mass print function with the desired formatting.

Example:

```
//--- print the values of the last 10 bars
   MqlRates rates[];
   if(CopyRates(_Symbol,_Period,1,10,rates))
     {
      ArrayPrint(rates);
      Print("Check\n[time]\t[open]\t[high]\t[low]\t[close]\t[tick_volume]\t[spread]\t
      for(int i=0;i<10;i++)
        {
         PrintFormat("[%d]\t%s\t%G\t%G\t%G\t%G\t%G\t%G\t%I64d\t",i,
         TimeToString(rates[i].time,TIME_DATE|TIME_MINUTES|TIME_SECONDS),
         rates[i].open,rates[i].high,rates[i].low,rates[i].close,
         rates[i].tick_volume,rates[i].spread,rates[i].real_volume);
        }
     }
   else
      PrintFormat("CopyRates failed, error code=%d",GetLastError());
//--- example of printing
/*

FileSave, FileLoad

ArrayRange

The function returns the number of elements in a selected array dimension.

```
int  ArrayRange(
   const void&   array[],      // array for check
   int           rank_index    // index of dimension
   );
```

Parameters

array[]

[in] Checked array.

rank_index

[in] Index of dimension.

Return Value

Number of elements in a selected array dimension.

Note

Since indexes start at zero, the number of the array dimensions is one greater than the index of the last dimension.

Example:

```
void OnStart()
  {
//--- create four-dimensional array
   double array[][5][2][4];
//--- set the size of the zero dimension
   ArrayResize(array,10,10);
//--- print dimensions
   int temp;
   for(int i=0;i<4;i++)
     {
      //--- receive the size of i dimension
      temp=ArrayRange(array,i);
      //--- print
      PrintFormat("dim = %d, range = %d",i,temp);
     }
//--- Result
// dim = 0, range = 10
// dim = 1, range = 5
// dim = 2, range = 2
// dim = 3, range = 4
  }
```

ArrayResize

The function sets a new size for the first dimension

```
int  ArrayResize(
   void&  array[],              // array passed by reference
   int    new_size,             // new array size
   int    reserve_size=0        // reserve size value (excess)
   );
```

Parameters

array[]

[out] Array for changing sizes.

new_size

[in] New size for the first dimension.

reserve_size=0

[in] Distributed size to get reserve.

Return Value

If executed successfully, it returns count of all elements contained in the array after resizing, otherwise, returns -1, and array is not resized.

If ArrayResize() is applied to a static array, a timeseries or an indicator buffer, the array size remains the same - these arrays will not be reallocated. In this case, if *new_size*<=ArraySize(*array*), the function will only return *new_size*; otherwise a value of -1 will be returned.

Note

The function can be applied only to dynamic arrays. It should be noted that you cannot change the size of dynamic arrays assigned as indicator buffers by the SetIndexBuffer() function. For indicator buffers, all operations of resizing are performed by the runtime subsystem of the terminal.

Total amount of elements in the array cannot exceed 2147483647.

With the frequent memory allocation, it is recommended to use a third parameter that sets a reserve to reduce the number of physical memory allocations. All the subsequent calls of ArrayResize do not lead to physical reallocation of memory, but only change the size of the first array dimension within the reserved memory. It should be remembered that the third parameter will be used only during physical memory allocation. For example:

```
ArrayResize(arr,1000,1000);
for(int i=1;i<3000;i++)
   ArrayResize(arr,i,1000);
```

In this case the memory will be reallocated twice, first before entering the 3000 iterations loop (the array size will be set to 1000), and the second time with i equal to 2000. If we skip the third parameter, there will be 2000 physical reallocations of memory, which will slow down the program.

Example:

```
//+------------------------------------------------------------------+
```

```
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- Counters
   ulong start=GetTickCount();
   ulong now;
   int   count=0;
//--- An array for demonstration of a quick version
   double arr[];
   ArrayResize(arr,100000,100000);
//--- Check how fast the variant with memory reservation works
   Print("--- Test Fast: ArrayResize(arr,100000,100000)");
   for(int i=1;i<=300000;i++)
     {
      //--- Set a new array size specifying the reserve of 100,000 elements!
      ArrayResize(arr,i,100000);
      //--- When reaching a round number, show the array size and the time spent
      if(ArraySize(arr)%100000==0)
        {
         now=GetTickCount();
         count++;
         PrintFormat("%d. ArraySize(arr)=%d Time=%d ms",count,ArraySize(arr),(now-sta
         start=now;
        }
     }
//--- Now show, how slow the version without memory reservation is
   double slow[];
   ArrayResize(slow,100000,100000);
//---
   count=0;
   start=GetTickCount();
   Print("---- Test Slow: ArrayResize(slow,100000)");
//---
   for(int i=1;i<=300000;i++)
     {
      //--- Set a new array size, but without the additional reserve
      ArrayResize(slow,i);
      //--- When reaching a round number, show the array size and the time spent
      if(ArraySize(slow)%100000==0)
        {
         now=GetTickCount();
         count++;
         PrintFormat("%d. ArraySize(slow)=%d Time=%d ms",count,ArraySize(slow),(now-st
         start=now;
        }
     }
  }
//--- A sample result of the script
```

```
/*
   Test_ArrayResize (EURUSD,H1)   --- Test Fast: ArrayResize(arr,100000,100000)
   Test_ArrayResize (EURUSD,H1)   1. ArraySize(arr)=100000 Time=0 ms
   Test_ArrayResize (EURUSD,H1)   2. ArraySize(arr)=200000 Time=0 ms
   Test_ArrayResize (EURUSD,H1)   3. ArraySize(arr)=300000 Time=0 ms
   Test_ArrayResize (EURUSD,H1)   ---- Test Slow: ArrayResize(slow,100000)
   Test_ArrayResize (EURUSD,H1)   1. ArraySize(slow)=100000 Time=0 ms
   Test_ArrayResize (EURUSD,H1)   2. ArraySize(slow)=200000 Time=0 ms
   Test_ArrayResize (EURUSD,H1)   3. ArraySize(slow)=300000 Time=228511 ms
*/
```

ArrayInitialize

ArrayInsert

Inserts the specified number of elements from a source array to a receiving one starting from a specified index.

```
bool  ArrayInsert(
   void&         dst_array[],          // receiving array
   const void&   src_array[],          // source array
   uint          dst_start,            // receiver array index to be inserted
   uint          src_start=0,          // source array index to be copied
   uint          count=WHOLE_ARRAY     // number of elements to insert
   );
```

Parameters

dst_array[]

[in][out] Receiving array the elements should be added to.

src_array[]

[in] Source array the elements are to be added from.

dst_start

[in] Index in the receiving array for inserting elements from the source array.

src_start=0

[in] Index in the source array, starting from which the elements of the source array are taken for insertion.

count

[in] Number of elements to be added from the source array. The WHOLE_ARRAY means all elements from the specified index up to the end of the array.

Return Value

Returns true if successful, otherwise - false. To get information about the error, call the GetLastError() function. Possible errors:

- 5052 - ERR_SMALL_ARRAY (the *start* and/or *count* parameters are set incorrectly or the *src_array[]* source array is empty),
- 5056 - ERR_SERIES_ARRAY (the array cannot be changed, indicator buffer),
- 4006 - ERR_INVALID_ARRAY (copying to oneself is not allowed, or the arrays are of different types, or there is a fixed-size array containing class objects or destructor structures),
- 4005 - ERR_STRUCT_WITHOBJECTS_ORCLASS (the array contains no POD structures meaning a simple copying is impossible),
- Errors occurred when changing the *dst_array[]* receiving array size are provided in the ArrayRemove() function description.

Note

If the function is used for a fixed-size array, the size of the *dst_array[]* receiving array itself does not change. Starting from the *dst_start* position, the elements of the receiving array are shifted to

the right (the last *counts* of the elements "come off"), while the elements copied from the source array take their place.

You cannot insert the elements to the dynamic arrays designated as the indicator buffers by the SetIndexBuffer() function. For indicator buffers, all size changing operations are performed by the terminal's executing subsystem.

In the source array, the elements are copied starting from the *src_start* index. The source array size remains unchanged. The elements to be added to the receiving array are not links to the source array elements. This means that subsequent changes of the elements in any of the two arrays are not reflected in the second one.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the fixed-size array and fill in the values
   int array_dest[10];
   for(int i=0;i<10;i++)
     {
      array_dest[i]=i;
     }
   //--- source array
   int array_source[10];
   for(int i=0;i<10;i++)
     {
      array_source[i]=10+i;
     }
//--- display arrays before inserting the elements
   Print("Before calling ArrayInsert()");
   ArrayPrint(array_dest);
   ArrayPrint(array_source);
//--- insert 3 elements from the source array and show the new set of the receiving ar
   ArrayInsert(array_dest,array_source,4,0,3);
   Print("After calling ArrayInsert()");
   ArrayPrint(array_dest);
/*
  Execution result
   Before calling ArrayInsert()
   0 1 2 3 4 5 6 7 8 9
   After calling ArrayInsert()
   0 1 2 3 10 11 12 7 8 9
*/
```

See also

ArrayRemove, ArrayCopy, ArrayResize, ArrayFree

ArrayRemove

Removes the specified number of elements from the array starting with a specified index.

```
bool  ArrayRemove(
   void&         array[],            // array of any type
   uint          start,              // index the removal starts from
   uint          count=WHOLE_ARRAY   // number of elements
   );
```

Parameters

array[]

[in][out] Array.

start

[in] Index, starting from which the array elements are removed.

count=WHOLE_ARRAY

[in] Number of removed elements. The WHOLE_ARRAY value means removing all elements from the specified index up the end of the array.

Return Value

Returns true if successful, otherwise - false. To get information about the error, call the GetLastError() function. Possible errors:

- 5052 - ERR_SMALL_ARRAY (too big *start* value),
- 5056 - ERR_SERIES_ARRAY (the array cannot be changed, indicator buffer),
- 4003 - ERR_INVALID_PARAMETER (too big *count* value),
- 4005 - ERR_STRUCT_WITHOBJECTS_ORCLASS (fixed-size array containing complex objects with the destructor),
- 4006 - ERR_INVALID_ARRAY (fixed-size array containing structure or class objects with a destructor).

Note

If the function is used for a fixed-size array, the array size does not change: the remaining "tail" is physically copied to the *start* position. For accurate understanding of how the function works, see the example below. "Physical" copying means the copied objects are not created by calling the constructor or copying operator. Instead, the binary representation of an object is copied. For this reason, you cannot apply the ArrayRemove() function to the fixed-size array containing objects with the destructor (the ERR_INVALID_ARRAY or ERR_STRUCT_WITHOBJECTS_ORCLASS error is activated). When removing such an object, the destructor should be called twice - for the original object and its copy.

You cannot remove elements from dynamic arrays designated as the indicator buffers by the SetIndexBuffer() function. This will result in the ERR_SERIES_ARRAY error. For indicator buffers, all size changing operations are performed by the terminal's executing subsystem.

Example:

```
//+------------------------------------------------------------------+
```

```
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the fixed-size array and fill in the values
   int array[10];
   for(int i=0;i<10;i++)
     {
      array[i]=i;
     }
//--- display the array before removing the elements
   Print("Before calling ArrayRemove()");
   ArrayPrint(array);
//--- delete 2 elements from the array and display the new set
   ArrayRemove(array,4,2);
   Print("After calling ArrayRemove()");
   ArrayPrint(array);
/*
  Execution result:
  Before calling ArrayRemove()
   0 1 2 3 4 5 6 7 8 9
  After calling ArrayRemove()
   0 1 2 3 6 7 8 9 8 9
*/
```

See also

ArrayInsert, ArrayCopy, ArrayResize, ArrayFree

ArrayReverse

Reverses the specified number of elements in the array starting with a specified index.

```
bool  ArrayReverse(
   void&         array[],            // array of any type
   uint          start=0,            // index to start reversing the array from
   uint          count=WHOLE_ARRAY   // number of elements
   );
```

Parameters

array[]

[in][out] Array.

start=0

[in] Index the array reversal starts from.

count=WHOLE_ARRAY

[in] Number of reversed elements. If WHOLE_ARRAY, then all array elements are moved in the inversed manner starting with the specified *start* index up to the end of the array.

Return Value

Returns true if successful, otherwise - false.

Note

The ArraySetAsSeries() function does not move the array elements physically. Instead, it only changes the indexation direction backwards to arrange the access to the elements as in the timeseries. The ArrayReverse() function physically moves the array elements so that the array is "reversed".

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the fixed-size array and fill in the values
   int array[10];
   for(int i=0;i<10;i++)
     {
      array[i]=i;
     }
//--- display the array before reversing the elements
   Print("Before calling ArrayReverse()");
   ArrayPrint(array);
//--- reverse 3 elements in the array and show the new set
   ArrayReverse(array,4,3);
   Print("After calling ArrayReverse()");
```

```
   ArrayPrint(array);
/*
  Execution result:
  Before calling ArrayReverse()
   0 1 2 3 4 5 6 7 8 9
  After calling ArrayReverse()
   0 1 2 3 6 5 4 7 8 9
*/
```

See also

ArrayInsert, ArrayRemove, ArrayCopy, ArrayResize, ArrayFree, ArrayGetAsSeries, ArraySetAsSeries

ArraySetAsSeries

The function sets the AS_SERIES flag to a selected object of a dynamic array, and elements will be indexed like in timeseries.

```
bool  ArraySetAsSeries(
   const void&  array[],     // array by reference
   bool         flag         // true denotes reverse order of indexing
   );
```

Parameters

array[]

[in][out] Numeric array to set.

flag

[in] Array indexing direction.

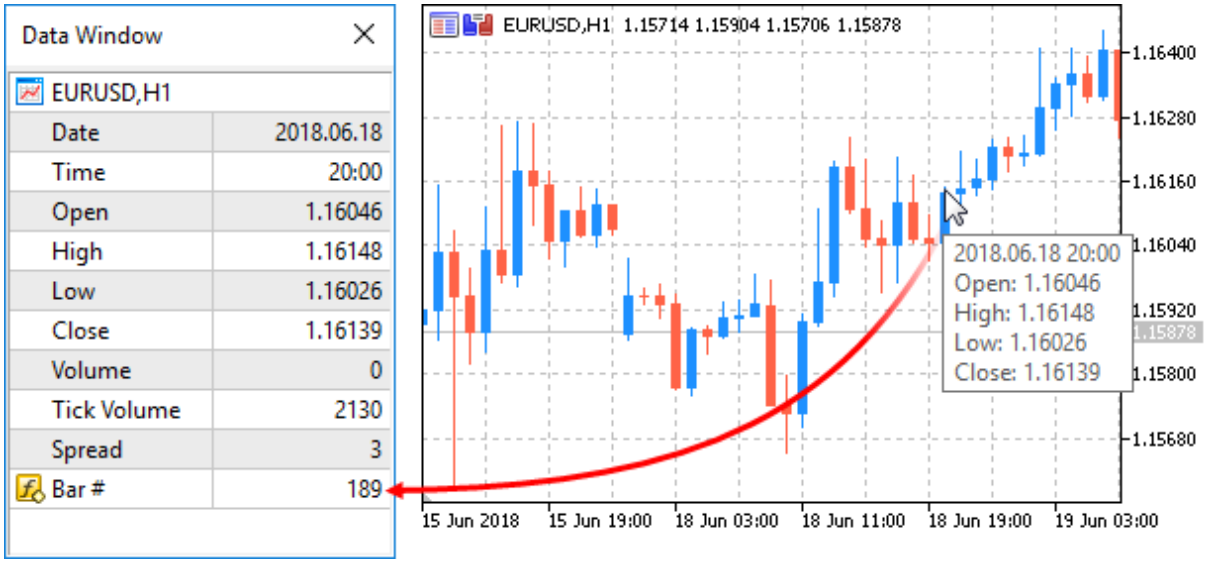
Return Value

The function returns true on success, otherwise - false.

Note

The AS_SERIES flag can't be set for multi-dimensional arrays or static arrays (arrays, whose size in square brackets is preset already on the compilation stage). Indexing in timeseries differs from a common array in that the elements of timeseries are indexed from the end towards the beginning (from the newest to oldest data).

Example: Indicator that shows bar number



```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot Numeration
```

```
#property indicator_label1  "Numeration"
#property indicator_type1   DRAW_LINE
#property indicator_color1  CLR_NONE
//--- indicator buffers
double         NumerationBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,NumerationBuffer,INDICATOR_DATA);
//--- set indexing for the buffer like in timeseries
   ArraySetAsSeries(NumerationBuffer,true);
//--- set accuracy of showing in DataWindow
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//--- how the name of the indicator array is displayed in DataWindow
   PlotIndexSetString(0,PLOT_LABEL,"Bar #");
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//---  we'll store the time of the current zero bar opening
   static datetime currentBarTimeOpen=0;
//--- revert access to array time[] - do it like in timeseries
   ArraySetAsSeries(time,true);
//--- If time of zero bar differs from the stored one
   if(currentBarTimeOpen!=time[0])
     {
     //--- enumerate all bars from the current to the chart depth
      for(int i=rates_total-1;i>=0;i--) NumerationBuffer[i]=i;
      currentBarTimeOpen=time[0];
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

ArraySize

The function returns the number of elements of a selected array.

```
int  ArraySize(
   const void&  array[]    // checked array
   );
```

Parameters

array[]

[in] Array of any type.

Return Value

Value of int type.

Note

For a one-dimensional array, the value to be returned by the ArraySize is equal to that of ArrayRange(array,0).

Example:

```
void OnStart()
  {
//--- create arrays
   double one_dim[];
   double four_dim[][10][5][2];
//--- sizes
   int one_dim_size=25;
   int reserve=20;
   int four_dim_size=5;
//--- auxiliary variable
   int size;
//--- allocate memory without backup
   ArrayResize(one_dim,one_dim_size);
   ArrayResize(four_dim,four_dim_size);
//--- 1. one-dimensional array
   Print("+============================================================+");
   Print("Array sizes:");
   Print("1. One-dimensional array");
   size=ArraySize(one_dim);
   PrintFormat("Zero dimension size = %d, Array size = %d",one_dim_size,size);
//--- 2. multidimensional array
   Print("2. Multidimensional array");
   size=ArraySize(four_dim);
   PrintFormat("Zero dimension size = %d, Array size = %d",four_dim_size,size);
//--- dimension sizes
   int d_1=ArrayRange(four_dim,1);
   int d_2=ArrayRange(four_dim,2);
   int d_3=ArrayRange(four_dim,3);
```

```
   Print("Check:");
   Print("Zero dimension = Array size / (First dimension * Second dimension * Third di
   PrintFormat("%d = %d / (%d * %d * %d)",size/(d_1*d_2*d_3),size,d_1,d_2,d_3);
//--- 3. one-dimensional array with memory backup
   Print("3. One-dimensional array with memory backup");
//--- double the value
   one_dim_size*=2;
//--- allocate memory with backup
   ArrayResize(one_dim,one_dim_size,reserve);
//--- print out the size
   size=ArraySize(one_dim);
   PrintFormat("Size with backup = %d, Actual array size = %d",one_dim_size+reserve,si
  }
```

ArraySort

Sorts the values in the first dimension of a multidimensional numeric array in the ascending order.

```
bool  ArraySort(
   void&  array[]      // array for sorting
   );
```

Parameters

array[]

[in][out] Numeric array for sorting.

Return Value

The function returns true on success, otherwise - false.

Note

An array is always sorted in the ascending order irrespective of the AS_SERIES flag value.

Functions ArraySort and ArrayBSearch accept any-dimensional arrays as a parameter. However, searching and sorting are always applied to the first (zero) dimension.

Example:

```
#property description "The indicator analyzes data for the last month and draws all ca
#property description "and large tick volumes. The tick volume array is sorted out"
#property description "to define such candlesticks. The candlesticks having the volume
#property description "per cent of the array are considered small. The candlesticks ha

ArrayBsearch

ArraySwap

Swaps the contents of two dynamic arrays of the same type. For multidimensional arrays, the number of elements in all dimensions except the first one should match.

```
bool  ArraySwap(
   void&  array1[],      // first array
   void&  array2[]       // second array
   );
```

Parameters

array1[]

[in][out] Array of numerical type.

array2[]

[in][out] Array of numerical type.

Return Value

Returns true if successful, otherwise false. In this case, GetLastError() returns the ERR_INVALID_ARRAY error code.

Note

The function accepts dynamic arrays of the same type and the same dimensions except the first one. For integer types, the sign is ignored, i.e. char==uchar)

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- arrays for storing quotes
   double source_array[][8];
   double   dest_array[][8];
   MqlRates rates[];
//--- get the data of the last 20 candles on the current timeframe
   int copied=CopyRates(NULL,0,0,20,rates);
   if(copied<=0)
     {
      PrintFormat("CopyRates(%s,0,0,20,rates) failed, error=%d",
                  Symbol(),GetLastError());
      return;
     }
//--- set the array size for the amount of copied data
   ArrayResize(source_array,copied);
//--- fill the rate_array_1[] array by data from rates[]
   for(int i=0;i<copied;i++)
     {
```

```
      source_array[i][0]=(double)rates[i].time;
      source_array[i][1]=rates[i].open;
      source_array[i][2]=rates[i].high;
      source_array[i][3]=rates[i].low;
      source_array[i][4]=rates[i].close;
      source_array[i][5]=(double)rates[i].tick_volume;
      source_array[i][6]=(double)rates[i].spread;
      source_array[i][7]=(double)rates[i].real_volume;
     }
//--- swap data between source_array[] and dest_array[]
   if(!ArraySwap(source_array,dest_array))
     {
      PrintFormat("ArraySwap(source_array,rate_array_2) failed, error code=%d",GetLast
      return;
     }
//--- ensure that the source array has become zero after the swap
   PrintFormat("ArraySwap() done: ArraySize(source_array)=%d",ArraySize(source_array))
//--- display the data of the dest_array[] destination array
   ArrayPrint(dest_array);
  }
```

Matrices and vectors

A matrix is a two-dimensional array of double, float, or complex numbers.

A vector is a one-dimensional array of double, float, or complex numbers. The vector has no indication of whether it is vertical or horizontal. It is determined from the use context. For example, the vector operation Dot assumes that the left vector is horizontal and the right one is vertical. If the type indication is required, one-row or one-column matrices can be used. However, this is generally not necessary.

Matrices and vectors allocate memory for data dynamically. In fact, matrices and vectors are objects that have certain properties, such as the type of data they contain and dimensions. Matrix and vector properties can be obtained using methods such as vector_a.Size(), matrix_b.Rows(), vector_c.Norm(), matrix_d.Cond() and others. Any dimension can be changed.

When creating and initializing matrices, so-called static methods are used (these are like static methods of a class). For example: matrix::Eye(), matrix::Identity(), matrix::Ones(), vector::Ones(), matrix: :Zeros(), vector::Zeros(), matrix::Full(), vector::Full(), matrix::Tri().

At the moment, matrix and vector operations do not imply the use of the complex data type, as this development direction has not yet been completed.

MQL5 supports passing of matrices and vectors to DLLs. This enables the import of functions utilizing the relevant types, from external variables.

Matrices and vectors are passed to a DLL as a pointer to a buffer. For example, to pass a matrix of type float, the corresponding parameter of the function exported from the DLL must take a float-type buffer pointer.

MQL5

```
#import "mmlib.dll"
bool sgemm(uint flags, matrix<float> &C, const matrix<float> &A, const matrix<float> &
#import
```

C++

```
extern "C" __declspec(dllexport) bool sgemm(UINT flags, float *C, const float *A, cons
```

In addition to buffers, you should pass matrix and vector sizes for correct processing.

All matrix and vector methods are listed below in alphabetical order.

Function	Action	Category
Activation	Compute activation function values and write them to the passed vector/matrix	Machine learning
ArgMax	Return the index of the maximum value	Statistics
ArgMin	Return the index of the minimum value	Statistics

Function	Action	Category
ArgSort	Return the sorted index	Manipulations
Assign	Copies a matrix, vector or array with auto cast	Initialization
Average	Compute the weighted average of matrix/vector values	Statistics
Cholesky	Compute the Cholesky decomposition	Transformations
Clip	Limits the elements of a matrix/vector to a given range of valid values	Manipulations
Col	Return a column vector. Write a vector to the specified column.	Manipulations
Cols	Return the number of columns in a matrix	Features
Compare	Compare the elements of two matrices/vectors with the specified precision	Manipulations
CompareByDigits	Compare the elements of two matrices/vectors with the significant figures precision	Manipulations
Cond	Compute the condition number of a matrix	Features
Convolve	Return the discrete, linear convolution of two vectors	Products
Copy	Return a copy of the given matrix/vector	Manipulations
CopyIndicatorBuffer	Get the data of the specified indicator buffer in the specified quantity to a vector	Initialization
CopyRates	Gets the historical series of the MqlRates structure of the specified symbol-period in the specified amount into a matrix or vector	Initialization
CopyTicks	Get ticks from an MqlTick structure into a matrix or a vector	Initialization
CopyTicksRange	Get ticks from an MqlTick structure into a matrix or a	Initialization

Function	Action	Category
	vector within the specified date range	
CorrCoef	Compute the Pearson correlation coefficient (linear correlation coefficient)	Products
Correlate	Compute the cross-correlation of two vectors	Products
Cov	Compute the covariance matrix	Products
CumProd	Return the cumulative product of matrix/vector elements, including those along the given axis	Statistics
CumSum	Return the cumulative sum of matrix/vector elements, including those along the given axis	Statistics
Derivative	Compute activation function derivative values and write them to the passed vector/matrix	Machine learning
Det	Compute the determinant of a square invertible matrix	Features
Diag	Extract a diagonal or construct a diagonal matrix	Manipulations
Dot	Dot product of two vectors	Products
Eig	Computes the eigenvalues and right eigenvectors of a square matrix	Transformations
EigVals	Computes the eigenvalues of a general matrix	Transformations
Eye	Return a matrix with ones on the diagonal and zeros elsewhere	Initialization
Fill	Fill an existing matrix or vector with the specified value	Initialization
Flat	Access a matrix element through one index instead of two	Manipulations

Function	Action	Category
Full	Create and return a new matrix filled with the given value	Initialization
GeMM	The GeMM (General Matrix Multiply) method implements the general multiplication of two matrices	Products
HasNan	Return the number of NaN values in a matrix/vector	Manipulations
Hsplit	Split a matrix horizontally into multiple submatrices. Same as Split with axis=0	Manipulations
Identity	Create an identity matrix of the specified size	Initialization
Init	Matrix or vector initialization	Initialization
Inner	Inner product of two matrices	Products
Inv	Compute the multiplicative inverse of a square invertible matrix by the Jordan-Gauss method	Solutions
Kron	Return Kronecker product of two matrices, matrix and vector, vector and matrix or two vectors	Products
Loss	Compute loss function values and write them to the passed vector/matrix	Machine learning
LstSq	Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices)	Solutions
LU	Implement an LU decomposition of a matrix: the product of a lower triangular matrix and an upper triangular matrix	Transformations
LUP	Implement an LUP factorization with partial permutation, which refers to LU decomposition with row permutations only: PA=LU	Transformations
MatMul	Matrix product of two matrices	Products

Function	Action	Category
Max	Return the maximum value in a matrix/vector	Statistics
Mean	Compute the arithmetic mean of element values	Statistics
Median	Compute the median of the matrix/vector elements	Statistics
Min	Return the minimum value in a matrix/vector	Statistics
Norm	Return matrix or vector norm	Features
Ones	Create and return a new matrix filled with ones	Initialization
Outer	Compute the outer product of two matrices or two vectors	Products
Percentile	Return the specified percentile of values of matrix/vector elements or elements along the specified axis	Statistics
PInv	Compute the pseudo-inverse of a matrix by the Moore-Penrose method	Solutions
Power	Raise a square matrix to an integer power	Products
Prod	Return the product of matrix/vector elements, which can also be executed for the given axis	Statistics
Ptp	Return the range of values of a matrix/vector or of the given matrix axis	Statistics
QR	Compute the qr factorization of a matrix	Transformations
Quantile	Return the specified quantile of values of matrix/vector elements or elements along the specified axis	Statistics
Rank	Return matrix rank using the Gaussian method	Features
RegressionMetric	Compute the regression metric as the deviation error from the	Statistics

Function	Action	Category
	regression line constructed on the specified data array	
Reshape	Change the shape of a matrix without changing its data	Manipulations
Resize	Return a new matrix with a changed shape and size	Manipulations
Row	Return a row vector. Write the vector to the specified row	Manipulations
Rows	Return the number of rows in a matrix	Features
Set	Sets the value for a vector element by the specified index	Manipulations
Size	Return the size of vector	Features
SLogDet	Compute the sign and logarithm of the determinant of an matrix	Features
Solve	Solve a linear matrix equation or a system of linear algebraic equations	Solutions
Sort	Sort by place	Manipulations
Spectrum	Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A	Features
Split	Split a matrix into multiple submatrices	Manipulations
Std	Return the standard deviation of values of matrix/vector elements or elements along the specified axis	Statistics
Sum	Return the sum of matrix/vector elements, which can also be executed for the given axis (axes)	Statistics
SVD	Singular value decomposition	Transformations
SwapCols	Swap columns in a matrix	Manipulations
SwapRows	Swap rows in a matrix	Manipulations
Trace	Return the sum along diagonals of the matrix	Features

Function	Action	Category
Transpose	Transpose (swap the axes) and return the modified matrix	Manipulations
Tri	Construct a matrix with ones on a specified diagonal and below, and zeros elsewhere	Initialization
TriL	Return a copy of a matrix with elements above the k-th diagonal zeroed. Lower triangular matrix	Manipulations
TriU	Return a copy of a matrix with the elements below the k-th diagonal zeroed. Upper triangular matrix	Manipulations
Var	Compute the variance of values of matrix/vector elements	Statistics
Vsplit	Split a matrix vertically into multiple submatrices. Same as Split with axis=1	Manipulations
Zeros	Create and return a new matrix filled with zeros	Initialization

Matrix and Vector Types

Matrix and vector are special data types in MQL5 which enable linear algebra operations. The following data types exist:

- matrix — a matrix containing double elements.
- matrixf — a matrix containing float elements.
- matrixc — a matrix containing complex elements.
- vector — a vector containing double elements.
- vectorf — a vector containing float elements.
- vectorc — a vector containing complex elements.

Template functions support notations like matrix<double>, matrix<float>, vector<double>, vector<float> instead of the corresponding types.

Matrix and vector initialization methods

Function	Action
Eye	Return a matrix with ones on the diagonal and zeros elsewhere
Identity	Create an identity matrix of the specified size
Ones	Create and return a new matrix filled with ones
Zeros	Create and return a new matrix filled with zeros
Full	Create and return a new matrix filled with given value
Tri	Construct a matrix with ones at and below the given diagonal and zeros elsewhere
Init	Initialize a matrix or a vector
Fill	Fill an existing matrix or vector with the specified value

Enumeration for matrix and vector operations

This section describes the enumerations that are used in various matrix and vector methods.

ENUM_AVERAGE_MODE

Smoothing type enumeration.

ID	Description
AVERAGE_NONE	No averaging. Results are provided for each label separately
AVERAGE_BINARY	Label 1 result for binary classification
AVERAGE_MICRO	Average error matrix result (confusion matrix)
AVERAGE_MACRO	Average result from the results of the error matrices of each label
AVERAGE_WEIGHTED	Weighted average result

ENUM_VECTOR_NORM

Enumeration of vector norms for vector::Norm.

ID	Description
VECTOR_NORM_INF	Inf norm
VECTOR_NORM_MINUS_INF	Minus Inf norm
VECTOR_NORM_P	Norm P

ENUM_MATRIX_NORM

Enumeration of matrix norms for matrix::Norm and for obtaining the matrix::Cond matrix condition number.

ID	Description
MATRIX_NORM_FROBENIUS	Frobenius norm
MATRIX_NORM_SPECTRAL	Spectral norm
MATRIX_NORM_NUCLEAR	Nuclear norm
MATRIX_NORM_INF	Inf norm
MATRIX_NORM_P1	P1 norm

ID	Description
MATRIX_NORM_P2	P2 norm
MATRIX_NORM_MINUS_INF	Minus Inf norm
MATRIX_NORM_MINUS_P1	Minus P1 norm
MATRIX_NORM_MINUS_P2	Minus P2 norm

ENUM_VECTOR_CONVOLVE

Enumeration for convolution vector::Convolve and cross-correlation vector::Correlate.

ID	Description
VECTOR_CONVOLVE_FULL	Convolve full
VECTOR_CONVOLVE_SAME	Convolve same
VECTOR_CONVOLVE_VALID	Convolve valid

ENUM_REGRESSION_METRIC

Enumeration of regression metrics for vector::RegressionMetric.

ID	Description
REGRESSION_MAE	Mean Absolute Error
REGRESSION_MSE	Mean Squared Error
REGRESSION_RMSE	Root Mean Squared Error
REGRESSION_R2	R-Squared
REGRESSION_MAPE	Mean Absolute Percentage Error
REGRESSION_MSPE	Mean Squared Percentage Error
REGRESSION_RMSLE	Root Mean Squared Logarithmic Error
REGRESSION_SMAPE	Symmetric Mean Absolute Percentage Error
REGRESSION_MAXE	Maximal Absolute Error
REGRESSION_MEDE	Median Absolute Error
REGRESSION_MPD	Mean Poisson Deviance
REGRESSION_MGD	Mean Gamma Deviance
REGRESSION_EXPV	Explained Variance

ENUM_CLASSIFICATION_METRIC

Enumeration of metrics for classification problems.

ID	Description
CLASSIFICATION_ACCURACY	Model quality in terms of prediction accuracy for all classes
CLASSIFICATION_AVERAGE_PRECISION	Average model accuracy
CLASSIFICATION_BALANCED_ACCURACY	Balanced prediction accuracy
CLASSIFICATION_F1	F1 score. Harmonic mean between the model precision and recall
CLASSIFICATION_JACCARD	Jaccard score
CLASSIFICATION_PRECISION	Model accuracy in predicting true positives for the target class
CLASSIFICATION_RECALL	Model completeness
CLASSIFICATION_ROC_AUC	Area under the error curve
CLASSIFICATION_TOP_K_ACCURACY	Frequency of the correct label appearing at the top of k predicted labels

ENUM_LOSS_FUNCTION

Enumeration for loss function calculations vector::Loss.

ID	Description
LOSS_MSE	Root mean square error
LOSS_MAE	Mean Absolute Error
LOSS_CCE	Categorical Crossentropy
LOSS_BCE	Binary Crossentropy
LOSS_MAPE	Mean Absolute Percentage Error
LOSS_MSLE	Mean Squared Logarithmic Error
LOSS_KLD	Kullback-Leibler Divergence
LOSS_COSINE	Cosine similarity/proximity
LOSS_POISSON	Poisson
LOSS_HINGE	Hinge

ID	Description
LOSS_SQ_HINGE	Squared Hinge
LOSS_CAT_HINGE	Categorical Hinge
LOSS_LOG_COSH	Logarithm of the Hyperbolic Cosine
LOSS_HUBER	Huber

ENUM_ACTIVATION_FUNCTION

Enumeration for the activation function vector::Activation and for the activation function derivative vector::Derivative.

ID	Description
AF_ELU	Exponential Linear Unit
AF_EXP	Exponential
AF_GELU	Gaussian Error Linear Unit
AF_HARD_SIGMOID	Hard Sigmoid
AF_LINEAR	Linear
AF_LRELU	Leaky Rectified Linear Unit
AF_RELU	REctified Linear Unit
AF_SELU	Scaled Exponential Linear Unit
AF_SIGMOID	Sigmoid
AF_SOFTMAX	Softmax
AF_SOFTPLUS	Softplus
AF_SOFTSIGN	Softsign
AF_SWISH	Swish
AF_TANH	The hyperbolic tangent function
AF_TRELU	Thresholded Rectified Linear Unit

ENUM_SORT_MODE

Enumeration of sort types for the Sort function.

ID	Description
SORT_ASCENDING	Sort ascending

ID	Description
SORT_DESCENDING	Sort descending

ENUM_MATRIX_AXIS

Enumeration for specifying the axis in all statistical functions for matrices.

ID	Description
AXIS_NONE	The axis is not specified. Calculation is performed over all matrix elements, as if it were a vector (see the Flat method).
AXIS_HORZ	Horizontal axis
AXIS_VERT	Vertical axis

Initialization

There are several ways to declare and initialize matrices and vectors.

Function	Action
Assign	Copies a matrix, vector or array with auto cast
CopyIndicatorBuffer	Get the data of the specified indicator buffer in the specified quantity to a vector
CopyRates	Gets the historical series of the MqlRates structure of the specified symbol-period in the specified amount into a matrix or vector
CopyTicks	Get ticks from an MqlTick structure into a matrix or a vector
CopyTicksRange	Get ticks from an MqlTick structure into a matrix or a vector within the specified date range
Eye	Return a matrix with ones on the diagonal and zeros elsewhere
Identity	Create an identity matrix of the specified size
Ones	Create and return a new matrix filled with ones
Zeros	Create and return a new matrix filled with zeros
Full	Create and return a new matrix filled with given value
Tri	Construct a matrix with ones at and below the given diagonal and zeros elsewhere
Init	Initialize a matrix or a vector
Fill	Fill an existing matrix or vector with the specified value

Declaration without specifying the size (no memory allocation for the data):

```
matrix          matrix_a;   // double type matrix
matrix<double>  matrix_a1;  // another way to declare a double matrix; can be used ir
matrixf         matrix_a2;  // float matrix
matrix<float>   matrix_a3;  // float matrix
vector          vector_a;   // double vector
vector<double>  vector_a1;
vectorf         vector_a2;  // float vector
vector<float>   vector_a3;
```

Declaration with the specified size (with memory allocation for the data, but without any initialization):

```
matrix          matrix_a(128,128);          // the parameters can be either constant
matrix<double>  matrix_a1(InpRows,InpCols); // or variables
matrixf         matrix_a2(1,128);           // analog of a horizontal vector
matrix<float>   matrix_a3(InpRows,1);       // analog of a vertical vector
```

```
  vector         vector_a(256);
  vector<double> vector_a1(InpSize);
  vectorf        vector_a2(SomeFunc());       // function SomeFunc returns a number o
  vector<float>  vector_a3(InpSize+16);       // expression can be used as a paramete
```

Declaration with initialization (matrix and vector sizes are determined by the initializing sequence):

```
  matrix         matrix_a={{0.1,0.2,0.3},{0.4,0.5,0.6}};
  matrix<double> matrix_a1=matrix_a;                    // must be matrices of the s
  matrixf        matrix_a2={{1,0,0},{0,1,0},{0,0,1}};
  matrix<float>  matrix_a3={{1,2},{3,4}};
  vector         vector_a={-5,-4,-3,-2,-1,0,1,2,3,4,5};
  vector<double> vector_a1={1,5,2.4,3.3};
  vectorf        vector_a2={0,1,2,3};
  vector<float>  vector_a3=vector_a2;                   // must be vectors of the sa
```

Declaration with initialization:

```
template<typename T>
void MatrixArange(matrix<T> &mat,T value=0.0,T step=1.0)
  {
   for(ulong i=0; i<mat.Rows(); i++)
     {
      for(ulong j=0; j<mat.Cols(); j++,value+=step)
         mat[i][j]=value;
     }
  }
template<typename T>
void VectorArange(vector<T> &vec,T value=0.0,T step=1.0)
  {
   for(ulong i=0; i<vec.Size(); i++,value+=step)
      vec[i]=value;
  }
...

  matrix  matrix_a(size_m,size_k,MatrixArange,-M_PI,0.1); // first an uninitialized ma
  matrixf matrix_a1(10,20,MatrixArange);                  // after creating the matrix
  vector  vector_a(size,VectorArange,-10.0);              // after creating the vector
  vectorf vector_a1(128,VectorArange);
```

Please note that the matrix or vector dimensions can be changed, since the memory for data is always dynamic.

Static methods

Static methods for creating matrices and vectors of the specified size, initialized in a certain way:

```
matrix          matrix_a =matrix::Eye(4,5,1);
matrix<double> matrix_a1=matrix::Full(3,4,M_PI);
matrixf         matrix_a2=matrixf::Identity(5,5);
matrixf<float> matrix_a3=matrixf::Ones(5,5);
matrix          matrix_a4=matrix::Tri(4,5,-1);
vector          vector_a =vector::Ones(256);
vectorf         vector_a1=vector<float>::Zeros(16);
vector<float>   vector_a2=vectorf::Full(128,float_value);
```

Methods for initializing already created matrices and vectors:

```
matrix  matrix_a;
matrix_a.Init(size_m,size_k,MatrixArange,-M_PI,0.1);
matrixf matrix_a1(3,4);
matrix_a1.Init(10,20,MatrixArange);
vector  vector_a;
vector_a.Init(128,VectorArange);
vectorf vector_a1(10);
vector_a1.Init(vector_size,VectorArange,start_value,step);

matrix_a.Fill(double_value);
vector_a1.Fill(FLT_MIN);
matrix_a1.Identity();
```

Assign

Copies a matrix, vector or array with auto cast.

```
bool matrix::Assign(
  const matrix<T>  &mat     // copied matrix
   );
bool matrix::Assign(
  const void       &array[] // copied array
   );
bool vector::Assign(
  const vector<T>  &vec     // copied vector
   );
bool vector::Assign(
  const void       &array[] // copied array
   );
```

Parameters

m, v or array

[in] The matrix, vector or array the values are copied from.

Return Value

Returns true if successful, otherwise — false.

Note

Unlike Copy, the Assign method allows copying arrays as well. In this case, the auto cast takes place, while the resulting matrix or vector adjusts to the size of the copied array.

Example:

```
//--- copy the matrices
  matrix a= {{2, 2}, {3, 3}, {4, 4}};
  matrix b=a+2;
  matrix c;
  Print("matrix a \n", a);
  Print("matrix b \n", b);
  c.Assign(b);
  Print("matrix c \n", a);

//--- copy the array to the matrix
  matrix double_matrix=matrix::Full(2,10,3.14);
  Print("double_matrix before Assign() \n", double_matrix);
  int int_arr[5][5]= {{1, 2}, {3, 4}, {5, 6}};
  Print("int_arr: ");
  ArrayPrint(int_arr);
  double_matrix.Assign(int_arr);
```

```
Print("double_matrix after Assign(int_arr) \n", double_matrix);
/*
 matrix a
 [[2,2]
  [3,3]
  [4,4]]
 matrix b
 [[4,4]
  [5,5]
  [6,6]]
 matrix c
 [[2,2]
  [3,3]
  [4,4]]

 double_matrix before Assign()
 [[3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14]
  [3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14,3.14]]

 int_arr:
     [,0][,1][,2][,3][,4]
 [0,]   1   2   0   0   0
 [1,]   3   4   0   0   0
 [2,]   5   6   0   0   0
 [3,]   0   0   0   0   0
 [4,]   0   0   0   0   0

 double_matrix after Assign(int_arr)
 [[1,2,0,0,0]
  [3,4,0,0,0]
  [5,6,0,0,0]
  [0,0,0,0,0]
  [0,0,0,0,0]]

*/
```

See also

Copy

CopyIndicatorBuffer

Get the data of the specified indicator buffer in the specified quantity to a vector.

The data will be copied into the vector locating the oldest element at the beginning of the physical memory allocated for the vector. There are three function options.

Access by the initial position and the number of required elements

```
bool  vector::CopyIndicatorBuffer(
   long      indicator_handle,     // indicator handle
   ulong     buffer_index,         // indicator buffer number
   ulong     start_pos,            // starting position to copy
   ulong     count                 // number of elements to copy
   );
```

Access by the start date and the number of required elements

```
bool  vector::CopyIndicatorBuffer(
   long      indicator_handle,     // indicator handle
   ulong     buffer_index,         // indicator buffer number
   datetime  start_time,           // from which date to copy
   ulong     count                 // number of elements to copy
   );
```

Access by the initial and final dates of the required time interval

```
bool  vector::CopyIndicatorBuffer(
   long      indicator_handle,     // indicator handle
   ulong     buffer_index,         // indicator buffer number
   datetime  start_time,           // from which date to copy
   datetime  stop_time             // up to which date to copy
   );
```

Parameters

indicator_handle

[in] The indicator handle obtained by the relevant indicator function.

buffer_index

[in] The number of the indicator buffer.

start_pos

[in] The number of the first copied element index.

count

[in] The number of copied elements.

start_time

[in] Bar time corresponding to the first element.

stop_time

[in] Bar time corresponding to the last element.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The elements of the copied data (the indicator buffer with index buffer_index) are counted down from the present to the past, and thus the starting position equal to 0 means the current bar (the indicator value for the current bar).

When copying an unknown amount of data, you should declare a vector without specifying a size (without allocating memory for the data), since the CopyBuffer() function tries to distribute the size of the receiving vector to the size of the copied data.

When partial copying of the indicator values is needed, you should use an intermediate vector into which the required quantity is copied. From this intermediate vector, you can copy the required number of values member by member, to the required places of the receiving vector.

If you are copying a predetermined amount of data, it is recommended to pre-declare a vector and specify its size to avoid unnecessary memory reallocation.

When requesting data from an indicator, the function immediately returns false if requested timeseries have not yet been constructed or they need to be downloaded from the server, while it initiates loading/constructing.

When requesting data from an EA or a script, download from the server is initiated if the terminal does not have the appropriate data locally, or construction of the necessary timeseries starts if the data can be constructed from the local history but the required timeframes are not ready yet. The function returns the amount that will be ready by the time the timeout expires.

See also

CopyBuffer

CopyRates

Gets the historical series of the MqlRates structure of the specified symbol-period in the specified amount into a matrix or vector. Elements are counted down from the present to the past, which means that the starting position equal to 0 means the current bar.

The data is copied so that the oldest element is placed at the beginning of the matrix/vector. There are three function options.

Access by the initial position and the number of required elements

```
bool  CopyRates(
   string           symbol,       // symbol name
   ENUM_TIMEFRAMES  period,       // period
   ulong            rates_mask,   // combination of flags to specify the requested se
   ulong            start,        // index of the initial bar copying starts from
   ulong            count         // how many to copy
   );
```

Access by the initial date and the number of required elements

```
bool  CopyRates(
   string           symbol,       // symbol name
   ENUM_TIMEFRAMES  period,       // period
   ulong            rates_mask,   // combination of flags to specify the requested se
   datetime         from,         // start date
   ulong            count         // how many to copy
   );
```

Access by the initial and final dates of the required time interval

```
bool  CopyRates(
   string           symbol,       // symbol name
   ENUM_TIMEFRAMES  period,       // period
   ulong            rates_mask,   // combination of flags to specify the requested se
   datetime         from,         // start date
   datetime         to            // end date
   );
```

Parameters

symbol

[in] Symbol.

period

[in] Period.

rates_mask

[in] The ENUM_COPY_RATES enumeration combination of flags specifying the type of requested series. When copying to a vector, only one value from the ENUM_COPY_RATES enumeration can be specified, otherwise an error occurs.

start

[in] First copied element index.

count

[in] Number of copied elements.

from

[in] Bar time corresponding to the first element.

to

[in] Bar time corresponding to the last element.

Return Value

Return true if successful, otherwise false in case of an error.

Note

If the interval of the requested data is completely outside the available data on the server, then the function returns false. If the data outside TERMINAL_MAXBARS (maximum number of bars on the chart) is requested, the function also returns false.

When requesting data from an EA or a script, download from the server is initiated if the terminal does not have the appropriate data locally, or construction of the necessary timeseries starts if the data can be constructed from the local history but they are not ready yet. The function returns the amount that will be ready by the time the timeout expires, however the history download continues, and the function returns more data during the next similar request.

When requesting data by the start date and the number of required items, only data whose date is less than (before) or equal to the specified one is returned. The interval is set and considered up to a second. In other words, the opening date of any bar the value is returned for (volume, spread, Open, High, Low, Close or Time) is always equal to or less than the specified one.

When requesting data in a given date range, only data that falls within the requested interval is returned. The interval is set and considered up to a second. In other words, the opening time of any bar the value is returned for (volume, spread, indicator buffer value, Open, High, Low, Close or Time) is always located in the requested interval.

For example, if the current day of the week is Saturday, the function returns 0 when attempting to copy data on the weekly timeframe by setting *start_time=Last_Tuesday* and *stop_time=Last_Friday* because the open time on the weekly timeframe always falls on Sunday, but not a single weekly bar falls within the specified range.

If you need to get the value corresponding to the current incomplete bar, then you can use the first call form indicating *start_pos*=0 and *count*=1.

ENUM_COPY_RATES

The ENUM_COPY_RATES enumeration contains the flags to specify the type of data to be passed to the matrix or array. The flag combination allows getting several series from the history in one request. The order of the rows in the matrix will correspond to the order of the values in the ENUM_COPY_RATES enumeration. In other words, the row with High data will always be higher in the matrix than the row with Low data.

ID	Value	Description
COPY_RATES_OPEN	1	Open price series
COPY_RATES_HIGH	2	High price series
COPY_RATES_LOW	4	Low price series
COPY_RATES_CLOSE	8	Close price series
COPY_RATES_TIME	16	Time series (bar open time) Getting time in float of the vector and the matrix (vectord and matrixf) causes losses of ~100 seconds since float accuracy is severely limited and integers greater than 1<<24 cannot be accurately represented in float.
COPY_RATES_VOLUME_TICK	32	Tick Volumes
COPY_RATES_VOLUME_REAL	64	Trade Volumes
COPY_RATES_SPREAD	128	Spreads
Combination		
COPY_RATES_OHLC	15	Open, High, Low and Close series
COPY_RATES_OHLCT	31	Open, High, Low, Close and Time series
Data arrangement		
COPY_RATES_VERTICAL	32768	Series are copied into the matrix along the vertical axis. The received series values will be arranged vertically in the matrix, i.e., the oldest data will be in the first row, while the most recent data will be in the last matrix row. With default copying, series are added into a matrix along the horizontal axis. The flag is only applicable when copying to a matrix.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- get quotes to the matrix
  matrix matrix_rates;
  if(matrix_rates.CopyRates(Symbol(), PERIOD_CURRENT, COPY_RATES_OHLCT, 1, 10))
```

```
    Print("matrix rates: \n", matrix_rates);
  else
    Print("matrix_rates.CopyRates failed. Error ", GetLastError());
//--- check
  MqlRates mql_rates[];
  if(CopyRates(Symbol(), PERIOD_CURRENT, 1, 10, mql_rates)>0)
   {
    Print("mql_rates array:");
    ArrayPrint(mql_rates);
   }
  else
    Print("CopyRates(Symbol(), PERIOD_CURRENT,1, 10, mql_rates). Error ", GetLastErro
//--- get quotes into the vector = invalid call
  vector vector_rates;
  if(vector_rates.CopyRates(Symbol(), PERIOD_CURRENT, COPY_RATES_OHLC, 1, 15))
    Print("vector_rates COPY_RATES_OHLC: \n", vector_rates);
  else
    Print("vector_rates.CopyRates COPY_RATES_OHLC failed. Error ", GetLastError());
//--- get close prices into the vector
  if(vector_rates.CopyRates(Symbol(), PERIOD_CURRENT, COPY_RATES_CLOSE, 1, 15))
    Print("vector_rates COPY_RATES_CLOSE: \n", vector_rates);
  else
    Print("vector_rates.CopyRates failed. Error ", GetLastError());
 };

CopyTicks

Get ticks from an MqlTick structure into a matrix or a vector. Elements are counted from the past to the present, which means that the tick with index 0 is the oldest one. To analyze a tick, check the *flags* field which shows what exactly has changed in the tick.

```
bool  matrix::CopyTicks(
   string           symbol,                // symbol name
   ulong            ticks_mask,            // mask indicating the type of ticks to be
   uint             flags=COPY_TICKS_ALL,  // flag indicating the type of ticks to be
   ulong            from_msc=0,            // time from which ticks are requested
   ulong            count=0                // number of ticks to be received
   );
```

Vector Method

```
bool  vector::CopyTicks(
   string           symbol,                // symbol name
   ulong            ticks_mask,            // mask indicating the type of ticks to be
   uint             flags=COPY_TICKS_ALL,  // flag indicating the type of ticks to be
   ulong            from_msc=0,            // time from which ticks are requested
   ulong            count=0                // number of ticks to be received
   );
```

Parameters

symbol

[in] Symbol.

ticks_mask

[in] A combination of flags from the ENUM_COPY_TICKS enumeration indicating the contents of the requested data. When copying to a vector, you can specify only one value from the ENUM_COPY_TICKS enumeration, otherwise an error will occur.

flags

[in] A flag defining the type of the requested ticks. COPY_TICKS_INFO means ticks cased by Bid and/or Ask changes, COPY_TICKS_TRADE — ticks with Last and Volume changes, COPY_TICKS_ALL — all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from_msc

[in] Time starting from which ticks are requested. Time is specified in milliseconds since 01/01/1970. If from_msc=0, the last number of ticks equal to 'count' are returned.

count

[in] The number of requested ticks. If parameters 'from_msc' and 'count' are not specified, all available ticks, but no more than 2000, will be written.

Return Value

Returns true on success or false if error occurs.

Note

The first call of CopyTicks() initiates synchronization of the relevant symbol's tick database stored on the hard drive. If the local database does not provide all the requested ticks, then missing ticks will be automatically downloaded from the trade server. Ticks from ***from_msc*** specified in CopyTicks() to the current moment will be synchronized. After that, all ticks arriving for this symbol will be added to the tick database thus keeping it in the synchronized state.

If *from_msc* and *count* parameters are not specified, all available ticks, but no more than 2000, will be written to the matrix/vector.

In indicators, the CopyTicks() method returns the result immediately: When called from an indicator, CopyTick() immediately returns all available ticks of a symbol and launches synchronization of the tick database if available data is not enough. All indicators on the same symbol operate in one common thread, so the indicator cannot wait for the completion of synchronization. After synchronization, CopyTicks() will return all requested ticks during the next call. In indicators, the OnCalculate() function is called after the arrival of each tick.

In Expert Advisors and scripts, CopyTicks() can wait for the result for 45 seconds: as distinct from indicators, every Expert Advisor or script operates in a separate thread, and therefore can wait up to 45 seconds for the synchronization to complete. If the required amount of ticks fails to be synchronized during this time, CopyTicks() will return available ticks by timeout and will continue synchronization. OnTick() in Expert Advisors is not a handler of every tick, while it only notifies the Expert Advisor about changes in the market. This can be a batch of changes: the terminal can simultaneously receive multiple ticks, while OnTick() will be called only once, to notify the Expert Advisor about the latest market state.

Rate of data return: the terminal stores 4096 last ticks for each instrument in the fast access cache (65536 ticks for symbols with the Market Depth running). Requests concerning this data are executed the fastest. If requested ticks for the current trading session are beyond the cache, CopyTicks() calls the ticks stored in the terminal memory. These requests require more time to complete. The slowest requests are those requesting ticks for other days, since the data is read from the drive in this case.

ENUM_COPY_TICKS

The ENUM_COPY_TICKS enumeration contains the flags to specify the type of data to be passed to the matrix or array. The flag combination allows getting several series from the history in one request. The order of the rows in the matrix will correspond to the order of the values in the ENUM_COPY_TICKS enumeration. In other words, the row with High data will always be higher in the matrix than the row with Low data.

ID	Value	Description
COPY_TICKS_TIME_MS	1	Tick time in milliseconds
COPY_TICKS_BID	2	Bid price
COPY_TICKS_ASK	4	Ask price
COPY_TICKS_LAST	8	Last price (last deal price)
COPY_TICKS_VOLUME	16	Last price Volume

ID	Value	Description
COPY_TICKS_FLAGS	32	Tick Flags
Data arrangement		
COPY_TICKS_VERTICAL	32768	Ticks are copied into the matrix along the vertical axis. The received ticks will be arranged vertically in the matrix, i.e., the oldest ticks will be in the first row, while the most recent ticks will be in the last matrix row. With default copying, ticks are added into a matrix along the horizontal axis. The flag is only applicable when copying to a matrix.

Analyze the tick flags to find out which data has changed:

- TICK_FLAG_BID — the tick has changed the bid price
- TICK_FLAG_ASK — the tick has changed the ask price
- TICK_FLAG_LAST — the tick has changed the last deal price
- TICK_FLAG_VOLUME — the tick has changed the volume
- TICK_FLAG_BUY — the tick is a result of a buy deal
- TICK_FLAG_SELL — the tick is a result of a sell deal

Access to Timeseries and Indicators, CopyTicks

CopyTicksRange

Get ticks from an MqlTick structure into a matrix or a vector within the specified date range. Elements are counted from the past to the present, which means that the tick with index 0 is the oldest one. To analyze a tick, check the *flags* field which shows what exactly has changed in the tick.

```
bool  matrix::CopyTicksRange(
   string           symbol,                 // symbol name
   ulong            ticks_mask,             // mask indicating the type of ticks to be
   uint             flags=COPY_TICKS_ALL,   // flag indicating the type of ticks to be
   ulong            from_msc=0,             // time from which ticks are requested
   ulong            to_msc=0                // time up to which ticks are requested
   );
```

Vector Method

```
bool  vector::CopyTicksRange(
   string           symbol,                 // symbol name
   ulong            ticks_mask,             // mask indicating the type of ticks to be
   uint             flags=COPY_TICKS_ALL,   // flag indicating the type of ticks to be
   ulong            from_msc=0,             // time from which ticks are requested
   ulong            to_msc=0                // time up to which ticks are requested
   );
```

Parameters

symbol

[in] Symbol.

ticks_mask

[in] A combination of flags from the ENUM_COPY_TICKS enumeration indicating the contents of the requested data. When copying to a vector, you can specify only one value from the ENUM_COPY_TICKS enumeration, otherwise an error will occur.

flags

[in] A flag defining the type of the requested ticks. COPY_TICKS_INFO means ticks cased by Bid and/or Ask changes, COPY_TICKS_TRADE — ticks with Last and Volume changes, COPY_TICKS_ALL — all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from_msc

[in] Time starting from which ticks are requested. Time is specified in milliseconds since 01/01/1970. If the 'from_msc' parameter is not specified, ticks from the beginning of the history are returned. Ticks with the time >= from_msc will be returned.

to_msc

[in] Time up to which ticks are requested. Time is specified in milliseconds since 01/01/1970. Ticks with the time <= to_msc are returned. If the to_msc parameter is not specified, all ticks up to the history end are returned.

Return Value

Returns true on success or false if error occurs. GetLastError() can return the following errors:

- ERR_HISTORY_TIMEOUT — timeout for tick synchronization has expired, the function has returned all it had.
- ERR_HISTORY_SMALL_BUFFER — static buffer is too small. Only the amount the array can store has been returned.
- ERR_NOT_ENOUGH_MEMORY — not enough memory to receive historical data from the specified range into a dynamic tick array. Failed to allocate enough memory for the tick array.

Analyze the tick flags to find out which data has changed:

- TICK_FLAG_BID — the tick has changed the bid price
- TICK_FLAG_ASK — the tick has changed the ask price
- TICK_FLAG_LAST — the tick has changed the last deal price
- TICK_FLAG_VOLUME — the tick has changed the volume
- TICK_FLAG_BUY — the tick is a result of a buy deal
- TICK_FLAG_SELL — the tick is a result of a sell deal

Note

The CopyTicksRange() method is used to request ticks from exactly the specified range. For example, ticks for a specific day in history. CopyTicks() allows specifying only the start date, for example, to receive all ticks from the beginning of the month up to now.

Access to Timeseries and Indicators, CopyTicksRange

Eye

A static function. Constructs a matrix having a specified size with ones on the main diagonal and zeros elsewhere. Returns a matrix with ones on the diagonal and zeros elsewhere.

```
static matrix matrix::Eye(
  const ulong  rows,         // number of rows
  const ulong  cols,         // number of columns
  const int    ndiag=0       // index of the diagonal
   );
```

Parameters

rows

[in] Number of rows in the output.

cols

[in] Number of columns in the output.

ndiag=0

[in] Index of the diagonal: 0 (the default) refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal.

Return Value

A matrix where all elements are equal to zero, except for the k-th diagonal, whose values are equal to one.

MQL5 example:

```
  matrix eye=matrix::Eye(3, 3);
  Print("eye = \n", eye);

  eye=matrix::Eye(4, 4,1);
  Print("eye = \n", eye);
  /*
   eye =
   [[1,0,0]
    [0,1,0]
    [0,0,1]]
   eye =
   [[0,1,0,0]
    [0,0,1,0]
    [0,0,0,1]
    [0,0,0,0]]
  */
```

Python example:

```
np.eye(3, dtype=int)
```

```
array([[1, 0, 0],
       [0, 1, 0],
       [0, 0, 1]])

 np.eye(4, k=1)
array([[0., 1., 0., 0.],
       [0., 0., 1., 0.],
       [0., 0., 0., 1.],
       [0., 0., 0., 0.]])
```

Identity

It is a static function which creates an identity matrix of the specified size (not necessarily square). An identity matrix contains ones on the main diagonal and zeros elsewhere. The main diagonal consists of the matrix elements having equal row and column indexes, such as [0,0],[1,1],[2,2] etc. Creates a new identity matrix.

There is also the method Identity that transforms an already existing matrix into an identity one.

```
static matrix matrix::Identity(
  const ulong  rows,         // number of rows
  const ulong  cols,         // number of columns
   );

void matrix::Identity();
```

Parameters

rows

[in] Number of rows (and columns) in n x n matrix.

Return Value

Return the identity matrix. The identity matrix is a square matrix with ones on the main diagonal.

MQL5 example:

```
  matrix identity=matrix::Identity(3,3);
  Print("identity = \n", identity);
/*
   identity =
   [[1,0,0]
    [0,1,0]
    [0,0,1]]
*/
  matrix identity2(3,5);
  identity2.Identity();
  Print("identity2 = \n", identity2);
/*
   identity2 =
   [[1,0,0,0,0]
    [0,1,0,0,0]
    [0,0,1,0,0]]
*/
```

Python example:

```
np.identity(3)
array([[1.,  0.,  0.],
```

```
        [0.,  1.,  0.],
        [0.,  0.,  1.]])
```

Ones

This is a static function that creates and returns a new matrix filled with ones.

```
static matrix matrix::Ones(
  const ulong  rows,      // number of rows
  const ulong  cols       // number of columns
   );

static vector vector::Ones(
  const ulong  size,      // vector size
   );
```

Parameters

rows

[in] Number of rows.

cols

[in] Number of columns.

Return Value

A new matrix of given rows and columns, filled with ones.

MQL5 example:

```
  matrix ones=matrix::Ones(4, 4);
  Print("ones = \n", ones);
/*
ones =
   [[1,1,1,1]
    [1,1,1,1]
    [1,1,1,1]
    [1,1,1,1]]
*/
```

Python example:

```
np.ones((4, 1))
array([[1.],
       [1.]])
```

Zeros

This is a static function that creates and returns a new matrix filled with zeros.

```
static matrix matrix::Zeros(
  const ulong  rows,      // number of rows
  const ulong  cols       // number of columns
   );

static vector vector::Zeros(
  const ulong  size,      // vector size
   );
```

Parameters

rows

[in] Number of rows.

cols

[in] Number of columns.

Return Value

A new matrix of given rows and columns, filled with zeros.

MQL5 example:

```
  matrix zeros=matrix::Zeros(3, 4);
  Print("zeros = \n", zeros);
/*
zeros =
   [[0,0,0,0]
    [0,0,0,0]
    [0,0,0,0]]
*/
```

Python example:

```
np.zeros((2, 1))
array([[ 0.],
       [ 0.]])
```

Full

The static function creates and returns a new matrix filled with given value.

```
static matrix matrix::Full(
  const ulong   rows,       // number or rows
  const ulong   cols,       // number of columns
  const double  value       // value to fill
   );

static vector vector::Full(
  const ulong   size,       // vector size
  const double  value       // value to fill
   );
```

Parameters

rows

[in] Number of rows.

cols

[in] Number of columns.

value

[in] Value to fill all the matrix elements.

Return Value

Return a new matrix of given rows and columns, filled with specified value.

MQL5 example:

```
  matrix full=matrix::Full(3,4,10);
  Print("full = \n", full);
/*
full =
   [[10,10,10,10]
    [10,10,10,10]
    [10,10,10,10]]
*/
```

Example

```
np.full((2, 2), 10)
array([[10, 10],
       [10, 10]])
```

Tri

This is a static function Construct a matrix with ones at and below the given diagonal and zeros elsewhere.

```
static matrix matrix::Tri(
  const ulong rows,         // number of rows
  const ulong cols,         // number of columns
  const int   ndiag=0       // number of diagonal
   );
```

Parameters

rows

[in] Number of rows in the array.

cols

[in] Number of columns in the array.

ndiag=0

[in] The sub-diagonal at and below which the array is filled. k = 0 is the main diagonal, while k < 0 is below it, and k > 0 is above. The default is 0.

Return Value

Array with its lower triangle filled with ones and zero elsewhere.

MQL5 example:

```
   matrix matrix_a=matrix::Tri(3,4,1);
   Print("Tri(3,4,1)\n",matrix_a);
   matrix_a=matrix::Tri(4,3,-1);
   Print("Tri(4,3,-1)\n",matrix_a);

/*
   Tri(3,4,1)
   [[1,1,0,0]
    [1,1,1,0]
    [1,1,1,1]]
   Tri(4,3,-1)
   [[0,0,0]
    [1,0,0]
    [1,1,0]
    [1,1,1]]
*/
```

Example

```
np.tri(3, 5, 2, dtype=int)
array([[1, 1, 1, 0, 0],
       [1, 1, 1, 1, 0],
       [1, 1, 1, 1, 1]])
```

Init

Initialize a matrix or a vector.

```
void matrix::Init(
  const ulong  rows,            // number of rows
  const ulong  cols,            // number of columns
  func_name    init_func=NULL,  // init function placed in some scope or static metho
   ...         parameters
   );

void vector::Init(
  const ulong  size,            // vector size
  func_name    init_func=NULL,  // init function placed in some scope or static metho
   ...         parameters
   );
```

Parameters

rows

[in] Number of rows.

cols

[in] Number of columns.

func_name

[in] Initializing function.

...

[in] Parameters of the initializing function.

Return Value

No return value.

Example

```
template<typename T>
void MatrixArange(matrix<T> &mat,T value=0.0,T step=1.0)
  {
   for(ulong i=0; i<mat.Rows(); i++)
     {
      for(ulong j=0; j<mat.Cols(); j++,value+=step)
         mat[i][j]=value;
     }
  }
template<typename T>
void VectorArange(vector<T> &vec,T value=0.0,T step=1.0)
  {
```

```
   for(ulong i=0; i<vec.Size(); i++,value+=step)
      vec[i]=value;
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
  int size_m=3, size_k=4;
  matrix  m(size_m,size_k,MatrixArange,-2.,0.1); // first an uninitialized matrix size
  Print("matrix m \n",m);                        // then function MatrixArange with th
  matrixf m_float(5,5,MatrixArange,-2.f,0.1f);   // after a matrix of float type is cr
  Print("matrix m_float \n",m_float);
  vector  v(size_k,VectorArange,-10.0);          // after a vector is created, VectorA
  Print("vector v \n",v);
  /*
   matrix m
   [[-2,-1.9,-1.8,-1.7]
    [-1.6,-1.5,-1.399999999999999,-1.299999999999999]
    [-1.199999999999999,-1.099999999999999,-0.9999999999999992,-0.8999999999999992]]
   matrix m_float
   [[-2,-1.9,-1.8,-1.6999999,-1.5999999]
    [-1.4999999,-1.3999999,-1.2999998,-1.1999998,-1.0999998]
    [-0.99999976,-0.89999974,-0.79999971,-0.69999969,-0.59999967]
    [-0.49999967,-0.39999968,-0.29999968,-0.19999969,-0.099999689]
    [3.1292439e-07,0.10000031,0.20000032,0.30000031,0.4000003]]
   vector v
   [-10,-9,-8,-7]
  */
  }
```

Fill

Fill an existing matrix or vector with the specified value.

```
void matrix::Fill(
  const double  value      // value to fill
   );

void vector::Fill(
  const double  value      // value to fill
   );
```

Parameters

value

[in] Value to fill all the matrix elements.

Return Value

No return value. The matrix is filled in place with the specified value.

Example

```
   matrix matrix_a(2,2);
   matrix_a.Fill(10);
   Print("matrix_a\n",matrix_a);

/*
  matrix_a
  [[10,10]
   [10,10]]
*/
```

Matrix and vector manipulations

These are methods for basic matrix operations: filling, copying, getting a part of a matrix, transposing, splitting and sorting.

There are also several methods for operations with matrix rows and columns.

Function	Action
HasNan	Return the number of NaN values in a matrix/vector
Transpose	Reverse or permute the axes of a matrix; returns the modified matrix
TriL	Return a copy of a matrix with elements above the k-th diagonal zeroed. Lower triangular matrix
TriU	Return a copy of a matrix with elements below the k-th diagonal zeroed. Upper triangular matrix
Diag	Extract a diagonal or construct a diagonal matrix
Row	Return a row vector. Write a vector to the specified row
Col	Return a column vector. Write a vector to the specified column
Copy	Return a copy of the given matrix/vector
Compare	Compare the elements of two matrices/vectors with the specified precision
CompareByDigits	Compare the elements of two matrices/vectors up to significant digits
Flat	Allows addressing a matrix element through one index instead of two
Clip	Limit the elements of a matrix/vector to a specified range of valid values
Reshape	Change the shape of a matrix without changing its data
Resize	Return a new matrix with a changed shape and size
SwapRows	Swap rows in a matrix
SwapCols	Swap columns in a matrix
Split	Split a matrix into multiple submatrices
Hsplit	Split a matrix horizontally into multiple submatrices. Same as Split with axis=0
Vsplit	Split a matrix vertically into multiple submatrices. Same as Split with axis=1
ArgSort	Indirectly sort a matrix or vector.
Sort	Sort a matrix or vector in place.

HasNan

Return the number of NaN values in a matrix/vector.

```
ulong vector::HasNan();

ulong matrix::HasNan();
```

Return Value

The number of matrix/vector elements that contain a NaN value.

Note

When comparing the appropriate pair of elements having NaN values, the Compare and CompareByDigits methods consider these elements equal, while in case of a usual comparison of floating-point numbers NaN != NaN.

Example:

```
void OnStart(void)
  {
   double x=sqrt(-1);

   Print("single: ",x==x);

   vector<double> v1={x};
   vector<double> v2={x};

   Print("vector: ", v1.Compare(v2,0)==0);
  }

/* Result:

 single: false
 vector: true
*/
```

See also

MathClassify, Compare, CompareByDigits

Transpose

Matrix transposition. Reverse or permute the axes of a matrix; returns the modified matrix.

```
matrix matrix::Transpose()
```

Return Value

Transposed matrix.

A simple matrix transposition algorithm in MQL5:

```
matrix MatrixTranspose(const matrix& matrix_a)
  {
   matrix matrix_c(matrix_a.Cols(),matrix_a.Rows());

   for(ulong i=0; i<matrix_c.Rows(); i++)
      for(ulong j=0; j<matrix_c.Cols(); j++)
         matrix_c[i][j]=matrix_a[j][i];

   return(matrix_c);
  }
```

MQL5 example:

```
  matrix a= {{0, 1, 2}, {3, 4, 5}};
  Print("matrix a \n", a);
  Print("a.Transpose() \n", a.Transpose());

  /*
  matrix a
  [[0,1,2]
   [3,4,5]]
  a.Transpose()
  [[0,3]
   [1,4]
   [2,5]]
  */
```

Python example:

```
import numpy as np

a = np.arange(6).reshape((2,3))
print("a \n",a)
print("np.transpose(a) \n",np.transpose(a))
```

```
a
 [[0 1 2]
 [3 4 5]]
np.transpose(a)
 [[0 3]
 [1 4]
 [2 5]]
```

TriL

Return a copy of a matrix with elements above the k-th diagonal zeroed. Lower triangular matrix.

```
matrix matrix::Tril(
  const int      ndiag=0      // index of diagonal
   );
```

Parameters

ndiag=0

[in] Diagonal above which to zero elements. ndiag = 0 (the default) is the main diagonal, ndiag < 0 is below it and ndiag > 0 is above.

Return Value

Array with its lower triangle filled with ones and zero elsewhere.

MQL5 example:

```
   matrix a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   matrix b=a.TriL(-1);
   Print("matrix b \n",b);

  /*
  matrix_c
  [[0,0,0]
  [4,0,0]
  [7,8,0]
  [10,11,12]]
  */
```

Python example:

```
import numpy as np

a=np.tril([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)

[[ 0  0  0]
 [ 4  0  0]
 [ 7  8  0]
 [10 11 12]]
```

TriU

Return a copy of a matrix with the elements below the k-th diagonal zeroed. Upper triangular matrix.

```
matrix matrix::Triu(
  const int      ndiag=0      // index of diagonal
   );
```

Parameters

ndiag=0

[in] Diagonal below which to zero elements. ndiag = 0 (the default) is the main diagonal, ndiag < 0 is below it and ndiag > 0 is above.

MQL5 example:

```
   matrix a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   matrix b=a.TriU(-1);
   Print("matrix b \n",b);

  /*
  matrix b
  [[1,2,3]
   [4,5,6]
   [0,8,9]
   [0,0,12]]
  */
```

Python example:

```
import numpy as np

a=np.triu([[1,2,3],[4,5,6],[7,8,9],[10,11,12]], -1)
print(a)

[[ 1  2  3]
 [ 4  5  6]
 [ 0  8  9]
 [ 0  0 12]]
```

Diag

Extract a diagonal or construct a diagonal matrix.

```
vector matrix::Diag(
  const int     ndiag=0      // number of diagonal
   );

void matrix::Diag(
  const vector  v,           // diagonal vector
  const int     ndiag=0      // number of diagonal
   );
```

Parameters

v

[in] A vector whose elements will be contained in the corresponding diagonal (ndiag=0 is the main diagonal).

ndiag=0

[in] Diagonal in question. The default is 0. Use ndiag>0 for diagonals above the main diagonal, and ndiag<0 for diagonals below the main diagonal.

Note

A diagonal can be set for unallocated matrices (which do not have dimensions). In this case, a zero matrix of the size will be created with the size corresponding to the size of the diagonal vector, after which the vector values will be populated in the corresponding diagonal. If the diagonal is set to an already existing matrix, the matrix dimensions do not change and the values of the matrix elements outside the diagonal vector do not change.

Example

```
   vector v1={1,2,3};
   matrix m1;
   m1.Diag(v1);
   Print("m1\n",m1);
   matrix m2;
   m2.Diag(v1,-1);
   Print("m2\n",m2);
   matrix m3;
   m3.Diag(v1,1);
   Print("m3\n",m3);
   matrix m4=matrix::Full(4,5,9);
   m4.Diag(v1,1);
   Print("m4\n",m4);

   Print("diag -1 - ",m4.Diag(-1));
```

```
   Print("diag 0 - ",m4.Diag());
   Print("diag 1 - ",m4.Diag(1));

  /*

  m1
  [[1,0,0]
  [0,2,0]
  [0,0,3]]
  m2
  [[0,0,0]
  [1,0,0]
  [0,2,0]
  [0,0,3]]
  m3
  [[0,1,0,0]
  [0,0,2,0]
  [0,0,0,3]]
  m4
  [[9,1,9,9,9]
  [9,9,2,9,9]
  [9,9,9,3,9]
  [9,9,9,9,9]]
  diag -1 - [9,9,9]
  diag 0 - [9,9,9,9]
  diag 1 - [1,2,3,9]
  */
```

Row

Return a row vector. Write a vector to the specified row

```
vector matrix::Row(
  const ulong   nrow      // row number
   );

void matrix::Row(
  const vector  v,        // row vector
  const ulong   nrow      // row number
   );
```

Parameters

nrow

[in] Number of row.

Return Value

Vector.

Note

A row can be set for unallocated matrices (which do not have dimensions). In this case, a zero matrix will be created with the size of the vector size x row number+1, after which the values of the vector elements will be populated in the corresponding row. If the row is set to an already existing matrix, the matrix dimensions do not change and the values of the matrix elements outside the row vector do not change.

Example

```
   vector v1={1,2,3};
   matrix m1;
   m1.Row(v1,1);
   Print("m1\n",m1);
   matrix m2=matrix::Full(4,5,7);
   m2.Row(v1,2);
   Print("m2\n",m2);

   Print("row 1 - ",m2.Row(1));
   Print("row 2 - ",m2.Row(2));

  /*
  m1
  [[0,0,0]
  [1,2,3]]
  m2
```

```
   [[7,7,7,7,7]
   [7,7,7,7,7]
   [1,2,3,7,7]
   [7,7,7,7,7]]
   row 1 - [7,7,7,7,7]
   row 2 - [1,2,3,7,7]
   */
```

Col

Return a column vector. Write a vector to the specified column.

```
vector matrix::Col(
  const ulong   ncol      // column number
   );

void matrix::Col(
  const vector  v,        // column vector
  const ulong   ncol      // column number
   );
```

Parameters

ncol

[in] Number of column.

Return Value

Vector.

Note

A column can be set for unallocated matrices (which do not have dimensions). In this case, a zero matrix will be created with the size of the vector size x column number+1, after which the values of the vector elements will be populated in the corresponding column. If the column is set to an already existing matrix, the matrix dimensions do not change and the values of the matrix elements outside the column vector do not change.

Example

```
   vector v1={1,2,3};
   matrix m1;
   m1.Col(v1,1);
   Print("m1\n",m1);
   matrix m2=matrix::Full(4,5,8);
   m2.Col(v1,2);
   Print("m2\n",m2);

   Print("col 1 - ",m2.Col(1));
   Print("col 2 - ",m2.Col(2));

  /*
  m1
  [[0,1]
  [0,2]
  [0,3]]
  m2
```

```
   [[8,8,1,8,8]
   [8,8,2,8,8]
   [8,8,3,8,8]
   [8,8,8,8,8]]
   col 1 - [8,8,8,8]
   col 2 - [1,2,3,8]
   */
```

Copy

Create a copy of the given matrix/vector.

```
bool matrix::Copy(
  const matrix&  a     // copied matrix
   );
bool vector::Copy(
  const vector&  v     // copied vector
   );
```

Parameters

v

[in] Matrix or vector to copy.

Return Value

Returns true on success, false otherwise.

MQL5 example:

```
  matrix a=matrix::Eye(3, 4);
  matrix b;
  b.Copy(a);
  matrix c=a;
  Print("matrix b \n", b);
  Print("matrix_c \n", c);

  /*
  /*
  matrix b
  [[1,0,0,0]
  [0,1,0,0]
  [0,0,1,0]]
  matrix_c
  [[1,0,0,0]
  [0,1,0,0]
  [0,0,1,0]]
  */
  */
```

Python example:

```
import numpy as np

a = np.eye(3,4)
print('a \n',a)
b = a
```

```
print('b \n',b)
c = np.copy(a)
print('c \n',c)

a
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
b
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
c
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
```

Compare

Compare the elements of two matrices/vectors with the specified precision.

```
ulong vector::Compare(
  const vector& vec,          // vector to compare
  const double  epsilon       // precision
   );

ulong matrix::Compare(
  const matrix& mat,          // matrix to compare
  const double  epsilon       // precision
   );
```

Parameters

vector_b

[in] Vector to compare.

epsilon

[in] Precision.

Return Value

The number of mismatched elements of the matrices or vectors being compared: 0 if the matrices are equal, greater than 0 otherwise.

Note

The comparison operators == or != execute an exact element-wise comparison. It is known that the exact comparison of real numbers is of limited use, so the epsilon comparison method was added. It may happen that one matrix can contain elements in a range, for example from 1e-20 to 1e+20. Such matrices can be processed using element-wise comparison up to significant figures.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4}};
   matrix matrix_i=matrix::Identity(3,3);
   matrix matrix_c=matrix_a.Inv();
   matrix matrix_check=matrix_a.MatMul(matrix_c);
   Print("matrix_check\n",matrix_check);

   ulong errors=matrix_check.Compare(matrix::Identity(3,3),1e-15);
   Print("errors=",errors);

  /*
```

```
matrix_check
[[1,0,0]
[4.440892098500626e-16,1,8.881784197001252e-16]
[4.440892098500626e-16,2.220446049250313e-16,0.9999999999999996]]
errors=0

*/
```

CompareByDigits

Compare the elements of two matrices/vectors with the significant digits precision.

```
ulong vector::CompareByDigits(
  const vector& vec,          // vector to compare
  const int     digits        // number of significant digits
   );

ulong matrix::CompareByDigits(
  const matrix& mat,          // matrix to compare
  const int     digits        // number of significant digits
   );
```

Parameters

vector_b

[in] Vector to compare.

digits

[in] Number of significant digits to compare.

epsilon

[in] Comparison precision. If two values differ in absolute value by less than the specified precision, they are considered equal.

Return Value

The number of mismatched elements of the matrices or vectors being compared: 0 if the matrices are equal, greater than 0 otherwise.

Note

The comparison operators == or != execute an exact element-wise comparison. It is known that the exact comparison of real numbers is of limited use, so the epsilon comparison method was added. It may happen that one matrix can contain elements in a range, for example from 1e-20 to 1e+20. Such matrices can be processed using element-wise comparison up to significant digits.

Example

```
   int    size_m=128;
   int    size_k=256;
   matrix matrix_a(size_m,size_k);
//--- fill the matrix
   double  value=0.0;
   for(int i=0; i<size_m; i++)
     {
      for(int j=0; j<size_k; j++)
        {
```

```
         if(i==j)
            matrix_a[i][j]=1.0+i;
         else
           {
            value+=1.0;
            matrix_a[i][j]=value/1e+20;
           }
        }
     }
//--- get another matrix
   matrix matrix_c = matrix_a * -1;

   ulong errors_epsilon=matrix_a.Compare(matrix_c,1e-15);
   ulong errors_digits=matrix_a.CompareByDigits(matrix_c,15);

   printf("Compare matrix %d x %d  errors_epsilon=%I64u  errors_digits=%I64u",size_m,s

  /*
  Compare matrix 128 x 256  errors_epsilon=128  errors_digits=32768
  */
```

Flat

Allows addressing a matrix element through one index instead of two.

```
bool matrix::Flat(
  const ulong   index,      // index
  const double  value       // value to set
   );

double matrix::Flat(
  const ulong   index,      // index
   );
```

Parameters

index

[in] Flat index

value

[in] Value to set by given index.

Return Value

Value by given index.

Note

For the matrix mat(3,3), access can be written as follows:

- reading: 'x=mat.Flat(4)', which is equivalent to 'x=mat[1][1]'
- writing: 'mat.Flat(5, 42)', equivalent to 'mat[1][2]=42'

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);
   ulong arg_max=matrix_a.ArgMax();
   Print("max_value=",matrix_a.Flat(arg_max));
   matrix_a.Flat(arg_max,0);
   arg_max=matrix_a.ArgMax();
   Print("max_value=",matrix_a.Flat(arg_max));

  /*
  matrix_a
  [[10,3,2]
   [1,8,12]
   [6,5,4]
   [7,11,9]]
```

```
   max_value=12.0
   max_value=11.0
   */
```

Clip

Limit the elements of a matrix/vector to a specified range of valid values.

```
bool matrix::Clip(
  const double  min_value,      // minimum value
  const double  max_value       // maximum value
   );
bool vector::Clip(
  const double  min_value,      // minimum value
  const double  max_value       // maximum value
   );
```

Parameters

min_value

[in] Minimum value.

max_value

[in] Maximum value.

Return Value

Returns true on success, false otherwise.

Note

The matrix (or vector) is processed in place. No copies are created.

Example

```
   matrix matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   bool res=matrix_a.Clip(4,8);
   Print("matrix_a\n",matrix_a);

  /*
  matrix_a
  [[4,4,4]
   [4,5,6]
   [7,8,8]
   [8,8,8]]
  */
```

Reshape

Change the shape of a matrix without changing its data.

```
void  Reshape(
  const ulong  rows,      // new number or rows
  const ulong  cols       // new number or columns
   );
```

Parameters

rows

[in] New number or rows.

cols

[in] New number or columns.

Note

The matrix is processed in place. No copies are created. Any size can be specified, i.e., rows_new*cols_new!=rows_old*cols_old. When the matrix buffer is increased, the extra values are undefined.

Example

```
matrix matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};

Print("matrix_a\n",matrix_a);
matrix_a.Reshape(2,6);
Print("Reshape(2,6)\n",matrix_a);
matrix_a.Reshape(3,5);
Print("Reshape(3,5)\n",matrix_a);
matrix_a.Reshape(2,4);
Print("Reshape(2,4)\n",matrix_a);

/*
matrix_a
[[1,2,3]
 [4,5,6]
 [7,8,9]
 [10,11,12]]
Reshape(2,6)
[[1,2,3,4,5,6]
 [7,8,9,10,11,12]]
Reshape(3,5)
[[1,2,3,4,5]
 [6,7,8,9,10]
 [11,12,0,3,0]]
Reshape(2,4)
[[1,2,3,4]
```

```
   [5,6,7,8]]
  */
```

Resize

Return a new matrix with a changed shape and size.

```
bool matrix::Resize(
  const ulong  rows,     // new number or rows
  const ulong  cols,     // new number or columns
  const ulong  reserve=0 // reserve amount in items
   );

bool vector::Resize(
  const ulong  size,     // new size.
  const ulong  reserve=0 // reserve amount in items.
   );
```

Parameters

rows

[in] New number or rows.

cols

[in] New number or columns.

Return Value

Returns true on success, false otherwise.

Note

The matrix (or vector) is processed in place. No copies are created. Any size can be specified, i.e., rows_new*cols_new!=rows_old*cols_old. Unlike Reshape, the matrix is processed row by row. When increasing the number of columns, the values of the extra columns are undefined. When increasing the number of rows, the values of elements in the new rows are undefined. When the number of columns is reduced, each row of the matrix is truncated.

Example

```
   matrix matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   Print("matrix_a\n",matrix_a);
   matrix_a.Resize(2,6);
   Print("Ressize(2,6)\n",matrix_a);
   matrix_a.Resize(3,5);
   Print("Resize(3,5)\n",matrix_a);
   matrix_a.Resize(2,4);
   Print("Resize(2,4)\n",matrix_a);

   /*
   matrix_a
   [[1,2,3]
```

```
    [4,5,6]
    [7,8,9]
    [10,11,12]]
  Ressize(2,6)
  [[1,2,3,4,5,6]
    [4,5,6,10,11,12]]
  Resize(3,5)
  [[1,2,3,4,5]
    [4,5,6,10,11]
    [11,12,3,8,8]]
  Resize(2,4)
  [[1,2,3,4]
    [4,5,6,10]]
  */
```

Set

Sets the value for a vector element by the specified index.

```
bool vector::Set(
  ulong   index,      // element index
  double  value       // value
   );
```

Parameters

index

[in] Index of the element the value needs to be set for.

value

[in] Value.

Return Value

Returns true if successful, otherwise - false.

Note

The Set method does the same thing as assigning a value using square brackets, namely: *vector[index]=value*. The method has been added to simplify transferring a code from languages where this type of notation is used. The example below shows both options for filling the vector with values by the specified index.

Example:

```
void OnStart()
  {
//---
   vector v1(10, VectorAssignValues);
   Print("v1 = ", v1);

   vector v2(10, VectorSetValues);
   Print("v2 = ", v2);
  }
 /* Result
  v1 = [1,2,4,8,16,32,64,128,256,512]
  v2 = [1,2,4,8,16,32,64,128,256,512]
  */
//+------------------------------------------------------------------------+
//| Fill a vector with powers of a number through the assignment operation |
//+------------------------------------------------------------------------+
void VectorAssignValues(vector& v, double initial=1)
  {
   double value=initial;
```

```
   for(ulong k=0; k<v.Size(); k++)
     {
      v[k]=value;
      value*=2;
     }
  }
//+------------------------------------------------------------------------------+
//| Fill a vector with powers of a number using the Set method                   |
//+------------------------------------------------------------------------------+
void VectorSetValues(vector& v, double initial=1)
  {
   double value=initial;
   for(ulong k=0; k<v.Size(); k++)
     {
      v.Set(k, value);
      value*=2;
     }
  }
```

SwapRows

Swap rows in a matrix.

```
bool matrix::SwapRows(
  const ulong  row1,     // index of first row
  const ulong  row2      // index of second row
   );
```

Parameters

row1

[in] Index of the first row.

row2

[in] Index of the second row.

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,6,7,8},
                    {9,10,11,12},
                    {13,14,15,16}};
   matrix matrix_i=matrix::Identity(4,4);
   matrix matrix_a1=matrix_a;
   matrix_a1.SwapRows(0,3);
   Print("matrix_a1\n",matrix_a1);

   matrix matrix_p=matrix_i;
   matrix_p.SwapRows(0,3);
   matrix matrix_c1=matrix_p.MatMul(matrix_a);
   Print("matrix_c1\n",matrix_c1);

  /*
  matrix_a1
  [[13,14,15,16]
   [5,6,7,8]
   [9,10,11,12]
   [1,2,3,4]]
  matrix_c1
  [[13,14,15,16]
   [5,6,7,8]
   [9,10,11,12]
   [1,2,3,4]]
  */
```

SwapCols

Swap columns in a matrix.

```
bool matrix::SwapCols(
  const ulong  row1,     // index of first column
  const ulong  row2      // index of second column
   );
```

Parameters

col1

[in] Index of the first column.

col2

[in] Index of the second column.

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,6,7,8},
                    {9,10,11,12},
                    {13,14,15,16}};
   matrix matrix_i=matrix::Identity(4,4);
   matrix matrix_a1=matrix_a;
   matrix_a1.SwapCols(0,3);
   Print("matrix_a1\n",matrix_a1);

   matrix matrix_p=matrix_i;
   matrix_p.SwapCols(0,3);
   matrix matrix_c1=matrix_a.MatMul(matrix_p);
   Print("matrix_c1\n",matrix_c1);

  /*
  matrix_a1
  [[4,2,3,1]
   [8,6,7,5]
   [12,10,11,9]
   [16,14,15,13]]
  matrix_c1
  [[4,2,3,1]
   [8,6,7,5]
   [12,10,11,9]
   [16,14,15,13]]
  */
```

Split

Split a matrix into multiple submatrices.

```
bool matrix::Split(
  const ulong  parts,      // number of submatrices
  const int    axis,       // axis
  matrix&      splitted[]  // array of resulting submatrices
   );

void matrix::Split(
  const ulong& parts[],    // sizes of submatrices
  const int    axis,       // axis
  matrix&      splitted[]  // array of resulting submatrices
   );
```

Parameters

parts

[in] The number of submatrices to divide the matrix into.

axis

[in] Axis. 0 - horizontal axis, 1 - vertical axis.

splitted

[out] Array of resulting submatrices.

Return Value

Returns true on success, false otherwise.

Note

If the number of submatrices is specified, then same size submatrices are obtained. It means that the matrix size (0 - the number of rows, 1 - the number of columns) must be divisible by 'parts' without a remainder. Submatrices of different sizes can be obtained using an array of submatrix sizes. The elements of the size array are used until the entire matrix is divided. If the array of sizes has ended, and the matrix has not yet been completely divided, the undivided remainder will be the last submatrix.

Example

```
   matrix matrix_a={{ 1, 2, 3, 4, 5, 6},
                    { 7, 8, 9,10,11,12},
                    {13,14,15,16,17,18},
                    {19,20,21,22,23,24},
                    {25,26,27,28,29,30}};
   matrix splitted[];
   ulong  parts[]={2,2};
```

```
 bool res=matrix_a.Split(2,0,splitted);
 Print(res,"  ",GetLastError());
 ResetLastError();
 for(uint i=0; i<splitted.Size(); i++)
    Print("splitted ",i,"\n",splitted[i]);

 res=matrix_a.Split(2,1,splitted);
 Print(res,"  ",GetLastError());
 for(uint i=0; i<splitted.Size(); i++)
    Print("splitted ",i,"\n",splitted[i]);

 res=matrix_a.Split(parts,0,splitted);
 Print(res,"  ",GetLastError());
 for(uint i=0; i<splitted.Size(); i++)
    Print("splitted ",i,"\n",splitted[i]);

/*
false  4003
true  0
splitted 0
[[1,2,3]
 [7,8,9]
 [13,14,15]
 [19,20,21]
 [25,26,27]]
splitted 1
[[4,5,6]
 [10,11,12]
 [16,17,18]
 [22,23,24]
 [28,29,30]]
true  0
splitted 0
[[1,2,3,4,5,6]
 [7,8,9,10,11,12]]
splitted 1
[[13,14,15,16,17,18]
 [19,20,21,22,23,24]]
splitted 2
[[25,26,27,28,29,30]]
*/
```

Hsplit

Split a matrix horizontally into multiple submatrices. Same as Split with axis=0

```
bool matrix::Hsplit(
  const ulong  parts,      // number of submatrices
  matrix&      splitted[]  // array of resulting submatrices
   );

void matrix::Hsplit(
  const ulong& parts[],    // sizes of submatrices
  matrix&      splitted[]  // array of resulting submatrices
   );
```

Parameters

parts

[in] The number of submatrices to divide the matrix into.

splitted

[out] Array of resulting submatrices.

Return Value

Returns true on success, false otherwise.

Note

If the number of submatrices is specified, then same size submatrices are obtained. It means that the number of rows must be divisible by 'parts' without a remainder. Submatrices of different sizes can be obtained using an array of submatrix sizes. The elements of the size array are used until the entire matrix is divided. If the array of sizes has ended, and the matrix has not yet been completely divided, the undivided remainder will be the last submatrix.

Example

```
   matrix matrix_a={{ 1, 2, 3, 4, 5, 6},
                    { 7, 8, 9,10,11,12},
                    {13,14,15,16,17,18},
                    {19,20,21,22,23,24},
                    {25,26,27,28,29,30}};
   matrix splitted[];
   ulong  parts[]={2,4};

   bool res=matrix_a.Hsplit(2,splitted);
   Print(res,"  ",GetLastError());
   ResetLastError();
   for(uint i=0; i<splitted.Size(); i++)
      Print("splitted ",i,"\n",splitted[i]);
```

```
 res=matrix_a.Hsplit(5,splitted);
 Print(res,"  ",GetLastError());
 for(uint i=0; i<splitted.Size(); i++)
    Print("splitted ",i,"\n",splitted[i]);

 res=matrix_a.Hsplit(parts,splitted);
 Print(res,"  ",GetLastError());
 for(uint i=0; i<splitted.Size(); i++)
    Print("splitted ",i,"\n",splitted[i]);

*/
```

Vsplit

Split a matrix vertically into multiple submatrices. Same as Split with axis=1

```
bool matrix::Vsplit(
  const ulong  parts,      // number of submatrices
  matrix&      splitted[]  // array of resulting submatrices
   );

void matrix::Vsplit(
  const ulong& parts[],    // sizes of submatrices
  matrix&      splitted[]  // array of resulting submatrices
   );
```

Parameters

parts

[in] The number of submatrices to divide the matrix into.

splitted

[out] Array of resulting submatrices.

Return Value

Returns true on success, false otherwise.

Note

If the number of submatrices is specified, then same size submatrices are obtained. It means that the number of columns must be divisible by 'parts' without a remainder. Submatrices of different sizes can be obtained using an array of submatrix sizes. The elements of the size array are used until the entire matrix is divided. If the array of sizes has ended, and the matrix has not yet been completely divided, the undivided remainder will be the last submatrix.

Example

```
   matrix matrix_a={{ 1, 2, 3, 4, 5, 6},
                    { 7, 8, 9,10,11,12},
                    {13,14,15,16,17,18}};
   matrix splitted[];
   ulong  parts[]={2,3};

   matrix_a.Vsplit(2,splitted);
   for(uint i=0; i<splitted.Size(); i++)
      Print("splitted ",i,"\n",splitted[i]);

   matrix_a.Vsplit(3,splitted);
   for(uint i=0; i<splitted.Size(); i++)
      Print("splitted ",i,"\n",splitted[i]);
```

```
   matrix_a.Vsplit(parts,splitted);
   for(uint i=0; i<splitted.Size(); i++)
      Print("splitted ",i,"\n",splitted[i]);

  /*
     splitted 0
     [[1,2,3]
      [7,8,9]
      [13,14,15]]
     splitted 1
     [[4,5,6]
      [10,11,12]
      [16,17,18]]

     splitted 0
     [[1,2]
      [7,8]
      [13,14]]
     splitted 1
     [[3,4]
      [9,10]
      [15,16]]
     splitted 2
     [[5,6]
      [11,12]
      [17,18]]

     splitted 0
     [[1,2]
      [7,8]
      [13,14]]
     splitted 1
     [[3,4,5]
      [9,10,11]
      [15,16,17]]
     splitted 2
     [[6]
      [12]
      [18]]

  */
```

ArgSort

Indirect sort of a matrix or vector.

```
vector vector::Sort(
  func_name  compare_func=NULL,  // comparison function
  T          context             // parameter for the custom sort function
   );

matrix matrix::Sort(
  func_name  compare_func=NULL   // comparison function
  T          context             // parameter for the custom sort function
   );

matrix matrix::Sort(
  const int  axis,               // axis for sorting
  func_name  compare_func=NULL   // comparison function
  T          context             // parameter for the custom sort function
   );
```

Parameters

axis

[in] The axing along which to sort: 0 is horizontal, 1 is vertical.

func_name

[in] Comparator. You can specify one of the values of the ENUM_SORT_MODE enumeration or your own comparison function. If no function is specified, ascending sort is used.

A custom comparison function can be of two types:

- int comparator(T x1,T x2)
- int comparator(T x1,T x2,TContext context)

Here T is the type of matrix or vector, and TContex is the type of the 'context' variable which is passed as an additional parameter to the Sort method.

context

[in] Additional optional parameter that can be passed to a custom sort function.

Return Value

Vector or matrix with the indexes of sorted elements. For example, the result [4,2,0,1,3] indicates that there should be an element with index 4 in the zero position, an element with index 2 in the first position, and so on.

Sort

Sort a matrix or vector in place.

```
void vector::Sort(
  func_name  compare_func=NULL,  // comparison function
  T          context             // parameter for the custom sort function
   );

void matrix::Sort(
  func_name  compare_func=NULL   // comparison function
  T          context             // parameter for the custom sort function
   );

void matrix::Sort(
  const int  axis,               // axis for sorting
  func_name  compare_func=NULL   // comparison function
  T          context             // parameter for the custom sort function
   );
```

Parameters

axis

[in] The axing along which to sort: 0 is horizontal, 1 is vertical.

func_name

[in] Comparator. You can specify one of the values of the ENUM_SORT_MODE enumeration or your own comparison function. If no function is specified, ascending sort is used.

A custom comparison function can be of two types:

- int comparator(T x1,T x2)
- int comparator(T x1,T x2,TContext context)

Here T is the type of matrix or vector, and TContex is the type of the 'context' variable which is passed as an additional parameter to the Sort method.

context

[in] Additional optional parameter that can be passed to a custom sort function.

Return Value

None. Sorting is performed in place, i.e. it is applied to the data of the matrix/vector for which the Sort method is called.

Example

```
//+------------------------------------------------------------------+
//| Sort function                                                    |
//+------------------------------------------------------------------+
int MyDoubleComparator(double x1,double x2,int sort_mode=0)
  {
```

```
   int res=x1<x2 ? -1 : (x1>x2 ? 1 : 0);
   return(sort_mode==0 ? res : -res);
  }
//+------------------------------------------------------------------+
//| Script start function                                            |
//+------------------------------------------------------------------+
void OnStart()
  {
   //--- fill the vector
   vector v(100);
   //--- sort ascending
   v.Sort(MyDoubleComparator);   // an additional parameter with the default value '0'
   Print(v);
   // sort descending
   v.Sort(MyDoubleComparator,1); // here the additional parameter '1' is explicitly sp
   Print(v);
  }
```

Mathematical operations with matrices and vectors

Mathematical operations, including addition, subtraction, multiplication and division, can be performed on matrices and vectors element-wise.

Mathematical functions were originally designed to perform relevant operations on scalar values. Most of the functions can be applied to matrices and vectors. These include MathAbs, MathArccos, MathArcsin, MathArctan, MathCeil, MathCos, MathExp, MathFloor, MathLog, MathLog10, MathMod, MathPow, MathRound, MathSin, MathSqrt, MathTan, MathExpm1, MathLog1p, MathArccosh, MathArcsinh, MathArctanh, MathCosh, MathSinh, and MathTanh. Such operations imply element-wise processing of matrices and vectors. Example

```
//---
  matrix a= {{1, 4}, {9, 16}};
  Print("matrix a=\n",a);
  a=MathSqrt(a);
  Print("MatrSqrt(a)=\n",a);
  /*
   matrix a=
   [[1,4]
    [9,16]]
   MatrSqrt(a)=
   [[1,2]
    [3,4]]
  */
```

For MathMod and MathPow, the second element can be either a scalar or a matrix/vector of the appropriate size.

The following example shows how to calculate the standard deviation by applying math functions to a vector.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- use the initializing function to fill the vector
  vector r(10, ArrayRandom); // array of random numbers from 0 to 1
//--- calculate the mean value
  double avr=r.Mean();       // array mean value
  vector d=r-avr;            // calculate an array of deviations from the mean
  Print("avr(r)=", avr);
  Print("r=", r);
  Print("d=", d);
  vector s2=MathPow(d, 2);   // array of squared deviations
  double sum=s2.Sum();       // sum of squared deviations
//--- calculate the standard deviation in two different methods
  double std=MathSqrt(sum/r.Size());
  Print(" std(r)=", std);
```

```
   Print("r.Std()=", r.Std());
 }
/*
   avr(r)=0.5300302133243813
   r=[0.8346201971495713,0.8031556138798182,0.6696676534318063,0.05386516922513505,0.54
   d=[0.30458998382519,0.2731254005554369,0.1396374401074251,-0.4761650440992462,0.0190
    std(r)=0.2838269732183663
   r.Std()=0.2838269732183663
*/
//+------------------------------------------------------------------+
//| Fills a vector with random values                                |
//+------------------------------------------------------------------+
void ArrayRandom(vector& v)
 {
  for(ulong i=0; i<v.Size(); i++)
    v[i]=double(MathRand())/32767.;
 }
```

Mathematical operations

Mathematical operations, including addition, subtraction, multiplication and division, can be performed on matrices and vectors element-wise.

Both matrices or both vectors must be of the same type and must have the same dimensions. Each element of the matrix operates on the corresponding element of the second matrix.

You can also use a scalar of the appropriate type (double, float or complex) as the second term (multiplier, subtrahend or divisor). In this case, each member of the matrix or vector will operate on the specified scalar.

```
   matrix matrix_a={{0.1,0.2,0.3},{0.4,0.5,0.6}};
   matrix matrix_b={{1,2,3},{4,5,6}};

   matrix matrix_c1=matrix_a+matrix_b;
   matrix matrix_c2=matrix_b-matrix_a;
   matrix matrix_c3=matrix_a*matrix_b;    // Hadamard product, not to be confused with m
   matrix matrix_c4=matrix_b/matrix_a;

   matrix_c1=matrix_a+1;
   matrix_c2=matrix_b-double_value;
   matrix_c3=matrix_a*M_PI;
   matrix_c4=matrix_b/0.1;

//--- operations in place are possible
   matrix_a+=matrix_b;
   matrix_a/=2;
```

The same operations are available for vectors.

Mathematical functions

The following mathematical functions can be applied to matrices and vectors: MathAbs, MathArccos, MathArcsin, MathArctan, MathCeil, MathCos, MathExp, MathFloor, MathLog, MathLog10, MathMod, MathPow, MathRound, MathSin, MathSqrt, MathTan, MathExpm1, MathLog1p, MathArccosh, MathArcsinh, MathArctanh, MathCosh, MathSinh, MathTanh. Such operations imply element-wise processing of matrices and vectors.

For MathMod and MathPow, the second element can be either a scalar or a matrix/vector of the appropriate size.

```
   matrix<T> mat1(128,128);
   matrix<T> mat3(mat1.Rows(),mat1.Cols());
   ulong     n,size=mat1.Rows()*mat1.Cols();
...
   mat2=MathPow(mat1,(T)1.9);
   for(n=0; n<size; n++)
     {
      T res=MathPow(mat1.Flat(n),(T)1.9);
      if(res!=mat2.Flat(n))
         errors++;
     }
   mat2=MathPow(mat1,mat3);
   for(n=0; n<size; n++)
     {
      T res=MathPow(mat1.Flat(n),mat3.Flat(n));
      if(res!=mat2.Flat(n))
         errors++;
     }
...
   vector<T> vec1(16384);
   vector<T> vec3(vec1.Size());
   ulong     n,size=vec1.Size();
...
   vec2=MathPow(vec1,(T)1.9);
   for(n=0; n<size; n++)
     {
      T res=MathPow(vec1[n],(T)1.9);
      if(res!=vec2[n])
         errors++;
     }
   vec2=MathPow(vec1,vec3);
   for(n=0; n<size; n++)
     {
      T res=MathPow(vec1[n],vec3[n]);
      if(res!=vec2[n])
         errors++;
     }
```

Matrix and vector products

Matrix and vector product calculations include:

- matrix multiplication
- vector multiplication
- computing covariance matrix
- computing the cross-correlation of two vectors
- computing the convolution of two vectors
- computing the correlation coefficient

Function	Action
MatMul	Matrix product of two matrices
GeMM	General matrix multiplication (GeMM)
Power	Raise a square matrix to the integer power
Dot	Dot product of two vectors
Kron	Return Kronecker product of two matrices, matrix and vector, vector and matrix or two vectors
Inner	Inner product of two matrices
Outer	Compute the outer product of two matrices or two vectors
CorrCoef	Compute the Pearson correlation coefficient (linear correlation coefficient)
Cov	Compute the covariance matrix
Correlate	Compute the cross-correlation of two vectors
Convolve	Return the discrete, linear convolution of two vectors

MatMul

The MatMul method, which enables the multiplication of matrices and vectors, has several overloads.

Multiplying a matrix by a matrix: `matrix[M][K] * matrix[K][N] = matrix[M][N]`

```
matrix  matrix::MatMul(
  const matrix&  b      // second matrix
   );
```

Multiplying a vector by a matrix: `horizontal vector[K] * matrix[K][N] = horizontal vector[N]`

```
vector  vector::MatMul(
  const matrix&  b      // matrix
   );
```

Multiplying a matrix by a vector: `matrix[M][K] * vertical vector[K] = vertical vector[M]`

```
vector  matrix::MatMul(
  const vector&  b      // vector
   );
```

Scalar vector multiplication: `horizontal vector * vertical vector = dot value`

```
scalar  vector::MatMul(
  const vector&  b      // second vector
   );
```

Parameters

b

[in] Matrix or vector.

Return Value

Matrix, vector, or scalar, depending on the method used.

Note

The matrices should be compatible for multiplication, i.e. the number of columns in the first matrix should be equal to the number of rows in the second matrix. Matrix multiplication is non-commutative: the result of multiplying the first matrix by the second one is not equal to the result of multiplying the second matrix by the first one in the general case.

The matrix product consists of all possible combinations of scalar products of the row vectors of the first matrix and the column vectors of the second matrix.

In scalar multiplication, vectors must have the same length.

When multiplying a vector and a matrix, the length of the vector must exactly match the number of columns in the matrix.

Naive matrix multiplication algorithm in MQL5:

```
matrix MatrixProduct(const matrix& matrix_a, const matrix& matrix_b)
  {
   matrix matrix_c;

   if(matrix_a.Cols()!=matrix_b.Rows())
      return(matrix_c);

   ulong M=matrix_a.Rows();
   ulong K=matrix_a.Cols();
   ulong N=matrix_b.Cols();
   matrix_c=matrix::Zeros(M,N);

   for(ulong m=0; m<M; m++)
      for(ulong k=0; k<K; k++)
         for(ulong n=0; n<N; n++)
            matrix_c[m][n]+=matrix_a[m][k]*matrix_b[k][n];

   return(matrix_c);
  }
```

Matrix multiplication example

```
   matrix a={{1, 0, 0},
             {0, 1, 0}};
   matrix b={{4, 1},
             {2, 2},
             {1, 3}};
   matrix c1=a.MatMul(b);
   matrix c2=b.MatMul(a);
   Print("c1 = \n", c1);
   Print("c2 = \n", c2);
/*
   c1 =
   [[4,1]
    [2,2]]
   c2 =
   [[4,1,0]
    [2,2,0]
    [1,3,0]]
*/
```

An example of multiplying a horizontal vector by a matrix

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
```

```
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create a 3x5 matrix
   matrix m35;
   m35.Init(3, 5, Arange);
//---
   vector v3 = {1, 2, 3};
   Print("Product of horizontal vector v and matrix m[3,5]");
   Print("On the left, vector v3 = ", v3);
   Print("On the right, matrix m35 = \n", m35);
   Print("v3.MatMul(m35) = horizontal vector v[5] \n", v3.MatMul(m35));

  /* Result
    Product of horizontal vector v3 and matrix m[3,5]
    On the left, vector v3 = [1,2,3]
    On the right, matrix m35 =
    [[0,1,2,3,4]
     [5,6,7,8,9]
     [10,11,12,13,14]]
    v3.MatMul(m35) = horizontal vector v[5]
    [40,46,52,58,64]
   */
  }
//+------------------------------------------------------------------+
//|  Fill the matrix with increasing values                          |
//+------------------------------------------------------------------+
void Arange(matrix & m, double start = 0, double step = 1)
  {
//---
   ulong cols = m.Cols();
   ulong rows = m.Rows();
   double value = start;
   for(ulong r = 0; r < rows; r++)
     {
      for(ulong c = 0; c < cols; c++)
        {
         m[r][c] = value;
         value += step;
        }
     }
//---
  }
```

An example of how to multiply a matrix by a vertical vector

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
```

```
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create a 3x5 matrix
   matrix m35;
   m35.Init(3, 5, Arange);
//---
   Print("Product of matrix m[3,5] and vertical vector v[5]");
   vector v5 = {1,2,3,4,5};
   Print("On the left, m35 = \n",m35);
   Print("On the right v5 = ",v5);
   Print("m35.MatMul(v5) = vertical vector v[3] \n",m35.MatMul(v5));

  /* Result
   Product of matrix m[3,5] and vertical vector v[5]
   On the left, m35 =
   [[0,1,2,3,4]
    [5,6,7,8,9]
    [10,11,12,13,14]]
   On the right, v5 = [1,2,3,4,5]
   m35.MatMul(v5) = vertical vector v[3]
   [40,115,190]
   */
  }
//+------------------------------------------------------------------+
//|  Fill the matrix with increasing values                          |
//+------------------------------------------------------------------+
void Arange(matrix & m, double start = 0, double step = 1)
  {
//---
   ulong cols = m.Cols();
   ulong rows = m.Rows();
   double value = start;
   for(ulong r = 0; r < rows; r++)
     {
      for(ulong c = 0; c < cols; c++)
        {
         m[r][c] = value;
         value += step;
        }
     }
//---
  }
```

An example of scalar (dot) product of vectors

```
void OnStart()
  {
```

```
//--- scalar product of a horizontal vector and a vertical one
   vector a= {1, 2, 3};  // horizontal vector
   vector b= {4, 5, 6};  // vertical vector
   Print("a = ", a);
   Print("b = ", b);
   Print("1) a.MatMul(b) = ", a.MatMul(b));
   //--- see that the Dot method generates the same result
   Print("2) a.Dot(b) = ", a.Dot(b));

  /* Result
   a = [1,2,3]
   b = [4,5,6]
   1) a.MatMul(b) = 32.0
   2) a.Dot(b) = 32.0
    */
  }
```

Dot, GeMM

GeMM

The GeMM (General Matrix Multiply) method implements the general multiplication of two matrices. The operation is defined as C ← α A B + β C , where A and B matrices can be optionally transposed. With a normal multiplication of matrices AB (MatMul), the *alpha* scalar is assumed to be equal to 1 and *beta* equal to zero.

The main difference between GeMM and MatMul in terms of efficiency is that MatMul always creates a new matrix/vector object, while GeMM works with an existing matrix object and does not re-create it. Therefore, when you use GeMM and pre-allocate memory for the corresponding matrix, then, while working with the same matrix sizes, there will be no memory reallocations. This can be an important advantage of GeMM for bulk computing, for example, when running optimizations in a strategy tester or when training a neural network.

Similar to MatMul, GeMM also has 4 overloads. However, the semantics of the fourth overload has been modified in order to enable the multiplication of a vertical vector with a and horizontal one.

In an existing matrix/vector object, it is not necessary to pre-allocate memory. The memory will be allocated and filled with zeros at the first GeMM call.

Multiplying a matrix by a matrix: `matrix C[M][N] = α * ( matrix A[M][K] * matrix B[K][N]) + β * matrix C[M][N]`

```
bool  matrix::GeMM(
  const matrix &A,     // first matrix
  const matrix &B,     // second matrix
  double alpha,        // alpha multiplier for product AB
  double beta,         // beta multiplier for matrix C
  uint   flags         // a combination of ENUM_GEMM values (bitwise OR), which determi
   );
```

Multiplying a vector by a matrix: `vector C[N] = α * ( vector A[K] * matrix B[K][N]) + β * vector C[N]`

```
bool  vector::GeMM(
  const vector &A,     // horizontal vector
  const matrix &B,     // matrix
  double alpha,        // alpha multiplier for product AB
  double beta,         // beta multiplier for vector C
  uint   flags         // ENUM_GEMM enumeration value that determines whether matrix A
   );
```

Multiplying a matrix by a vector: `vector C[M] = α * ( matrix A[M][K] * vector B[K] * ) + β * vector C[M]`

```
bool  vector::GeMM(
  const matrix &A,     // matrix
  const vector &B,     // vertical vector
  double alpha,        // alpha multiplier for product AB
  double beta,         // beta multiplier for vector C
  uint   flags         // ENUM_GEMM enumeration value that determines whether matrix B
   );
```

Multiplying a vector by a vector: `matrix C[M][N] = α * ( vector A[M] * vector B[N] * ) + β * matrix C[M][N]`. This overload returns a matrix, unlike MatMul where it returns a scalar.

```
bool  matrix::GeMM(
  const vector &A,     // first vector
  const vector &B,     // second vector
  double alpha,        // alpha multiplier for product AB
  double beta,         // beta for matrix C
  uint   flags         // ENUM_GEMM enumeration value that determines whether matrix C
   );
```

Parameters

A

[in] Matrix or vector.

B

[in] Matrix or vector.

alpha

[in] Alpha multiplier for the AB product.

beta

[in] Beta multiplier for the resulting C matrix.

flags

[in] The ENUM_GEMM enumeration value that determines whether matrices A, B and C are transposed.

Return Value

Returns true on success or false otherwise.

ENUM_GEMM

Enumeration of flags for the GeMM method.

ID	Description
TRANSP_A	Use transposed matrix A
TRANSP_B	Use transposed matrix B
TRANSP_C	Use transposed matrix C

Note

Matrices and vectors of float, double and complex types can be used as parameters A and B. The template variants of the GeMM method are as follows:

```
bool matrix<T>::GeMM(const matrix<T> &A,const matrix<T> &B,T alpha,T beta,ulong flags)
```

```
bool matrix<T>::GeMM(const vector<T> &A,const vector<T> &B,T alpha,T beta,ulong flags)

bool vector<T>::GeMM(const vector<T> &A,const matrix<T> &B,T alpha,T beta,ulong flags)
bool vector<T>::GeMM(const matrix<T> &A,const vector<T> &B,T alpha,T beta,ulong flags)
```

Basically the general matrix multiplication function is described as:

```
C[m,n] = α *Sum(A[m,k]*B[k,n]) + β*C[m,n]
```

with the following sizes: matrix A is M x K, matrix B is K x N and matrix C is M x N.

Thus, the matrices should be compatible for multiplication, i.e. the number of columns in the first matrix should be equal to the number of rows in the second matrix. Matrix multiplication is non-commutative: the result of multiplying the first matrix by the second one is not equal to the result of multiplying the second matrix by the first one in the general case.

Example:

```
void OnStart()
  {
   vector vector_a= {1, 2, 3, 4, 5};
   vector vector_b= {4, 3, 2, 1};
   matrix matrix_c;
//--- calculate GeMM for two vectors
   matrix_c.GeMM(vector_a, vector_b, 1, 0);
   Print("matrix_c:\n ", matrix_c, "\n");
   /*
   matrix_c:
    [[4,3,2,1]
    [8,6,4,2]
    [12,9,6,3]
    [16,12,8,4]
    [20,15,10,5]]
   */
//--- create matrices as vectors
   matrix matrix_a(5, 1);
   matrix matrix_b(1, 4);
   matrix_a.Col(vector_a, 0);
   matrix_b.Row(vector_b, 0);
   Print("matrix_a:\n ", matrix_a);
   Print("matrix_b:\n ", matrix_b);
   /*
   matrix_a:
   [[1]
   [2]
   [3]
   [4]
```

```
    [5]]
    matrix_b:
    [[4,3,2,1]]
    */
//-- calculate GeMM for two matrices and get the same result
    matrix_c.GeMM(matrix_a, matrix_b, 1, 0);
    Print("matrix_c:\n ", matrix_c);
    /*
    matrix_c:
     [[4,3,2,1]
     [8,6,4,2]
     [12,9,6,3]
     [16,12,8,4]
     [20,15,10,5]]
    */
  }
```

See also

MatMul

Power

Raise a square matrix to the integer power.

```
matrix matrix::Power(
  const int  power      // power
   );
```

Parameters

power

[in] The exponent can be any integer, positive, negative, or zero.

Return Value

Matrix.

Note

The resulting matrix has the same size as the original matrix. In raised to the power of 0, the identity matrix is returned. The positive power n means that the original matrix is multiplied n times by itself. The negative power -n means that the original matrix is first inverted, and then the inverted matrix is multiplied by itself n times.

A simple algorithm for raising a matrix to a power in MQL5:

```
bool MatrixPower(matrix& c, const matrix& a, const int power)
  {
//--- matrix must be square
   if(a.Rows()!=a.Cols())
      return(false);
//--- the size of the resulting matrix is exactly the same
   ulong  rows=a.Rows();
   ulong  cols=a.Cols();
   matrix result(rows,cols);
//--- when raised to zero, return the identity matrix
   if(power==0)
      result.Identity();
   else
     {
      //--- for a negative degree, first invert the matrix
      if(power<0)
        {
         matrix inverted=a.Inv();
         result=inverted;
         for(int i=-1; i>power; i--)
            result=result.MatMul(inverted);
        }
```

```
      else
        {
         result=a;
         for(int i=1; i<power; i++)
            result=result.MatMul(a);
        }
     }
//---
   c=result;
   return(true);
  }
```

MQL5 example:

```
  matrix i= {{0, 1}, {-1, 0}};
  Print("i:\n", i);

  Print("i.Power(3):\n", i.Power(3));

  Print("i.Power(0):\n", i.Power(0));

  Print("i.Power(-3):\n", i.Power(-3));

  /*
  i:
  [[0,1]
   [-1,0]]

  i.Power(3):
  [[0,-1]
   [1,0]]

  i.Power(0):
  [[1,0]
   [0,1]]

  i.Power(-3):
  [[0, -1]
   [1,0]]
  */
```

Python example:

```
import numpy as np
from numpy.linalg import matrix_power

# matrix equiv. of the imaginary unit
```

```
i = np.array([[0, 1], [-1, 0]])
print("i:\n",i)

# should = -i
print("matrix_power(i, 3) :\n",matrix_power(i, 3) )

print("matrix_power(i, 0):\n",matrix_power(i, 0))

# should = 1/(-i) = i, but w/ f.p. elements
print("matrix_power(i, -3):\n",matrix_power(i, -3))

i:
 [[ 0  1]
 [-1  0]]

matrix_power(i, 3) :
 [[ 0 -1]
 [ 1  0]]

matrix_power(i, 0):
 [[1 0]
 [0 1]]

matrix_power(i, -3):
 [[ 0.  1.]
 [-1.  0.]]
```

Dot

Dot product of two vectors.

```
double vector::Dot(
  const vector&  b      // second vector
   );
```

Parameters

b

[in] Vector.

Return Value

Scalar.

Note

The dot product of two matrices is the matrix product matrix::MatMul().

A simple algorithm for the scalar product of vectors in MQL5:

```
double VectorDot(const vector& vector_a, const vector& vector_b)
  {
   double dot=0;

   if(vector_a.Size()==vector_b.Size())
     {
      for(ulong i=0; i<vector_a.Size(); i++)
         dot+=vector_a[i]*vector_b[i];
     }

   return(dot);
  }
```

MQL5 example:

```
   for(ulong i=0; i<rows; i++)
     {
      vector v1=a.Row(i);
      for(ulong j=0; j<cols; j++)
        {
         vector v2=b.Row(j);
         result[i][j]=v1.Dot(v2);
        }
     }
```

Python example:

```
import numpy as np

a = [1, 0, 0, 1]
b = [4, 1, 2, 2]
print(np.dot(a, b))

>>> 6
```

Kron

Return Kronecker product of two matrices, matrix and vector, vector and matrix or two vectors.

```
matrix matrix::Kron(
  const matrix&  b      // second matrix
   );

matrix matrix::Kron(
  const vector&  b      // vector
   );

matrix vector::Kron(
  const matrix&  b      // matrix
   );

matrix vector::Kron(
  const vector&  b      // second vector
   );
```

Parameters

b

[in] second matrix.

Return Value

Matrix.

Note

The Kronecker product is also referred to as the block matrix multiplication.

A simple algorithm for the Kronecker product for two matrices in MQL5:

```
matrix MatrixKronecker(const matrix& matrix_a,const matrix& matrix_b)
  {
   ulong  M=matrix_a.Rows();
   ulong  N=matrix_a.Cols();
   ulong  P=matrix_b.Rows();
   ulong  Q=matrix_b.Cols();
   matrix matrix_c(M*P,N*Q);

   for(ulong m=0; m<M; m++)
      for(ulong n=0; n<N; n++)
         for(ulong p=0; p<P; p++)
            for(ulong q=0; q<Q; q++)
```

```
                matrix_c[m*P+p][n*Q+q]=matrix_a[m][n] * matrix_b[p][q];

   return(matrix_c);
  }
```

MQL5 example:

```
   matrix a={{1,2,3},{4,5,6}};
   matrix b=matrix::Identity(2,2);
   vector v={1,2};

   Print(a.Kron(b));
   Print(a.Kron(v));

  /*
   [[1,0,2,0,3,0]
    [0,1,0,2,0,3]
    [4,0,5,0,6,0]
    [0,4,0,5,0,6]]

   [[1,2,2,4,3,6]
    [4,8,5,10,6,12]]
  */
```

Python example:

```
import numpy as np

A = np.arange(1,7).reshape(2,3)
B = np.identity(2)
V = [1,2]
print(np.kron(A, B))
print("")
print(np.kron(A, V))

[[1. 0. 2. 0. 3. 0.]
 [0. 1. 0. 2. 0. 3.]
 [4. 0. 5. 0. 6. 0.]
 [0. 4. 0. 5. 0. 6.]]

[[ 1  2  2  4  3  6]
 [ 4  8  5 10  6 12]]
```

Inner

Inner product of two matrices.

```
matrix matrix::Inner(
  const matrix&  b      // second matrix
   );
```

Parameters

b

[in] Matrix.

Return Value

Matrix.

Note

The inner product for two vectors is the dot product of the two vectors vector::Dot().

A simple algorithm for the inner product of two matrices in MQL5:

```
bool MatrixInner(matrix& c, const matrix& a, const matrix& b)
  {
//--- the number of columns must equal
   if(a.Cols()!=b.Cols())
      return(false);
//--- size of the resulting matrix depends on the number of vectors in each of the mat
   ulong  rows=a.Rows();
   ulong  cols=b.Rows();
   matrix result(rows,cols);
//---
   for(ulong i=0; i<rows; i++)
     {
      vector v1=a.Row(i);
      for(ulong j=0; j<cols; j++)
        {
         vector v2=b.Row(j);
         result[i][j]=v1.Dot(v2);
        }
     }
//---
   c=result;
   return(true);
  }
```

MQL5 example:

```
   matrix a={{0,1,2},{3,4,5}};
   matrix b={{0,1,2},{3,4,5},{6,7,8}};
   matrix c=a.Inner(b);
   Print(c);
   matrix a1={{0,1,2}};
   matrix c1=a1.Inner(b);
   Print(c1);

  /*
  [[5,14,23]
  [14,50,86]]
  [[5,14,23]]
  */
```

Python example:

```
import numpy as np

A = np.arange(6).reshape(2, 3)
B = np.arange(9).reshape(3, 3)
A1= np.arange(3)
print(np.inner(A, B))
print("");
print(np.inner(A1, B))

import numpy as np

A = np.arange(6).reshape(2, 3)
B = np.arange(9).reshape(3, 3)
A1= np.arange(3)
print(np.inner(A, B))
print("");
print(np.inner(A1, B))
```

Outer

Compute the outer product of two matrices or two vectors.

```
matrix matrix::Outer(
  const matrix&  b      // second matrix
   );

matrix vector::Outer(
  const vector&  b      // second vector
   );
```

Parameters

b

[in] Matrix.

Return Value

Matrix.

Note

The outer product, like the Kronecker product, is also a block matrix (and vector) multiplication.

A simple algorithm for the outer product of two matrices in MQL5:

```
matrix MatrixOuter(const matrix& matrix_a, const matrix& matrix_b)
  {
//--- size of the resulting matrix depends on the matrix sizes
   ulong  rows=matrix_a.Rows()*matrix_a.Cols();
   ulong  cols=matrix_b.Rows()*matrix_b.Cols();
   matrix matrix_c(rows,cols);
   ulong  cols_a=matrix_a.Cols();
   ulong  cols_b=matrix_b.Cols();
//---
   for(ulong i=0; i<rows; i++)
     {
      ulong row_a=i/cols_a;
      ulong col_a=i%cols_a;
      for(ulong j=0; j<cols; j++)
        {
         ulong row_b=j/cols_b;
         ulong col_b=j%cols_b;
         matrix_c[i][j]=matrix_a[row_a][col_a] * matrix_b[row_b][col_b];
        }
     }
```

```
//---
   return(matrix_c);
  }
```

MQL5 example:

```
   vector vector_a={0,1,2,3,4,5};
   vector vector_b={0,1,2,3,4,5,6};
   Print("vector_a.Outer\n",vector_a.Outer(vector_b));
   Print("vector_a.Kron\n",vector_a.Kron(vector_b));

   matrix matrix_a={{0,1,2},{3,4,5}};
   matrix matrix_b={{0,1,2},{3,4,5},{6,7,8}};
   Print("matrix_a.Outer\n",matrix_a.Outer(matrix_b));
   Print("matrix_a.Kron\n",matrix_a.Kron(matrix_b));

  /*
   vector_a.Outer
   [[0,0,0,0,0,0,0]
    [0,1,2,3,4,5,6]
    [0,2,4,6,8,10,12]
    [0,3,6,9,12,15,18]
    [0,4,8,12,16,20,24]
    [0,5,10,15,20,25,30]]
   vector_a.Kron
   [[0,0,0,0,0,0,0,0,1,2,3,4,5,6,0,2,4,6,8,10,12,0,3,6,9,12,15,18,0,4,8,12,16,20,24,0,
   matrix_a.Outer
   [[0,0,0,0,0,0,0,0,0]
    [0,1,2,3,4,5,6,7,8]
    [0,2,4,6,8,10,12,14,16]
    [0,3,6,9,12,15,18,21,24]
    [0,4,8,12,16,20,24,28,32]
    [0,5,10,15,20,25,30,35,40]]
   matrix_a.Kron
   [[0,0,0,0,1,2,0,2,4]
    [0,0,0,3,4,5,6,8,10]
    [0,0,0,6,7,8,12,14,16]
    [0,3,6,0,4,8,0,5,10]
    [9,12,15,12,16,20,15,20,25]
    [18,21,24,24,28,32,30,35,40]]
   */
```

Python example:

```
import numpy as np

A = np.arange(6)
```

```
B = np.arange(7)
print("np.outer")
print(np.outer(A, B))
print("np.kron")
print(np.kron(A, B))

A = np.arange(6).reshape(2, 3)
B = np.arange(9).reshape(3, 3)
print("np.outer")
print(np.outer(A, B))
print("np.kron")

np.outer
[[ 0  0  0  0  0  0  0]
 [ 0  1  2  3  4  5  6]
 [ 0  2  4  6  8 10 12]
 [ 0  3  6  9 12 15 18]
 [ 0  4  8 12 16 20 24]
 [ 0  5 10 15 20 25 30]]
np.kron
[ 0  0  0  0  0  0  0  0  1  2  3  4  5  6  0  2  4  6  8 10 12  0  3  6
  9 12 15 18  0  4  8 12 16 20 24  0  5 10 15 20 25 30]
np.outer
[[ 0  0  0  0  0  0  0  0  0]
 [ 0  1  2  3  4  5  6  7  8]
 [ 0  2  4  6  8 10 12 14 16]
 [ 0  3  6  9 12 15 18 21 24]
 [ 0  4  8 12 16 20 24 28 32]
 [ 0  5 10 15 20 25 30 35 40]]
np.kron
[[ 0  0  0  0  1  2  0  2  4]
 [ 0  0  0  3  4  5  6  8 10]
 [ 0  0  0  6  7  8 12 14 16]
 [ 0  3  6  0  4  8  0  5 10]
 [ 9 12 15 12 16 20 15 20 25]
 [18 21 24 24 28 32 30 35 40]]
```

CorrCoef

Compute the Pearson correlation coefficient (linear correlation coefficient).

```
matrix matrix::CorrCoef(
  const bool    rowvar=true  // rows or cols vectors of observations
);

scalar vector::CorrCoef(
  const vector&  b           // second vector
);
```

Return Value

Pearson product-moment correlation coefficients.

Note

The correlation coefficient is in the range [-1, 1].

Due to floating point rounding the resulting array may not be Hermitian, the diagonal elements may not be 1, and the elements may not satisfy the inequality abs(a) <= 1. The real and imaginary parts are clipped to the interval [-1, 1] in an attempt to improve on that situation but is not much help in the complex case.

A simple algorithm for calculating the correlation coefficient of two vectors using MQL5:

```
double VectorCorrelation(const vector& vector_x,const vector& vector_y)
  {
   ulong n=vector_x.Size()<vector_y.Size() ? vector_x.Size() : vector_y.Size();
   if(n<=1)
      return(0);

   ulong  i;
   double xmean=0;
   double ymean=0;
   for(i=0; i<n; i++)
     {
      if(!MathIsValidNumber(vector_x[i]))
         return(0);
      if(!MathIsValidNumber(vector_y[i]))
         return(0);
      xmean+=vector_x[i];
      ymean+=vector_y[i];
     }
   xmean/=(double)n;
   ymean/=(double)n;
```

```
   double s=0;
   double xv=0;
   double yv=0;
   double t1=0;
   double t2=0;
//--- calculation
   s=0;
   for(i=0; i<n; i++)
     {
      t1=vector_x[i]-xmean;
      t2=vector_y[i]-ymean;
      xv+=t1*t1;
      yv+=t2*t2;
      s+=t1*t2;
     }
//--- check
   if(xv==0 || yv==0)
      return(0);
//--- return result
   return(s/(MathSqrt(xv)*MathSqrt(yv)));
  }
```

MQL5 example:

```
   vectorf vector_a={1,2,3,4,5};
   vectorf vector_b={0,1,0.5,2,2.5};
   Print("vectors correlation ",vector_a.CorrCoef(vector_b));
//---
   matrixf matrix_a={{1,2,3,4,5},
                     {0,1,0.5,2,2.5}};
   Print("matrix rows correlation\n",matrix_a.CorrCoef());
   matrixf matrix_a2=matrix_a.Transpose();
   Print("transposed matrix cols correlation\n",matrix_a2.CorrCoef(false));
   matrixf matrix_a3={{1.0f, 2.0f, 3.0f, 4.0f, 5.0f},
                      {0.0f, 1.0f, 0.5f, 2.0f, 2.5f},
                      {0.1f, 1.0f, 2.0f, 1.0f, 0.3f}};
   Print("rows correlation\n",matrix_a3.CorrCoef());
   Print("cols correlation\n",matrix_a3.CorrCoef(false));

  /*

 [0.83773586 0.88385151 0.92527551 0.98827406 1.        ]]
```

Cov

Compute the covariance matrix.

```
matrix matrix::Cov(
  const bool    rowvar=true  // rows or cols vectors of observations
);

matrix vector::Cov(
  const vector&  b           // second vector
);
```

Parameters

b

[in] Second vector.

Note

Compute the covariance matrix.

A simple algorithm for calculating the covariance matrix of two vectors using MQL5:

```
bool VectorCovariation(const vector& vector_a,const vector& vector_b,matrix& matrix_c)
  {
   int i,j;
   int m=2;
   int n=(int)(vector_a.Size()<vector_b.Size()?vector_a.Size():vector_b.Size());
//--- checks
   if(n<=1)
      return(false);
   for(i=0; i<n; i++)
     {
      if(!MathIsValidNumber(vector_a[i]))
         return(false);
      if(!MathIsValidNumber(vector_b[i]))
         return(false);
     }
//---
   matrix matrix_x(2,n);
   matrix_x.Row(vector_a,0);
   matrix_x.Row(vector_b,1);
   vector t=vector::Zeros(m);
//--- calculation
   for(i=0; i<m; i++)
      for(j=0; j<n; j++)
         t[i]+=matrix_x[i][j]/double(n);
   for(i=0; i<m; i++)
      for(j=0; j<n; j++)
```

```
         matrix_x[i][j]-=t[i];
//--- syrk C=alpha*A^H*A+beta*C (beta=0 and not considered)
   matrix_c=matrix::Zeros(m,m);
   for(i=0; i<m; i++)
     {
      for(j=0; j<n; j++)
        {
         double v=matrix_x[i][j]/(n-1);
         for(int i_=i; i_<m; i_++)
            matrix_c[i][i_]+=v*matrix_x[i_][j];
        }
     }
//--- force symmetricity
   for(i=0; i<m-1; i++)
      for(j=i+1; j<m; j++)
         matrix_c[j][i]=matrix_c[i][j];
//---
   return(true);
  }
```

MQL5 example:

```
   matrix matrix_a={{3,-2.1},{1.1,-1},{0.12,4.3}};
   Print("covariation cols\n",matrix_a.Cov(false));
   Print("covariation rows\n",matrix_a.Cov());

   vector vector_a=matrix_a.Col(0);
   vector vector_b=matrix_a.Col(1);
   Print("covariation vectors\n",vector_a.Cov(vector_b));

  /*
   covariation cols
   [[2.144133333333333,-4.286]
    [-4.286,11.71]]
   covariation rows

    [-10.659,-4.389,8.736199999999998]]
   covariation vectors
   [[2.144133333333333,-4.286]
    [-4.286,11.71]]
  */
```

Python example:

```
import numpy as np
matrix_a=np.array([[3,-2.1],[1.1,-1],[0.12,4.3]])
```

```
matrix_c=np.cov(matrix_a,rowvar=False)
print("covariation cols\n",matrix_c)
matrix_c2=np.cov(matrix_a)
print("covariation rows\n",matrix_c2)

vector_a=matrix_a[:,0]
vector_b=matrix_a[:,1]
matrix_c3=np.cov(vector_a,vector_b)
print("covariation vectors\n",matrix_c3)

covariation cols
 [[ 2.14413333 -4.286     ]
 [-4.286      11.71      ]]
covariation rows
 [[ 13.005    5.355  -10.659 ]
 [  5.355    2.205   -4.389 ]
 [-10.659   -4.389    8.7362]]
covariation vectors
 [[ 2.14413333 -4.286     ]
 [-4.286      11.71      ]]
```

Correlate

Compute the cross-correlation of two vectors.

```
vector vector::Correlate(
  const vector&           v,        // vector
  ENUM_VECTOR_CONVOLVE    mode      // mode
   );
```

Parameters

v

[in] Second vector.

mode

[in] The 'mode' parameter determines the linear convolution calculation mode. Value from the ENUM_VECTOR_CONVOLVE enumeration.

Return Value

Cross-correlation of two vectors.

Note

The 'mode' parameter determines the linear convolution calculation mode.

A simple algorithm for calculating the correlation coefficient of two vectors using MQL5:

```
vector VectorCrossCorrelationFull(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=m+n-1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
      for(int i_=i; i_<i+m; i_++)
         c[i_]+=b[n-i-1]*a[i_-i];

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorCrossCorrelationSame(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n);
   vector c=vector::Zeros(size);
```

```
   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-size/2+1;
         if(k>=0 && k<size)
            c[k]+=b[n-i-1]*a[i_-i];
        }
     }

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorCrossCorrelationValid(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n)-MathMin(m,n)+1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-n+1;
         if(k>=0 && k<size)
            c[k]+=b[n-i-1]*a[i_-i];
        }
     }

   return(c);
  }
```

MQL5 example:

```
   vector a={1,2,3,4,5};
   vector b={0,1,0.5};

   Print("full\n",a.Correlate(b,VECTOR_CONVOLVE_FULL));
   Print("same\n",a.Correlate(b,VECTOR_CONVOLVE_SAME));
   Print("valid\n",a.Correlate(b,VECTOR_CONVOLVE_VALID));
   Print("full\n",b.Correlate(a,VECTOR_CONVOLVE_FULL));

  /*
   full
```

```
   [0.5,2,3.5,5,6.5,5,0]
   same
   [2,3.5,5,6.5,5]
   valid
   [3.5,5,6.5]
   full
   [0,5,6.5,5,3.5,2,0.5]
  */
```

Python example:

```
import numpy as np
a=[1,2,3,4,5]
b=[0,1,0.5]

print("full\n",np.correlate(a,b,'full'))
print("same\n",np.correlate(a,b,'same'));
print("valid\n",np.correlate(a,b,'valid'));
print("full\n",np.correlate(b,a,'full'))

full
 [0.5 2.  3.5 5.  6.5 5.  0. ]
same
 [2.  3.5 5.  6.5 5. ]
valid
 [3.5 5.  6.5]
full
 [0.  5.  6.5 5.  3.5 2.  0.5]
```

Convolve

Return the discrete, linear convolution of two vectors

```
vector vector::Convolve(
  const vector&            v,         // vector
  ENUM_VECTOR_CONVOLVE     mode       // mode
   );
```

Parameters

v

[out] Second vector.

mode

[in] The 'mode' parameter determines the linear convolution calculation mode ENUM_VECTOR_CONVOLVE.

Return Value

Discrete, linear convolution of two vectors.

A simple algorithm for calculating the convolution of two vectors in MQL5:

```
vector VectorConvolutionFull(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionFull(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=m+n-1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
      for(int i_=i; i_<i+m; i_++)
         c[i_]+=b[i]*a[i_-i];

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorConvolutionSame(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionSame(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
```

```
   int    size=MathMax(m,n);
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-size/2+1;
         if(k>=0 && k<size)
            c[k]+=b[i]*a[i_-i];
        }
     }

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorConvolutionValid(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionValid(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n)-MathMin(m,n)+1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-n+1;
         if(k>=0 && k<size)
            c[k]+=b[i]*a[i_-i];
        }
     }

   return(c);
  }
```

MQL5 example:

```
  vector a= {1, 2, 3, 4, 5};
  vector b= {0, 1, 0.5};

  Print("full\n", a.Convolve(b, VECTOR_CONVOLVE_FULL));
  Print("same\n", a.Convolve(b, VECTOR_CONVOLVE_SAME));
```

```
  Print("valid\n", a.Convolve(b, VECTOR_CONVOLVE_VALID));

  /*
   full
   [0,1,2.5,4,5.5,7,2.5]
   same
   [1,2.5,4,5.5,7]
   valid
   [2.5,4,5.5]
  */
```

Python example:

```
import numpy as np
a=[1,2,3,4,5]
b=[0,1,0.5]

print("full\n",np.convolve(a,b,'full'))
print("same\n",np.convolve(a,b,'same'));
print("valid\n",np.convolve(a,b,'valid'));

full
 [0.  1.  2.5 4.  5.5 7.  2.5]
same
 [1.  2.5 4.  5.5 7. ]
valid
 [2.5 4.  5.5]
```

Matrix transformations

Matrix decomposition can be used in the following cases:

- as an intermediate step when solving systems of linear equations
- for matrix inversion
- when calculating determinants
- when finding eigenvalues and eigenvectors of a matrix
- when computing analytic functions of matrices
- when using the least squares method
- in the numerical solution of differential equations

Different matrix decomposition types are used depending on the problem.

Function	Action
Cholesky	Computes the Cholesky decomposition
Eig	Computes the eigenvalues and right eigenvectors of a square matrix
EigVals	Computes the eigenvalues of a general matrix
LU	LU factorization of a matrix as the product of a lower triangular matrix and an upper triangular matrix
LUP	LUP factorization with partial pivoting, which refers to LU decomposition with row permutations only: PA=LU
QR	Compute the qr factorization of a matrix
SVD	Singular Value Decomposition

Cholesky

Compute the Cholesky decomposition.

```
bool matrix::Cholesky(
  matrix&  L      // matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

Return Value

Returns true on success, false otherwise.

Note

Return the Cholesky decomposition, L * L.H, of the square matrix a, where L is lower-triangular and .H is the conjugate transpose operator (which is the ordinary transpose if a is real-valued). a must be Hermitian (symmetric if real-valued) and positive-definite. No checking is performed to verify whether a is Hermitian or not. In addition, only the lower-triangular and diagonal elements of a are used. Only L is actually returned.

Example

```
matrix matrix_a= {{5.7998084, -2.1825367}, {-2.1825367, 9.85910595}};
matrix matrix_l;
Print("matrix_a\n", matrix_a);

matrix_a.Cholesky(matrix_l);
Print("matrix_l\n", matrix_l);
Print("check\n", matrix_l.MatMul(matrix_l.Transpose()));

/*
matrix_a
[[5.7998084,-2.1825367]
 [-2.1825367,9.85910595]]
matrix_l
[[2.408279136645086,0]
 [-0.9062640068544704,3.006291985133859]]
check
[[5.7998084,-2.1825367]
 [-2.1825367,9.85910595]]
*/
```

Eig

Compute the eigenvalues and right eigenvectors of a square matrix.

```
bool matrix::Eig(
  matrix&  eigen_vectors,     // matrix of eigenvectors
  vector&  eigen_values       // vector of eigenvalues
   );
```

Parameters

eigen_vectors

[out] Matrix of vertical eigenvectors.

eigen_values

[out] Vector of eigenvalues.

Return Value

Returns true on success, false otherwise.

Example

```
#property script_show_inputs
//--- input parameters
input int  InpSize1   =512;
input int  InpSize2   =256;
input int  InpSize3   =1024;
//+------------------------------------------------------------------+
//| Filling the test square invertible matrix                        |
//+------------------------------------------------------------------+
template<typename T>
void MatrixFill(matrix<T> &matrix_a)
 {
  ulong size_m=matrix_a.Rows();
  ulong size_k=matrix_a.Cols();
  T     value=0.0;
//--- fill the matrix
  for(ulong i=0; i<size_m; i++)
   {
    for(ulong j=0; j<size_k; j++)
     {
      if(i==j)
        matrix_a[i][j]=T(1.0+i);
      else
       {
        value+=1.0;
        matrix_a[i][j]=value;
       }
     }
```

```
   }
 }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

Test passed
*/

//+------------------------------------------------------------------+
//|  Testing the Eig method                                          |
//+------------------------------------------------------------------+
template<typename T>
int TestEigen(const int size_m)
 {
  int vectors=0;
  matrix<T> matrix_a(size_m, size_m);
  matrix<T> matrix_v(size_m, size_m);
  vector<T> vector_e(size_m);
//--- populate the square matrix
  MatrixFill(matrix_a);
//--- microseconds will be measured
  ulong t1=GetMicrosecondCount();
//--- Eigen Solver
  matrix_a.Eig(matrix_v, vector_e);
```

```
//--- measure
  ulong t2=GetMicrosecondCount();
//--- check if A * v = lambda * v
  for(ulong n=0; n<vector_e.Size(); n++)
   {
    vector<T> eigen_vector=matrix_v.Col(n);
    vector<T> vector_c1   =eigen_vector*vector_e[n];
    vector<T> vector_c2   =matrix_a.MatMul(eigen_vector);

    //--- too many devisions, weaken the precision check down to 10th digit
    ulong errors=vector_c1.CompareByDigits(vector_c2, sizeof(T)==sizeof(double) ? 10 :
    if(int(errors)<size_m/10)
      vectors++;
   }
  double elapsed_time=double(t2-t1)/1000.0;
  printf("Eigen solver of %s matrix %d x %d  %s  vectors=%d  time=%.3f ms",
         typename(T), size_m, size_m, vectors>0?"passed":"failed", vectors, elapsed_ti
  return(vectors==0);
 }
```

EigVals

Compute the eigenvalues of a general matrix.

```
bool matrix::EigVals(
  vector&  eigen_values      // vector of eigenvalues
   );
```

Parameters

eigen_values

[out] Vector of right eigenvalues.

Return Value

Returns true on success, false otherwise.

Note

The only difference between EigVals and Eig is that EigVals does not calculate eigenvectors, while it only calculates eigenvalues.

LU

LU factorization of a matrix as the product of a lower triangular matrix and an upper triangular matrix.

```
bool matrix::LU(
  matrix&  L,      // lower triangular matrix
  matrix&  U       // upper triangular matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

U

[out] Upper triangular matrix.

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,2,6,7},
                    {8,9,3,10},
                    {11,12,14,4}};
   matrix matrix_l,matrix_u;
//--- LU decomposition
   matrix_a.LU(matrix_l,matrix_u);
   Print("matrix_l\n",matrix_l);
   Print("matrix_u\n",matrix_u);
//--- check if A = L * U
   Print("check\n",matrix_l.MatMul(matrix_u));

   */
```

LUP

LUP factorization with partial pivoting, which refers to LU decomposition with row permutations only: PA=LU.

```
bool  LUP(
  matrix&  L,      // lower triangular matrix
  matrix&  U,      // upper triangular matrix
  matrix&  P       // permutations matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

U

[out] Upper triangular matrix.

P

[out] Permutations matrix

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,2,6,7},
                    {8,9,3,10},
                    {11,12,14,4}};
   matrix matrix_l,matrix_u,matrix_p;
//--- LUP decomposition
   matrix_a.LUP(matrix_l,matrix_u,matrix_p);
   Print("matrix_l\n",matrix_l);
   Print("matrix_u\n",matrix_u);
   Print("matrix_p\n",matrix_p);
//--- check if P * A = L * U
   Print("P * A\n",matrix_p.MatMul(matrix_a));
   Print("L * U\n",matrix_l.MatMul(matrix_u));

  */
```

QR

Compute the qr factorization of a matrix.

```
bool  QR(
  matrix&  Q,      // matrix with orthonormal columns
  matrix&  R       // upper-triangular matrix
   );
```

Parameters

Q

[out] A matrix with orthonormal columns. When mode = 'complete' the result is an orthogonal/unitary matrix depending on whether or not a is real/complex. The determinant may be either +/- 1 in that case. In case the number of dimensions in the input array is greater than 2 then a stack of the matrices with above properties is returned.

R key

[out] Upper triangular matrix.

Return Value

Returns true on success, false otherwise.

Example

```
//---  A*x = b
  matrix A = {{0, 1}, {1, 1}, {1, 1}, {2, 1}};
  Print("A \n", A);
  vector b = {1, 2, 2, 3};
  Print("b \n", b);
//--- A = Q*R
  matrix q, r;
  A.QR(q, r);
  Print("q \n", q);
  Print("r \n", r);
  matrix qr=q.MatMul(r);
  Print("qr \n", qr);

```

SVD

Singular Value Decomposition.

```
bool matrix::SVD(
  matrix&  U,                    // unitary matrix
  matrix&  V,                    // unitary matrix
  vector&  singular_values       // singular values vector
   );
```

Parameters

U

[out] Unitary matrix of order m, consisting of left singular vectors.

V

[out] Unitary matrix of order n, consisting of right singular vectors.

singular_values

[out] Singular values

Return Value

Returns true on success, false otherwise.

Example

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a=a-4;
  Print("matrix a \n", a);
  a.Reshape(3, 3);
  matrix b=a;
  Print("matrix b \n", b);
//--- execute SVD decomposition
  matrix U, V;
  vector singular_values;
  b.SVD(U, V, singular_values);
  Print("U \n", U);
  Print("V \n", V);
  Print("singular_values = ", singular_values);

// check block
//--- U * singular diagonal * V = A

Statistical methods

Methods for computing descriptive statistics of matrices and vectors.

Function	Action
ArgMax	Return the index of the maximum value
ArgMin	Return the index of the minimum value
Max	Return the maximum value in a matrix/vector
Min	Return the minimum value in a matrix/vector
Ptp	Return the range of values of a matrix/vector or of the given matrix axis
Sum	Return the sum of the matrix/vector elements which can also be performed for the given axis (axes)
Prod	Return the product of the matrix/vector elements which can also be performed for the given axis
CumSum	Return the cumulative sum of matrix/vector elements, including those along the given axis
CumProd	Return the cumulative product of matrix/vector elements, including those along the given axis
Percentile	Return the specified percentile of values of matrix/vector elements or elements along the specified axis
Quantile	Return the specified quantile of values of matrix/vector elements or elements along the specified axis
Median	Compute the median of the matrix/vector elements
Mean	Compute the arithmetic mean of element values
Average	Compute the weighted mean of matrix/vector values
Std	Return the standard deviation of values of matrix/vector elements or of elements along the given axis
Var	Compute the variance of values of matrix/vector elements
LinearRegression	Calculate a vector/matrix with calculated linear regression values

ArgMax

Return the index of the maximum value.

```
ulong vector::ArgMax();

ulong matrix::ArgMax();

vector matrix::ArgMax(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Index of the maximum value.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_max=matrix_a.ArgMax(0);
   vector rows_max=matrix_a.ArgMax(1);
   ulong  matrix_max=matrix_a.ArgMax();

   Print("cols_max=",cols_max);
   Print("rows_max=",rows_max);
   Print("max index ",matrix_max,"  max value ",matrix_a.Flat(matrix_max));

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_max=[0,3,1]
   rows_max=[0,2,0,1]
   max index 5  max value 12.0
   */
```

ArgMin

Return the index of the minimum value.

```
ulong vector::ArgMin();

ulong matrix::ArgMin();

vector matrix::ArgMin(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Index of the minimum value.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_min=matrix_a.ArgMin(0);
   vector rows_min=matrix_a.ArgMin(1);
   ulong  matrix_min=matrix_a.ArgMin();

   Print("cols_min=",cols_min);
   Print("rows_min=",rows_min);
   Print("min index ",matrix_min,"  min value ",matrix_a.Flat(matrix_min));

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_min=[1,0,0]
   rows_min=[2,0,2,0]
   min index 3  min value 1.0
   */
```

Max

Return the maximum value in a matrix/vector.

```
double vector::Max();

double matrix::Max();

vector matrix::Max(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Maximum value in a matrix/vector.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_max=matrix_a.Max(0);
   vector rows_max=matrix_a.Max(1);
   double matrix_max=matrix_a.Max();

   Print("cols_max=",cols_max);
   Print("rows_max=",rows_max);
   Print("max value ",matrix_max);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_max=[10,11,12]
   rows_max=[10,12,6,11]
   max value 12.0
   */
```

Min

Return the minimum value in a matrix/vector.

```
double vector::Min();

double matrix::Min();

vector matrix::Min(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Minimum value in a matrix/vector.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_min=matrix_a.Min(0);
   vector rows_min=matrix_a.Min(1);
   double matrix_min=matrix_a.Min();

   Print("cols_min=",cols_min);
   Print("rows_min=",rows_min);
   Print("min value ",matrix_min);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_min=[1,3,2]
   rows_min=[2,1,4,7]
   min value 1.0
   */
```

Ptp

Return the range of values of a matrix/vector or of the given matrix axis, equivalent to Max() - Min(). Ptp - Peak to peak.

```
double vector::Ptp();

double matrix::Ptp();

vector matrix::Ptp(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Vector with ranges of values (maximum - minimum) .

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_ptp=matrix_a.Ptp(0);
   vector rows_ptp=matrix_a.Ptp(1);
   double matrix_ptp=matrix_a.Ptp();

   Print("cols_ptp  ",cols_ptp);
   Print("rows_ptp  ",rows_ptp);
   Print("ptp value  ",matrix_ptp);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_ptp [9,8,10]
   rows_ptp [8,11,2,4]
   ptp value  11.0
   */
```

Sum

Return the sum of the matrix/vector elements which can also be performed for the given axis (axes).

```
double vector::Sum();

double matrix::Sum();

vector matrix::Sum(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Sum of the matrix/vector elements which can also be performed for the given axis (axes).

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_sum=matrix_a.Sum(0);
   vector rows_sum=matrix_a.Sum(1);
   double matrix_sum=matrix_a.Sum();

   Print("cols_sum=",cols_sum);
   Print("rows_sum=",rows_sum);
   Print("sum value ",matrix_sum);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_sum=[24,27,27]
   rows_sum=[15,21,15,27]
   sum value 78.0
   */
```

Prod

Return the product of the matrix/vector elements which can also be performed for the given axis.

```
double vector::Prod(
  const double  initial=1      // initial multiplier
   );

double matrix::Prod(
  const double  initial=1      // initial multiplier
   );

vector matrix::Prod(
  const int     axis,          // axis
  const double  initial=1      // initial multiplier
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

initial=1

[in] Initial multiplier.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_prod=matrix_a.Prod(0);
   vector rows_prod=matrix_a.Prod(1);
   double matrix_prod=matrix_a.Prod();

   Print("cols_prod=",cols_prod);
   cols_prod=matrix_a.Prod(0,0.1);
   Print("cols_prod=",cols_prod);
   Print("rows_prod=",rows_prod);
   Print("prod value ",matrix_prod);

  /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_prod=[420,1320,864]
   cols_prod=[42,132,86.40000000000001]
   rows_prod=[60,96,120,693]
```

```
   prod value 479001600.0
*/
```

CumSum

Return the cumulative sum of matrix/vector elements, including those along the given axis.

```
vector vector::CumSum();

vector matrix::CumSum();

matrix matrix::CumSum(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Cumulative sum of the elements along the given axis.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   matrix cols_cumsum=matrix_a.CumSum(0);
   matrix rows_cumsum=matrix_a.CumSum(1);
   vector cumsum_values=matrix_a.CumSum();

   Print("cols_cumsum\n",cols_cumsum);
   Print("rows_cumsum\n",rows_cumsum);
   Print("cumsum values  ",cumsum_values);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_cumsum
   [[10,3,2]
    [11,11,14]
    [17,16,18]
    [24,27,27]]
   rows_cumsum
   [[10,13,15]
    [1,9,21]
    [6,11,15]
```

```
    [7,18,27]]
   cumsum values  [10,13,15,16,24,36,42,47,51,58,69,78]
   */
```

CumProd

Return the cumulative product of matrix/vector elements, including those along the given axis.

```
vector vector::CumProd();

vector matrix::CumProd();

matrix matrix::CumProd(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis for each column (i.e., over the rows), 1 — vertical axis for each row (i.e. over the columns)

Return Value

Cumulative product of the elements along the given axis.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   matrix cols_cumprod=matrix_a.CumProd(0);
   matrix rows_cumprod=matrix_a.CumProd(1);
   vector cumprod_values=matrix_a.CumProd();

   Print("cols_cumprod\n",cols_cumprod);
   Print("rows_cumprod\n",rows_cumprod);
   Print("cumprod values  ",cumprod_values);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_cumprod
   [[10,3,2]
    [10,24,24]
    [60,120,96]
    [420,1320,864]]
   rows_cumprod
   [[10,30,60]
    [1,8,96]
```

```
    [6,30,120]
    [7,77,693]]
   cumprod values  [10,30,60,60,480,5760,34560,172800,691200,4838400,53222400,47900160
   */
```

Percentile

Return the specified percentile of values of matrix/vector elements or elements along the specified axis.

```
double vector::Percentile(
  const int  percent      //
   );

double matrix::Percentile(
  const int  percent      //
   );

vector matrix::Percentile(
  const int  percent,     //
  const int  axis         // axis
   );
```

Parameters

percent

[in] Percentiles to compute, which must be between 0 and 100 inclusive.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Percentile: scalar or vector.

Note

Valid values of the 'percent' parameter are in the range [0, 100]. A linear algorithm is used to calculate percentiles. The correct calculation of percentiles requires the sequence to be sorted.

Example

```
   matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_percentile=matrix_a.Percentile(50,0);
   vectorf rows_percentile=matrix_a.Percentile(50,1);
   float matrix_percentile=matrix_a.Percentile(50);

   Print("cols_percentile ",cols_percentile);
   Print("rows_percentile ",rows_percentile);
   Print("percentile value  ",matrix_percentile);

   /*
```

```
   matrix_a
   [[1,2,3]
    [4,5,6]
    [7,8,9]
    [10,11,12]]
   cols_percentile [5.5,6.5,7.5]
   rows_percentile [2,5,8,11]
   percentile value  6.5
   */
```

Quantile

Return the specified quantile of values of matrix/vector elements or elements along the specified axis.

```
double vector::Quantile(
  const double quantile      // quantile
   );

double matrix::Quantile(
  const double quantile      // quantile
   );

vector matrix::Quantile(
  const double quantile,     // quantile
  const int    axis          // axis
   );
```

Parameters

quantile

[in] Quantile to compute, which must be between 0 and 1 inclusive.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Quantile: scalar or vector.

Note

The 'quantile' parameter takes values in the range [0, 1]. A linear algorithm is used to calculate quantiles. The correct calculation of quantiles requires the sequence to be sorted.

Example

```
   matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_quantile=matrix_a.Quantile(0.5,0);
   vectorf rows_quantile=matrix_a.Quantile(0.5,1);
   float matrix_quantile=matrix_a.Quantile(0.5);

   Print("cols_quantile ",cols_quantile);
   Print("rows_quantile ",rows_quantile);
   Print("quantile value  ",matrix_quantile);

   /*
   matrix_a
```

```
   [[1,2,3]
    [4,5,6]
    [7,8,9]
    [10,11,12]]
   cols_quantile [5.5,6.5,7.5]
   rows_quantile [2,5,8,11]
   quantile value  6.5
   */
```

Median

Compute the median of the matrix/vector elements.

```
double vector::Median();

double matrix::Median();

vector matrix::Median(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Median: scalar or vector.

Note

The median is the middle value that separates the highest half of the array/vector elements from the lowest half of elements. Same as Quantile(0.5) and Percentile(50). The correct calculation of median requires the sequence to be sorted.

Example

```
matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
Print("matrix_a\n",matrix_a);

vectorf cols_median=matrix_a.Median(0);
vectorf rows_median=matrix_a.Median(1);
float matrix_median=matrix_a.Median();

Print("cols_median ",cols_median);
Print("rows_median ",rows_median);
Print("median value  ",matrix_median);

/*
matrix_a
[[1,2,3]
 [4,5,6]
 [7,8,9]
 [10,11,12]]
cols_median [5.5,6.5,7.5]
```

```
   rows_median [2,5,8,11]
   median value  6.5
   */
```

Mean

Compute the arithmetic mean of element values.

```
double vector::Mean();

double matrix::Mean();

vector matrix::Mean(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Arithmetic mean of element values.

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_mean=matrix_a.Mean(0);
   vectorf rows_mean=matrix_a.Mean(1);
   float matrix_mean=matrix_a.Mean();

   Print("cols_mean ",cols_mean);
   Print("rows_mean ",rows_mean);
   Print("mean value  ",matrix_mean);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_mean [6,6.75,6.75]
   rows_mean [5,7,5,9]
   mean value  6.5
   */
```

Average

Compute the weighted mean of matrix/vector values.

```
double vector::Average(
  const vector& weigts      // weights vector
   );

double matrix::Average(
  const matrix& weigts      // weights matrix
);

vector matrix::Average(
  const matrix& weigts,     // weights matrix
  const int     axis        // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Weighted mean: scalar or vector.

Note

The weight matrix/vector is associated with the main matrix/vector.

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   matrixf matrix_w=matrixf::Ones(4,3);
   Print("matrix_a\n",matrix_a);

   vectorf cols_average=matrix_a.Average(matrix_w,0);
   vectorf rows_average=matrix_a.Average(matrix_w,1);
   float matrix_average=matrix_a.Average(matrix_w);

   Print("cols_average ",cols_average);
   Print("rows_average ",rows_average);
   Print("average value  ",matrix_average);

   /*
   matrix_a
   [[10,3,2]
```

```
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_average [6,6.75,6.75]
   rows_average [5,7,5,9]
   average value  6.5
   */ value  6.5
```

Std

Return the standard deviation of values of matrix/vector elements or of elements along the given axis.

```
double vector::Std();

double matrix::Std();

vector matrix::Std(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Standard_deviation: scalar or vector.

Note

The standard deviation is the square root of the average of the squared deviations from the mean, i. e., std = sqrt(mean(x)), where x = abs(a - a.mean())**2.

The average squared deviation is typically calculated as x.sum() / N, where N = len(x).

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_std=matrix_a.Std(0);
   vectorf rows_std=matrix_a.Std(1);
   float matrix_std=matrix_a.Std();

   Print("cols_std ",cols_std);
   Print("rows_std ",rows_std);
   Print("std value  ",matrix_std);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
```

```
   cols_std [3.2403703,3.0310888,3.9607449]
   rows_std [3.5590262,4.5460606,0.81649661,1.6329932]
   std value  3.452052593231201
   */
```

Var

Compute the variance of values of matrix/vector elements.

```
double vector::Var();

double matrix::Var();

vector matrix::Var(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Variance: scalar or vector.

Note

The variance is the average of the squared deviations from the mean, i.e., var = mean(x), where x = abs(a - a.mean())**2.

The mean is typically calculated as x.sum() / N, where N = len(x).

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_var=matrix_a.Var(0);
   vectorf rows_var=matrix_a.Var(1);
   float matrix_var=matrix_a.Var();

   Print("cols_var ",cols_var);
   Print("rows_var ",rows_var);
   Print("var value  ",matrix_var);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_var [10.5,9.1875,15.6875]
```

```
   rows_var [12.666667,20.666666,0.66666669,2.6666667]
   var value  11.916666984558105
   */
```

LinearRegression

Calculate a vector/matrix with calculated linear regression values.

```
vector vector::LinearRegression();

matrix matrix::LinearRegression(
  ENUM_MATRIX_AXIS  axis=AXIS_NONE      // axis along which regression is calculated
   );
```

Parameters

axis

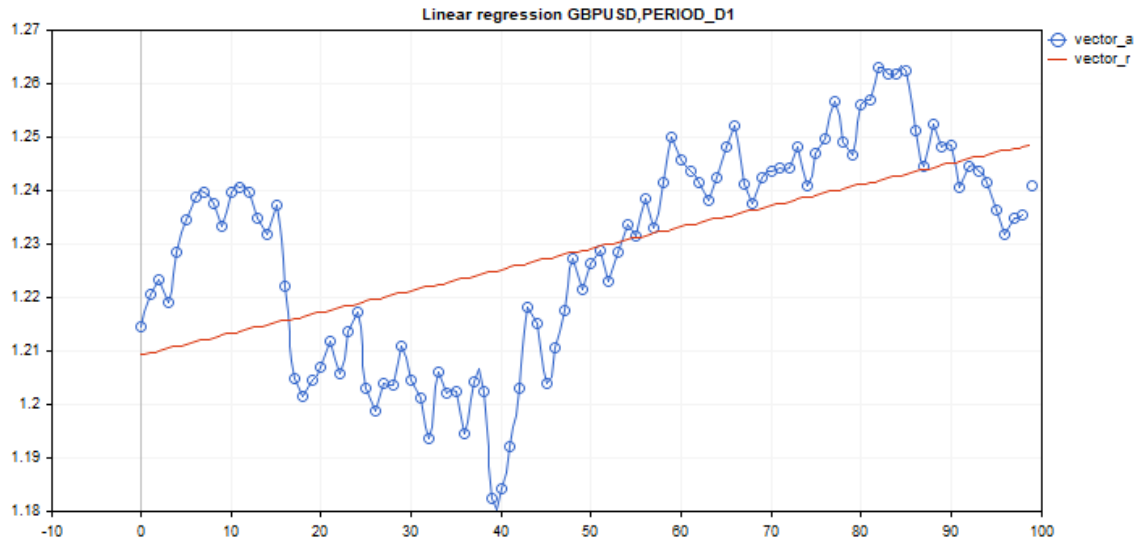
[in] Specifying the axis along which the regression is calculated. ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

Return Value

Vector or matrix with calculated linear regression values.

Note

Linear regression is calculated using the standard regression equation: y (x) = a * x + b, where a is the line slope, while b is its Y axis shift.



Example:

```
#include <Graphics\Graphic.mqh>

#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

//+------------------------------------------------------------------+
```

```
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector vector_a;
   vector_a.CopyRates(_Symbol,_Period,COPY_RATES_CLOSE,1,100);
   vector vector_r=vector_a.LinearRegression();

//--- switch off chart show
   ChartSetInteger(0,CHART_SHOW,false);

//--- arrays for drawing a graph
   double x[];
   double y1[];
   double y2[];
   ArrayResize(x,uint(vector_a.Size()));
   ArrayResize(y1,uint(vector_a.Size()));
   ArrayResize(y2,uint(vector_a.Size()));
   for(ulong i=0; i<vector_a.Size(); i++)
     {
      x[i]=(double)i;
      y1[i]=vector_a[i];
      y2[i]=vector_r[i];
     }

//--- graph title
   string title="Linear regression "+_Symbol+","+EnumToString(_Period);

   long   chart=0;
   string name="LinearRegression";

//--- create graph
   CGraphic graphic;
   graphic.Create(chart,name,0,0,0,GRAPH_WIDTH,GRAPH_HEIGHT);
   graphic.BackgroundMain(title);
   graphic.BackgroundMainSize(12);

//--- activation function graph
   CCurve *curvef=graphic.CurveAdd(x,y1,CURVE_POINTS_AND_LINES);
   curvef.Name("vector_a");
   curvef.LinesWidth(2);
   curvef.LinesSmooth(true);
   curvef.LinesSmoothTension(1);
   curvef.LinesSmoothStep(10);

//--- derivatives of activation function
   CCurve *curved=graphic.CurveAdd(x,y2,CURVE_LINES);
   curved.Name("vector_r");
   curved.LinesWidth(2);
```

```
   curved.LinesSmooth(true);
   curved.LinesSmoothTension(1);
   curved.LinesSmoothStep(10);
   graphic.CurvePlotAll();
   graphic.Update();

//--- endless loop to recognize pressed keyboard buttons
   while(!IsStopped())
     {
      //--- press escape button to quit program
      if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
         break;
      //--- press PdDn to save graph picture
      if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0)
        {
         string file_names[];
         if(FileSelectDialog("Save Picture",NULL,"All files (*.*)|*.*",FSD_WRITE_FILE,
            continue;
         ChartScreenShot(0,file_names[0],GRAPH_WIDTH,GRAPH_HEIGHT);
        }
      Sleep(10);
     }

//--- clean up
   graphic.Destroy();
   ObjectDelete(chart,name);
   ChartSetInteger(0,CHART_SHOW,true);
  }
```

ENUM_MATRIX_AXIS

Enumeration for specifying the axis in all statistical functions for matrices.

ID	Description
AXIS_NONE	The axis is not specified. Calculation is performed over all matrix elements, as if it were a vector (see the Flat method).
AXIS_HORZ	Horizontal axis
AXIS_VERT	Vertical axis

Feature methods

These methods enable the receiving of matrix features, such as:

- number of rows
- number of columns
- norm
- condition number
- determinant
- matrix rank
- trace
- spectrum

Function	Action
Rows	Return the number of rows in a matrix
Cols	Return the number of columns in a matrix
Size	Return the size of vector
Norm	Return matrix or vector norm
Cond	Compute the condition number of a matrix
Det	Compute the determinant of a square invertible matrix
SLogDet	Compute the sign and logarithm of the determinant of an matrix
Rank	Return matrix rank using the Gaussian method
Trace	Return the sum along diagonals of the matrix
Spectrum	Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A

Rows

Return the number of rows in a matrix.

```
ulong matrix::Rows()
```

Return Value

Integer.

Example

```
matrix m= {{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}};
m.Reshape(3, 4);
Print("matrix m \n" , m);
Print("m.Rows()=", m.Rows());
Print("m.Cols()=", m.Cols());

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 m.Rows()=3
 m.Cols()=4
*/
```

Cols

Return the number of columns in a matrix.

```
ulong matrix::Cols()
```

Return Value

Integer.

Example

```
matrix m= {{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}};
m.Reshape(3, 4);
Print("matrix m \n" , m);
Print("m.Cols()=", m.Cols());
Print("m.Rows()=", m.Rows());

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 m.Cols()=4
 m.Rows()=3
*/
```

Size

Return the size of vector.

```
ulong vector::Size()
```

Return Value

Integer.

Example

```
matrix m={{1,2,3,4,5,6,7,8,9,10,11,12}};
m.Reshape(3,4);
Print("matrix m\n",m);
vector v=m.Row(1);
Print("v.Size()=",v.Size());
Print("v=",v);

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 v.Size()=4
 v=[5,6,7,8]
*/
```

Norm

Return matrix or vector norm.

```
double vector::Norm(
  const ENUM_VECTOR_NORM  norm,     // vector norm
  const int               norm_p=2  // number of p-norm in case of VECTOR_NORM_P
   );

double matrix::Norm(
  const ENUM_MATRIX_NORM  norm      // matrix norm
   );
```

Parameters

norm

[in] Norm order

Return Value

Matrix or vector norm.

Note

- VECTOR_NORM_INF is the maximum absolute value among vector elements.
- VECTOR_NORM_MINUS_INF is the minimum absolute value of a vector.
- VECTOR_NORM_P is the P-norm of the vector. If norm_p=0, then this is the number of non-zero vector elements. norm_p=1 is the sum of absolute values of vector elements. norm_p=2 is the square root of the sum of squares of vector element values. P-norm can be negative.
- MATRIX_NORM_FROBENIUS is the square root of the sum of the squares of the matrix element values. The Frobenius norm and the vector P2-norm are consistent.
- MATRIX_NORM_SPECTRAL is the maximum value of the matrix spectrum.
- MATRIX_NORM_NUCLEAR is the sum of the singular values of the matrix.
- MATRIX_NORM_INF is the maximum vector p1-norm among the vertical vectors of the matrix. The matrix inf-norm and the vector inf-norm are consistent.
- MATRIX_NORM_MINUS_INF is the minimum vector p1-norm among the vertical vectors of the matrix.
- MATRIX_NORM_P1 is the maximum vector p1-norm among horizontal matrix vectors.
- MATRIX_NORM_MINUS_P1 is the minimum vector p1-norm among horizontal matrix vectors.
- MATRIX_NORM_P2 is the highest singular value of the matrix.
- MATRIX_NORM_MINUS_P2 is the lowest singular value of a matrix.

A simple algorithm for calculating the P-norm of a vector in MQL5:

```
double VectorNormP(const vector& v,int norm_value)
  {
   ulong  i;
```

```
   double norm=0.0;
//---
   switch(norm_value)
     {
      case 0 :
         for(i=0; i<v.Size(); i++)
            if(v[i]!=0)
               norm+=1.0;
         break;
      case 1 :
         for(i=0; i<v.Size(); i++)
            norm+=MathAbs(v[i]);
         break;
      case 2 :
         for(i=0; i<v.Size(); i++)
            norm+=v[i]*v[i];
         norm=MathSqrt(norm);
         break;
      default :
         for(i=0; i<v.Size(); i++)
            norm+=MathPow(MathAbs(v[i]),norm_value);
         norm=MathPow(norm,1.0/norm_value);
     }
//---
   return(norm);
  }
```

MQL5 example:

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a=a-4;
  Print("matrix a \n", a);
  a.Reshape(3, 3);
  matrix b=a;
  Print("matrix b \n", b);
  Print("b.Norm(MATRIX_NORM_P2)=", b.Norm(MATRIX_NORM_FROBENIUS));
  Print("b.Norm(MATRIX_NORM_FROBENIUS)=", b.Norm(MATRIX_NORM_FROBENIUS));
  Print("b.Norm(MATRIX_NORM_INF)", b.Norm(MATRIX_NORM_INF));
  Print("b.Norm(MATRIX_NORM_MINUS_INF)", b.Norm(MATRIX_NORM_MINUS_INF));
  Print("b.Norm(MATRIX_NORM_P1)=)", b.Norm(MATRIX_NORM_P1));
  Print("b.Norm(MATRIX_NORM_MINUS_P1)=", b.Norm(MATRIX_NORM_MINUS_P1));
  Print("b.Norm(MATRIX_NORM_P2)=", b.Norm(MATRIX_NORM_P2));
  Print("b.Norm(MATRIX_NORM_MINUS_P2)=", b.Norm(MATRIX_NORM_MINUS_P2));

  /*
  matrix a
  [[-4,-3,-2,-1,0,1,2,3,4]]
  matrix b
  [[-4,-3,-2]
```

```
   [-1,0,1]
   [2,3,4]]
   b.Norm(MATRIX_NORM_P2)=7.745966692414834
   b.Norm(MATRIX_NORM_FROBENIUS)=7.745966692414834
   b.Norm(MATRIX_NORM_INF)9.0
   b.Norm(MATRIX_NORM_MINUS_INF)2.0
   b.Norm(MATRIX_NORM_P1)=)7.0
   b.Norm(MATRIX_NORM_MINUS_P1)=6.0
   b.Norm(MATRIX_NORM_P2)=7.348469228349533
   b.Norm(MATRIX_NORM_MINUS_P2)=1.857033188519056e-16
   */
```

Python example:

```
import numpy as np
from numpy import linalg as LA
a = np.arange(9) - 4
print("a \n",a)
b = a.reshape((3, 3))
print("b \n",b)
print("LA.norm(b)=",LA.norm(b))
print("LA.norm(b, 'fro')=",LA.norm(b, 'fro'))
print("LA.norm(b, np.inf)=",LA.norm(b, np.inf))
print("LA.norm(b, -np.inf)=",LA.norm(b, -np.inf))
print("LA.norm(b, 1)=",LA.norm(b, 1))
print("LA.norm(b, -1)=",LA.norm(b, -1))
print("LA.norm(b, 2)=",LA.norm(b, 2))
print("LA.norm(b, -2)=",LA.norm(b, -2))

a
 [-4 -3 -2 -1  0  1  2  3  4]
b
 [[-4 -3 -2]
 [-1  0  1]
 [ 2  3  4]]
LA.norm(b)= 7.745966692414834
LA.norm(b, 'fro')= 7.745966692414834
LA.norm(b, np.inf)= 9.0
LA.norm(b, -np.inf)= 2.0
LA.norm(b, 1)= 7.0
LA.norm(b, -1)= 6.0
LA.norm(b, 2)= 7.3484692283495345
LA.norm(b, -2)= 1.857033188519056e-16
```

Cond

Compute the condition number of a matrix.

```
double matrix::Cond(
  const ENUM_MATRIX_NORM  norm      // matrix norm
   );
```

Parameters

norm

[in] Order of the norm from ENUM_MATRIX_NORM

Return Value

The condition number of the matrix. May be infinite.

Note

The condition number of x is defined as the norm of x times the norm of the inverse of x [1]. The norm can be the usual L2-norm (root-of-sum-of-squares) or one of a number of other matrix norms.

The condition umber is the K value equal to the product of the matrix A norms and its inverse. Matrices with a high condition number are called ill-conditioned. Those with a low condition number are called well-conditioned. The inverse matrix is obtained using pseudo-inversion, so as not to be limited by the condition of squareness and non-singularity of the matrix.

An exception is the spectral condition number.

A simple algorithm for calculating the spectral condition number in MQL5:

```
double MatrixCondSpectral(matrix& a)
  {
   double norm=0.0;
   vector v=a.Spectrum();

   if(v.Size()>0)
     {
      double max_norm=v[0];
      double min_norm=v[0];
      for(ulong i=1; i<v.Size(); i++)
        {
         double real=MathAbs(v[i]);
         if(max_norm<real)
            max_norm=real;
         if(min_norm>real)
            min_norm=real;
        }
      max_norm=MathSqrt(max_norm);
```

```
      min_norm=MathSqrt(min_norm);
      if(min_norm>0.0)
         norm=max_norm/min_norm;
     }

  return(norm);
 }
```

MQL5 example:

```
 matrix a= {{1, 0, -1}, {0, 1, 0}, { 1, 0, 1}};
 Print("a.Cond(MATRIX_NORM_P2)=", a.Cond(MATRIX_NORM_P2));
 Print("a.Cond(MATRIX_NORM_FROBENIUS)=", a.Cond(MATRIX_NORM_FROBENIUS));
 Print("a.Cond(MATRIX_NORM_INF)=", a.Cond(MATRIX_NORM_INF));
 Print("a.Cond(MATRIX_NORM_MINUS_INF)=", a.Cond(MATRIX_NORM_MINUS_INF));
 Print("a.Cond(MATRIX_NORM_P1)=)", a.Cond(MATRIX_NORM_P1));
 Print("a.Cond(MATRIX_NORM_MINUS_P1)=", a.Cond(MATRIX_NORM_MINUS_P1));
 Print("a.Cond(MATRIX_NORM_P2)=", a.Cond(MATRIX_NORM_P2));
 Print("a.Cond(MATRIX_NORM_MINUS_P2)=", a.Cond(MATRIX_NORM_MINUS_P2));

 /*
 matrix a
 [[1,0,-1]
 [0,1,0]
 [1,0,1]]
 a.Cond(MATRIX_NORM_P2)=1.414213562373095
 a.Cond(MATRIX_NORM_FROBENIUS)=3.162277660168379
 a.Cond(MATRIX_NORM_INF)=2.0
 a.Cond(MATRIX_NORM_MINUS_INF)=0.9999999999999997
 a.Cond(MATRIX_NORM_P1)=)2.0
 a.Cond(MATRIX_NORM_MINUS_P1)=0.9999999999999998
 a.Cond(MATRIX_NORM_P2)=1.414213562373095
 a.Cond(MATRIX_NORM_MINUS_P2)=0.7071067811865472
 */
```

Python example:

```
import numpy as np
from numpy import linalg as LA
a = np.array([[1, 0, -1], [0, 1, 0], [1, 0, 1]])
print("a \n",a)
print("LA.cond(a)=",LA.cond(a))
print("LA.cond(a, 'fro')=",LA.cond(a, 'fro'))
print("LA.cond(a, np.inf)=",LA.cond(a, np.inf))
print("LA.cond(a, -np.inf)=",LA.cond(a, -np.inf))
print("LA.cond(a, 1)=",LA.cond(a, 1))
print("LA.cond(a, -1)=",LA.cond(a, -1))
```

```
print("LA.cond(a, 2)=",LA.cond(a, 2))
print("LA.cond(a, -2)=",LA.cond(a, -2))

a
 [[ 1  0 -1]
 [ 0  1  0]
 [ 1  0  1]]
LA.cond(a)= 1.4142135623730951
LA.cond(a, 'fro')= 3.1622776601683795
LA.cond(a, np.inf)= 2.0
LA.cond(a, -np.inf)= 1.0
LA.cond(a, 1)= 2.0
LA.cond(a, -1)= 1.0
LA.cond(a, 2)= 1.4142135623730951
LA.cond(a, -2)= 0.7071067811865475
```

Det

Compute the determinant of a square invertible matrix.

```
double matrix::Det()
```

Return Value

Determinant of matrix.

Note

2nd and 3rd order matrix determinants are calculated according to the Sarrus rule. d2=a11*a22-a12*a21; d3=a11*a22*a33+a12*a23*a31+a13*a21*a32-a13*a22*a31-a11*a23*a32-a12*a21*a33

The determinant is calculated by the Gaussian method by reducing the matrix to an upper triangular form. The determinant of an upper triangular matrix is equal to the product of the main diagonal elements.

If at least one matrix row or column is zero, the determinant is zero.

If two or more matrix rows or columns are linearly dependent, its determinant is zero.

The determinant of a matrix is equal to the product of its eigenvalues.

MQL5 example:

```
matrix m={{1,2},{3,4}};
double det=m.Det();
Print("matrix m\n",m);
Print("det(m)=",det);
/*
matrix m
[[1,2]
 [3,4]]
det(m)=-2.0
*/
```

Python example:

```
import numpy as np

a = np.array([[1, 2], [3, 4]])
print('a \n',a)
print('nnp.linalg.det(a) \n',np.linalg.det(a))

a
 [[1 2]
 [3 4]]
```

```
np.linalg.det(a)
 -2.0000000000000004
```

SLogDet

Compute the sign and logarithm of a matrix determinant.

```
double matrix::SLogDet(
  int&  sign      // sign
   );
```

Parameters

sign

[out] The sign of the determinant. If the sign is even, the determinant is positive.

Return Value

A number representing the sign of the determinant.

Note

The determinant is calculated by the Gaussian method by reducing the matrix to an upper triangular form. The determinant of an upper triangular matrix is equal to the product of the main diagonal elements. The logarithm of a product is equal to the sum of the logarithms. Therefore, in case of an overflow when calculating the determinant, you can use the SLogDet method.

If the sign is even, the determinant is positive.

Example

```
a = np.array([[1, 2], [3, 4]])
(sign, logdet) = np.linalg.slogdet(a)
(sign, logdet) (-1, 0.69314718055994529) # may vary  sign * np.exp(logdet) -2.0
```

Rank

Return matrix rank using the Gaussian method.

```
int  Rank()
```

Return Value

Rank of matrix.

Note

The rank of a system of rows (or columns) of a matrix A that has m rows and n columns is the maximum number of linearly independent rows (or columns). Several rows (columns) are called linearly independent if none of them can be expressed linearly in terms of others. The rank of the row system is always equal to the rank of the column system. This value is called the rank of the matrix.

MQL5 example:

```
matrix a=matrix::Eye(4, 4);;
Print("matrix a \n", a);
Print("a.Rank()=", a.Rank());

matrix I=matrix::Eye(4, 4);
I[3, 3] = 0.;     // rank deficient matrix
Print("I \n", I);
Print("I.Rank()=", I.Rank());

matrix b=matrix::Ones(1, 4);
Print("b \n", b);
Print("b.Rank()=", b.Rank());;// 1 dimension - rank 1 unless all 0

matrix  zeros=matrix::Zeros(4, 1);
Print("zeros \n", zeros);
Print("zeros.Rank()=", zeros.Rank());

/*
matrix a
[[1,0,0,0]
[0,1,0,0]
[0,0,1,0]
[0,0,0,1]]
a.Rank()=4

I
[[1,0,0,0]
[0,1,0,0]
```

```
  [0,0,1,0]
  [0,0,0,0]]
  I.Rank()=3

  b
  [[1,1,1,1]]
  b.Rank()=1

  zeros
  [[0]
  [0]
  [0]
  [0]]
  zeros.Rank()=0
  */
```

Python example:

```
import numpy as np
from numpy.linalg import matrix_rank
a=(np.eye(4)) # Full rank matrix
print("a \n", a)
print("matrix_rank(a)=",matrix_rank(a))
I=np.eye(4)
I[-1,-1] = 0. # rank deficient matrix
print("I \n",I)
print("matrix_rank(I)=",matrix_rank(I))

b=np.ones((4,))
print("b \n",b)
print("matrix_rank(b)=",matrix_rank(b)) # 1 dimension - rank 1 unless all 0

zeros=np.zeros((4,))
print("zeroes \n",zeros)
print("matrix_rank(zeros)=",matrix_rank(zeros))

a
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]
 [0. 0. 0. 1.]]
matrix_rank(a)= 4

I
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]
 [0. 0. 0. 0.]]
```

```
matrix_rank(I)= 3

b
 [1. 1. 1. 1.]
matrix_rank(b)= 1

zeroes
 [0. 0. 0. 0.]
matrix_rank(zeros)= 0
```

Trace

Return the sum along diagonals of the matrix.

```
double matrix::Trace()
```

Return Value

The sum along the diagonal.

Note

The trace of a matrix is equal to the sum of its eigenvalues.

MQL5 example:

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a.Reshape(3, 3);
  Print("matrix a \n", a);
  Print("a.Trace() \n", a.Trace());

  /*
  matrix a
  [[0,1,2]
  [3,4,5]
  [6,7,8]]
  a.Trace()
  12.0
  */
```

Python example:

```
a = np.arange(9).reshape((3,3))
print('a \n',a)
print('np.trace(a) \n',np.trace(a))

a
 [[0 1 2]
 [3 4 5]
 [6 7 8]]

np.trace(a)
 12
```

Spectrum

Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A.

```
vector matrix::Spectrum()
```

Return Value

Spectrum of a matrix as a vector of matrix eigenvalues.

Example

```
double MatrixCondSpectral(matrix& a)
  {
   double norm=0.0;
   vector v=a.Spectrum();

   if(v.Size()>0)
     {
      double max_norm=v[0];
      double min_norm=v[0];
      for(ulong i=1; i<v.Size(); i++)
        {
         double real=MathAbs(v[i]);
         if(max_norm<real)
            max_norm=real;
         if(min_norm>real)
            min_norm=real;
        }
      max_norm=MathSqrt(max_norm);
      min_norm=MathSqrt(min_norm);
      if(min_norm>0.0)
         norm=max_norm/min_norm;
     }

   return(norm);
  }
```

Matrix methods for solving systems of linear equations

Methods for solving systems of linear equations and calculating the inverse matrix.

Function	Action
Solve	Solve a linear matrix equation, or system of linear algebraic equations
LstSq	Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices)
Inv	Compute the (multiplicative) inverse of a square non-degenerate matrix by the Jordan-Gauss method
PInv	Compute the pseudo-inverse of a matrix by the Moore-Penrose method

Solve

Solve a linear matrix equation, or system of linear algebraic equations.

```
vector matrix::Solve(
  const vector  b      // ordinate or 'dependent variable' values
   );
```

Parameters

b

[in] Ordinate or 'dependent variable' values. (Vector of free terms).

Return Value

Vector with solution to the system a * x = b.

Note

If at least one matrix row or column is zero, the system has no solution.

If two or more matrix rows or columns are linearly dependent, the system has no solution.

Example

```
//--- SLAE solution
   vector_x=matrix_a.Solve(vector_b);
//--- check if a * x = b
   result_vector=matrix_a.MatMul(vector_x);
   errors=vector_b.Compare(result_vector,1e-12);
```

LstSq

Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices).

```
vector matrix::LstSq(
  const vector  b      // ordinate or 'dependent variable' values
   );
```

Parameters

b

[in] Ordinate or 'dependent variable' values. (Vector of free terms)

Return Value

Vector with solution to the system a * x = b. This is true only for systems that have an exact solution.

Example

```
   matrix a={{3, 2},
             {4,-5},
             {3, 3}};
   vector b={7,40,3};
//---
   vector x=a.LstSq(b);
//--- check, must be [5, -4]
   Print("x=", x);
//--- check, must be [7, 40, 3]
   vector b1=a.MatMul(x);
   Print("b1=",b1);

/*
  x=[5.000000000000002,-4]
  b1=[7.000000000000005,40.00000000000001,3.000000000000005]
*/
```

Inv

Compute the multiplicative inverse of a square invertible matrix by the Jordan-Gauss method.

```
matrix matrix::Inv()
```

Return Value

Multiplicative inverse of the matrix.

Note

The product of the original matrix and the inverse matrix is the identity matrix.

If at least one matrix row or column is zero, the inverse matrix cannot be obtained.

If two or more matrix rows or columns are linearly dependent, the inverse matrix cannot be obtained.

Example

```
int TestInverse(const int size_m)
  {
   int    i,j,errors=0;
   matrix matrix_a(size_m,size_m);
//--- populate the square matrix
   MatrixTestFirst(matrix_a);
//--- microseconds will be measured
   ulong t1=GetMicrosecondCount();
//--- get the inverse matrix
   matrix inverse=matrix_a.Inv();
//--- measure
   ulong t2=GetMicrosecondCount();
//--- check the correctness
   matrix identity=matrix_a.MatMul(inverse);
//---
   for(i=0; i<size_m; i++)
     {
      for(j=0; j<size_m; j++)
        {
         double value;
         //--- ones must be along the diagonal
         if(i==j)
            value=1.0;
         else
            value=0.0;
         if(MathClassify(identity[i][j])>FP_ZERO)
            errors++;
         else
```

```
            {
             if(identity[i][j]!=value)
               {
                double diff=MathAbs(identity[i][j]-value);
                //--- too many multiplications and devisions, so reduce the check accu
                if(diff>1e-9)
                   errors++;
               }
            }
         }
      }
//---
   double elapsed_time=double(t2-t1)/1000.0;
   printf("Inversion of matrix %d x %d  %s  errors=%d  time=%.3f ms",size_m,size_m,er
   return(errors);
  }
```

PInv

Compute the pseudo-inverse of a matrix by the Moore-Penrose method.

```
matrix matrix::PInv()
```

Return Value

The pseudo-inverse of matrix.

Example

```
int TestPseudoInverse(const int size_m, const int size_k)
  {
   matrix matrix_a(size_m,size_k);
   matrix matrix_inverted(size_k,size_m);
   matrix matrix_temp;
   matrix matrix_a2;
//--- fill the matrix
   MatrixTestFirst(matrix_a);
//--- invert
   matrix_inverted=matrix_a.PInv();
//--- check the correctness
   int errors=0;
//--- A * A+ * A = A   (A+ is a pseudo-inverse of A)
   matrix_temp=matrix_a.MatMul(matrix_inverted);
   matrix_a2=matrix_temp.MatMul(matrix_a);
   errors=(int)matrix_a.CompareByDigits(matrix_a2,10);

   printf("PseudoInversion %s matrix_size  %d x %d  errors=%d",errors==0?"passed":"fa
//---
   return(errors);
  }
```

Machine learning

These methods are used in machine learning.

The neural network activation function determines the output value of a neuron depending on the weighted sum of inputs. The selection of the activation function has a big impact on the neural network performance. Different model parts (layers) can use different activation functions.

In addition to all known activation functions, MQL5 also offers their derivatives. Function derivatives enable an efficient update of model parameters based on the error received in learning.

A neural network aims at finding an algorithm that minimizes the error in learning, for which the loss function is used. The value of the loss function indicates by how much the value predicted by the model deviates from the real one. Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Function	Action
Activation	Compute activation function values and write them to the passed vector/matrix
Derivative	Compute activation function derivative values and write them to the passed vector/matrix
Loss	Compute loss function values and write them to the passed vector/matrix
LossGradient	Compute a vector or matrix of loss function gradients
RegressionMetric	Compute the regression metric as the deviation error from the regression line constructed on the specified data array
ConfusionMatrix	Compute confusion matrix. The method is applied to the vector of predicted values
ConfusionMatrixMultilabel	Compute confusion matrix for each label. The method is applied to the vector of predicted values
ClassificationMetric	Compute the classification metric to evaluate the quality of the predicted data compared to the true data The method is applied to the vector of predicted values
ClassificationScore	Compute the classification metric to evaluate the quality of the predicted data compared to the true data
PrecisionRecall	Compute values to construct a precision-recall curve. Similarly to ClassificationScore, this method is applied to the vector of true values
ReceiverOperatingCharacteristic	Compute values to construct the Receiver Operating Characteristic (ROC) curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

Example

This example demonstrates the training of a model using matrix operations. The model is trained for the function (a + b + c)^2 / (a^2 + b^2 + c^2). We input the initial data matrix, in which a, b and c are contained in different columns. The function result is obtained at the model output.

```
matrix weights1, weights2, weights3;                // matrices of weights
matrix output1, output2, result;                    // matrices of neural layer outputs
input int layer1 = 200;                             // the size of the first hidden lay
input int layer2 = 200;                             // the size of the second hidden la
input int Epochs = 20000;                           // the number of training epochs
input double lr = 3e-6;                             // learning rate

      !temp.Col(vector::Ones(temp.Rows()), weights1.Rows() - 1))
      return false;
   weights1 = weights1 + temp.Transpose().MatMul(loss) * lr;
//--- return result
   return true;
  }
//+------------------------------------------------------------------+
//| Model testing method                                             |
//+------------------------------------------------------------------+
bool Test(matrix &data, matrix &target)
  {
//--- feedfarward on test data
   if(!FeedForward(data))
      return false;
//--- log the model calculation results and true values
   PrintFormat("Test loss %.5f", result.Loss(target, LOSS_MSE));
   ulong total = data.Rows();
   for(ulong i = 0; i < total; i++)
      PrintFormat("(%.2f + %.2f + %.2f)^2 / (%.2f^2 + %.2f^2 + %.2f^2) =  Net %.2f, Ta
                  data[i, 0], data[i, 1], data[i, 2], result[i, 0], target[i, 0]);
//--- return result
   return true;
  }
//+------------------------------------------------------------------+
```

Activation

Compute activation function values and write them to the passed vector/matrix.

```
bool vector::Activation(
  vector&                    vect_out,      // vector to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   ...                                     // additional parameters
   );

bool matrix::Activation(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation      // activation function
   );

bool matrix::Activation(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
  ENUM_MATRIX_AXIS           axis,          // axis
   ...                                     // additional parameters
   );
```

Parameters

vect_out/matrix_out

[out] Vector or matrix to get the computed values of the activation function.

activation

[in] Activation function from the ENUM_ACTIVATION_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameters required for some activation functions. If no parameters are specified, default values are used.

Return Value

Returns true if successful, otherwise - false.

Additional Parameters

Some activation functions accept additional parameters. If no parameters are specified, default values are used

```
AF_ELU  (Exponential Linear Unit)
  double alpha=1.0

Activation function: if(x>=0) f(x) = x
                     else f(x) = alpha * (exp(x)-1)

AF_LINEAR
  double alpha=1.0
  double beta=0.0

Activation function: f(x) = alpha*x + beta

AF_LRELU   (Leaky REctified Linear Unit)
  double alpha=0.3

Activation function: if(x>=0) f(x)=x
                     else f(x) = alpha*x

AF_RELU  (REctified Linear Unit)
  double alpha=0.0
  double max_value=0.0
  double treshold=0.0

Activation function: if(alpha==0) f(x) = max(x,0)
                     else if(x>max_value) f(x) = x
                     else f(x) = alpha*(x - treshold)

AF_SWISH
  double beta=1.0

Activation function: f(x) = x / (1+exp(-x*beta))

AF_TRELU   (Thresholded REctified Linear Unit)
  double theta=1.0

Activation function: if(x>theta) f(x) = x
                     else f(x) = 0

AF_PRELU   (Parametric REctified Linear Unit)
  double alpha[] - learned array of coeefficients
```

```
Activation function: if(x[i]>=0) f(x)[i] = x[i]
                     else f(x)[i] = alpha[i] * x[i]
```

Note

In artificial neural networks, the activation function of a neuron determines the output signal, which is defined by an input signal or a set of input signals. The selection of the activation function has a big impact on the neural network performance. Different model parts (layers) can use different activation functions.

Examples of using additional parameters:

```
vector x={0.1, 0.4, 0.9, 2.0, -5.0, 0.0, -0.1};
vector y;

x.Activation(y,AF_ELU);
Print(y);
x.Activation(y,AF_ELU,2.0);
Print(y);

Print("");
x.Activation(y,AF_LINEAR);
Print(y);
x.Activation(y,AF_LINEAR,2.0);
Print(y);
x.Activation(y,AF_LINEAR,2.0,5.0);
Print(y);

Print("");
x.Activation(y,AF_LRELU);
Print(y);
x.Activation(y,AF_LRELU,1.0);
Print(y);
x.Activation(y,AF_LRELU,0.1);
Print(y);

Print("");
x.Activation(y,AF_RELU);
Print(y);
x.Activation(y,AF_RELU,2.0,0.5);
Print(y);
x.Activation(y,AF_RELU,2.0,0.5,1.0);
Print(y);

Print("");
x.Activation(y,AF_SWISH);
Print(y);
```

```
   x.Activation(y,AF_SWISH,2.0);
   Print(y);

   Print("");
   x.Activation(y,AF_TRELU);
   Print(y);
   x.Activation(y,AF_TRELU,0.3);
   Print(y);

   Print("");
   vector a=vector::Full(x.Size(),2.0);
   x.Activation(y,AF_PRELU,a);
   Print(y);

*/
```

Derivative

Compute activation function derivative values and write them to the passed vector/matrix

```
bool vector::Derivative(
  vector&                    vect_out,      // vector to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   ...                                      // additional parameters
   );

bool matrix::Derivative(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   );

bool matrix::Derivative(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
  ENUM_MATRIX_AXIS           axis,          // axis
   ...                                      // additional parameters
   );
```

Parameters

vect_out/matrix_out

[out] Vector or matrix to get the computed values of the derivative of the activation function.

activation

[in] Activation function from the ENUM_ACTIVATION_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameters are the same as that of the activation functions. Only some activation functions accept additional parameters. If no parameters are specified, default values are used.

Return Value

Returns true if successful, otherwise - false.

Note

Function derivatives enable an efficient update of model parameters based on the error received in learning during the error backpropagation.

Loss

Compute the value of the loss function.

```
double vector::Loss(
  const vector&       vect_true,     // vector of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   ...                               // additional parameter
   );

double matrix::Loss(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   );

double matrix::Loss(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
  ENUM_MATRIX_AXIS    axis,          // axis
   ...                               // additional parameter
   );
```

Parameters

vect_true/matrix_true

[in] Vector or matrix of true values.

loss

[in] Loss function from the ENUM_LOSS_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameter 'delta' can only be used by the Hubert loss function (LOSS_HUBER)

Return Value

double value.

How the 'delta' parameter is used in the Hubert loss function (LOSS_HUBER)

```
   double delta = 1.0;
   double error = fabs(y - x);
   if(error<delta)
      loss = 0.5 * error^2;
   else
```

```
      loss = 0.5 * delta^2 + delta * (error - delta);
```

Note

A neural network aims at finding the algorithms that minimize the error on the training sample, for which the loss function is used.

The value of the loss function indicates by how much the value predicted by the model deviates from the real one.

Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Example of calling the Hubert loss function:

```
   vector y_true = {0.0, 1.0, 0.0, 0.0};
   vector y_pred = {0.6, 0.4, 0.4, 0.6};
   double loss=y_pred.Loss(y_true,LOSS_HUBER);
   Print(loss);
   double loss2=y_pred.Loss(y_true,LOSS_HUBER,0.5);
   Print(loss2);

/* Result
   0.155
   0.15125
*/
```

LossGradient

Compute a vector or matrix of loss function gradients.

```
vector vector::LossGradient(
  const vector&       vect_true,     // vector of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function type
   ...                               // additional parameter
   );

matrix matrix::LossGradient(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   );

matrix matrix::LossGradient(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
  ENUM_MATRIX_AXIS    axis,          // axis
   ...                               // additional parameter
   );
```

Parameters

vect_true/matrix_true

[in] Vector or matrix of true values.

loss

[in] Loss function from the ENUM_LOSS_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameter 'delta' can only be used by the Hubert loss function (LOSS_HUBER)

Return Value

Vector or matrix of loss function gradient values. The gradient is the partial derivative with respect to dx (x is the predicted value) of the loss function at a given point.

Note

Gradients are used in neural networks to adjust the weight matrix weights during backpropagation, when training the model.

A neural network aims at finding the algorithms that minimize the error on the training sample, for which the loss function is used.

Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Example of calculating loss function gradients

```
   matrixf y_true={{ 1, 2, 3, 4 },
                   { 5, 6, 7, 8 },
                   { 9,10,11,12 }};
   matrixf y_pred={{ 1, 2, 3, 4 },
                   {11,10, 9, 8 },
                   { 5, 6, 7,12 }};
   matrixf loss_gradient =y_pred.LossGradient(y_true,LOSS_MAE);
   matrixf loss_gradienth=y_pred.LossGradient(y_true,LOSS_MAE,AXIS_HORZ);
   matrixf loss_gradientv=y_pred.LossGradient(y_true,LOSS_MAE,AXIS_VERT);
   Print("loss gradients\n",loss_gradient);
   Print("loss gradients on horizontal axis\n",loss_gradienth);
   Print("loss gradients on vertical axis\n",loss_gradientv);

/* Result
   loss gradients
   [[0,0,0,0]
    [0.083333336,0.083333336,0.083333336,0]
    [-0.083333336,-0.083333336,-0.083333336,0]]
   loss gradients on horizontal axis
   [[0,0,0,0]
    [0.33333334,0.33333334,0.33333334,0]
    [-0.33333334,-0.33333334,-0.33333334,0]]
   loss gradients on vertical axis
   [[0,0,0,0]
    [0.25,0.25,0.25,0]
    [-0.25,-0.25,-0.25,0]]
*/
```

RegressionMetric

Compute the regression metric to evaluate the quality of the predicted data compared to the true data

```
double vector::RegressionMetric(
   const vector&           vector_true,   // vector of true values
   ENUM_REGRESSION_METRIC  metric         // metric type
   );

double matrix::RegressionMetric(
   const matrix&           matrix_true,   // matrix of true values
   ENUM_REGRESSION_METRIC  metric         // metric type
);

vector matrix::RegressionMetric(
   const matrix&           matrix_true,   // matrix of true values
   ENUM_REGRESSION_METRIC  metric,        // metric type
   int                     axis           // axis
   );
```

Parameters

vector_true/matrix_true

[in] Vector or matrix of true values.

metric

[in] Metric type from the ENUM_REGRESSION_METRIC enumeration.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

The calculated metric which evaluates the quality of the predicted data compared to the true data.

Note

- REGRESSION_MAE — mean absolute error which represents the absolute differences between predicted values and corresponding true values
- REGRESSION_MSE — mean square error which represents the squared differences between predicted values and corresponding true values
- REGRESSION_RMSE — square root of MSE
- REGRESSION_R2 - 1 — MSE(regression) / MSE(mean)
- REGRESSION_MAPE — MAE as a percentage
- REGRESSION_MSPE — MSE as a percentage
- REGRESSION_RMSLE — RMSE computed on a logarithmic scale

Example:

```
   vector y_true = {3, -0.5, 2, 7};
   vector y_pred = {2.5, 0.0, 2, 8};
//---
   double mse=y_pred.RegressionMetric(y_true,REGRESSION_MSE);
   Print("mse=",mse);
//---
   double mae=y_pred.RegressionMetric(y_true,REGRESSION_MAE);
   Print("mae=",mae);
//---
   double r2=y_pred.RegressionMetric(y_true,REGRESSION_R2);
   Print("r2=",r2);

  /* Result
   mae=0.375
   mse=0.5
   r2=0.9486081370449679
   */
```

ConfusionMatrix

Compute confusion matrix. The method is applied to the vector of predicted values.

```
matrix vector::ConfusionMatrix(
   const vector&        vect_true      // vector of true values
   );

matrix vector::ConfusionMatrix(
   const vector&        vect_true,     // vector of true values
   uint                 label          // label value
   );
```

Parameters

vect_true

[in] Vector of true values.

label

[in] Label value for calculating the confusion matrix.

Return Value

Confusion matrix. If a label value is not specified, a multi-class confusion matrix is returned, where each label is matched to each other label individually. If a label value is specified, a 2 x 2 matrix is returned, in which the specified label is considered positive, while all other labels are negative (ovr, one vs rest).

Note

Confusion matrix C is such that Cij is equal to the number of observations known to be in group i and predicted to be in group j. Thus in binary classification, the count of true negatives (TN) is C00, false negatives (FN) is C10, true positives (TP) is C11 and false positives (FP) is C01.

In other words, the matrix can be graphically represented as follows:

TN	FP
FN	TP

The sizes of the vector of true values and the vector of predicted values should be the same.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};
   matrix confusion=y_pred.ConfusionMatrix(y_true);
```

```
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,0);
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,1);
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,2);
   Print(confusion);

/*
  [[3,0,0,0,0,0,0,0,0,0]
   [0,3,0,0,0,0,0,0,0,0]
   [0,0,1,0,1,0,0,1,0,0]
   [0,0,0,1,0,0,0,1,0,0]
   [0,0,1,0,3,0,0,0,0,1]
   [0,0,0,0,0,2,0,0,0,0]
   [1,0,0,0,0,1,1,0,0,0]
   [0,0,0,0,0,0,0,2,0,1]
   [0,0,1,0,0,0,0,0,0,1]
   [0,0,0,0,0,0,0,0,0,4]]
  [[26,1]
   [0,3]]
  [[27,0]
   [0,3]]
  [[25,2]
   [2,1]]
*/
```

ConfusionMatrixMultilabel

Compute confusion matrix for each label. The method is applied to the vector of predicted values.

```
uint vector::ConfusionMatrixMultiLabel(
   const vector&       vect_true,     // vector of true values
   matrix&             confusions[]   // array of calculated confusion matrices
   );
```

Parameters

vect_true

[in] Vector of true values.

confusions

[out] An array of 2 x 2 matrices with computed confusion matrices for each label.

Return Value

Size of the array of calculated confusion matrices. In case of failure, it returns 0

Note

The result array can be dynamic or static. If the array is static, then it must be no less in size than the number of classes.

The sizes of the vector of true values and the vector of predicted values should be the same.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};
   matrix label_confusions[12];

   uint   res=y_pred.ConfusionMatrixMultiLabel(y_true,label_confusions);
   Print("res=",res,"  size=",label_confusions.Size());
   for(uint i=0; i<res; i++)
      Print(label_confusions[i]);

/*
  res=10  size=12
  [[26,1]
   [0,3]]
  [[27,0]
   [0,3]]
  [[25,2]
   [2,1]]
```

```
   [[28,0]
    [1,1]]
   [[24,1]
    [2,3]]
   [[27,1]
    [0,2]]
   [[27,0]
    [2,1]]
   [[25,2]
    [1,2]]
   [[28,0]
    [2,0]]
   [[23,3]
    [0,4]]
*/
```

ClassificationMetric

Compute the classification metric to evaluate the quality of the predicted data compared to the true data. The method is applied to the vector of predicted values.

```
vector vector::ClassificationMetric(
   const vector&               vect_true,     // vector of true values
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   );

vector vector::ClassificationMetric(
   const vector&               vect_true,     // vector of true values
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   ENUM_AVERAGE_MODE           mode           // averaging mode
   );
```

Parameters

vect_true

[in] Vector of true values.

metric

[in] Metric type from the ENUM_CLASSIFICATION_METRIC enumeration. Values other than CLASSIFICATION_TOP_K_ACCURACY, CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC (used in the ClassificationScore method) are applied.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Used for the CLASSIFICATION_F1, CLASSIFICATION_JACCARD, CLASSIFICATION_PRECISION and CLASSIFICATION_RECALL metrics.

Return Value

A vector containing the calculated metric. In the case of the AVERAGE_NONE averaging mode, the vector contains metric values for each class without averaging. (For example, in case of the binary classification, this would be two metrics for 'false' and 'true' respectively).

Note about averaging modes

AVERAGE_BINARY is only meaningful for binary classification.

AVERAGE_MICRO — calculate metrics globally by counting the total true positives, false negatives and false positives.

AVERAGE_MACRO — calculate metrics for each label and find their unweighted mean. This does not take label imbalance into account.

AVERAGE_WEIGHTED — calculate metrics for each label and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

Note

In case of binary classification, we can input not only an n x 2 matrix, where the first column contains probabilities for a negative label, and the second column contains probabilities for a positive label, but also a matrix consisting of one column with positive probabilities. This is because binary classification models can return either two probabilities or one probability for a positive label.

Example:

```
vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};

ClassificationScore

Compute the classification metric to evaluate the quality of the predicted data compared to the true data.

Unlike other methods in the Machine Learning section, this one applies to the vector of true values rather than the vector of predicted values.

```
vector vector::ClassificationScore(
   const matrix&               pred_scores,   // matrix containing probability distribu
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   ENUM_AVERAGE_MODE           mode          // averaging mode
   );

vector vector::ClassificationScore(
   const matrix&               pred_scores,   // matrix containing probability distribu
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   int                         param         // additional parameter
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows should correspond to the size of the vector of true values.

metric

[in] Metric type from the ENUM_CLASSIFICATION_METRIC enumeration. The CLASSIFICATION_TOP_K_ACCURACY, CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC values are used.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Used for the CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC metrics.

param

[in] In case of the CLASSIFICATION_TOP_K_ACCURACY metric, the integer K value should be specified instead of the averaging mode.

Return Value

A vector containing the calculated metric. In the case of the AVERAGE_NONE averaging mode, the vector contains metric values for each class without averaging. (For example, in case of the binary classification, this would be two metrics for 'false' and 'true' respectively).

Note about averaging modes

AVERAGE_BINARY is only meaningful for binary classification.

AVERAGE_MICRO — calculate metrics globally by considering each element of the label indicator matrix as a label. The label indicator matrix refers to a matrix with a set of probabilities for each label.

AVERAGE_MACRO — calculate metrics for each label and find their unweighted mean. This does not take label imbalance into account.

AVERAGE_WEIGHTED — calculate metrics for each label and find their average weighted by support (the number of true instances for each label).

Note

In case of binary classification, we can input not only an n x 2 matrix, where the first column contains probabilities for a negative label, and the second column contains probabilities for a positive label, but also a matrix consisting of one column with positive probabilities. This is because binary classification models can return either two probabilities or one probability for a positive label.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   //vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};

//--- label scores          0         1         2         3         4         5

*/
```

PrecisionRecall

Compute values to construct a precision-recall curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

```
bool vector::PrecisionRecall(
   const matrix&                 pred_scores,   // matrix containing the probability
   const ENUM_ENUM_AVERAGE_MODE  mode           // averaging mode
   matrix&                       precision,     // calculated precision values for ea
   matrix&                       recall,        // calculated recall values for each
   matrix&                       thresholds,    // threshold values sorted in descend
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows must correspond to the size of the vector of true values.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Only AVERAGE_NONE, AVERAGE_BINARY and AVERAGE_MICRO are used.

precision

[out] A matrix with calculated precision curve values. If no averaging is applied (AVERAGE_NONE), the number of rows in the matrix corresponds to the number of model classes. The number of columns corresponds to the size of the vector of true values (or the number of rows in the probability distribution matrix pred_score). In the case of microaveraging, the number of rows in the matrix corresponds to the total number of threshold values, excluding duplicates.

recall

[out] A matrix with calculated recall curve values.

threshold

[out] Threshold matrix obtained by sorting the probability matrix

Note

See notes for the ClassificationScore method.

Example

An example of collecting statistics from the mnist.onnx model (99% accuracy).

```
//--- data for classification metrics
   vectorf y_true(images);
   vectorf y_pred(images);
   matrixf y_scores(images,10);
//--- input-output
   matrixf image(28,28);
```

```
   vectorf result(10);

//--- testing
   for(int test=0; test<images; test++)
     {
      image=test_data[test].image;
      if(!OnnxRun(model,ONNX_DEFAULT,image,result))
        {
         Print("OnnxRun error ",GetLastError());
         break;
        }
      result.Activation(result,AF_SOFTMAX);
      //--- collect data
      y_true[test]=(float)test_data[test].label;
      y_pred[test]=(float)result.ArgMax();
      y_scores.Row(result,test);
     }    }
```

Accuracy calculation

```
   vectorf accuracy=y_pred.ClassificationMetric(y_true,CLASSIFICATION_ACCURACY);
   PrintFormat("accuracy=%f",accuracy[0]);

accuracy=0.989000
```

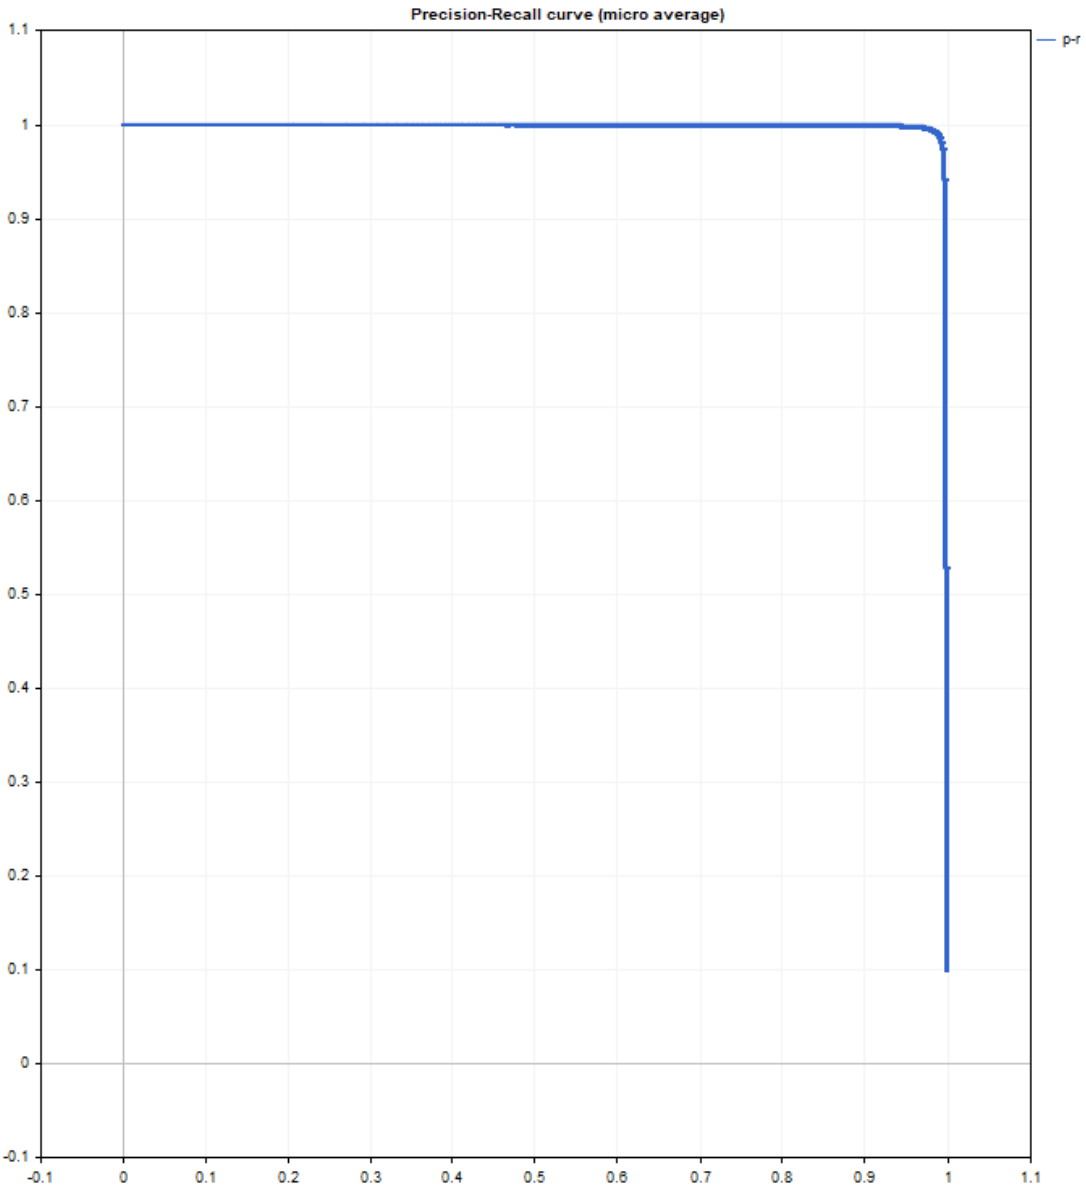
An example of plotting precision-recall graphs, where precision values are plotted on the y-axis and recall values are plotted on the x-axis. Also precision and recall graphs are plotted separately, with threshold values plotted on the x-axis

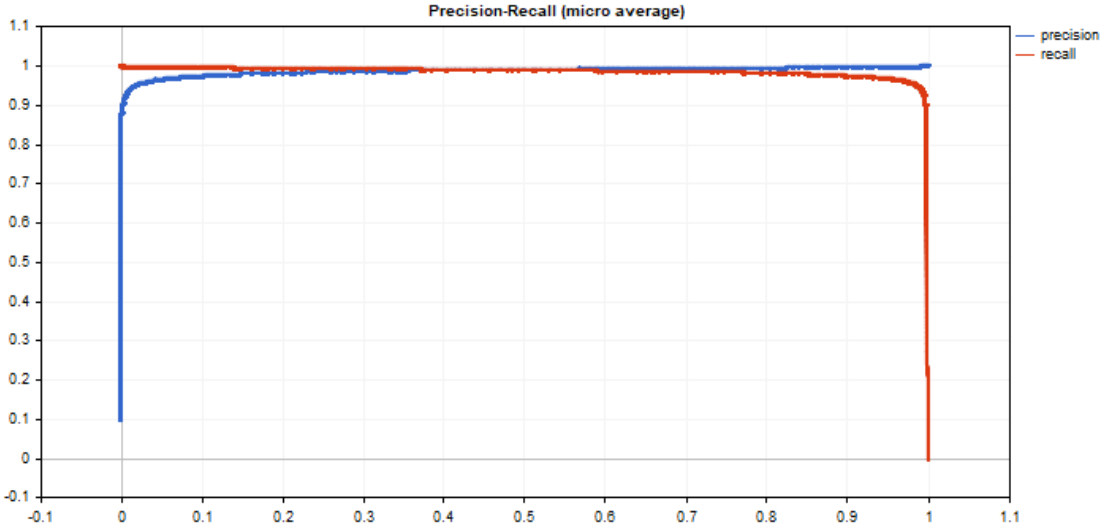
```
   if(y_true.PrecisionRecall(y_scores,AVERAGE_MICRO,mat_precision,mat_recall,mat_thres
     {
      double precision[],recall[],thres[];
      ArrayResize(precision,mat_thres.Cols());
      ArrayResize(recall,mat_thres.Cols());
      ArrayResize(thres,mat_thres.Cols());

      for(uint i=0; i<thres.Size(); i++)
        {
         precision[i]=mat_precision[0][i];
         recall[i]=mat_recall[0][i];
         thres[i]=mat_thres[0][i];
        }
      thres[0]=thres[1]+0.001;

      PlotCurve("Precision-Recall curve (micro average)","p-r","",recall,precision);
      Plot2Curves("Precision-Recall (micro average)","precision","recall",thres,precis
     }
```

Resulting curves:





ReceiverOperatingCharacteristic

Compute values to construct the Receiver Operating Characteristic (ROC) curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

```
bool vector::ReceiverOperatingCharacteristic(
   const matrix&                 pred_scores,   // matrix containing the probability
   const ENUM_ENUM_AVERAGE_MODE  mode           // averaging mode
   matrix&                       fpr,           // calculated false positive rate valu
   matrix&                       tpr,           // calculated true positive rate value
   matrix&                       thresholds,    // threshold values sorted in descendi
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows must correspond to the size of the vector of true values.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Only AVERAGE_NONE, AVERAGE_BINARY and AVERAGE_MICRO are used.

fpr

[out] A matrix with calculated values of the false positive rate curve. If no averaging is applied (AVERAGE_NONE), the number of rows in the matrix corresponds to the number of model classes. The number of columns corresponds to the size of the vector of true values (or the number of rows in the probability distribution matrix pred_score). In the case of microaveraging, the number of rows in the matrix corresponds to the total number of threshold values, excluding duplicates.

tpr

[out] A matrix with calculated values of the true positive rate curve.

threshold

[out] Threshold matrix obtained by sorting the probability matrix

Note

See notes for the ClassificationScore method.

Example

An example of plotting ROC graphs, where tpr values are plotted on the y-axis and fpr values are plotted on the x-axis. Also fpr and tpr graphs are plotted separately, with threshold values plotted on the x-axis

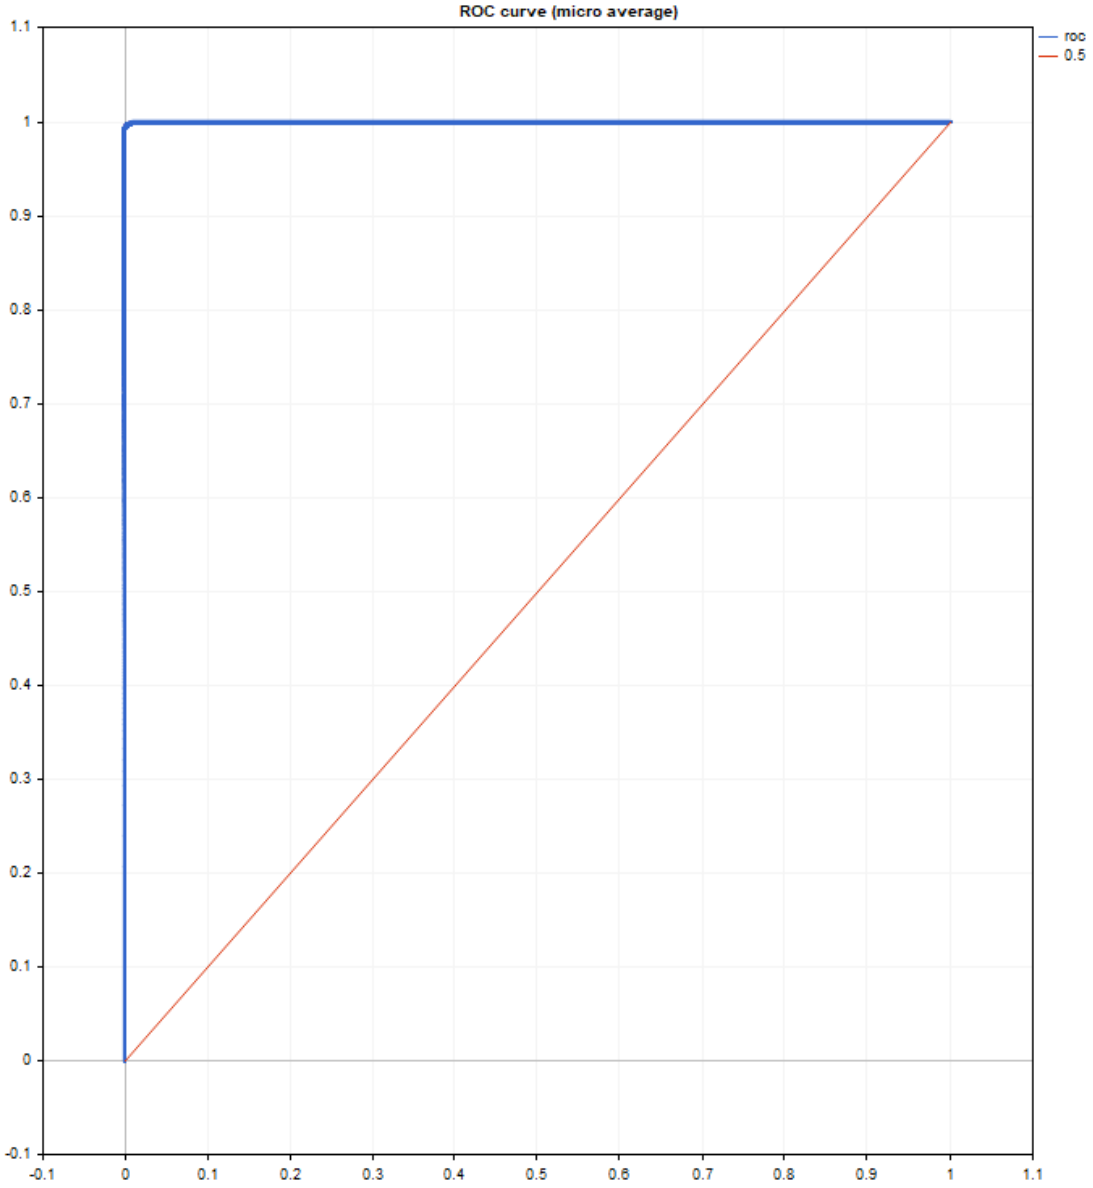
```
   matrixf mat_thres;
   matrixf mat_fpr;
   matrixf mat_tpr;
```

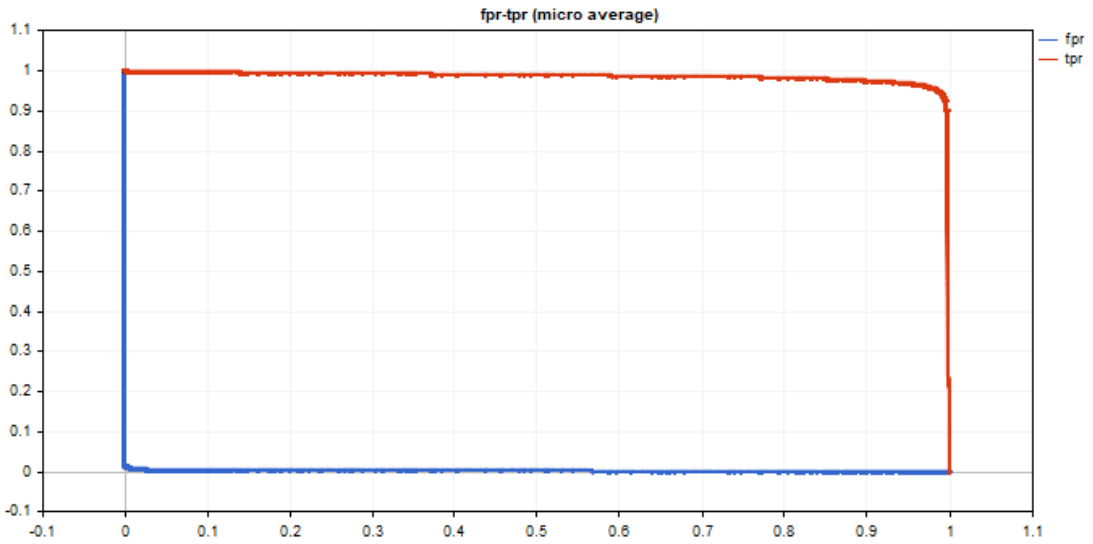
```
   if(y_true.ReceiverOperatingCharacteristic(y_scores,AVERAGE_MICRO,mat_fpr,mat_tpr,ma
     {
      double fpr[],tpr[],thres[];
      ArrayResize(fpr,mat_thres.Cols());
      ArrayResize(tpr,mat_thres.Cols());
      ArrayResize(thres,mat_thres.Cols());

      for(uint i=0; i<fpr.Size(); i++)
        {
         fpr[i]=mat_fpr[0][i];
         tpr[i]=mat_tpr[0][i];
         thres[i]=mat_thres[0][i];
        }
      thres[0]=thres[1]+0.001;

      PlotCurve("ROC curve (micro average)","roc","0.5",fpr,tpr);
      Plot2Curves("fpr-tpr (micro average)","fpr","tpr",thres,fpr,tpr);
     }
```

Resulting curves:





The graph output code is simple and based on the <Graphics/Graphic.mqh> standard library.

The examples use the data of the mnist.onnx model. The code is presented in the PrecisionRecall method description.

ROC AUC is close to ideal.

```
roc auc score micro = [0.99991]
```

Conversion Functions

This is a group of functions that provide conversion of data from one format into another.

The NormalizeDouble() function must be specially noted as it provides the necessary accuracy of the price presentation. In trading operations, no unnormalized prices may be used if their accuracy even a digit exceeds that required by the trade server.

Function	Action
CharToString	Converting a symbol code into a one-character string
DoubleToString	Converting a numeric value to a text line with a specified accuracy
EnumToString	Converting an enumeration value of any type to string
NormalizeDouble	Rounding of a floating point number to a specified accuracy
StringToDouble	Converting a string containing a symbol representation of number into number of double type
StringToInteger	Converting a string containing a symbol representation of number into number of long type
StringToTime	Converting a string containing time or date in "yyyy.mm.dd [hh:mi]" format into datetime type
TimeToString	Converting a value containing time in seconds elapsed since 01.01.1970 into a string of "yyyy.mm.dd hh:mi" format
IntegerToString	Converting int into a string of preset length
ShortToString	Converting symbol code (unicode) into one-symbol string
ShortArrayToString	Copying array part into a string
StringToShortArray	Symbol-wise copying a string to a selected part of array of ushort type
CharArrayToString	Converting symbol code (ansi) into one-symbol array
StringToCharArray	Symbol-wise copying a string converted from Unicode to ANSI, to a selected place of array of uchar type
CharArrayToStruct	Copy uchar type array to POD structure
StructToCharArray	Copy POD structure to uchar type array
ColorToARGB	Converting color type to uint type to receive ARGB representation of the color.
ColorToString	Converting color value into string as "R,G,B"
StringToColor	Converting "R,G,B" string or string with color name into color type value
StringFormat	Converting number into string according to preset format

See also

Use of a Codepage

CharToString

Converting a symbol code into a one-character string.

```
string  CharToString(
   uchar  char_code      // numeric code of symbol
   );
```

Parameters

char_code

[in] Code of ANSI symbol.

Return Value

String with a ANSI symbol.

See also

StringToCharArray, ShortToString, StringGetCharacter

CharArrayToString

It copies and converts part of array of uchar type into a returned string.

```
string  CharArrayToString(
   uchar  array[],               // array
   int    start=0,               // starting position in the array
   int    count=-1               // number of symbols
   uint    codepage=CP_ACP       // code page
   );
```

Parameters

array[]

[in] Array of uchar type.

start=0

[in] Position from which copying starts. by default 0 is used.

count=-1

[in] Number of array elements for copying. Defines the length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.

codepage=CP_ACP

[in] The value of the code page. There is a number of built-in constants for the most used code pages.

Return Value

String.

See also

StringToCharArray, ShortArrayToString, Use of a Codepage

CharArrayToStruct

Copy uchar type array to POD structure.

```
bool  CharArrayToStruct(
   void&          struct_object,     // structure
   const uchar&   char_array[],      // array
   uint           start_pos=0        // starting position in the array
   );
```

Parameters

struct_object

[in] Reference to any type of POD structure (containing only simple data types).

char_array[]

[in] uchar type array.

start_pos=0

[in] Position in the array, data copying starts from.

Return Value

Returns true if successful, otherwise false.

See also

StringToCharArray, ShortArrayToString, StructToCharArray, Use of a Codepage, FileReadStruct, Unions (union), MathSwap

StructToCharArray

Copy POD structure to uchar type array.

```
bool  StructToCharArray(
   const void&  struct_object,      // structure
   uchar&       char_array[],       // array
   uint         start_pos=0         // starting position in the array
   );
```

Parameters

struct_object

[in] Reference to any type of POD structure (containing only simple data types).

char_array[]

[in] uchar type array.

start_pos=0

[in] Position in the array, starting from which the copied data are added.

Return Value

Returns true if successful, otherwise false.

Note

When copying, the dynamic array automatically expands (ArrayResize) if there is not enough space. If the array cannot be expanded up to the required value, the function returns an error.

See also

StringToCharArray, ShortArrayToString,CharArrayToStruct, Use of a Codepage, FileWriteStruct, Unions (union), MathSwap

ColorToARGB

The function converts color type into uint type to get ARGB representation of the color. ARGB color format is used to generate a graphical resource, text display, as well as for CCanvas standard library class.

```
uint  ColorToARGB(
   color  clr,          // converted color in color format
   uchar  alpha=255     // alpha channel managing color transparency
   );
```

Parameters

clr

[in] Color value in color type variable.

alpha

[in] The value of the alpha channel used to receive the color in ARGB format. The value may be set from 0 (a color of a foreground pixel does not change the display of an underlying one) up to 255 (a color of an underlying pixel is completely replaced by the foreground pixel's one). Color transparency in percentage terms is calculated as (1-alpha/255)*100%. In other words, the lesser value of the alpha channel leads to more transparent color.

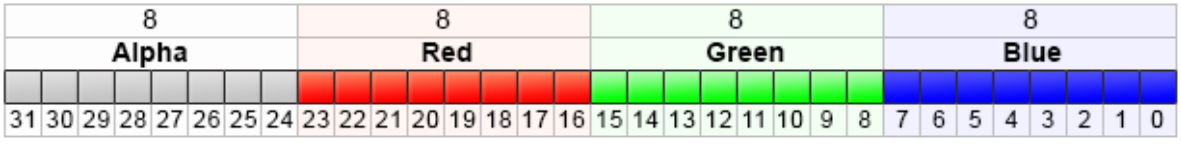
Return Value

Presenting the color in ARGB format where Alfa, Red, Green, Blue (alpha channel, red, green, blue) values are set in series in four uint type bytes.

Note

RGB is a basic and commonly used format for pixel color description on a screen in computer graphics. Names of basic colors are used to set red, green and blue color components. Each component is described by one byte specifying the color saturation in the range of 0 to 255 (0x00 to 0XFF in hexadecimal format). Since the white color contains all colors, it is described as 0xFFFFFF, that is, each one of three components is presented by the maximum value of 0xFF.

However, some tasks require to specify the color transparency to describe the look of an image in case it is covered by the color with some degree of transparency. The concept of alpha channel is introduced for such cases. It is implemented as an additional component of RGB format. ARGB format structure is shown below.



ARGB values are typically expressed using hexadecimal format with each pair of digits representing the values of Alpha, Red, Green and Blue channels, respectively. For example, 80FFFF00 color represents 50.2% opaque yellow. Initially, 0x80 sets 50.2% alpha value, as it is 50.2% of 0xFF value. Then, the first FF pair defines the highest value of the red component; the next FF pair is like the previous but for the green component; the final 00 pair represents the lowest value the blue component can have (absence of blue). Combination of green and red colors yields yellow one. If the

alpha channel is not used, the entry can be reduced down to 6 RRGGBB digits, this is why the alpha channel values are stored in the top bits of uint integer type.

Depending on the context, hexadecimal digits can be written with '0x' or '#' prefix, for example, 80FFFF00, 0x80FFFF00 or #80FFFF00.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set transparency
   uchar alpha=0x55;  // 0x55 means 55/255=21.6 % of transparency
   //--- derive conversion to ARGB for clrBlue color
   PrintFormat("0x%.8X - clrBlue",clrBlue);
   PrintFormat("0x%.8X - clrBlue ARGB with alpha=0x55 (transparency 21.6%%)",ColorToAR
   //--- derive conversion to ARGB for clrGreen color
   PrintFormat("0x%.8X - clrGreen",clrGreen);
   PrintFormat("0x%.8X - clrGreen ARGB with alpha=0x55 (transparency 21.6%%)",ColorToA
   //--- derive conversion to ARGB for clrRed color
   PrintFormat("0x%.8X - clrRed",clrRed);
   PrintFormat("0x%.8X - clrRed ARGB with alpha=0x55 (transparency 21.6%%)",ColorToARG
  }
```

See also

Resources, ResourceCreate(), TextOut(), color type, char, short, int and long types

ColorToString

It converts color value into string of "R,G,B" form.

```
string  ColorToString(
   color  color_value,     // color value
   bool   color_name       // show color name or not
   );
```

Parameters

color_value

[in] Color value in color type variable.

color_name

[in] Return color name if it is identical to one of predefined color constants.

Return Value

String presentation of color as "R,G,B", where R, G and B are decimal constants from 0 to 255 converted into a string. If the color_name=true parameter is set, it will try to convert color value into color name.

Example:

```
   string clr=ColorToString(C'0,255,0'); // green color
   Print(clr);

   clr=ColorToString(C'0,255,0',true);   // get color constant
   Print(clr);
```

See also

StringToColor, ColorToARGB

DoubleToString

Converting numeric value into text string.

```
string  DoubleToString(
   double  value,      // number
   int     digits=8    // number of digits after decimal point
   );
```

Parameters

value

[in] Value with a floating point.

digits

[in] Accuracy format. If the *digits* value is in the range between 0 and 16, a string presentation of a number with the specified number of digits after the point will be obtained. If the *digits* value is in the range between -1 and -16, a string representation of a number in the scientific format with the specified number of digits after the decimal point will be obtained. In all other cases the string value will contain 8 digits after the decimal point.

Return Value

String containing a symbol representation of a number with the specified accuracy.

Example:

```
   Print("DoubleToString(120.0 + M_PI) : ",DoubleToString(120.0+M_PI));
   Print("DoubleToString(120.0 + M_PI,16) : ",DoubleToString(120.0+M_PI,16));
   Print("DoubleToString(120.0 + M_PI,-16) : ",DoubleToString(120.0+M_PI,-16));
   Print("DoubleToString(120.0 + M_PI,-1) : ",DoubleToString(120.0+M_PI,-1));
   Print("DoubleToString(120.0 + M_PI,-20) : ",DoubleToString(120.0+M_PI,-20));
```

See also

NormalizeDouble, StringToDouble

EnumToString

Converting an enumeration value of any type to a text form.

```
string  EnumToString(
   any_enum  value      // any type enumeration value
   );
```

Parameters

value

[in] Any type enumeration value.

Return Value

A string with a text representation of the enumeration. To get the error message call the GetLastError() function.

Note

The function can set the following error values in the _LastError variable:

- ERR_INTERNAL_ERROR - error of the execution environment
- ERR_NOT_ENOUGH_MEMORY - not enough memory to complete the operation
- ERR_INVALID_PARAMETER - can't allow the name of the enumeration value

Example:

```
enum interval  // enumeration of named constants
  {
   month=1,     // one-month interval
   two_months,  // two months
   quarter,     // three months - a quarter
   halfyear=6,  // half a year
   year=12,     // a year - 12 months
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set the time interval equal to one month
   interval period=month;
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- set the time interval equal to a quarter (three months)
   period=quarter;
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- set the time interval equal to one year (12 months)
   period=year;
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- check how the order type is shown
```

```
   ENUM_ORDER_TYPE type=ORDER_TYPE_BUY;
   Print(EnumToString(type)+"="+IntegerToString(type));

//--- check how incorrect values are shown
   type=WRONG_VALUE;
   Print(EnumToString(type)+"="+IntegerToString(type));

// Result:
// month=1
// quarter=3
// year=12
// ORDER_TYPE_BUY=0
// ENUM_ORDER_TYPE::-1=-1
  }
```

See also

Enumerations, Input variables

IntegerToString

This function converts value of integer type into a string of a specified length and returns the obtained string.

```
string  IntegerToString(
   long    number,              // number
   int     str_len=0,           // length of result string
   ushort  fill_symbol=' '      // filler
   );
```

Parameters

number

[in] Number for conversion.

str_len=0

[in] String length. If the resulting string length is larger than the specified one, the string is not cut off. If it is smaller, filler symbols will be added to the left.

fill_symbol=' '

[in] Filler symbol. By default it is a space.

Return Value

String.

See also

StringToInteger

ShortToString

It converts the symbol code (unicode) into one-symbol string and returns resulting string.

```
string  ShortToString(
   ushort  symbol_code      // symbol
   );
```

Parameters

symbol_code

[in] Symbol code. Instead of a symbol code you can use literal string containing a symbol or a literal string with 2-byte hexadecimal code corresponding to the symbol from the Unicode table.

Return Value

String.

See also

StringToCharArray, CharToString, StringGetCharacter

ShortArrayToString

It copies part of array into a returned string.

```
string  ShortArrayToString(
   ushort  array[],      // array
   int     start=0,      // starting position in the array
   int     count=-1      // number of symbols
   );
```

Parameters

array[]

[in] Array of ushort type (analog of wchar_t type).

start=0

[in] Position, from which copying starts, Default - 0.

count=-1

[in] Number of array elements to copy. Defines the length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.

Return Value

String.

See also

StringToShortArray, CharArrayToString, Use of a Codepage

TimeToString

Converting a value containing time in seconds elapsed since 01.01.1970 into a string of "yyyy.mm.dd hh:mi" format.

```
string  TimeToString(
   datetime  value,                          // number
   int       mode=TIME_DATE|TIME_MINUTES     // output format
   );
```

Parameters

value

[in] Time in seconds from 00:00 1970/01/01.

mode=TIME_DATE|TIME_MINUTES

[in] Additional data input mode. Can be one or combined flag:
TIME_DATE gets result as "yyyy.mm.dd",
TIME_MINUTES gets result as "hh:mi",
TIME_SECONDS gets results as "hh:mi:ss".

Return Value

String.

See also

StringToTime, TimeToStruct

NormalizeDouble

Rounding floating point number to a specified accuracy.

```
double  NormalizeDouble(
   double   value,      // normalized number
   int      digits      // number of digits after decimal point
   );
```

Parameters

value

[in] Value with a floating point.

digits

[in] Accuracy format, number of digits after point (0-8).

Return Value

Value of double type with preset accuracy.

Note

Calculated values of StopLoss, TakeProfit, and values of open prices for pending orders must be normalized with the accuracy, the value of which can be obtained by Digits().

Please note that when output to Journal using the Print() function, a normalized number may contain a greater number of decimal places than you expect. For example, for:

```
   double a=76.671;              // A normalized number with three decimal places
   Print("Print(76.671)=",a);    // Output as is
   Print("DoubleToString(a,8)=",DoubleToString(a,8)); // Output with a preset accuracy
```

you will have the following in the terminal:

```
   DoubleToString(a,8)=76.67100000

   Print(76.671)=76.67100000000001
```

Example:

```
   double pi=M_PI;
   Print("pi = ",DoubleToString(pi,16));

   double pi_3=NormalizeDouble(M_PI,3);
   Print("NormalizeDouble(pi,3) = ",DoubleToString(pi_3,16))
   ;
   double pi_8=NormalizeDouble(M_PI,8);
   Print("NormalizeDouble(pi,8) = ",DoubleToString(pi_8,16));

   double pi_0=NormalizeDouble(M_PI,0);
   Print("NormalizeDouble(pi,0) = ",DoubleToString(pi_0,16));
/*
   Result:
```

```
   pi= 3.1415926535897931
   NormalizeDouble(pi,3)= 3.1419999999999999
   NormalizeDouble(pi,8)= 3.1415926499999998
   NormalizeDouble(pi,0)= 3.0000000000000000
*/
```

See also

DoubleToString, Real types (double, float), Typecasting

StringToCharArray

Symbol-wise copies a string converted from Unicode to ANSI, to a selected place of array of uchar type. It returns the number of copied elements.

```
int  StringToCharArray(
   string  text_string,          // source string
   uchar&  array[],              // array
   int     start=0,              // starting position in the array
   int     count=-1              // number of symbols
   uint    codepage=CP_ACP       // code page
   );
```

Parameters

text_string

[in] String to copy.

array[]

[out] Array of uchar type.

start=0

[in] Position from which copying starts. Default - 0.

count=-1

[in] Number of array elements to copy. Defines length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0. Terminal 0 will also be copied to the recipient array, in this case the size of a dynamic array can be increased if necessary to the size of the string. If the size of the dynamic array exceeds the length of the string, the size of the array will not be reduced.

codepage=CP_ACP

[in] The value of the code page. For the most-used code pages provide appropriate constants.

Return Value

Number of copied elements.

See also

CharArrayToString, StringToShortArray, Use of a Codepage

StringToColor

Converting "R,G,B" string or string with color name into color type value.

```
color  StringToColor(
   string  color_string      // string representation of color
   );
```

Parameters

color_string

[in] String representation of a color of "R,G,B" type or name of one of predefined Web-colors.

Return Value

Color value.

Example:

```
   color str_color=StringToColor("0,127,0");
   Print(str_color);
   Print((string)str_color);
//--- change color a little
   str_color=StringToColor("0,128,0");
   Print(str_color);
   Print((string)str_color);
```

See also

ColorToString, ColorToARGB

StringToDouble

The function converts string containing a symbol representation of number into number of double type.

```
double  StringToDouble(
   string  value      // string
   );
```

Parameters

value

[in] String containing a symbol representation of a number.

Return Value

Value of double type.

See also

NormalizeDouble, Real types (double, float), Typecasting

StringToInteger

The function converts string containing a symbol representation of number into number of long (integer) type.

```
long  StringToInteger(
   string  value      // string
   );
```

Parameters

value

[in] String containing a number.

Return Value

Value of long type.

See also

IntegerToString, Real types (double, float), Typecasting

StringToShortArray

The function symbol-wise copies a string into a specified place of an array of ushort type. It returns the number of copied elements.

```
int  StringToShortArray(
   string  text_string,      // source string
   ushort& array[],          // array
   int     start=0,          // starting position in the array
   int     count=-1          // number of symbols
   );
```

Parameters

text_string

[in] String to copy

array[]

[out] Array of ushort type (analog of wchar_t type).

start=0

[in] Position, from which copying starts. Default - 0.

count=-1

[in] Number of array elements to copy. Defines length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.Terminal 0 will also be copied to the recipient array, in this case the size of a dynamic array can be increased if necessary to the size of the string. If the size of the dynamic array exceeds the length of the string, the size of the array will not be reduced.

Return Value

Number of copied elements.

StringToTime

Transforms the string containing time and/or date in the "yyyy.mm.dd [hh:mi]" format into the datetime type number.

```
datetime  StringToTime(
   const string  time_string      // date string
   );
```

Parameters

time_string

[in] String in one of the specified formats:

- "yyyy.mm.dd [hh:mi]"
- "yyyy.mm.dd [hh:mi:ss]"
- "yyyymmdd [hh:mi:ss]"
- "yyyymmdd [hhmiss]"
- "yyyy/mm/dd [hh:mi:ss]"
- "yyyy-mm-dd [hh:mi:ss]"

Return Value

datetime type value containing the number of seconds elapsed since 01.01.1970.

Note

Any sequence of space and tabulation characters between date and time is considered to be a single space to avoid additional processing of the *time_string* before calling StringToTime().

TimeToString, TimeToStruct

StringFormat

The function formats obtained parameters and returns a string.

```
string  StringFormat(
   string  format,     // string with format description
   ...     ...         // parameters
   );
```

Parameters

format

[in] String containing method of formatting. Formatting rules are the same as for the PrintFormat function.

...

[in] Parameters, separated by a comma.

Return Value

String.

Example:

```
void OnStart()
  {
//--- string variables
   string output_string;
   string temp_string;
   string format_string;
//--- prepare the specification header
   temp_string=StringFormat("Contract specification for %s:\n",_Symbol);
   StringAdd(output_string,temp_string);
//--- int value output
   int digits=(int)SymbolInfoInteger(_Symbol,SYMBOL_DIGITS);
   temp_string=StringFormat("   SYMBOL_DIGITS = %d (number of digits after the decimal
                            digits);
   StringAdd(output_string,temp_string);
//--- double value output with variable number of digits after the decimal point
   double point_value=SymbolInfoDouble(_Symbol,SYMBOL_POINT);
   format_string=StringFormat("   SYMBOL_POINT = %%.%df (point value)\n",
                              digits);
   temp_string=StringFormat(format_string,point_value);
   StringAdd(output_string,temp_string);
//--- int value output

Mathematical Functions

A set of mathematical and trigonometric functions.

Math functions were originally designed to perform relevant operations on scalar values. From this build on, most of the functions can be applied to matrices and vectors. These include MathAbs, MathArccos, MathArcsin, MathArctan, MathCeil, MathCos, MathExp, MathFloor, MathLog, MathLog10, MathMod, MathPow, MathRound, MathSin, MathSqrt, MathTan, MathExpm1, MathLog1p, MathArccosh, MathArcsinh, MathArctanh, MathCosh, MathSinh, and MathTanh. Such operations imply element-wise handling of matrices or vectors. Example:

```
//---
  matrix a= {{1, 4}, {9, 16}};
  Print("matrix a=\n",a);
  a=MathSqrt(a);
  Print("MatrSqrt(a)=\n",a);
  /*
   matrix a=
   [[1,4]
    [9,16]]
   MatrSqrt(a)=
   [[1,2]
    [3,4]]
  */
```

For MathMod and MathPow, the second element can be either a scalar or a matrix/vector of the appropriate size.

Function	Action
MathAbs	Returns absolute value (modulus) of the specified numeric value
MathArccos	Returns the arc cosine of x in radians
MathArcsin	Returns the arc sine of x in radians
MathArctan	Returns the arc tangent of x in radians
MathArctan2	Return the angle (in radians) whose tangent is the quotient of two specified numbers
MathClassify	Returns the type of a real number
MathCeil	Returns integer numeric value closest from above
MathCos	Returns the cosine of a number
MathExp	Returns exponent of a number
MathFloor	Returns integer numeric value closest from below
MathLog	Returns natural logarithm
MathLog10	Returns the logarithm of a number by base 10

Function	Action
MathMax	Returns the maximal value of the two numeric values
MathMin	Returns the minimal value of the two numeric values
MathMod	Returns the real remainder after the division of two numbers
MathPow	Raises the base to the specified power
MathRand	Returns a pseudorandom value within the range of 0 to 32767
MathRound	Rounds of a value to the nearest integer
MathSin	Returns the sine of a number
MathSqrt	Returns a square root
MathSrand	Sets the starting point for generating a series of pseudorandom integers
MathTan	Returns the tangent of a number
MathIsValidNumber	Checks the correctness of a real number
MathExpm1	Returns the value of the expression MathExp(x)-1
MathLog1p	Returns the value of the expression MathLog(1+x)
MathArccosh	Returns the hyperbolic arccosine
MathArcsinh	Returns the hyperbolic arcsine
MathArctanh	Returns the hyperbolic arctangent
MathCosh	Returns the hyperbolic cosine
MathSinh	Returns the hyperbolic sine
MathTanh	Returns the hyperbolic tangent
MathSwap	Change the order of bytes in the ushort/uint/ushort types value

MathAbs

The function returns the absolute value (modulus) of the specified numeric value.

```
double  MathAbs(
   double  value      // numeric value
   );
```

Parameters

value

[in] Numeric value.

Return Value

Value of double type more than or equal to zero.

Note

Instead the MathAbs() function you can use fabs().

MathArccos

The function returns the arccosine of x within the range 0 to π in radians.

```
double  MathArccos(
   double  val     // -1<val<1
   );
```

Parameters

val

[in] The val value between -1 and 1, the arc cosine of which is to be calculated.

Return Value

Arc cosine of a number in radians. If val is less than -1 or more than 1, the function returns NaN (indeterminate value).

Note

Instead of the MathArccos() function you can use acos().

See also

Real types (double, float)

MathArcsin

The function returns the arc sine of x within the range of -π/2 to π/2 radians.

```
double  MathArcsin(
   double  val      // -1<value<1
   );
```

Parameters

val

[in] The val value between -1 and 1, the arc sine of which is to be calculated.

Return Value

Arc sine of the val number in radians within the range of -π/2 to π/2 radians. If val is less than -1 or more than 1, the function returns NaN (indeterminate value).

Note

Instead of the MathArcsin() function you can use asin().

See also

Real types (double, float)

MathArctan

The function returns the arc tangent of x. If x is equal to 0, the function returns 0.

```
double  MathArctan(
   double  value      // tangent
   );
```

Parameters

value

[in] A number representing a tangent.

Return Value

MathArctan returns a value within the range of -π/2 to π/2 radians.

Note

Instead of the MathArctan() function you can use atan().

MathArctan2

Return the angle (in radians) whose tangent is the quotient of two specified numbers.

```
double MathArctan2(
 double y     // The y coordinate of a point
 double x     // The x coordinate of a point
  );
```

Parameters

y

[in] Y coordinate value.

x

[in] X coordinate value.

Return Value

MathArctan2 returns an angle, θ, within the range from -π to π radians, so that MathTan(θ)=y/x.

Please note as follows:

- For (x, y) in quadrant 1, 0< θ < π/2
- For (x, y) in quadrant 2, π/2< θ ≤ π
- For (x, y) in quadrant 3, -π < θ < -π/2
- For (x, y) in quadrant 4, -π/2 < θ < 0

For points on the boundaries of the quadrants, the return value is the following:

- If y is 0 and x is not negative, θ = 0.
- If y is 0 and x is negative, θ = π.
- If y is positive and x is 0, θ = π/2.
- If y is negative and x is 0, θ = -π/2.
- If y is 0 and x is 0, θ = 0.

Note

Instead of the MathArctan2() function, you can use the atan2() function.

MathClassify

Determines the type of a real number and returns a result as a value from the ENUM_FP_CLASS enumeration

```
ENUM_FP_CLASS  MathClassify(
   double  value      // real number
   );
```

Parameters

value

[in] The real number to be checked

Return Value

A value from the ENUM_FP_CLASS enumeration

ENUM_FP_CLASS

ID	Description
FP_SUBNORMAL	A subnormal number which is closer to zero than the smallest representable normal number DBL_MIN (2.2250738585072014e-308)
FP_NORMAL	A normal number in the range between 2.2250738585072014e-308 and 1.7976931348623158e+308
FP_ZERO	A positive or a negative zero
FP_INFINITE	A number which cannot be represented by the appropriate type, positive or negative infinity
FP_NAN	Not a number.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- test NaN
  double nan=double("nan");
  PrintFormat("Test NaN: %G is %s, MathIsValidNumber(NaN)=%s",
              nan,
              EnumToString(MathClassify(nan)),
              (string)MathIsValidNumber(nan));
//--- test infinity
  double inf=double("inf");
  PrintFormat("Test Inf: %G is %s, MathIsValidNumber(inf)=%s",
```

```
               inf,
               EnumToString(MathClassify(inf)),
               (string)MathIsValidNumber(inf));
//--- test normal value
  double normal=1.2345e6;
  PrintFormat("Test Normal: %G is %s, MathIsValidNumber(normal)=%s",
               normal,
               EnumToString(MathClassify(normal)),
               (string)MathIsValidNumber(normal));
//--- test subnormal value
  double sub_normal=DBL_MIN/2.0;
  PrintFormat("Test Subnormal: %G is %s, MathIsValidNumber(sub_normal)=%s",
               sub_normal,
               EnumToString(MathClassify(sub_normal)),
               (string)MathIsValidNumber(sub_normal));
//--- test zero value
  double zero=0.0/(-1);
  PrintFormat("Test Zero: %G is %s, MathIsValidNumber(zero)=%s",
               zero,
               EnumToString(MathClassify(zero)),
               (string)MathIsValidNumber(zero));
 }
 /*
 Result:
   Test NaN: NAN is FP_NAN, MathIsValidNumber(NaN)=false
   Test Inf: INF is FP_INFINITE, MathIsValidNumber(inf)=false
   Test Normal: 1.2345E+06 is FP_NORMAL, MathIsValidNumber(normal)=true
   Test Subnormal: 1.11254E-308 is FP_SUBNORMAL, MathIsValidNumber(sub_normal)=true
   Test Zero: -0 is FP_ZERO, MathIsValidNumber(zero)=true
*/
//+------------------------------------------------------------------+
```

See also

Real types (double, float), MathIsValidNumber

MathCeil

The function returns integer numeric value closest from above.

```
double  MathCeil(
   double  val      // number
   );
```

Parameters

val

[in] Numeric value.

Return Value

Numeric value representing the smallest integer that exceeds or equals to val.

Note

Instead of the MathCeil() function you can use ceil().

MathCos

The function returns the cosine of an angle.

```
double  MathCos(
   double  value      // number
   );
```

Parameters

value

[in] Angle in radians.

Return Value

Value of double type within the range of -1 to 1.

Note

Instead of MathCos() you can use cos().

MathExp

The function returns the value of e raised to the power of d.

```
double  MathExp(
   double  value      // power for the number e
   );
```

Parameters

value

[in] A number specifying the power.

Return Value

A number of double type. In case of overflow the function returns INF (infinity), in case of underflow MathExp returns 0.

Note

Instead of MathExp() you can use exp().

See also

Real types (double, float)

MathFloor

The function returns integer numeric value closest from below.

```
double  MathFloor(
   double  val     // number
   );
```

Parameters

val

[in] Numeric value.

Return Value

A numeric value representing the largest integer that is less than or equal to val.

Note

Instead of MathFloor() you can use floor().

MathLog

The function returns a natural logarithm.

```
double  MathLog(
   double  val      // value to take the logarithm
   );
```

Parameters

val

[in] Value logarithm of which is to be found.

Return Value

The natural logarithm of val in case of success. If val is negative, the function returns NaN (undetermined value). If val is equal to 0, the function returns INF (infinity).

Note

Instead of MathLog() you can use log().

See also

Real types (double, float)

MathLog

Returns the logarithm of a number by base 10.

```
double  MathLog10(
   double  val      // number to take logarithm
   );
```

Parameters

val

[in] Numeric value the common logarithm of which is to be calculated.

Return Value

The common logarithm in case of success. If val is negative, the function returns NaN (undetermined value). If val is equal to 0, the function returns INF (infinity).

Note

Instead of MathLog10() you can use log10().

See also

Real types (double, float)

MathMax

The function returns the maximal value of two values.

```
double  MathMax(
   double  value1,      // first value
   double  value2       // second value
   );
```

Parameters

value1

[in] First numeric value.

value2

[in] Second numeric value.

Return Value

The largest of the two values.

Note

Instead of MathMax() you can use fmax(). Functions fmax(), fmin(), MathMax(), MathMin() can work with integer types without typecasting them to the type of double.

If parameters of different types are passed into a function, the parameter of the smaller type is automatically cast to the larger type. The type of the return value corresponds to the larger type.

If data of the same type are passed, no casting is performed.

MathMin

The function returns the minimal value of two values.

```
double  MathMin(
   double  value1,      // first value
   double  value2       // second value
   );
```

Parameters

value1

[in] First numeric value.

value2

[in] Second numeric value.

Return Value

The smallest of the two values.

Note

Instead of MathMin() you can use fmin(). Functions fmax(), fmin(), MathMax(), MathMin() can work with integer types without typecasting them to the type of double.

If parameters of different types are passed into a function, the parameter of the smaller type is automatically cast to the larger type. The type of the return value corresponds to the larger type.

If data of the same type are passed, no casting is performed.

MathMod

The function returns the real remainder of division of two numbers.

```
double  MathMod(
   double  value,       // dividend value
   double  value2       // divisor value
   );
```

Parameters

value

[in] Dividend value.

value2

[in] Divisor value.

Return Value

The MathMod function calculates the real remainder f from expression val/y so that val = i * y + f , where i is an integer, f has the same sign as val, and the absolute value of f is less than the absolute value of y.

Note

Instead of MathMod() you can use fmod().

MathPow

The function raises a base to a specified power.

```
double  MathPow(
   double  base,          // base
   double  exponent       // exponent value
   );
```

Parameters

base

[in] Base.

exponent

[in] Exponent value.

Return Value

Value of base raised to the specified power.

Note

Instead of MathPow() you can use pow().

MathRand

Returns a pseudorandom integer within the range of 0 to 32767.

```
int  MathRand();
```

Return Value

Integer value within the range of 0 to 32767.

Note

Before the first call of the function, it's necessary to call MathSrand to set the generator of pseudorandom numbers to the initial state.

Note

Instead of MathRand() you can use rand().

MathRound

The function returns a value rounded off to the nearest integer of the specified numeric value.

```
double  MathRound(
   double  value      // value to be rounded
   );
```

Parameters

value

[in] Numeric value before rounding.

Return Value

Value rounded till to the nearest integer.

Note

Instead of MathRound() you can use round().

MathSin

Returns the sine of a specified angle.

```
double  MathSin(
   double  value      // argument in radians
   );
```

Parameters

value

[in] Angle in radians.

Return Value

Sine of an angle measured in radians. Returns value within the range of -1 to 1.

Note

Instead of MathSin() you can use sin().

MathSqrt

Returns the square root of a number.

```
double  MathSqrt(
   double  value      // positive number
   );
```

Parameters

value

[in] Positive numeric value.

Return Value

Square root of value. If value is negative, MathSqrt returns NaN (indeterminate value).

Note

Instead of MathSqrt() you can use sqrt().

See also

Real types (double, float)

MathSrand

Sets the starting point for generating a series of pseudorandom integers.

```
void  MathSrand(
   int  seed      // initializing number
   );
```

Parameters

seed

[in] Starting number for the sequence of random numbers.

Return Value

No return value.

Note

The MathRand() function is used for generating a sequence of pseudorandom numbers. Call of MathSrand() with a certain initializing number allows to always produces the same sequence of pseudorandom numbers.

To ensure receipt of non-recurring sequence, use the call of MathSrand(GetTickCount()), since the value of GetTickCount() increases from the moment of the start of the operating system and is not repeated within 49 days, until the built-in counter of milliseconds overflows. Use of MathSrand(TimeCurrent()) is not suitable, because the TimeCurrent() function returns the time of the last tick, which can be unchanged for a long time, for example at the weekend.

Initialization of the random number generator using MathSrand() for indicators and Expert Advisors is better performed in the OnInit() handler; it saves you from the following multiple restarts of the generator in OnTick() and OnCalculate().

Instead of the MathSrand() function you can use the srand() function.

Example:

```
#property description "The indicator shows the central limit theorem, which states:"
#property description "The sum of a sufficiently large number of weakly dependent ranc
#property description "having approximately equal magnitude (none of the summands dom
#property description "or makes a determining contribution to the sum), has a distribu

         //--- A remainder in the division by 7 will return a value from 0 to 6
         rand_index+=MathRand()%7;
        }
      //--- Increase the value in the cell number rand_index by 1
      LabelBuffer[rand_index]++;
     }
//--- Exit the OnCalculate() handler
   return(rates_total);
  }
```

MathTan

The function returns a tangent of a number.

```
double  MathTan(
   double  rad      // argument in radians
   );
```

Parameters

rad

[in] Angle in radians.

Return Value

Tangent of rad. If rad is greater than or equal to 263, or less than or equal to -263, a loss of significance in the result occurs, in which case the function returns an indefinite number.

Note

Instead of MathTan() you can use tan().

See also

Real types (double, float)

MathIsValidNumber

It checks the correctness of a real number.

```
bool  MathIsValidNumber(
   double  number      // number to check
   );
```

Parameters

number

[in] Checked numeric value.

Return Value

It returns true, if the checked value is an acceptable real number. If the checked value is a plus or minus infinity, or "not a number" (NaN), the function returns false.

Example:

```
   double abnormal=MathArcsin(2.0);
   if(!MathIsValidNumber(abnormal)) Print("Attention! MathArcsin(2.0) = ",abnormal);
```

See also

Real types (double, float)

MathExpm1

Returns the value of the expression MathExp(x)-1.

```
double  MathExpm1(
   double  value      // power for the number e
   );
```

Parameters

value

[in] The number specifying the power.

Return Value

A value of the double type. In case of overflow the function returns INF (infinity), in case of underflow MathExpm1 returns 0.

Note

At values of *x* close to 0, the MathExpm1(x) function generates much more accurate values than the MathExp(x)-1 function.

Instead of the MathExpm1() function you can use the expm1() function.

See also

Real types (double, float)

MathLog1p

Returns the value of the expression MathLog(1+x).

```
double  MathLog1p(
   double  value      // value to take the logarithm
   );
```

Parameters

value

[in] The value, the logarithm of which is to be calculated.

Return Value

The natural logarithm of the value (value + 1) if successful. If value is < -1, the function returns NaN (undefined value). If value is equal to -1, the function returns INF (infinity).

Note

At values of x close to 0, the MathLog1p(x) function generates much more accurate values than the MathLog(1+x) function.

Instead of the MathLog1p() function you can use the log1p() function.

See also

Real types (double, float)

MathArccosh

Returns the hyperbolic arccosine.

```
double  MathArccosh(
   double  value     // 1 <= value < ∞
   );
```

Parameters

value

[in] The value, the hyperbolic arccosine of which is to be calculated.

Return Value

The hyperbolic arccosine of the number. If value is less than +1, the function returns NaN (undefined value).

Note

Instead of the MathArccosh() function you can use the acosh() function.

See also

Real types (double, float)

MathArcsinh

Returns the hyperbolic arcsine.

```
double  MathArcsinh(
   double  value      // -∞ < value < +∞
   );
```

Parameters

val

[in] The value, the hyperbolic arcsine of which is to be calculated.

Return Value

The hyperbolic arcsine of the number.

Note

Instead of the MathArcsinh() function you can use the asinh() function.

See also

Real types (double, float)

MathArctanh

Returns the hyperbolic arctangent.

```
double  MathArctanh(
   double  value      // value in the range of -1 < value < 1
   );
```

Parameters

value

[in] Number within the range of -1 < value < 1, which represents the tangent.

Return Value

The hyperbolic arctangent of the number.

Note

Instead of the MathArctanh() function you can use the atanh() function.

MathCosh

Returns the hyperbolic cosine of the number.

```
double  MathCosh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic cosine of the number, value within the range of +1 to positive infinity.

Note

Instead of the MathCosh() function you can use the cosh() function.

MathSinh

Returns the hyperbolic sine of the number.

```
double  MathSinh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic sine of the number.

Note

Instead of the MathSinh() function you can use the sinh() function.

MathTanh

Returns the hyperbolic tangent of the number.

```
double  MathTanh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic tangent of the number, value within the range of -1 to +1.

Note

Instead of the MathTanh() function you can use the tanh() function.

See also

Real types (double, float)

MathSwap

Change the order of bytes in the ushort type value.

```
ushort  MathSwap(
   ushort  value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

ushort value with the reverse byte order.

MathSwap

Change the order of bytes in the uint type value.

```
uint  MathSwap(
   uint   value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

uint value with the reverse byte order.

MathSwap

Change the order of bytes in the ulong type value.

```
ulong  MathSwap(
   ulong  value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

ulong value with the reverse byte order.

String Functions

This is a group of functions intended for working with data of the string type.

Function	Action
StringAdd	Adds a string to the end of another string
StringBufferLen	Returns the size of buffer allocated for the string
StringCompare	Compares two strings and returns 1 if the first string is greater than the second; 0 - if the strings are equal; -1 (minus 1) - if the first string is less than the second one
StringConcatenate	Forms a string of parameters passed
StringFill	Fills out a specified string by selected symbols
StringFind	Search for a substring in a string
StringGetCharacter	Returns the value of a number located in the specified string position
StringInit	Initializes string by specified symbols and provides the specified string length
StringLen	Returns the number of symbols in a string
StringSetLength	Sets a specified length (in characters) for a string
StringReplace	Replaces all the found substrings of a string by a set sequence of symbols
StringReserve	Reserves the buffer of a specified size for a string in memory.
StringSetCharacter	Returns a copy of a string with a changed value of a symbol in a specified position
StringSplit	Gets substrings by a specified separator from the specified string, returns the number of substrings obtained
StringSubstr	Extracts a substring from a text string starting from a specified position
StringToLower	Transforms all symbols of a selected string to lowercase
StringToUpper	Transforms all symbols of a selected string into capitals
StringTrimLeft	Cuts line feed characters, spaces and tabs in the left part of the string
StringTrimRight	Cuts line feed characters, spaces and tabs in the right part of the string

StringAdd

The function adds a substring to the end of a string.

```
bool  StringAdd(
   string&  string_var,        // string, to which we add
   string   add_substring      // string, which is added
   );
```

Parameters

string_var

[in][out] String, to which another one is added.

add_substring

[in] String that is added to the end of a source string.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Example:

```
void OnStart()
  {
   long length=1000000;
   string a="a",b="b",c;
//--- first method
   uint start=GetTickCount(),stop;
   long i;
   for(i=0;i<length;i++)
     {
      c=a+b;
     }
   stop=GetTickCount();
   Print("time for 'c = a + b' = ",(stop-start)," milliseconds, i = ",i);

//--- second method
   start=GetTickCount();
   for(i=0;i<length;i++)
     {
      StringAdd(a,b);
     }
   stop=GetTickCount();
   Print("time for 'StringAdd(a,b)' = ",(stop-start)," milliseconds, i = ",i);

//--- third method
   start=GetTickCount();
   a="a"; // re-initialize variable a
   for(i=0;i<length;i++)
```

```
      {
       StringConcatenate(c,a,b);
      }
   stop=GetTickCount();
   Print("time for 'StringConcatenate(c,a,b)' = ",(stop-start)," milliseconds, i = ",i
  }
```

See also

StringConcatenate, StringSplit, StringSubstr

StringBufferLen

The function returns the size of buffer allocated for the string.

```
int  StringBufferLen(
   string  string_var      // string
   )
```

Parameters

string_var

[in] String.

Return Value

The value 0 means that the string is constant and buffer size can't be changed. -1 means that the string belongs to the client terminal, and modification of the buffer contents can have indeterminate results.

Example:

```
void OnStart()
  {
   long length=1000;
   string a="a",b="b";
//---
   long i;
   Print("before: StringBufferLen(a) = ",StringBufferLen(a),
         "  StringLen(a) = ",StringLen(a));
   for(i=0;i<length;i++)
     {
      StringAdd(a,b);
     }
   Print("after: StringBufferLen(a) = ",StringBufferLen(a),
         "  StringLen(a) = ",StringLen(a));
  }
```

See also

StringAdd, StringInit, StringLen, StringFill

StringCompare

The function compares two strings and returns the comparison result in form of an integer.

```
int  StringCompare(
   const string&  string1,                // the first string in the comparison
   const string&  string2,                // the second string in the comparison
   bool           case_sensitive=true     // case sensitivity mode selection for the
   );
```

Parameters

string1

[in] The first string.

string2

[in] The second string.

case_sensitive=true

[in] Case sensitivity mode selection. If it is true, then "A">"a". If it is false, then "A"="a". By default the value is equal to true.

Return Value

- -1 (minus one), if string1<string2
- 0 (zero), if string1=string2
- 1 (one), if string1>string2

Note

The strings are compared symbol by symbol, the symbols are compared in the alphabetic order in accordance with the current code page.

Example:

```
void OnStart()
  {
//--- what is larger - apple or home?
   string s1="Apple";
   string s2="home";

//--- compare case sensitive
   int result1=StringCompare(s1,s2);
   if(result1>0) PrintFormat("Case sensitive comparison: %s > %s",s1,s2);
   else
     {
      if(result1<0)PrintFormat("Case sensitive comparison: %s < %s",s1,s2);
      else PrintFormat("Case sensitive comparison: %s = %s",s1,s2);
     }

//--- compare case-insensitive
   int result2=StringCompare(s1,s2,false);
   if(result2>0) PrintFormat("Case insensitive comparison: %s > %s",s1,s2);
   else
```

```
      {
       if(result2<0)PrintFormat("Case insensitive comparison: %s < %s",s1,s2);
       else PrintFormat("Case insensitive comparison: %s = %s",s1,s2);
      }
/* Result:
     Case-sensitive comparison: Apple < home
     Case insensitive comparison: Apple < home
*/
  }
```

See also

String Type, CharToString(), ShortToString(), StringToCharArray(), StringToShortArray(), StringGetCharacter(), Use of a Codepage

StringConcatenate

The function forms a string of passed parameters and returns the size of the formed string. Parameters can be of any type. Number of parameters can't be less than 2 or more than 64.

```
int  StringConcatenate(
   string&  string_var,    // string to form
   void argument1          // first parameter of any simple type
   void argument2          // second parameter of any simple type
   ...                     // next parameter of any simple type
   );
```

Parameters

string_var

[out] String that will be formed as a result of concatenation.

argumentN

[in] Any comma separated values. From 2 to 63 parameters of any simple type.

Return Value

Returns the string length, formed by concatenation of parameters transformed into string type. Parameters are transformed into strings according to the same rules as in Print() and Comment().

See also

StringAdd, StringSplit, StringSubstr

StringFill

It fills out a selected string by specified symbols.

```
bool  StringFill(
   string&   string_var,       // string to fill
   ushort    character         // symbol that will fill the string
   );
```

Parameters

string_var

[in][out] String, that will be filled out by the selected symbol.

character

[in] Symbol, by which the string will be filled out.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Note

Filling out a string at place means that symbols are inserted directly to the string without transitional operations of new string creation or copying. This allows to save the operation time.

Example:

```
void OnStart()
  {
   string str;
   StringInit(str,20,'_');
   Print("str = ",str);
   StringFill(str,0);
   Print("str = ",str,": StringBufferLen(str) = ", StringBufferLen(str));
  }
// Result
//   str = ____________________
//   str =  : StringBufferLen(str) = 20
//
```

See also

StringBufferLen, StringLen, StringInit

StringFind

Search for a substring in a string.

```
int  StringFind(
   string  string_value,         // string in which search is made
   string  match_substring,      // what is searched
   int     start_pos=0           // from what position search starts
   );
```

Parameters

string_value

[in] String, in which search is made.

match_substring

[in] Searched substring.

start_pos=0

[in] Position in the string from which search is started.

Return Value

Returns position number in a string, from which the searched substring starts, or -1, if the substring is not found.

See also

StringSubstr, StringGetCharacter, StringLen, StringLen

StringGetCharacter

Returns value of a symbol, located in the specified position of a string.

```
ushort  StringGetCharacter(
   string  string_value,      // string
   int     pos                // symbol position in the string
   );
```

Parameters

string_value

[in] String.

pos

[in] Position of a symbol in the string. Can be from 0 to StringLen(text) -1.

Return Value

Symbol code or 0 in case of an error. To get the error code call GetLastError().

See also

StringSetCharacter, StringBufferLen, StringLen, StringFill, StringInit, StringToCharArray, StringToShortArray

StringInit

Initializes a string by specified symbols and provides the specified string size.

```
bool  StringInit(
   string&    string_var,       // string to initialize
   int        new_len=0,        // required string length after initialization
   ushort     character=0       // symbol, by which the string will be filled
   );
```

Parameters

string_var

[in][out] String that should be initialized and deinitialized.

new_len=0

[in] String length after initialization. If length=0, it deinitializes the string, i.e. the string buffer is cleared and the buffer address is zeroed.

character=0

[in] Symbol to fill the string.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Note

If character=0 and the length new_len>0, the buffer of the string of indicated length will be distributed and filled by zeroes. The string length will be equal to zero, because the whole buffer is filled out by string terminators.

Example:

```
void OnStart()
  {
//---
   string str;
   StringInit(str,200,0);
   Print("str = ",str,": StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
  }
/*  Result
str = : StringBufferLen(str) = 200   StringLen(str) = 0
*/
```

See also

StringBufferLen, StringLen

StringLen

Returns the number of symbols in a string.

```
int  StringLen(
   string  string_value      // string
   );
```

Parameters

string_value

[in] String to calculate length.

Return Value

Number of symbols in a string without the ending zero.

See also

StringBufferLen, StringTrimLeft, StringTrimRight, StringToCharArray, StringToShortArray

StringSetLength

Sets a specified length (in characters) for a string.

```
bool  StringSetLength(
   string&     string_var,       // string
   uint        new_length        // new string length
   );
```

Parameters

string_var

[in][out] String, for which a new length in characters should be set.

new_capacity

[in] Required string length in characters. If new_length is less than the current size, the excessive characters are discarded.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

TheStringSetLength() function does not change the size of the buffer allocated for a string.

See also

StringLen, StringBufferLen, StringReserve StringInit, StringSetCharacter

StringReplace

It replaces all the found substrings of a string by a set sequence of symbols.

```
int  StringReplace(
   string&         str,              // the string in which substrings will be replace
   const string    find,             // the searched substring
   const string    replacement       // the substring that will be inserted to the fou
   );
```

Parameters

str

[in][out] The string in which you are going to replace substrings.

find

[in] The desired substring to replace.

replacement

[in] The string that will be inserted instead of the found one.

Return Value

The function returns the number of replacements in case of success, otherwise -1. To get an error code call the GetLastError() function.

Note

If the function has run successfully but no replacements have been made (the substring to replace was not found), it returns 0.

The error can result from incorrect *str* or *find* parameters (empty or non-initialized string, see StringInit()). Besides, the error occurs if there is not enough memory to complete the replacement.

Example:

```
  string text="The quick brown fox jumped over the lazy dog.";
  int replaced=StringReplace(text,"quick","slow");
  replaced+=StringReplace(text,"brown","black");
  replaced+=StringReplace(text,"fox","bear");
  Print("Replaced: ", replaced,". Result=",text);

//  Result
//  Replaced: 3. Result=The slow black bear jumped over the lazy dog.
//
```

See also

StringSetCharacter(), StringSubstr()

StringReserve

Reserves the buffer of a specified size for a string in memory.

```
bool  StringReserve(
   string&     string_var,       // string
   uint        new_capacity      // buffer size for storing a string
   );
```

Parameters

string_var

[in][out] String the buffer size should change the size for.

new_capacity

[in] Buffer size required for a string. If the new_capacity size is less than the string length, the size of the current buffer does not change.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Generally, the string size is not equal to the size of the buffer meant for storing the string. When creating a string, the appropriate buffer is usually allocated with a margin. The StringReserve() function allows managing the buffer size and specify the optimal size for future operations.

Unlike StringInit(), the StringReserve() function does not change the string contents and does not fill it with characters.

Example:

```
void OnStart()
  {
   string s;
//--- check the operation speed without using StringReserve
   ulong t0=GetMicrosecondCount();
   for(int i=0; i< 1024; i++)
      s+=" "+(string)i;
   ulong msc_no_reserve=GetMicrosecondCount()-t0;
   s=NULL;
//--- now, let's do the same using StringReserve
   StringReserve(s,1024 * 3);
   t0=GetMicrosecondCount();
   for(int i=0; i< 1024; i++)
      s+=" "+(string)i;
   ulong msc_reserve=GetMicrosecondCount()-t0;
//--- check the time
   Print("Test with StringReserve passed for "+(string)msc_reserve+" msc");
   Print("Test without StringReserve passed for "+(string)msc_no_reserve+" msc");
/* Result:
```

```
      Test with StringReserve passed for 50 msc
      Test without StringReserve passed for 121 msc
*/
  }
```

See also

StringBufferLen, StringSetLength, StringInit, StringSetCharacter

StringSetCharacter

Returns copy of a string with a changed character in a specified position.

```
bool  StringSetCharacter(
   string&   string_var,       // string
   int       pos,              // position
   ushort    character         // character
   );
```

Parameters

string_var

[in][out] String.

pos

[in] Position of a character in a string. Can be from 0 to StringLen(text).

character

[in] Symbol code Unicode.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Note

If pos is less than string length and the symbol code value = 0, the string is cut off (but the buffer size, distributed for the string remains unchanged). The string length becomes equal to pos.

If *pos* is equal to string length, the specified symbol is added at the string end, and the length is enlarged by one.

Example:

```
void OnStart()
  {
   string str="0123456789";
   Print("before: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
//--- add zero value in the middle
   StringSetCharacter(str,6,0);
   Print("after: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
//--- add symbol at the end
   int size=StringLen(str);
   StringSetCharacter(str,size,'+');
   Print("addition: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
  }
/* Result
   before: str = 0123456789 ,StringBufferLen(str) = 0    StringLen(str) = 10
```

```
    after: str = 012345 ,StringBufferLen(str) = 16   StringLen(str) = 6
   addition: str = 012345+ ,StringBufferLen(str) = 16   StringLen(str) = 7
*/
```

See also

StringBufferLen, StringLen, StringFill, StringInit, CharToString, ShortToString, CharArrayToString, ShortArrayToString

StringSplit

Gets substrings by a specified separator from the specified string, returns the number of substrings obtained.

```
int  StringSplit(
   const string   string_value,       // A string to search in
   const ushort   separator,          // A separator using which substrings will be se
   string         & result[]          // An array passed by reference to get the found
   );
```

Parameters

string_value

[in] The string from which you need to get substrings. The string will not change.

pos

[in] The code of the separator character. To get the code, you can use the StringGetCharacter() function.

result[]

[out] An array of strings where the obtained substrings are located.

Return Value

The number of substrings in the result[] array. If the separator is not found in the passed string, only one source string will be placed in the array.

If string_value is empty or NULL, the function will return zero. In case of an error the function returns -1. To get the error code, call the GetLastError() function.

Example:

```
string to_split="_life_is_good_"; // A string to split into substrings
   string sep="_";                // A separator as a character
   ushort u_sep;                  // The code of the separator character
   string result[];               // An array to get strings
   //--- Get the separator code
   u_sep=StringGetCharacter(sep,0);
   //--- Split the string to substrings
   int k=StringSplit(to_split,u_sep,result);
   //--- Show a comment
   PrintFormat("Strings obtained: %d. Used separator '%s' with the code %d",k,sep,u_se
   //--- Now output all obtained strings
   if(k>0)
     {
      for(int i=0;i<k;i++)
        {
         PrintFormat("result[%d]=\"%s\"",i,result[i]);
        }
     }
```

See also

StringReplace(), StringSubstr(), StringConcatenate()

StringSubstr

Extracts a substring from a text string starting from the specified position.

```
string  StringSubstr(
   string  string_value,      // string
   int     start_pos,         // position to start with
   int     length=-1          // length of extracted string
   );
```

Parameters

string_value

[in] String to extract a substring from.

start_pos

[in] Initial position of a substring. Can be from 0 to StringLen(text) -1.

length=-1

[in] Length of an extracted substring. If the parameter value is equal to -1 or parameter isn't set, the substring will be extracted from the indicated position till the string end.

Return Value

Copy of a extracted substring, if possible. Otherwise returns an empty string.

See also

StringSplit, StringFind, StringGetCharacter

StringToLower

Transforms all symbols of a selected string into lowercase.

```
bool  StringToLower(
   string&  string_var      // string to process
   );
```

Parameters

string_var

[in][out] String.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

See also

StringToUpper, StringTrimLeft, StringTrimRight

StringToUpper

Transforms all symbols of a selected string into capitals.

```
bool  StringToUpper(
   string&  string_var      // string to process
   );
```

Parameters

string_var

[in][out] String.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

See also

StringToLower, StringTrimLeft, StringTrimRight

StringTrimLeft

The function cuts line feed characters, spaces and tabs in the left part of the string till the first meaningful symbol. The string is modified at place.

```
int  StringTrimLeft(
   string&  string_var      // string to cut
   );
```

Parameters

string_var

[in][out] String that will be cut from the left.

Return Value

Returns the number of cut symbols.

See also

StringTrimRight, StringToLower, StringToUpper

StringTrimRight

The function cuts line feed characters, spaces and tabs in the right part of the string after the last meaningful symbol. The string is modified at place.

```
int  StringTrimRight(
   string&  string_var      // string to cut
   );
```

Parameters

string_var

[in][out] String that will be cut from the right.

Return Value

Returns the number of cut symbols.

See also

StringTrimLeft, StringToLower, StringToUpper

Date and Time

This is the group of functions for working with data of datetime type (an integer that represents the number of seconds elapsed from 0 hours of January 1, 1970).

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

Function	Action
TimeCurrent	Returns the last known server time (time of the last quote receipt) in the datetime format
TimeTradeServer	Returns the current calculation time of the trade server
TimeLocal	Returns the local computer time in datetime format
TimeGMT	Returns GMT in datetime format with the Daylight Saving Time by local time of the computer, where the client terminal is running
TimeDaylightSavings	Returns the sign of Daylight Saving Time switch
TimeGMTOffset	Returns the current difference between GMT time and the local computer time in seconds, taking into account DST switch
TimeToStruct	Converts a datetime value into a variable of MqlDateTime structure type
StructToTime	Converts a variable of MqlDateTime structure type into a datetime value

TimeCurrent

Returns the last known server time, time of the last quote receipt for one of the symbols selected in the "Market Watch" window. In the OnTick() handler, this function returns the time of the received handled tick. In other cases (for example, call in handlers OnInit(), OnDeinit(), OnTimer() and so on) this is the time of the last quote receipt for any symbol available in the "Market Watch" window, the time shown in the title of this window. The time value is formed on a trade server and does not depend on the time settings on your computer. There are 2 variants of the function.

Call without parameters

```
datetime  TimeCurrent();
```

Call with MqlDateTime type parameter

```
datetime  TimeCurrent(
   MqlDateTime&  dt_struct      // structure type variable
   );
```

Parameters

dt_struct

[out] MqlDateTime structure type variable.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeCurrent() is simulated according to historical data.

TimeTradeServer

Returns the calculated current time of the trade server. Unlike TimeCurrent(), the calculation of the time value is performed in the client terminal and depends on the time settings on your computer. There are 2 variants of the function.

Call without parameters

```
datetime  TimeTradeServer();
```

Call with MqlDateTime type parameter

```
datetime  TimeTradeServer(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeTradeServer() is simulated according to historical data and always equal to TimeCurrent().

TimeLocal

Returns the local time of a computer, where the client terminal is running. There are 2 variants of the function.

Call without parameters

```
datetime  TimeLocal();
```

Call with MqlDateTime type parameter

```
datetime  TimeLocal(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeLocal() is always equal to TimeCurrent() simulated server time.

TimeGMT

Returns the GMT, which is calculated taking into account the DST switch by the local time on the computer where the client terminal is running. There are 2 variants of the function.

Call without parameters

```
datetime  TimeGMT();
```

Call with MqlDateTime type parameter

```
datetime  TimeGMT(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeGMT() is always equal to TimeTradeServer() simulated server time.

TimeDaylightSavings

Returns correction for daylight saving time in seconds, if the switch to summer time has been made. It depends on the time settings of your computer.

```
int  TimeDaylightSavings();
```

Return Value

If switch to winter (standard) time has been made, it returns 0.

TimeGMTOffset

Returns the current difference between GMT time and the local computer time in seconds, taking into account switch to winter or summer time. Depends on the time settings of your computer.

```
int  TimeGMTOffset();
```

Return Value

The value of int type, representing the current difference between GMT time and the local time of the computer TimeLocal in seconds.

```
TimeGMTOffset() =  TimeGMT() - TimeLocal()
```

TimeToStruct

Converts a value of datetime type (number of seconds since 01.01.1970) into a structure variable MqlDateTime.

```
bool  TimeToStruct(
   datetime      dt,            // date and time
   MqlDateTime&  dt_struct      // structure for the adoption of values
   );
```

Parameters

dt

[in] Date value to convert.

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

True if successful, otherwise false. To get information about the error, call the GetLastError() function.

StructToTime

Converts a structure variable MqlDateTime into a value of datetime type and returns the resulting value.

```
datetime  StructToTime(
   MqlDateTime&  dt_struct      // structure of the date and time
   );
```

Parameters

dt_struct

[in] Variable of structure type MqlDateTime.

Return Value

The value of datetime type containing the number of seconds since 01.01.1970.

Account Information

Functions that return parameters of the current account.

Function	Action
AccountInfoDouble	Returns a value of double type of the corresponding account property
AccountInfoInteger	Returns a value of integer type (bool, int or long) of the corresponding account property
AccountInfoString	Returns a value string type corresponding account property

AccountInfoDouble

Returns the value of the appropriate account property.

```
double  AccountInfoDouble(
   ENUM_ACCOUNT_INFO_DOUBLE  property_id      // Property identifier
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_DOUBLE.

Return Value

Value of double type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoDouble()
   printf("ACCOUNT_BALANCE =  %G",AccountInfoDouble(ACCOUNT_BALANCE));
   printf("ACCOUNT_CREDIT =  %G",AccountInfoDouble(ACCOUNT_CREDIT));
   printf("ACCOUNT_PROFIT =  %G",AccountInfoDouble(ACCOUNT_PROFIT));
   printf("ACCOUNT_EQUITY =  %G",AccountInfoDouble(ACCOUNT_EQUITY));
   printf("ACCOUNT_MARGIN =  %G",AccountInfoDouble(ACCOUNT_MARGIN));
   printf("ACCOUNT_MARGIN_FREE =  %G",AccountInfoDouble(ACCOUNT_MARGIN_FREE));
   printf("ACCOUNT_MARGIN_LEVEL =  %G",AccountInfoDouble(ACCOUNT_MARGIN_LEVEL));
   printf("ACCOUNT_MARGIN_SO_CALL = %G",AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL));
   printf("ACCOUNT_MARGIN_SO_SO = %G",AccountInfoDouble(ACCOUNT_MARGIN_SO_SO));
  }
```

See also

SymbolInfoDouble, SymbolInfoString, SymbolInfoInteger, PrintFormat

AccountInfoInteger

Returns the value of the appropriate account property.

```
long  AccountInfoInteger(
   ENUM_ACCOUNT_INFO_INTEGER  property_id      // Identifier of the property
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_INTEGER.

Return Value

Value of long type.

Note

The property must be of bool, int or long type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoInteger()
   printf("ACCOUNT_LOGIN =  %d",AccountInfoInteger(ACCOUNT_LOGIN));
   printf("ACCOUNT_LEVERAGE =  %d",AccountInfoInteger(ACCOUNT_LEVERAGE));
   bool thisAccountTradeAllowed=AccountInfoInteger(ACCOUNT_TRADE_ALLOWED);
   bool EATradeAllowed=AccountInfoInteger(ACCOUNT_TRADE_EXPERT);
   ENUM_ACCOUNT_TRADE_MODE tradeMode=(ENUM_ACCOUNT_TRADE_MODE)AccountInfoInteger(ACCOU
   ENUM_ACCOUNT_STOPOUT_MODE stopOutMode=(ENUM_ACCOUNT_STOPOUT_MODE)AccountInfoIntege

//--- Inform about the possibility to perform a trade operation
   if(thisAccountTradeAllowed)
      Print("Trade for this account is permitted");
   else
      Print("Trade for this account is prohibited!");

//--- Find out if it is possible to trade on this account by Expert Advisors
   if(EATradeAllowed)
      Print("Trade by Expert Advisors is permitted for this account");
   else
      Print("Trade by Expert Advisors is prohibited for this account!");

//--- Find out the account type
   switch(tradeMode)
     {
      case(ACCOUNT_TRADE_MODE_DEMO):
         Print("This is a demo account");
         break;
      case(ACCOUNT_TRADE_MODE_CONTEST):
```

```
         Print("This is a competition account");
         break;
      default:Print("This is a real account!");
     }

//--- Find out the StopOut level setting mode
   switch(stopOutMode)
     {
      case(ACCOUNT_STOPOUT_MODE_PERCENT):
         Print("The StopOut level is specified percentage");
         break;
      default:Print("The StopOut level is specified in monetary terms");
     }
  }
```

See also

Account Information

AccountInfoString

Returns the value of the appropriate account property.

```
string  AccountInfoString(
   ENUM_ACCOUNT_INFO_STRING  property_id      // Property identifier
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_STRING.

Return Value

Value of string type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoString()
   Print("The name of the broker = ",AccountInfoString(ACCOUNT_COMPANY));
   Print("Deposit currency = ",AccountInfoString(ACCOUNT_CURRENCY));
   Print("Client name = ",AccountInfoString(ACCOUNT_NAME));
   Print("The name of the trade server = ",AccountInfoString(ACCOUNT_SERVER));
  }
```

Account Information

State Checking

Functions that return parameters of the current state of the client terminal

Function	Action
GetLastError	Returns the last error
IsStopped	Returns true, if an mql5 program has been commanded to stop its operation
UninitializeReason	Returns the code of the reason for deinitialization
TerminalInfoInteger	Returns an integer value of a corresponding property of the mql5 program environment
TerminalInfoDouble	Returns a double value of a corresponding property of the mql5 program environment
TerminalInfoString	Returns a string value of a corresponding property of the mql5 program environment
MQLInfoInteger	Returns an integer value of a corresponding property of a running mql5 program
MQLInfoString	Returns a string value of a corresponding property of a running mql5 program
Symbol	Returns the name of a symbol of the current chart
Period	Returns the current chart timeframe
Digits	Returns the number of decimal digits determining the accuracy of the price value of the current chart symbol
Point	Returns the point size of the current symbol in the quote currency

GetLastError

Returns the contents of the system variable _LastError.

```
int  GetLastError();
```

Return Value

Returns the value of the last error that occurred during the execution of an mql5 program.

Note

After the function call, the contents of _LastError are not reset. To reset this variable, you need to call ResetLastError().

See also

Trade Server Return Codes

IsStopped

Checks the forced shutdown of an mql5 program.

```
bool  IsStopped();
```

Return Value

Returns true, if the _StopFlag system variable contains a value other than 0. A nonzero value is written into _StopFlag, if a mql5 program has been commanded to complete its operation. In this case, you must immediately terminate the program, otherwise the program will be completed forcibly from the outside after 3 seconds.

UninitializeReason

Returns the code of a reason for deinitialization.

```
int  UninitializeReason();
```

Return Value

Returns the value of _UninitReason which is formed before OnDeinit() is called. Value depends on the reasons that led to deinitialization.

TerminalInfoInteger

Returns the value of a corresponding property of the mql5 program environment.

```
int  TerminalInfoInteger(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_INTEGER enumeration.

Return Value

Value of int type.

TerminalInfoDouble

Returns the value of a corresponding property of the mql5 program environment.

```
double  TerminalInfoDouble(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_DOUBLE enumeration.

Return Value

Value of double type.

TerminalInfoString

Returns the value of a corresponding property of the mql5 program environment. The property must be of string type.

```
string  TerminalInfoString(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_STRING enumeration.

Return Value

Value of string type.

MQLInfoInteger

Returns the value of a corresponding property of a running mql5 program.

```
int  MQLInfoInteger(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of values of the ENUM_MQL_INFO_INTEGER enumeration.

Return Value

Value of int type.

MQLInfoString

Returns the value of a corresponding property of a running mql5 program.

```
string  MQLInfoString(
   int  property_id      // Identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the ENUM_MQL_INFO_STRING enumeration.

Return Value

Value of string type.

Symbol

Returns the name of a symbol of the current chart.

```
string  Symbol();
```

Return Value

Value of the _Symbol system variable, which stores the name of the current chart symbol.

Note

Unlike Expert Advisors, indicators and scripts, services are not bound to a specific chart. Therefore, Symbol() returns an empty string ("") for a service.

Period

Returns the current chart timeframe.

```
ENUM_TIMEFRAMES  Period();
```

Return Value

The contents of the _Period variable that contains the value of the current chart timeframe. The value can be one of the values of the ENUM_TIMEFRAMES enumeration.

Note

Unlike Expert Advisors, indicators and scripts, services are not bound to a specific chart. Therefore, Period() returns 0 for a service.

See also

PeriodSeconds, Chart timeframes, Date and Time, Visibility of objects

Digits

Returns the number of decimal digits determining the accuracy of price of the current chart symbol.

```
int  Digits();
```

Return Value

The value of the _Digits variable which stores the number of decimal digits determining the accuracy of price of the current chart symbol.

Point

Returns the point size of the current symbol in the quote currency.

```
double  Point();
```

Return Value

The value of the _Point variable which stores the point size of the current symbol in the quote currency.

Event Handling

The MQL5 language provides handling of certain predefined events. The functions for handling these events should be defined in an MQL5 program: function name, return type, a set of parameters (if any) and their types should strictly correspond to the description of an event handling function.

The client terminal event handler uses the return and parameter types to identify functions processing an event. If a certain function has some parameters or a return type not corresponding to the descriptions below, such a function cannot be used for handling an event.

Function	Description
OnStart	The function is called when the Start event occurs to perform actions set in the script
OnInit	The function is called in indicators and EAs when the Init event occurs to initialize a launched MQL5 program
OnDeinit	The function is called in indicators and EAs when the Deinit event occurs to de-initialize a launched MQL5 program
OnTick	The function is called in EAs when the NewTick event occurs to handle a new quote
OnCalculate	The function is called in indicators when the Calculate event occurs to handle price data changes
OnTimer	The function is called in indicators and EAs during the Timer periodic event generated by the terminal at fixed time intervals
OnTrade	The function is called in EAs during the Trade event generated at the end of a trading operation on a trade server
OnTradeTransaction	The function is called in EAs when the TradeTransaction event occurs to process a trade request execution results
OnBookEvent	The function is called in EAs when the BookEvent event occurs to process changes in the market depth
OnChartEvent	The function is called in indicators and EAs when the ChartEvent event occurs to process chart changes made by a user or an MQL5 program
OnTester	The function is called in EAs when the Tester event occurs to perform necessary actions after testing an EA on history data
OnTesterInit	The function is called in EAs when the TesterInit event occurs to perform necessary actions before optimization in the strategy tester
OnTesterDeinit	The function is called in EAs when the TesterDeinit event occurs after EA optimization in the strategy tester
OnTesterPass	The function is called in EAs when the TesterPass even occurs to handle an arrival of a new data frame during EA optimization in the strategy tester

The client terminal sends incoming events to corresponding open charts. Also, events may be generated by charts (chart events) or mql5 programs (custom events). Generating graphical object creation/deletion events can be enabled/disabled by setting the CHART_EVENT_OBJECT_CREATE and CHART_EVENT_OBJECT_DELETE chart properties. Each mql5 application and chart have their own queue of events where all newly arrived events are placed.

A program gets events only from the chart it is running on. All events are handled one after another in the order of their receipt. If the queue already contains the NewTick event or this event is in the processing stage, then the new NewTick event is not added to mql5 application queue. Similarly, if the ChartEvent is already in an mql5 program queue or such an event is being handled, then a new event of this type is not placed into a queue. Timer event handling is processed in the same way – if the Timer event is already in the queue or is being handled, no new timer event is set into a queue.

Event queues have a limited but sufficient size, so the queue overflow is unlikely for a correctly developed program. When the queue overflows, new events are discarded without being set into a queue.

It is strongly recommended not to use infinite loops to handle events. Possible exceptions are scripts handling a single Start event.

Libraries do not handle any events.

OnStart

The function is called in scripts and services when the Start event occurs. The function is intended for one-time execution of actions implemented in a program. There are two function types.

The version that returns the result

```
int  OnStart(void);
```

Return Value

The value of int type displayed in the Journal tab.

The entry "script script_name removed (result code N)" is created in the terminal journal after a script execution is complete. Here N is a value returned by the OnStart() function.

The entry "service service_name stopped (result code N)" is created in the terminal journal after a service execution is complete. Here N is a value returned by the OnStart() function.

The OnStart() call that returns the execution result is recommended for use since it not only allows for a script or service execution, but also returns an error code or other useful data to analyze the program execution result.

The version without a result return is left only for compatibility with old codes. It is not recommended for use

```
void  OnStart(void);
```

Note

OnStart() is the only function for handling events in scripts and services. No other events are sent to these programs. In turn, the Start event is not passed to EAs and custom indicators.

Sample script:

```
//--- macros for working with colors
#define XRGB(r,g,b)     (0xFF000000|(uchar(r)<<16)|(uchar(g)<<8)|uchar(b))
#define GETRGB(clr)     ((clr)&0xFFFFFF)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set a downward candle color
   Comment("Set a downward candle color");
   ChartSetInteger(0,CHART_COLOR_CANDLE_BEAR,GetRandomColor());
   ChartRedraw(); // update the chart immediately without waiting for a new tick
   Sleep(1000);   // pause for 1 second to see all the changes
//--- set an upward candle color
   Comment("Set an upward candle color");
   ChartSetInteger(0,CHART_COLOR_CANDLE_BULL,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set the background color
```

```
   Comment("Set the background color");
   ChartSetInteger(0,CHART_COLOR_BACKGROUND,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of Ask line
   Comment("Set color of Ask line");
   ChartSetInteger(0,CHART_COLOR_ASK,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of Bid line
   Comment("Set color of Bid line");
   ChartSetInteger(0,CHART_COLOR_BID,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of a downward bar and a downward candle frame
   Comment("Set color of a downward bar and a downward candle frame");
   ChartSetInteger(0,CHART_COLOR_CHART_DOWN,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of a chart line and Doji candlesticks
   Comment("Set color of a chart line and Doji candlesticks");
   ChartSetInteger(0,CHART_COLOR_CHART_LINE,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of an upward bar and an upward candle frame

Event handling functions, Program running, Client terminal events

OnInit

The function is called in indicators and EAs when the Init event occurs. It is used to initialize a running MQL5 program. There are two function types.

The **version that returns the result**

```
int  OnInit(void);
```

Return Value

int type value, zero means successful initialization.

When returning INIT_FAILED, the EA is forcibly unloaded from the chart.

When returning INIT_FAILED, the indicator is not unloaded from the chart. The indicator remaining on the chart is non-operational — event handlers are not called in the indicator.

The OnInit() call that returns the execution result is recommended for use since it not only allows for program initialization, but also returns an error code in case of an early program termination.

The version without a result return is left only for compatibility with old codes. It is not recommended for use

```
void  OnInit(void);
```

Note
