The Init event is generated immediately after loading an EA or an indicator. The event is not generated for scripts. The OnInit() function is used to initialize an MQL5 program. If OnInit() has a return value of int type, the non-zero return code means failed initialization and generates the Deinit event with the REASON_INITFAILED deinitialization reason code.

OnInit() function of void type always means successful initialization and is not recommended for use.

For optimizing the EA inputs, it is recommended to use values from the ENUM_INIT_RETCODE enumeration as a return code. These values are intended for establishing the optimization process management, including selection of the most suitable test agents. It is possible to request data on agent configuration and resources (number of cores, free memory amount, etc.) using the TerminalInfoInteger() function during the EA initialization before launching the test. Based on the obtained data, you can either allow using the test agent or ban it from optimizing the EA.

ID	Description
INIT_SUCCEEDED	Initialization successful, EA test can be continued. This code means the same as the zero value - the EA initialization in the tester is successful.
INIT_FAILED	Initialization failed. There is no point in continuing the test due to unavoidable errors. For example, it is impossible to create an indicator necessary for the EA operation. The return of this value means the same as returning the value different from zero - EA initialization in the tester failed.

ID	Description
INIT_PARAMETERS_INCORRECT	Designed to denote an incorrect set of input parameters by a programmer. In the general optimization table, the result string with this return code is highlighted in red. A test for such a set of EA inputs is not performed. The agent is ready to receive a new task. When this value is received, the strategy tester does not pass this task to other agents for repeated execution.
INIT_AGENT_NOT_SUITABLE	No program execution errors during initialization. However, for some reasons, the agent is not suitable for conducting a test. For example, there is not enough RAM, no OpenCL support, etc. After returning this code, the agent no longer receives tasks until the very end of this optimization.

Using OnInit() returning INIT_FAILED/INIT_PARAMETERS_INCORRECT in the tester have some peculiarities that should be considered when optimizing EAs:

- the set of parameters the OnInit() returned INIT_PARAMETERS_INCORRECT for is considered unsuitable for testing and is not used to obtain the next population during genetic optimization. Too many "discarded" parameter sets may lead to incorrect results when searching for optimal EA parameters. The search algorithm assumes that the optimization criterion function is smooth and has no gaps on the entire multitude of input parameters.
- if OnInit() returns INIT_FAILED, this means that a test cannot be launched, and the EA is unloaded from the agent's memory. The EA is loaded again to perform the next pass with a new set of parameters. Launching the next optimization pass takes much more time as compared to calling TesterStop().

Sample OnInit() function for an EA

```
//--- input parameters
input int      ma_period=20; // moving average period

//--- handle of the indicator used in the EA
int indicator_handle;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- check ma_period validity
   if(ma_period<=0)
     {
      PrintFormat("Invalid ma_period input value: %d",ma_period);
      return (INIT_PARAMETERS_INCORRECT);
     }
//--- during optimization
   if(MQLInfoInteger(MQL_OPTIMIZATION))
     {
```

```
      //--- check available RAM for the agent
      int available_memory_mb=TerminalInfoInteger(TERMINAL_MEMORY_TOTAL);
      if(available_memory_mb<2000)
        {
         PrintFormat("Insufficient memory for the test agent: %d MB",
                     available_memory_mb);
         return (INIT_AGENT_NOT_SUITABLE);
        }
     }
//--- check for the indicator
   indicator_handle=iCustom(_Symbol,_Period,"My_Indicator",ma_period);
   if(indicator_handle==INVALID_HANDLE)
     {
      PrintFormat("Failed to generate My_Indicator handle. Error code %d",
                  GetLastError());
      return (INIT_FAILED);
     }
//--- EA initialization successful
   return(INIT_SUCCEEDED);
  }
```

OnDeinit

The function is called in indicators and EAs when the Deinit event occurs. It is used to deinitialize a running MQL5 program.

```
void  OnDeinit(
   const int  reason         // deinitialization reason code
   );
```

Parameters

reason

[in] Deinitialization reason code.

Return Value

No return value

Note

Deinit event is generated for EAs and indicators in the following cases:

- before a re-initialization due to the change of a symbol or a chart period the mql5 program is attached to;
- before a re-initialization due to the change of the inputs;
- before unloading an mql5 program.

The *reason* parameter may have the following values:

Constant	Value	Description
REASON_PROGRAM	0	The EA has stopped working calling the ExpertRemove() function
REASON_REMOVE	1	Program removed from a chart
REASON_RECOMPILE	2	Program recompiled
REASON_CHARTCHANGE	3	A symbol or a chart period is changed
REASON_CHARTCLOSE	4	Chart closed
REASON_PARAMETERS	5	Inputs changed by a user
REASON_ACCOUNT	6	Another account has been activated or reconnection to the trade server has occurred due to changes in the account settings
REASON_TEMPLATE	7	Another chart template applied
REASON_INITFAILED	8	The OnInit() handler returned a non-zero value
REASON_CLOSE	9	Terminal closed

EA deinitialization reason codes can be received by the UninitializeReason() function or from the predefined _UninitReason variable.

Sample OnInit() and OnDeinit() functions for the EA

```
input int fake_parameter=3;      // useless parameter
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- Get the number of a build where the program is compiled
   Print(__FUNCTION__," Build #",__MQLBUILD__);
//--- Reset reason code can also be obtained in OnInit()
   Print(__FUNCTION__," Deinitialization reason code can be received during the EA res
//--- The first way to get a deinitialization reason code
   Print(__FUNCTION__," _UninitReason = ",getUninitReasonText(_UninitReason));
//--- The second way to get a deinitialization reason code
   Print(__FUNCTION__," UninitializeReason() = ",getUninitReasonText(UninitializeReasc
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- The first way to get a deinitialization reason code
   Print(__FUNCTION__," Deinitialization reason code = ",reason);
//--- The second way to get a deinitialization reason code
   Print(__FUNCTION__," _UninitReason = ",getUninitReasonText(_UninitReason));
//--- The third way to get a deinitialization reason code
   Print(__FUNCTION__," UninitializeReason() = ",getUninitReasonText(UninitializeReasc
  }
//+------------------------------------------------------------------+
//| Return a textual description of the deinitialization reason code |
//+------------------------------------------------------------------+
string getUninitReasonText(int reasonCode)
  {
   string text="";
//---
   switch(reasonCode)
     {
      case REASON_ACCOUNT:
         text="Account was changed";break;
      case REASON_CHARTCHANGE:
         text="Symbol or timeframe was changed";break;
      case REASON_CHARTCLOSE:
         text="Chart was closed";break;
      case REASON_PARAMETERS:
         text="Input-parameter was changed";break;
      case REASON_RECOMPILE:
         text="Program "+__FILE__+" was recompiled";break;
```

```
      case REASON_REMOVE:
         text="Program "+__FILE__+" was removed from chart";break;
      case REASON_TEMPLATE:
         text="New template was applied to chart";break;
      default:text="Another reason";
     }
//---
   return text;
  }
```

OnTick

The function is called in EAs when the NewTick event occurs to handle a new quote.

```
void  OnTick(void);
```

Return Value

No return value

Note

The NewTick event is generated only for EAs upon receiving a new tick for a symbol of the chart the EA is attached to. There is no point in defining the OnTick() function in a custom indicator or a script since a NewTick event is not generated for them.

The Tick event is generated only for EAs, but this does not mean that EAs have to feature the OnTick() function, since Timer, BookEvent and ChartEvent events are also generated for EAs in addition to NewTick.

All events are handled one after another in the order of their receipt. If the queue already contains the NewTick event or this event is in the processing stage, then the new NewTick event is not added to mql5 application queue.

The NewTick event is generated regardless of whether auto trading is enabled (AutoTrading button). Disabled auto trading means only a ban on sending trade requests from an EA. The EA operation is not stopped.

Disabling auto trading by pressing the AutoTrading button does not interrupt the current execution of the OnTick() function.

Example of the EA featuring its entire trading logic in the OnTick() function

```
//+------------------------------------------------------------------+

OnCalculate

The function is called in the indicators when the Calculate event occurs for processing price data changes. There are two function types. Only one of them can be used within a single indicator.

Calculation based on data array

```
int  OnCalculate(
   const int        rates_total,       // price[] array size
   const int        prev_calculated,   // number of handled bars at the previous call
   const int        begin,             // index number in the price[] array meaningful
   const double&    price[]            // array of values for calculation
   );
```

Calculations based on the current timeframe timeseries

```
int  OnCalculate(
   const int        rates_total,       // size of input time series
   const int        prev_calculated,   // number of handled bars at the previous call
   const datetime&  time[],            // Time array
   const double&    open[],            // Open array
   const double&    high[],            // High array
   const double&    low[],             // Low array
   const double&    close[],           // Close array
   const long&      tick_volume[],     // Tick Volume array
   const long&      volume[],          // Real Volume array
   const int&       spread[]           // Spread array
   );
```

Parameters

rates_total

[in] Size of the price[] array or input series available to the indicator for calculation. In the second function type, the parameter value corresponds to the number of bars on the chart it is launched at.

prev_calculated

[in] Contains the value returned by the OnCalculate() function during the previous call. It is designed to skip the bars that have not changed since the previous launch of this function.

begin

[in] Index value in the price[] array meaningful data starts from. It allows you to skip missing or initial data, for which there are no correct values.

price[]

[in] Array of values for calculations. One of the price timeseries or a calculated indicator buffer can be passed as the price[] array. Type of data passed for calculation can be defined using the _AppliedTo predefined variable.

time{}

[in] Array with bar open time values.

open[]

[in] Array with Open price values.

high[]

[in] Array with High price values.

low[]

[in] Array with Low price values.

close[]

[in] Array with Close price values.

tick_volume[]

[in] Array with tick volume values.

volume[]

[in] Array with trade volume values.

spread[]

[in] Array with spread values for bars.

Return Value

int type value to be passed as the *prev_calculated* parameter during the next function call.

Note

If the OnCalculate() function is equal to zero, no indicator values are shown in the DataWindow of the client terminal.

If the price data have been changed since the last call of the OnCalculate() function (a deeper history has been loaded or gaps in the history have been filled), the value of the *prev_calculated* input parameter is set to zero by the terminal itself.

To define the indexing direction in the *time[]*, *open[]*, *high[]*, *low[]*, *close[]*, *tick_volume[]*, *volume[]* and *spread[]* arrays, call the ArrayGetAsSeries() function. In order not to depend on defaults, call the ArraySetAsSeries() function for the arrays to work with.

When using the first function type, a necessary timeseries or indicator is selected by a user as the price[] array in the Parameters tab when launching the indicator. To do this, specify the necessary element in the drop-down list of the "Apply to" field.

To get custom indicator values from other mql5 programs, the iCustom() function is used. It returns the indicator handle for subsequent operations. It is also possible to specify the required *price []* array or the handle of another indicator. This parameter should be passed the last in the list of input variables of a custom indicator.

It is necessary to use the connection between the value returned by the OnCalculate() function and the *prev_calculated* second input parameter. When calling the function, the *prev_calculated* parameter contains the value returned by the OnCalculate() function during the previous call. This makes it possible to implement resource-saving algorithms for calculating a custom indicator in order to avoid repetitive calculations for the bars that have not changed since the previous launch of this function.

Sample indicator

OnTimer

The function is called in EAs during the Timer event generated by the terminal at fixed time intervals.

```
void  OnTimer(void);
```

Return Value

No return value

Note

The Timer event is periodically generated by the client terminal for an EA, which activated the timer using the EventSetTimer() function. Usually, this function is called in the OnInit() function. When the EA stops working, the timer should be eliminated using EventKillTimer(), which is usually called in the OnDeinit() function.

Each Expert Advisor and each indicator work with its own timer receiving events solely from this timer. During mql5 application shutdown, the timer is forcibly destroyed in case it has been created but has not been disabled by EventKillTimer() function.

If you need to receive timer events more frequently than once per second, use EventSetMillisecondTimer() for creating a high-resolution timer.

In general, when the timer period is reduced, the testing time is increased, as the handler of timer events is called more often. When working in real-time mode, timer events are generated no more than 1 time in 10-16 milliseconds due to hardware limitations.

Only one timer can be launched for each program. Each mql5 application and chart have their own queue of events where all newly arrived events are placed. If the queue already contains Timer event or this event is in the processing stage, then the new Timer event is not added to mql5 application queue.

Sample EA with the OnTimer() handler

```
//+------------------------------------------------------------------+

OnTrade

The function is called in EAs when the Trade event occurs. The function is meant for processing changes in order, position and trade lists.

```
void  OnTrade(void);
```

Return Value

No return value

Note

OnTrade() is called only for Expert Advisors. It is not used in indicators and scripts even if you add there a function with the same name and type.

For any trade action (placing a pending order, opening/closing a position, placing stops, activating pending orders, etc.), the history of orders and trades and/or the list of positions and current orders is changed appropriately.

When handling an order, a trade server sends the terminal a message about the incoming Trade event. To retrieve relevant data on orders and trades from history, it is necessary to perform a trading history request using HistorySelect() first.

The trade events are generated by the server in case of:

- changing active orders,
- changing positions,
- changing deals,
- changing trade history.

Each Trade event may appear as a result of one or several trade requests. Trade requests are sent to the server using OrderSend() or OrderSendAsync(). Each request can lead to several trade events. You cannot rely on the statement "One request - one Trade event", since the processing of events may be performed in several stages, and each operation may change the state of orders, positions and the trade history.

OnTrade() handler is called after the appropriate OnTradeTransaction() calls. In general, there is no exact correlation in the number of OnTrade () and OnTradeTransaction () calls. One OnTrade() call corresponds to one or several OnTradeTransaction calls.

Sample EA with OnTrade() handler

OnTradeTransaction

The function is called in EAs when the TradeTransaction event occurs. The function is meant for handling trade request execution results.

```
void  OnTradeTransaction()
   const MqlTradeTransaction&    trans,     // trade transaction structure
   const MqlTradeRequest&        request,   // request structure
   const MqlTradeResult&         result     // response structure
   );
```

Parameters

trans

[in] MqlTradeTransaction type variable describing a transaction made on a trading account.

request

[in] MqlTradeRequest type variable describing a trade request that led to a transaction. It contains the values for TRADE_TRANSACTION_REQUEST type transaction only.

result

[in] MqlTradeResult type variable containing an execution result of a trade request that led to a transaction. It contains the values for TRADE_TRANSACTION_REQUEST type transaction only.

Return Value

No return value

Note

OnTradeTransaction() is called to handle the TradeTransaction event sent by the trade server to the terminal in the following cases:

- sending a trade request from an MQL5 program using the OrderSend()/OrderSendAsync() functions and its subsequent execution;
- sending a trade request manually via the GUI and its subsequent execution;
- activations of pending and stop orders on the server;
- performing operations on the trade server side.

Data on transaction type is contained in the *type* field of the *trans* variable. Types of trade transactions are described in the ENUM_TRADE_TRANSACTION_TYPE enumeration:

- TRADE_TRANSACTION_ORDER_ADD - adding a new active order
- TRADE_TRANSACTION_ORDER_UPDATE - changing an existing order
- TRADE_TRANSACTION_ORDER_DELETE - deleting an order from the list of active ones
- TRADE_TRANSACTION_DEAL_ADD - adding a deal to history
- TRADE_TRANSACTION_DEAL_UPDATE - changing a deal in history
- TRADE_TRANSACTION_DEAL_DELETE - deleting a deal from history
- TRADE_TRANSACTION_HISTORY_ADD - adding an order to history as a result of execution or cancelation
- TRADE_TRANSACTION_HISTORY_UPDATE - changing an order in the order history
- TRADE_TRANSACTION_HISTORY_DELETE - deleting an order from the order history
- TRADE_TRANSACTION_POSITION - position change not related to a trade execution

- TRADE_TRANSACTION_REQUEST - notification that a trade request has been processed by the server and the result of its processing has been received.

When handling transactions of TRADE_TRANSACTION_REQUEST type, it is necessary to analyze the second and third parameters of the OnTradeTransaction() function - *request* and *result* - to receive additional information.

Sending a buy trade request leads to a chain of trade transactions on a trading account: 1) request is accepted for processing, 2) an appropriate purchase order is created for the account, 3) the order is then executed, 4) the executed order is removed from the list of active ones, 5) adding to the history of orders, 6) the subsequent transaction is added to history and 7) a new position is created. All these stages are trade transactions. The arrival of each such transaction to the terminal is the TradeTransaction event. Priority of these transactions' arrival at the terminal is not guaranteed. Thus, you should not expect that one group of transactions will arrive after another one when developing your trading algorithm.

When transactions are processed by the EA's OnTradeTransaction() handler, the terminal goes on handling the incoming trade transactions. Thus, the trading account status may change at the course of OnTradeTransaction() operation. For example, while an MQL5 program handles adding a new order, it can be executed, deleted from the list of open orders and moved to history. The program is notified of all these events.

Transactions queue length comprises 1024 elements. If OnTradeTransaction() handles yet another transaction for too long, the previous ones can be superseded by new transactions in the queue.

OnTrade() handler is called after the appropriate OnTradeTransaction() calls. In general, there is no exact correlation in the number of OnTrade () and OnTradeTransaction () calls. One OnTrade() call corresponds to one or several OnTradeTransaction calls.

Each Trade event may appear as a result of one or several trade requests. Trade requests are sent to the server using OrderSend() or OrderSendAsync(). Each request can lead to several trade events. You cannot rely on the statement "One request - one Trade event", since the processing of events may be performed in several stages and each operation may change the state of orders, positions and the trade history.

OnBookEvent

The function is called in indicators and EAs when the BookEvent event occurs. It is meant for handling Depth of Market changes.

```
void  OnBookEvent(
   const string&  symbol          // symbol
   );
```

Parameters

symbol

[in] Name of a symbol the BookEvent has arrived for

Return Value

No return value

Note

To get the BookEvent events for any symbol, simply subscribe to receive them for this symbol using the MarketBookAdd() function. To cancel subscription for receiving the BookEvent for a certain symbol, call the MarketBookRelease() function.

The BookEvent broadcasts within the entire chart. This means that if one application on a chart subscribes to the BookEvent using the MarketBookAdd function, all other indicators and EAs launched on the same chart and having the OnBookEvent() handler receive this event as well. Therefore, it is necessary to analyze a symbol name passed to the OnBookEvent() handler as the *symbol* parameter.

Separate BookEvent counters sorted by symbols are provided for all applications running on the same chart. This means that each chart may have multiple subscriptions to different symbols, and a counter is provided for each symbol. Subscribing and unsubscribing from BookEvent changes the subscription counter for specified symbols only within one chart. In other words, there may be two adjacent charts to the BookEvent for the same symbol but different subscription counter values.

The initial subscription counter value is zero. At each MarketBookAdd() call, the subscription counter for a specified symbol on the chart is increased by one (chart symbol and symbol in MarketBookAdd() do not have to match). When calling MarketBookRelease(), the counter of subscriptions for a specified symbol within the chart is decreased by one. The BookEvent events for any symbol are broadcast within the chart till the counter is equal to zero. Therefore, it is important that each MQL5 program that contains MarketBookAdd () calls correctly unsubscribes from getting events for each symbol using MarketBookRelease () at the end of its work. To achieve this, the number of MarketBookAdd() and MarketBookRelease() calls should be even for each call during the entire MQL5 program lifetime. Using flags or custom subscription counters within the program allows you to safely work with BookEvent events and prevents disabling subscriptions for getting this event in third-party programs within the same chart.

BookEvent events are never skipped and are always placed into a queue even if handling the previous BookEvent handling is not over yet.

OnChartEvent

The function is called in indicators and EAs when the ChartEvent event occurs. The function is meant for handling chart changes made by a user or an MQL5 program.

```
void  OnChartEvent()
   const int       id,       // event ID
   const long&     lparam,   // long type event parameter
   const double&   dparam,   // double type event parameter
   const string&   sparam    // string type event parameter
   );
```

Parameters

id

[in] Event ID from the ENUM_CHART_EVENT enumeration.

lparam

[in] long type event parameter

dparam

[in] double type event parameter

sparam

[in] string type event parameter

Return Value

No return value

Note

There are 11 types of events that can be handled using the predefined OnChartEvent() function. 65535 IDs from CHARTEVENT_CUSTOM to CHARTEVENT_CUSTOM_LAST inclusive are provided for custom events. To generate a custom event, use the EventChartCustom() function.

Short event description from the ENUM_CHART_EVENT enumeration:

- CHARTEVENT_KEYDOWN — pressing a key on the keyboard when a chart window is in focus;
- CHARTEVENT_MOUSE_MOVE — moving the mouse and mouse button clicks (if CHART_EVENT_MOUSE_MOVE=true for a chart);
- CHARTEVENT_OBJECT_CREATE — create a graphical object (if CHART_EVENT_OBJECT_CREATE=true for a chart);
- CHARTEVENT_OBJECT_CHANGE — change object properties via the properties dialog;
- CHARTEVENT_OBJECT_DELETE — delete a graphical object (if CHART_EVENT_OBJECT_DELETE=true for a chart);
- CHARTEVENT_CLICK — clicking on a chart;
- CHARTEVENT_OBJECT_CLICK — mouse click on a graphical object belonging to a chart;
- CHARTEVENT_OBJECT_DRAG — dragging a graphical object with a mouse;
- CHARTEVENT_OBJECT_ENDEDIT — finish editing text in the Edit input box of a graphical object (OBJ_EDIT);
- CHARTEVENT_CHART_CHANGE — change a chart;

- CHARTEVENT_CUSTOM+n — custom event ID, where n is within the range from 0 to 65535. CHARTEVENT_CUSTOM_LAST contains the last acceptable custom event ID (CHARTEVENT_CUSTOM+65535).

All MQL5 programs work in threads other than the main thread of the application. The main application thread is responsible for handling all Windows system messages and, in its turn, generates Windows messages for its own application as a result of this handling. For example, moving the mouse on a chart (WM_MOUSE_MOVE event) generates several system messages for subsequent rendering of the application window, and also sends internal messages to experts and indicators launched on the chart. A situation may occur, where the main application thread has not yet processed the WM_PAINT system message (and therefore has not yet rendered the modified chart), while an EA or an indicator has already received the mouse movement event. In this case, the chart property CHART_FIRST_VISIBLE_BAR will be changed only after the chart is rendered.

For each event type, the inputs of the OnChartEvent() function have certain values necessary for handling that event. The table lists events and values passed via the parameters.

Event	'id' parameter value	'lparam' parameter value	'dparam' parameter value	'sparam' parameter value
Keystroke event	CHARTEVENT_KEYDOWN	pressed button code	The number of keypresses generated while the key was held in the pressed state	String value of the bit mask, which describes the status of the keyboard keys
Mouse events (if CHART_EVENT_MOUSE_MOVE=true for a chart)	CHARTEVENT_MOUSE_MOVE	X coordinate	Y coordinate	String value of the bit mask, which describes the status of the mouse keys
Mouse wheel event (if CHART_EVENT_MOUSE_WHEEL=true for the chart)	CHARTEVENT_MOUSE_WHEEL	Flags of states of keys and mouse buttons, X and Y coordinates of the cursor. See the description in the example	The Delta value of the mouse wheel scroll	—
Creating a graphical object (if CHART_EVENT_OBJECT_CREATE=true for a chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of a created graphical object
Changing object properties via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of a changed graphical object

Event	'id' parameter value	'lparam' parameter value	'dparam' parameter value	'sparam' parameter value
Removing a graphical object (if CHART_EVENT_OBJECT_DELETE =true for a chart)	CHARTEVENT_OBJECT_DELETE	—	—	Name of a removed graphical object
Mouse click on a chart	CHARTEVENT_CLICK	X coordinate	Y coordinate	—
Mouse click on a graphical object	CHARTEVENT_OBJECT_CLICK	X coordinate	Y coordinate	Name of a graphical object the event has occurred on
Moving a graphical object with mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of a moved graphical object
Finishing a text editing in the "Input field" graphical object input box	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the "Input field" graphical object, in which text editing completed
Resizing the chart or modifying the chart properties via the properties dialog window	CHARTEVENT_CHART_CHANGE	—	—	—
Custom event with N number	CHARTEVENT_CUSTOM+N	Value defined by the EventChartCustom() function	Value defined by the EventChartCustom() function	Value defined by the EventChartCustom() function

OnTester

The function is called in Expert Advisors when the Tester event occurs to perform necessary actions after testing.

```
double  OnTester(void);
```

Return Value

Value of the custom criterion optimization for assessing test results.

Note

The OnTester() function can be used only when testing EAs and is intended primarily for the calculation of a value that is used as a 'Custom max' criterion when optimizing input parameters.

During the genetic optimization, sorting results within one generation is performed in descending order. This means that the results with the highest value are deemed the best from the optimization criterion point of view. The worst values for such sorting are placed at the end and are subsequently discarded. Therefore, they do not take part in forming the next generation.

Thus, the OnTester() function allows you not only to create and save your own test results reports, but also control the optimization process to find the best parameters of the trading strategy.

Below is an **example** of calculating the custom criterion optimization. The idea is to calculate the linear regression of the balance graph. It is described in the article Optimizing a strategy using balance graph and comparing results with "Balance + max Sharpe Ratio" criterion.

```

OnTesterInit

The function is called in EAs when the TesterInit event occurs to perform necessary actions before optimization in the strategy tester. There are two function types.

The **version that returns the result**

```
int  OnTesterInit(void);
```

Return Value

int type value, zero means successful initialization of an EA launched on a chart before optimization starts.

The OnTesterInit() call that returns the execution result is recommended for use since it not only allows for program initialization, but also returns an error code in case of an early optimization stop. Return of any value other than INIT_SUCCEEDED (0) means an error, no optimization is launched.

The version without a result return is left only for compatibility with old codes. Not recommended for use

```
void  OnTesterInit(void);
```

Note

The TesterInit event is generated before EA optimization in the strategy tester starts. At this event, an EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart. It has the symbol and the period that have been specified in the tester.

Such an event receives the TesterInit, TesterDeinit and TesterPass events, but not Init, Deinit and NewTick ones. Accordingly, all necessary logic for processing the results of each pass during optimization should be implemented in the OnTesterInit (), OnTesterDeinit () and OnTesterPass () handlers.

The result of each single pass during a strategy optimization can be passed via a frame from the OnTester () handler using the FrameAdd () function.

The OnTesterInit() function is used to initiate an Expert Advisor before start of optimization for further processing of optimization results. It is always used together with the OnTesterDeinit() handler.

The time for OnTesterInit() execution is limited. If it is exceeded, the EA is forcibly stopped, while the optimization itself is canceled. A message is displayed in the tester journal:

```
TesterOnTesterInit works too long. Tester cannot be initialized.
```

The example is taken from OnTick. The OnTesterInit() handler is added for setting optimization parameters:

```

OnTesterDeinit

The function is called in EAs when the TesterDeinit event occurs after EA optimization.

```
void  OnTesterDeinit(void);
```

Return Value

No return value

Note

The TesterDeinit event is generated after the end of EA optimization in the strategy tester.

An EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart during the optimization start. It has the symbol and the period that have been specified in the tester. The function is designed for the final processing of all optimization results.

Keep in mind that optimization frames sent by test agents using the FrameAdd() function may come in bundles and take time to deliver. Therefore, not all frames, as well as TesterPass events, may arrive and be processed in OnTesterPass() before the end of optimization. If you want to receive all belated frames in OnTesterDeinit(), place the code block using the FrameNext() function.

See also

Testing trading strategies, Working with optimization results, TesterStatistics, OnTesterInit, OnTesterPass, ParameterGetRange, ParameterSetRange

OnTesterPass

The function is called in EAs when the TesterPass event occurs for handling a new data frame during EA optimization.

```
void  OnTesterPass(void);
```

Return Value

No return value

Note

The TesterPass event is generated automatically when receiving a frame during an Expert Advisor optimization in the strategy tester.

An EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart during the optimization start. It has the symbol and the period that have been specified in the tester. The function is meant for handling frames received from test agents during optimization. The frame containing test results should be sent from the OnTester() handler using the FrameAdd() function.

Keep in mind that optimization frames sent by test agents using the FrameAdd() function may come in bundles and take time to deliver. Therefore, not all frames, as well as TesterPass events, may arrive and be processed in OnTesterPass() before the end of optimization. If you want to receive all belated frames in OnTesterDeinit(), place the code block using the FrameNext() function.

After completing OnTesterDeinit() optimization, it is possible to sort all received frames again using the FrameFirst()/FrameFilter and FrameNext() functions.

Getting Market Information

These are functions intended for receiving information about the market state.

Function	Action
SymbolsTotal	Returns the number of available (selected in Market Watch or all) symbols
SymbolExist	Checks if a symbol with a specified name exists
SymbolName	Returns the name of a specified symbol
SymbolSelect	Selects a symbol in the Market Watch window or removes a symbol from the window
SymbolIsSynchronized	Checks whether data of a selected symbol in the terminal are synchronized with data on the trade server
SymbolInfoDouble	Returns the double value of the symbol for the corresponding property
SymbolInfoInteger	Returns a value of an integer type (long, datetime, int or bool) of a specified symbol for the corresponding property
SymbolInfoString	Returns a value of the string type of a specified symbol for the corresponding property
SymbolInfoMarginRate	Returns the margin rates depending on the order type and direction
SymbolInfoTick	Returns the current prices for the specified symbol in a variable of the MqlTick type
SymbolInfoSessionQuote	Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.
SymbolInfoSessionTrade	Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.
MarketBookAdd	Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes
MarketBookRelease	Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes
MarketBookGet	Returns a structure array MqlBookInfo containing records of the Depth of Market of a specified symbol

SymbolsTotal

Returns the number of available (selected in Market Watch or all) symbols.

```
int  SymbolsTotal(
   bool  selected      // True - only symbols in MarketWatch
   );
```

Parameters

selected

[in] Request mode. Can be true or false.

Return Value

If the 'selected' parameter is true, the function returns the number of symbols selected in MarketWatch. If the value is false, it returns the total number of all symbols.

SymbolExist

Checks if a symbol with a specified name exists.

```
bool  SymbolExist(
   const string  name,     // symbol name
   bool&   is_custom       // custom symbol property
   );
```

Parameters

name

[in] Symbol name.

is_custom

[out] Custom symbol property set upon successful execution. If true, the detected symbol is a custom one.

Return Value

If false, the symbol is not found among standard and custom ones.

See also

SymbolsTotal, SymbolSelect, Custom symbols

SymbolName

Returns the name of a symbol.

```
string  SymbolName(
   int   pos,           // number in the list
   bool  selected       // true - only symbols in MarketWatch
   );
```

Parameters

pos

[in] Order number of a symbol.

selected

[in] Request mode. If the value is true, the symbol is taken from the list of symbols selected in MarketWatch. If the value is false, the symbol is taken from the general list.

Return Value

Value of string type with the symbol name.

SymbolSelect

Selects a symbol in the Market Watch window or removes a symbol from the window.

```
bool  SymbolSelect(
   string  name,        // symbol name
   bool    select       // add or remove
   );
```

Parameters

name

[in] Symbol name.

select

[in] Switch. If the value is false, a symbol should be removed from MarketWatch, otherwise a symbol should be selected in this window. A symbol can't be removed if the symbol chart is open, or there are open positions for this symbol.

Return Value

In case of failure returns false.

SymbolIsSynchronized

The function checks whether data of a selected symbol in the terminal are synchronized with data on the trade server.

```
bool  SymbolIsSynchronized(
   string  name,        // symbol name
   );
```

Parameters

name

[in] Symbol name.

Return value

If data are synchronized, returns 'true'; otherwise returns 'false'.

See also

SymbolInfoInteger, Organizing Data Access

SymbolInfoDouble

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  SymbolInfoDouble(
   string                    name,        // symbol
   ENUM_SYMBOL_INFO_DOUBLE   prop_id      // identifier of the property
   );
```

2. Returns true or false depending on whether a function is successfully performed. In case of success, the value of the property is placed into a recipient variable, passed by reference by the last parameter.

```
bool  SymbolInfoDouble(
   string                    name,        // symbol
   ENUM_SYMBOL_INFO_DOUBLE   prop_id,     // identifier of the property
   double&                   double_var   // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_DOUBLE enumeration.

double_var

[out] Variable of double type receiving the value of the requested property.

Return Value

The value of double type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

The SymbolInfoMarginRate() function provides data on the amount of charged margin depending on the order type and direction.

Example:

```
void OnTick()
  {
//--- obtain spread from the symbol properties
   bool spreadfloat=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD_FLOAT);
   string comm=StringFormat("Spread %s = %I64d points\r\n",
                            spreadfloat?"floating":"fixed",
                            SymbolInfoInteger(Symbol(),SYMBOL_SPREAD));
//--- now let's calculate the spread by ourselves
   double ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   double bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   double spread=ask-bid;
   int spread_points=(int)MathRound(spread/SymbolInfoDouble(Symbol(),SYMBOL_POINT));
   comm=comm+"Calculated spread = "+(string)spread_points+" points";
   Comment(comm);
  }
```

SymbolInfoInteger

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  SymbolInfoInteger(
   string                     name,      // symbol
   ENUM_SYMBOL_INFO_INTEGER   prop_id    // identifier of a property

   );
```

2. Returns true or false depending on whether a function is successfully performed. In case of success, the value of the property is placed into a recipient variable, passed by reference by the last parameter.

```
bool  SymbolInfoInteger(
   string                     name,      // symbol
   ENUM_SYMBOL_INFO_INTEGER   prop_id,   // identifier of a property
   long&                      long_var   // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_INTEGER enumeration.

long_var

[out] Variable of the long type receiving the value of the requested property.

Return Value

The value of long type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

Example:

```
void OnTick()
  {
//--- obtain spread from the symbol properties
   bool spreadfloat=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD_FLOAT);
   string comm=StringFormat("Spread %s = %I64d points\r\n",
                            spreadfloat?"floating":"fixed",
                            SymbolInfoInteger(Symbol(),SYMBOL_SPREAD));
//--- now let's calculate the spread by ourselves
   double ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   double bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   double spread=ask-bid;
   int spread_points=(int)MathRound(spread/SymbolInfoDouble(Symbol(),SYMBOL_POINT));
   comm=comm+"Calculated spread = "+(string)spread_points+" points";
   Comment(comm);
  }
```

SymbolInfoString

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  SymbolInfoString(
   string                    name,         // Symbol
   ENUM_SYMBOL_INFO_STRING   prop_id       // Property identifier
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a placeholder variable passed by reference in the last parameter.

```
bool  SymbolInfoString(
   string                    name,         // Symbol
   ENUM_SYMBOL_INFO_STRING   prop_id,      // Property identifier
   string&                   string_var    // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_STRING enumeration.

string_var

[out] Variable of the string type receiving the value of the requested property.

Return Value

The value of string type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

SymbolInfoMarginRate

Returns the margin rates depending on the order type and direction.

```
bool  SymbolInfoMarginRate(
   string             name,                    // symbol name
   ENUM_ORDER_TYPE    order_type,              // order type
   double&            initial_margin_rate,     // initial margin rate
   double&            maintenance_margin_rate  // maintenance margin rate
   );
```

Parameters

name

[in] Symbol name.

order_type

[in] Order type.

initial_margin_rate

[in] A double type variable for receiving an initial margin rate. Initial margin is a security deposit for 1 lot deal in the appropriate direction. Multiplying the rate by the initial margin, we receive the amount of funds to be reserved on the account when placing an order of the specified type.

maintenance_margin_rate

[out] A double type variable for receiving a maintenance margin rate. Maintenance margin is a minimum amount for maintaining an open position of 1 lot in the appropriate direction. Multiplying the rate by the maintenance margin, we receive the amount of funds to be reserved on the account after an order of the specified type is activated.

Return Value

Returns true if request for properties is successful, otherwise false.

SymbolInfoTick

The function returns current prices of a specified symbol in a variable of the MqlTick type.

```
bool  SymbolInfoTick(
   string    symbol,      // symbol name
   MqlTick&  tick         // reference to a structure
   );
```

Parameters

symbol

[in] Symbol name.

tick

[out] Link to the structure of the MqlTick type, to which the current prices and time of the last price update will be placed.

Return Value

The function returns true if successful, otherwise returns false.

SymbolInfoSessionQuote

Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.

```
bool  SymbolInfoSessionQuote(
   string            name,                // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,         // day of the week
   uint              session_index,       // session index
   datetime&         from,                // time of the session beginning
   datetime&         to                   // time of the session end
   );
```

Parameters

name

[in] Symbol name.

ENUM_DAY_OF_WEEK

[in] Day of the week, value of enumeration ENUM_DAY_OF_WEEK.

uint

[in] Ordinal number of a session, whose beginning and end time we want to receive. Indexing of sessions starts with 0.

from

[out] Session beginning time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

to

[out] Session end time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

Return Value

If data for the specified session, symbol and day of the week are received, returns true, otherwise returns false.

See also

Symbol Properties, TimeToStruct, Data Structures

SymbolInfoSessionTrade

Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.

```
bool  SymbolInfoSessionTrade(
   string            name,                // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,         // day of the week
   uint              session_index,       // session index
   datetime&         from,                // session beginning time
   datetime&         to                   // session end time
   );
```

Parameters

name

[in] Symbol name.

ENUM_DAY_OF_WEEK

[in] Day of the week, value of enumeration ENUM_DAY_OF_WEEK.

uint

[in] Ordinal number of a session, whose beginning and end time we want to receive. Indexing of sessions starts with 0.

from

[out] Session beginning time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

to

[out] Session end time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

Return value

If data for the specified session, symbol and day of the week are received, returns true, otherwise returns false.

See also

Symbol Properties, TimeToStruct, Data Structures

MarketBookAdd

Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes.

```
bool  MarketBookAdd(
   string  symbol      // symbol
   );
```

Parameters

symbol

[in] The name of a symbol, whose Depth of Market is to be used in the Expert Advisor or script.

Return Value

The true value if opened successfully, otherwise false.

Note

Normally, this function must be called from the OnInit() function or in the class constructor. To handle incoming alerts, in the Expert Advisor program must contain the function void OnBookEvent(string& symbol).

See also

Structure of Depth of Market, Structures and Classes

MarketBookRelease

Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes.

```
bool  MarketBookRelease(
   string  symbol      // symbol
   );
```

Parameters

symbol

[in] Symbol name.

Return Value

The true value if closed successfully, otherwise false.

Note

Normally, this function must be called from the OnDeinit() function, if the corresponding MarketBookAdd() function has been called in the OnInit() function. Or it must be called from the class destructor, if the corresponding MarketBookAdd() function has been called from the class constructor.

See also

Structure of Depth of Market, Structures and Classes

MarketBookGet

Returns a structure array MqlBookInfo containing records of the Depth of Market of a specified symbol.

```
bool  MarketBookGet(
   string        symbol,      // symbol
   MqlBookInfo&  book[]       // reference to an array
   );
```

Parameters

symbol

[in] Symbol name.

book[]

[in] Reference to an array of Depth of Market records. The array can be pre-allocated for a sufficient number of records. If a dynamic array hasn't been pre-allocated in the operating memory, the client terminal will distribute the array itself.

Return Value

Returns true in case of success, otherwise false.

Note

The Depth of Market must be pre-opened by the MarketBookAdd() function.

Example:

```
   MqlBookInfo priceArray[];
   bool getBook=MarketBookGet(NULL,priceArray);
   if(getBook)
     {
      int size=ArraySize(priceArray);
      Print("MarketBookInfo for ",Symbol());
      for(int i=0;i<size;i++)
        {
         Print(i+":",priceArray[i].price
               +"    Volume = "+priceArray[i].volume,

Economic calendar functions

This section describes the functions for working with the economic calendar available directly in the MetaTrader platform. The economic calendar is a ready-made encyclopedia featuring descriptions of macroeconomic indicators, their release dates and degrees of importance. Relevant values of macroeconomic indicators are sent to the MetaTrader platform right at the moment of publication and are displayed on a chart as tags allowing you to visually track the required indicators by countries, currencies and importance.

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

Economic calendar functions allow conducting the auto analysis of incoming events according to custom importance criteria from a perspective of necessary countries/currencies.

Function	Action
CalendarCountryById	Get a country description by its ID
CalendarEventById	Get an event description by its ID
CalendarValueById	Get an event value description by its ID
CalendarCountries	Get the array of country names available in the calendar
CalendarEventByCountry	Get the array of descriptions of all events available in the calendar by a specified country code
CalendarEventByCurrency	Get the array of descriptions of all events available in the calendar by a specified currency
CalendarValueHistoryByEvent	Get the array of values for all events in a specified time range by an event ID
CalendarValueHistory	Get the array of values for all events in a specified time range with the ability to sort by country and/or currency
CalendarValueLastByEvent	Get the array of event values by its ID since the calendar database status with a specified change_id
CalendarValueLast	Get the array of values for all events with the ability to sort by country and/or currency since the calendar database status with a specified change_id

CalendarCountryById

Get a country description by its ID.

```
bool  CalendarCountryById(
   const long           country_id,     // country ID
   MqlCalendarCountry&  country         // variable for receiving a country descripti
   );
```

Parameters

country_id

[in] Country ID (ISO 3166-1).

country

[out] MqlCalendarCountry type variable for receiving a country description.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the list of countries from the economic calendar
   MqlCalendarCountry countries[];
   int count=CalendarCountries(countries);
//--- check the result
   if(count==0)
      PrintFormat("CalendarCountries() returned 0! Error %d",GetLastError());
//--- if there are two or more countries
   if(count>=2)
     {
      MqlCalendarCountry country;
      //--- now get a country description by its ID
      if(CalendarCountryById(countries[1].id, country))
        {
         //--- prepare a country description
         string descr="id = "+IntegerToString(country.id)+"\n";
         descr+=("name = " + country.name+"\n");
         descr+=("code = " + country.code+"\n");
         descr+=("currency = " + country.currency+"\n");
         descr+=("currency_symbol = " + country.currency_symbol+"\n");
```

```
         descr+=("url_name = " + country.url_name);
         //--- display a country description
         Print(descr);
        }
      else
         Print("CalendarCountryById() failed. Error ",GetLastError());
     }
//---
  }
/*
  Result:
   id = 999
   name = European Union
   code = EU
   currency = EUR
   currency_symbol = €
   url_name = european-union
*/
```

CalendarCountries, CalendarEventByCountry

CalendarEventById

Get an event description by its ID.

```
bool  CalendarEventById(
   ulong                event_id,      // event ID
   MqlCalendarEvent&    event          // variable for receiving an event description
   );
```

Parameters

event_id

[in] Event ID.

event

[out] MqlCalendarEvent type variable for receiving an event description.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for Germany (ISO 3166-1 Alpha-2)
   string germany_code="DE";
//--- get Germany events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(germany_code,events);
//--- display Germany events in the Journal
   if(events_count>0)
     {
      PrintFormat("Germany events: %d",events_count);
      ArrayPrint(events);
     }
   else
     {
      PrintFormat("Failed to receive events for the country code %s, error %d",
                  germany_code,GetLastError());
      //--- script early completion
      return;
     }
//--- get description of the last event from the events[] array
```

```
   MqlCalendarEvent event;
   ulong event_id=events[events_count-1].id;
   if(CalendarEventById(event_id,event))
     {
      MqlCalendarCountry country;
      CalendarCountryById(event.country_id,country);
      PrintFormat("Event description with event_id=%d received",event_id);
      PrintFormat("Country: %s (country code = %d)",country.name,event.country_id);
      PrintFormat("Event name: %s",event.name);
      PrintFormat("Event code: %s",event.event_code);
      PrintFormat("Event importance: %s",EnumToString((ENUM_CALENDAR_EVENT_IMPORTANCE)
      PrintFormat("Event type: %s",EnumToString((ENUM_CALENDAR_EVENT_TYPE)event.type))
      PrintFormat("Event sector: %s",EnumToString((ENUM_CALENDAR_EVENT_SECTOR)event.se
      PrintFormat("Event frequency: %s",EnumToString((ENUM_CALENDAR_EVENT_FREQUENCY)ev
      PrintFormat("Event release mode: %s",EnumToString((ENUM_CALENDAR_EVENT_TIMEMODE)
      PrintFormat("Event measurement unit: %s",EnumToString((ENUM_CALENDAR_EVENT_UNIT)
      PrintFormat("Number of decimal places: %d",event.digits);
      PrintFormat("Source URL: %s",event.source_url);
     }
   else
      PrintFormat("Failed to get event description for event_d=%s, error %d",
                  event_id,GetLastError());
  }
/*

CalendarEventByCountry, CalendarEventByCurrency, CalendarValueById

CalendarValueById

Get an event value description by its ID.

```
bool  CalendarValueById(
   ulong                value_id,      // event value ID
   MqlCalendarValue&    value          // variable for receiving an event value
   );
```

Parameters

value_id

[in] Event value ID.

value

[out] MqlCalendarValue type variable for receiving an event description. See the example of handling calendar events.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for Japan (ISO 3166-1 Alpha-2)
```

```
   string japan_code="JP";
//--- set the boundaries of the interval we take the events from
   datetime date_from=D'01.01.2018';  // take all events from 2018
   datetime date_to=0;                // 0 means all known events, including the ones
//--- get the array of the Japan event values
   MqlCalendarValue values[];
   int values_count=CalendarValueHistory(values,date_from,date_to,japan_code);
//--- move along the detected event values
   if(values_count>0)
     {
      PrintFormat("Number of values for Japan events: %d",values_count);
      //--- delete all "empty" values (actual_value==-9223372036854775808)
      for(int i=values_count-1;i>=0;i--)
        {
         if(values[i].actual_value==-9223372036854775808)
            ArrayRemove(values,i,1);
        }
      PrintFormat("Number of values after deleting empty ones: %d",ArraySize(values));
     }
   else
     {
      PrintFormat("Failed to receive events for the country code %s, error %d",
                  japan_code,GetLastError());
      //--- script early completion
      return;
     }
//--- leave no more than 10 values in the values[] array
   if(ArraySize(values)>10)
     {
      PrintFormat("Reduce the list of values to 10 and display them");
      ArrayRemove(values,0,ArraySize(values)-10);
     }
   ArrayPrint(values);

//--- now let's display how to get an event value description based on the known value
   for(int i=0;i<ArraySize(values);i++)
     {
      MqlCalendarValue value;
      CalendarValueById(values[i].id,value);
      PrintFormat("%d: value_id=%d value=%d impact=%s",
                  i,values[i].id,value.actual_value,EnumToString(ENUM_CALENDAR_EVENT_I
     }
//---
  }
/*
  Result:

CalendarCountries

Get the array of country names available in the Calendar.

```
int  CalendarCountries(
   MqlCalendarCountry&  countries[]         // array for receiving a list of Calendar
   );
```

Parameters

countries[]

[out] An array of MqlCalendarCountry type for receiving all Calendar countries' descriptions.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all countries, only the ones that managed to fit in were received).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the list of countries from the economic calendar
   MqlCalendarCountry countries[];
   int count=CalendarCountries(countries);
//--- display the array in the Journal
   if(count>0)
      ArrayPrint(countries);
   else
      PrintFormat("CalendarCountries() returned 0! Error %d",GetLastError());

CalendarEventByCountry, CalendarCountryById

CalendarEventByCountry

Get the array of descriptions of all events available in the Calendar by a specified country code.

```
int  CalendarEventByCountry(
   string               country_code,     // country code name (ISO 3166-1 alpha-2)
   MqlCalendarEvent&    events[]          // variable for receiving the description ar
   );
```

Parameters

country_code

[in] Country code name (ISO 3166-1 alpha-2)

events[]

[out] MqlCalendarEvent type array for receiving descriptions of all events for a specified country.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- errors of failed execution of ArrayResize()

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get EU events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(EU_code,events);
//--- display EU events in the Journal
   if(events_count>0)
     {
      PrintFormat("EU events: %d",events_count);
      ArrayPrint(events);
     }
//---
  }
/*
  Result:

CalendarCountries, CalendarCountryById

CalendarEventByCurrency

Get the array of descriptions of all events available in the Calendar by a specified currency.

```
int  CalendarEventByCurrency(
   const string         currency,     // country currency code name
   MqlCalendarEvent&    events[]      // variable for receiving the description array
   );
```

Parameters

currency

[in] Country currency code name.

events[]

[out] MqlCalendarEvent type array for receiving descriptions of all events for a specified currency.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- errors of failed execution of ArrayResize()

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the array for receiving economic calendar events
      MqlCalendarEvent events[];
//--- get EU currency events
      int count = CalendarEventByCurrency("EUR",events);
      Print("count = ", count);
//--- 10 events are sufficient for the current example
      if(count>10)
         ArrayResize(events,10);
//--- display events in the Journal
      ArrayPrint(events);
  }
/*
  Result:

CalendarEventById, CalendarEventByCountry

CalendarValueHistoryByEvent

Get the array of values for all events in a specified time range by an event ID.

```
int  CalendarValueHistoryByEvent(
   ulong              event_id,          // event ID
   MqlCalendarValue&  values[],          // array for value descriptions
   datetime           datetime_from,     // left border of a time range
   datetime           datetime_to=0      // right border of a time range
   );
```

Parameters

event_id

[in] Event ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

datetime_from

[in] Initial date of a time range events are selected from by a specified ID, while *datetime_from* < *datetime_to*.

datetime_to=0

[in] End date of a time range events are selected from by a specified ID. If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

Return Value

If successful, return the number of available values in the 'values' array, otherwise -1. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get EU events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(EU_code,events);
//--- display EU events in the Journal
   if(events_count>0)
     {
      PrintFormat("EU events: %d",events_count);
      //--- reduce the event list, 10 events are sufficient for analysis
      ArrayResize(events,10);
      ArrayPrint(events);
     }
//--- see that the "ECB Interest Rate Decision" event has event_id=999010007
   ulong event_id=events[6].id;        // the event's ID may change in the Calendar, s
   string event_name=events[6].name;   // name of a Calendar event
   PrintFormat("Get values for event_name=%s event_id=%d",event_name,event_id);
//--- get all values of the "ECB Interest Rate Decision" event
   MqlCalendarValue values[];
//--- set the boundaries of the interval we take the events from
   datetime date_from=0;           // take all events from the beginning of the availa
   datetime date_to=D'01.01.2016'; // take events not older than 2016
   if(CalendarValueHistoryByEvent(event_id,values,date_from,date_to))
     {
      PrintFormat("Received values for %s: %d",
                  event_name,ArraySize(values));
      //--- reduce the value list, 10 events are sufficient for analysis
      ArrayResize(values,10);
      ArrayPrint(values);
     }
   else
     {
      PrintFormat("Error! Failed to get values for event_id=%d",event_id);
      PrintFormat("Error code: %d",GetLastError());
     }
  }
//---
```

CalendarCountries, CalendarEventByCountry, CalendarValueHistory, CalendarEventById, CalendarValueById

CalendarValueHistory

Get the array of values for all events in a specified time range with the ability to sort by country and/or currency.

```
int  CalendarValueHistory(
   MqlCalendarValue&  values[],              // array for value descriptions
   datetime           datetime_from,         // left border of a time range
   datetime           datetime_to=0          // right border of a time range
   const string       country_code=NULL,     // country code name (ISO 3166-1 alpha-2)
   const string       currency=NULL          // country currency code name
   );
```

Parameters

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

datetime_from

[in] Initial date of a time range events are selected from by a specified ID, while *datetime_from* < *datetime_to*.

datetime_to=0

[in] End date of a time range events are selected from by a specified ID. If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

country_code=NULL

[in] Country code name (ISO 3166-1 alpha-2)

currency=NULL

[in] Country currency code name.

Return Value

If successful, return the number of available values in the 'values' array, otherwise -1. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

For the *country_code* and *currency* filters, NULL and "" values are equivalent and mean the absence of the filter.

For *country_code*, the *code* field of the MqlCalendarCountry structure, for example "US", "RU" or "EU", should be used.

For *currency*, the *currency* field of the MqlCalendarCountry structure, for example "USD", "RUB" or "EUR", should be used.

The filters are applied by conjunction, i.e. logical 'AND' is used to select only the values of events both conditions (country and currency) are simultaneously met for.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get all EU event values
   MqlCalendarValue values[];
//--- set the boundaries of the interval we take the events from
   datetime date_from=D'01.01.2018';  // take all events from 2018
   datetime date_to=0;                // 0 means all known events, including the ones
//--- request EU event history since 2018 year
   if(CalendarValueHistory(values,date_from,date_to,EU_code))
     {
      PrintFormat("Received event values for country_code=%s: %d",
                  EU_code,ArraySize(values));
      //--- decrease the size of the array for outputting to the Journal
      ArrayResize(values,10);
//--- display event values in the Journal
      ArrayPrint(values);
```

```
      }
    else
      {
       PrintFormat("Error! Failed to receive events for country_code=%s",EU_code);
       PrintFormat("Error code: %d",GetLastError());
      }
//---
  }

CalendarValueLastByEvent

Get the array of event values by its ID since the Calendar database status with a specified change_id.

```
int  CalendarValueLastByEvent(
   ulong                event_id,      // event ID
   ulong&               change_id,     // Calendar change ID
   MqlCalendarValue&    values[]       // array for value descriptions
   );
```

Parameters

event_id

[in] Event ID.

change_id

[in][out] Change ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

Return Value

Number of received event values. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If *change_id* = 0 is passed to the function, the function always returns zero but the current calendar database is returned to *change_id*.

The function returns the array for a specified news and a new *change_id* that can be used for subsequent calls of the function to receive the new values of the news. Thus, it is possible to update values for a specified news by calling this function with the last known *change_id*.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

CalendarValueLast, CalendarValueHistory, CalendarValueHistoryByEvent, CalendarValueById

CalendarValueLast

Get the array of values for all events with the ability to sort by country and/or currency since the calendar database status with a specified change_id.

```
int  CalendarValueLast(
   ulong&               change_id,              // change ID
   MqlCalendarValue&    values[],               // array for value descriptions
   const string         country_code=NULL,      // country code name (ISO 3166-1 alpha-
   const string         currency=NULL           // country currency code name
   );
```

Parameters

change_id

[in][out] Change ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

country_code=NULL

[in] Country code name (ISO 3166-1 alpha-2)

currency=NULL

[in] Country currency code name.

Return Value

Number of received event values. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If *change_id* = 0 is passed to the function, you will get the current *change_id* of the calendar database to that parameter; and the function returns 0

For the *country_code* and *currency* filters, NULL and "" values are equivalent and mean the absence of the filter.

For *country_code*, the *code* field of the MqlCalendarCountry structure, for example "US", "RU" or "EU", should be used.

For *currency*, the *currency* field of the MqlCalendarCountry structure, for example "USD", "RUB" or "EUR", should be used.

The filters are applied by conjunction, i.e. logical 'AND' is used to select only the values of events both conditions (country and currency) are simultaneously met for

The function returns the array for a specified news and a new *change_id* that can be used for subsequent calls of the function to receive the new values of the news. Thus, it is possible to update values for a specified news by calling this function with the last known *change_id*.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Access to Timeseries and Indicator Data

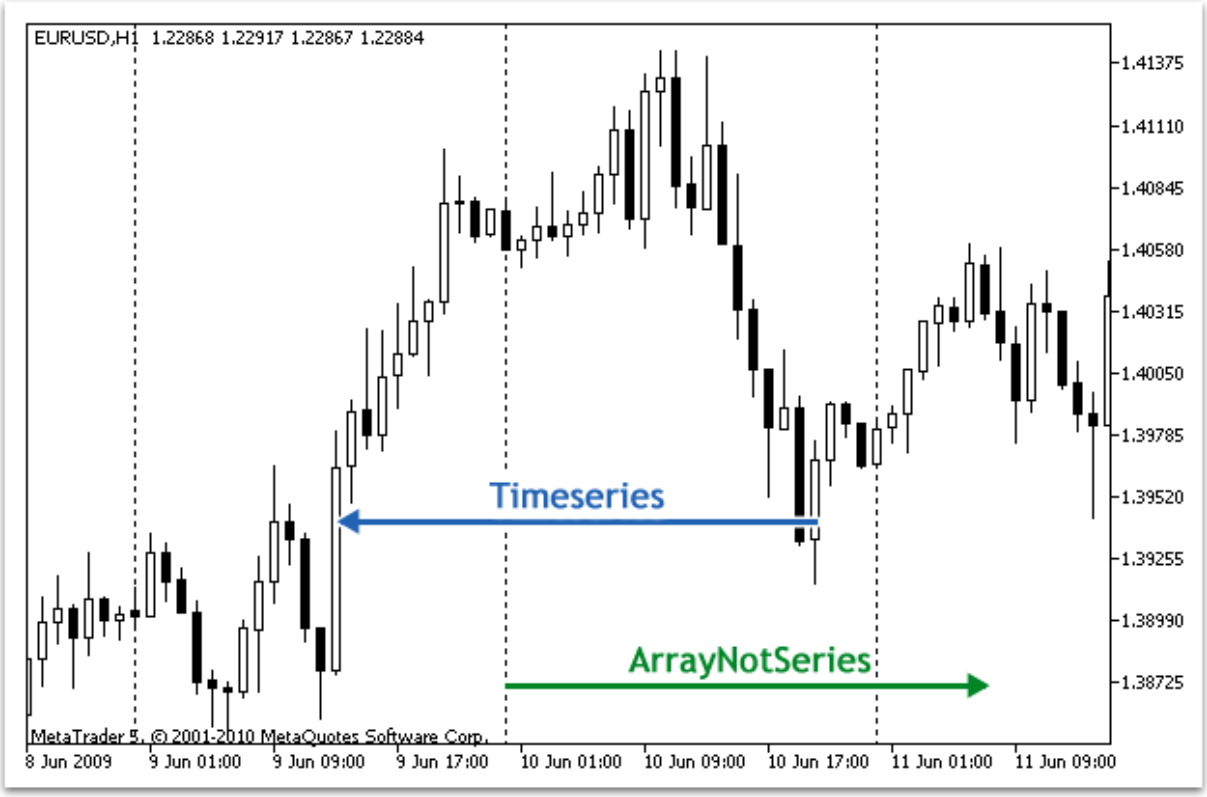
These are functions for working with timeseries and indicators. A timeseries differs from the usual data array by its reverse ordering - elements of timeseries are indexed from the end of an array to its begin (from the most recent data to the oldest ones). To copy the time-series values and indicator data, it's recommended to use dynamic arrays only, because copying functions are designed to allocate the necessary size of arrays that receive values.

There is an **important exception** to this rule: if timeseries and indicator values need to be copied often, for example at each call of OnTick() in Expert Advisors or at each call of OnCalculate() in indicators, in this case one should better use statically distributed arrays, because **operations of memory allocation** for dynamic arrays **require additional time**, and this will have effect during testing and optimization.

When using functions accessing timeseries and indicator values, indexing direction should be taken into account. This is described in the Indexing Direction in Arrays, Buffers and Timeseries section.

Access to indicator and timeseries data is implemented irrespective of the fact whether the requested data are ready (the so called asynchronous access). This is critically important for the calculation of custom indicator, so if there are no data, functions of *Copy...()* type immediately return an error. However, when accessing form Expert Advisors and scripts, several attempts to receive data are made in a small pause, which is aimed at providing some time necessary to download required timeseries or to calculate indicator values.

The Organizing Data Access section describes details of receiving, storing and requesting price data in the MetaTrader 5 client terminal.



It is historically accepted that an access to the price data in an array is performed from the end of the data. Physically, the new data are always written at the array end, but the index of the array is always

equal to zero. The 0 index in the timeseries array denotes data of the current bar, i.e. the bar that corresponds to the unfinished time interval in this timeframe.

A timeframe is the time period, during which a single price bar is formed. There are 21 predefined standard timeframes.

Function	Action
SeriesInfoInteger	Returns information about the state of historical data
Bars	Returns the number of bars count in the history for a specified symbol and period
BarsCalculated	Returns the number of calculated data in an indicator buffer or -1 in the case of error (data hasn't been calculated yet)
IndicatorCreate	Returns the handle to the specified technical indicator created by an array of MqlParam type parameters
IndicatorParameters	Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters
IndicatorRelease	Removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else
CopyBuffer	Gets data of a specified buffer from a specified indicator into an array
CopyRates	Gets history data of the Rates structure for a specified symbol and period into an array
CopySeries	Gets the synchronized timeseries from the Rates structure for the specified symbol-period and the specified amount
CopyTime	Gets history data on bar opening time for a specified symbol and period into an array
CopyOpen	Gets history data on bar opening price for a specified symbol and period into an array
CopyHigh	Gets history data on maximal bar price for a specified symbol and period into an array
CopyLow	Gets history data on minimal bar price for a specified symbol and period into an array
CopyClose	Gets history data on bar closing price for a specified symbol and period into an array
CopyTickVolume	Gets history data on tick volumes for a specified symbol and period into an array
CopyRealVolume	Gets history data on trade volumes for a specified symbol and period into an array
CopySpread	Gets history data on spreads for a specified symbol and period into an array

Function	Action
CopyTicks	Gets ticks in the MqlTick format into ticks_array
CopyTicksRange	Gets ticks in the MqlTick format within the specified date range to ticks_array
iBars	Returns the number of bars of a corresponding symbol and period, available in history
iBarShift	Returns the index of the bar corresponding to the specified time
iClose	Returns the Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iHigh	Returns the High price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iHighest	Returns the index of the highest value found on the corresponding chart (shift relative to the current bar)
iLow	Returns the Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iLowest	Returns the index of the smallest value found on the corresponding chart (shift relative to the current bar)
iOpen	Returns the Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iTime	Returns the opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart
iTickVolume	Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iRealVolume	Returns the real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iVolume	Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iSpread	Returns the spread value of the bar (indicated by the 'shift' parameter) on the corresponding chart

Despite the fact that by using the ArraySetAsSeries() function it is possible to set up in arrays access to elements like that in timeseries, it should be remembered that the array elements are physically stored in one and the same order - only indexing direction changes. To demonstrate this fact let's perform an example:

```
   datetime TimeAsSeries[];
//--- set access to the array like to a timeseries
   ArraySetAsSeries(TimeAsSeries,true);
   ResetLastError();
   int copied=CopyTime(NULL,0,0,10,TimeAsSeries);
   if(copied<=0)
```

```
      {
       Print("The copy operation of the open time values for last 10 bars has failed");
       return;
      }
   Print("TimeCurrent =",TimeCurrent());
   Print("ArraySize(Time) =",ArraySize(TimeAsSeries));
   int size=ArraySize(TimeAsSeries);
   for(int i=0;i<size;i++)
      {
       Print("TimeAsSeries["+i+"] =",TimeAsSeries[i]);
      }

   datetime ArrayNotSeries[];
   ArraySetAsSeries(ArrayNotSeries,false);
   ResetLastError();
   copied=CopyTime(NULL,0,0,10,ArrayNotSeries);
   if(copied<=0)
      {
       Print("The copy operation of the open time values for last 10 bars has failed");
       return;
      }
   size=ArraySize(ArrayNotSeries);
   for(int i=size-1;i>=0;i--)
      {
       Print("ArrayNotSeries["+i+"] =",ArrayNotSeries[i]);
      }
```

As a result we will get the output like this:

```
TimeCurrent = 2009.06.11 14:16:23
ArraySize(Time) = 10
TimeAsSeries[0] = 2009.06.11 14:00:00
TimeAsSeries[1] = 2009.06.11 13:00:00
TimeAsSeries[2] = 2009.06.11 12:00:00
TimeAsSeries[3] = 2009.06.11 11:00:00
TimeAsSeries[4] = 2009.06.11 10:00:00
TimeAsSeries[5] = 2009.06.11 09:00:00
TimeAsSeries[6] = 2009.06.11 08:00:00
TimeAsSeries[7] = 2009.06.11 07:00:00
TimeAsSeries[8] = 2009.06.11 06:00:00
TimeAsSeries[9] = 2009.06.11 05:00:00

ArrayNotSeries[9] = 2009.06.11 14:00:00
ArrayNotSeries[8] = 2009.06.11 13:00:00
ArrayNotSeries[7] = 2009.06.11 12:00:00
ArrayNotSeries[6] = 2009.06.11 11:00:00
ArrayNotSeries[5] = 2009.06.11 10:00:00
ArrayNotSeries[4] = 2009.06.11 09:00:00
ArrayNotSeries[3] = 2009.06.11 08:00:00
```

```
ArrayNotSeries[2] = 2009.06.11 07:00:00
ArrayNotSeries[1] = 2009.06.11 06:00:00
ArrayNotSeries[0] = 2009.06.11 05:00:00
```

As we see from the output, as the index of TimeAsSeries array increases, the time value of the index decreases, i.e. we move from the present to the past. For the common array ArrayNotSeries the result is different - as index grows, we move from past to present.

Indexing Direction in Arrays, Buffers and Timeseries

The default indexing of all arrays and indicator buffers is left to right. The index of the first element is always equal to zero. Thus, the very first element of an array or indicator buffer with index 0 is by default on the extreme left position, while the last element is on the extreme right position.

An indicator buffer is a dynamic array of type double, whose size is managed by the client terminals, so that it always corresponds to the number of bars the indicator is calculated on. A usual dynamic array of type double is assigned as an indicator buffer using the SetIndexBuffer() function. Indicator buffers do not require setting of their size using function ArrayResize() - this will be done by the executing system of the terminal.

Timeseries are arrays with reverse indexing, i.e. the first element of a timeseries is in the extreme right position, and the last element is in the extreme left position. Timeseries being used for storing history price data and contain the time information, we can say that the newest data are placed in the extreme right position of the timeseries, while the oldest data are in the extreme left position.

So the timeseries element with index 0 contains the information about the latest quote of a symbol. If a timeseries contains data on a daily timeframe, data of the current yet uncompleted day are located on the zero position, and the position with index 1 contains yesterday data.

Changing the Indexing Direction

Function ArraySetAsSeries() allows changing the method of accessing elements of a dynamic array; the physical order of data storing in the computer memory is not changed at that. This function simply changes the method of addressing array elements, so when copying one array to another using function ArrayCopy(), the contents of the recipient array will not depend on the indexing direction in the source array.

Direction of indexing cannot be changed for statically distributed arrays. Even if an array was passed as a parameter to a function, attempts to change the indexing direction inside this function will bring no effect.

For indicator buffers, like for usual arrays, indexing direction can also be set as backward (like in timeseries), i.e. reference to the zero position in the indicator buffer will mean reference to the last value on the corresponding indicator buffer and this will correspond to the value of the indicator on the latest bar. Still, the physical location of indicator bars will be unchanged.

Receiving Price Data in Indicators

Each custom indicator must necessarily contain the OnCalculate() function, to which price data required for calculating values in indicator buffers are passed. Indexing direction in these passed arrays can be found out using function ArrayGetAsSeries().

Arrays passed to the function reflect price data, i.e. these arrays have the sign of a timeseries and function ArrayIsSeries() will return true when checking these arrays. However, in any case indexing direction should be checked only by function ArrayGetAsSeries().

In order not to be dependent on default values, ArraySetAsSeries() should be unconditionally called for the arrays you are going to work with, and set the required direction.

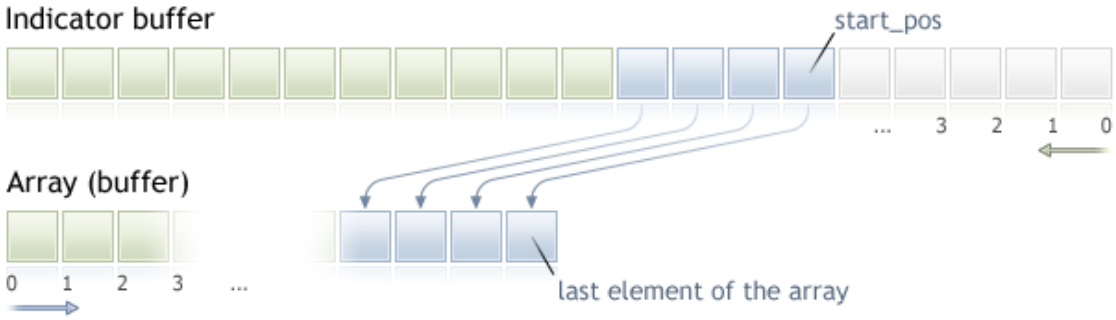
Receiving Price Data and Indicator Values

Default indexing direction of all arrays in Expert Advisors, indicators and scripts is left-to-right. If necessary, in any mql5 program you can request timeseries values on any symbol and timeframe, as well as values of indicators calculated on any symbol and timeframe.

Use functions Copy...() for these purposes:

- CopyBuffer - copy values of an indicator buffer to an array of double type;
- CopyRates - copy price history to an array of structures MqlRates;
- CopyTime - copy Time values to an array of datetime type;
- CopyOpen - copy Open values to an array of double type;
- CopyHigh - copy High values to an array of double type;
- CopyLow - copy Low values to an array of double type;
- CopyClose - copy Close values to an array of double type;
- CopyTickVolume - copy tick volumes to an array of long type;
- CopyRealVolume - copy equity volumes to a long type array;
- CopySpread - copy the spread history to an array of int type;

All these functions work in a similar way. Let's consider the data obtaining mechanism on the example of CopyBuffer(). It is implied that the indexing direction of requested data is that of timeseries, and the position with index 0 (zero) stores data of the current yet uncompleted bar. In order to get access to these data we need to copy the necessary volume of data into the recipient array, e.g. into array *buffer*.



When copying we need to specify the starting position in the source array, starting from which data will be copied to the recipient array. In case of success, the specified number of elements will be copied to the recipient array from the source array (from the indicator buffer in this case). Irrespective of the indexing value set in the recipient array, copying is always performed as is shown in the above figure.

If it is expected that price data will be handled in a loop with a large number of iterations, it is advisable that you check the fact of forced program termination using the IsStopped() function:

```
int copied=CopyBuffer(ma_handle,// Indicator handle
                      0,        // The index of the indicator buffer
                      0,        // Start position for copying
                      number,   // Number of values to copy
                      Buffer    // The array that receives the values
```

```
                        );
if(copied<0) return;
int k=0;
while(k<copied && !IsStopped())
  {
   //--- Get the value for the k index
   double value=Buffer[k];
   // ...
   // work with value
   k++;
  }
```

Example:

```
input int per=10; // period of the exponent
int ma_handle;    // indicator handle
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//---
   ma_handle=iMA(_Symbol,0,per,0,MODE_EMA,PRICE_CLOSE);
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//---
   double ema[10];
   int copied=CopyBuffer(ma_handle,// indicator handle
                         0,        // index of the indicator buffer
                         0,        // starting position to copy from
                         10,       // number of values for copying
                         ema       // value receiving array
                         );
   if(copied<0) return;
// .... further code
  }
```

Organizing Data Access

Organizing Data Access

In this section questions connected with obtaining, storing and requesting price data (timeseries) are considered.

Receiving Data from a Trade Server

Before price data become available in the MetaTrader 5 terminal, they must be received and processed. To receive data, connection to the MetaTrader 5 trade server must be established. Data are received in the form of packed blocks of minute bars from the server upon the request of a terminal.

The mechanism of server reference for data doesn't depend on how the request has been initiated - by a user when navigating in a chart or in a program way in the MQL5 language.

Storing Intermediate Data

Data received from a server are automatically unpacked and saved in the HCC intermediate format. Data on each symbol are written into a separate folder: *terminal_directory*\bases*server_name*\history*symbol_name*. For example, data on EURUSD received from the MetaQuotes-Demo server will be stored in *terminal_directory*\bases\MetaQuotes-Demo\history\EURUSD\.

Data are written into files with .hcc extension. Each file stores data of minute bars for one year. For example, the file named 2009.hcc in the EURUSD folder contains minute bars of EURUSD for year 2009. These files are used for preparing price data for all timeframes and are not intended for direct access.

Obtaining Data on a Necessary Timeframe out of Intermediate Data

Intermediate HCC files are used as the data source for building price data for requested timeframes in the HC format. Data of HC format are timeseries that are maximally prepared for a quick access. They are created upon a request of a chart or a MQL5 program. The volume of data should not exceed the value of the "Max bars in charts" parameter. Data are stored for further using in files with hc extension.

To save resources, data on a timeframe are stored and saved in RAM only if necessary. If not called for a long time, they are released from RAM and saved into a file. For each timeframe, data are prepared regardless of whether there are ready data for other timeframes or not. Rules of forming and accessing data are the same for all timeframes. I.e., despite the fact that the unit data stored in HCC is one minute (M1), the availability of HCC data doesn't mean the availability of data on M1 timeframe as HC in the same volume.

Receipt of new data from a server calls automatic update of used price data in HC format of all timeframes. It also leads to the recalculation of all indicators that implicitly use them as input data for calculations.

Parameter "Max bars in chart"

The "Max bars in charts" parameter restricts number of bars in HC format available to charts, indicators and mql5 programs. This is valid for all available timeframes and serves, first of all, to save computer resources.

When setting a large value of this parameter, it should be remembered, that if deep history price data for small timeframes are available, memory used for storing timeseries and indicator buffers can become hundreds of megabytes and reach the RAM restriction for the client terminal program (2Gb for 32-bit applications of MS Windows).

Change of the "Max bars in charts" comes into effect after the client terminal is restarted. Change of this parameter causes neither automatic referring to a server for additional data, nor forming of additional bars of timeseries. Additional price data are requested from the server, and timeseries are updated taking into account the new limitation, in case of either chart scroll to the area with no data, or when data are requested by a mql5 program.

Volume of data requested from the server corresponds to the required number of bars of this timeframe with the "Max bars in charts" parameter taken into account. The restriction set by this parameter is not strict, and in some cases the number of available bars for a timeframe can be a little more than the current parameter value.

Data Availability

Presence of data on HCC format or even in the prepared for using HC format does not always denote the absolute availability of these data to be shown in a chart or to be used in MQL5 programs.

When accessing to price data or indicator values from a mql5 program it should be remembered that their availability in a certain moment of time or starting from a certain moment of time is not guaranteed. It is connected with the fact that with the purpose of saving resources, the full copy of data necessary for a mql5 program isn't stored in MetaTrader 5; only direct access to the terminal database is given.

The price history for all timeframes is built from common data of HCC format, and any update of data from a server leads to the update of data for all timeframes and to the recalculation of indicators. Due to this access to data can be closed, even if these data were available a moment ago.

Synchronization of the Terminal Data and Server Data

Since a mql5 program can call data from any symbol and timeframe, there is a possibility that data of a necessary timeseries are not formed yet in the terminal or the necessary price data aren't synchronized with the trade server. In this case it's hard to predict the latency time.

Algorithms using "do-nothing" loops are not the best solution. The only exception in this case are scripts, because they do not have any alternative algorithm choice due to not having event handling. For custom indicators such algorithms, as well as any other "do-nothing" loops are strongly not recommended, because they lead to termination of calculation of all indicators and any other handling of price data of the symbol.

For Expert Advisors and indicators, it is better to use the event model of handling. If during handling of OnTick() or OnCalculate() event, data receipt for the required timeseries failed, you should exit the event handler, relying on the access availability during the next call of the handler.

Example of a Script for Adding History

Let's consider the example of a script that executes a request to receive history for the selected symbol from a trade server. The script is intended for running in a chart of a selected symbol;

timeframe doesn't matter, because, as it was mentioned above, price data are received from a trade server as packed one minute data, from which any predefined timeseries is constructed then.

Write all actions concerning data receipt as a separate function CheckLoadHistory(symbol, timeframe, start_date):

```
int CheckLoadHistory(string symbol,ENUM_TIMEFRAMES period,datetime start_date)
  {
  }
```

The CheckLoadHistory() function is designed as a universal function that can be called from any program (Expert Advisor, script or indicator); and therefore it requires three input parameters: symbol name, period and start date to indicate the beginning of price history you need.

Insert necessary checks into the function code before requesting the missing history. First of all, we should make sure that the symbol name and period value are correct:

```
   if(symbol==NULL || symbol=="") symbol=Symbol();
   if(period==PERIOD_CURRENT)     period=Period();
```

Then let's make sure that the symbol is available in the MarketWatch window, i.e., the history for the symbol will be available when sending a request to a trade server. If there is no such a symbol in MarketWatch, add it using the SymbolSelect() function.

```
   if(!SymbolInfoInteger(symbol,SYMBOL_SELECT))
     {f
      if(GetLastError()==ERR_MARKET_UNKNOWN_SYMBOL) return(-1);
      SymbolSelect(symbol,true);
     }
```

Now we should receive the start date of the available history for the indicated symbol/period pair. Perhaps, the value of the input parameter startdate, passed to CheckLoadHistory(), is within the available history; then request to a trade server is not needed. In order to obtain the very first date for the symbol-period as of the moment, the SeriesInfoInteger() function with the SERIES_FIRSTDATE modifier is used.

```
   SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date);
   if(first_date>0 && first_date<=start_date) return(1);
```

The next important check is checking the type of the program, from which the function is called. Note that it is not desirable to send a request to update the timeseries from indicator with the same period. The undesirability of requesting data on the same symbol-period as that of the indicator is conditioned by the fact that update of history data is performed in the same thread where the indicator operates. So the possibility of deadlock occurrence is high. To check this use the MQL5InfoInteger() function with the MQL5_PROGRAM_TYPE modifier.

```
   if(MQL5InfoInteger(MQL5_PROGRAM_TYPE)==PROGRAM_INDICATOR && Period()==period && Sy
      return(-4);
```

If all the checks have been passed successfully, make the last attempt to do without referring to the trade server. First let's find out the start date, for which minute data in HCC format are available. Request this value using the SeriesInfoInteger() function with the SERIES_TERMINAL_FIRSTDATE modifier and again compare it to the value of the start_date parameter.

```
   if(SeriesInfoInteger(symbol,PERIOD_M1,SERIES_TERMINAL_FIRSTDATE,first_date))
     {
      //--- there is loaded data to build timeseries
      if(first_date>0)
        {
         //--- force timeseries build
         CopyTime(symbol,period,first_date+PeriodSeconds(period),1,times);
         //--- check date
         if(SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date))
            if(first_date>0 && first_date<=start_date) return(2);
        }
     }
```

If after all the checks the execution thread is still in the body of the CheckLoadHistory() function, it means there is a necessity to request the missing price data from a trade server. First, return the value of "Max bars in chart" using the TerminalInfoInteger() function:

```
   int max_bars=TerminalInfoInteger(TERMINAL_MAXBARS);
```

We'll need it to prevent requesting extra data. Then find the very first date in the symbol history on the trade server (regardless of the period) using already known function SeriesInfoInteger() with the SERIES_SERVER_FIRSTDATE modifier.

```
   datetime first_server_date=0;
   while(!SeriesInfoInteger(symbol,PERIOD_M1,SERIES_SERVER_FIRSTDATE,first_server_date
      Sleep(5);
```

Since the request is an asynchronous operation, the function is called in the loop with a small delay of 5 milliseconds until the first_server_date variable receives a value, or the loop execution is terminated by a user (IsStopped() will return *true* in this case). Let's indicate a correct value of the start date, starting from which we request price data from a trade server.

```
   if(first_server_date>start_date) start_date=first_server_date;
   if(first_date>0 && first_date<first_server_date)
      Print("Warning: first server date ",first_server_date," for ",
symbol," does not match to first series date ",first_date);
```

If the start date *first_server_date* of the server is lower than the start date *first_date* of the symbol in HCC format, the corresponding entry will be output in the journal.

Now we are ready to make a request to a trade server asking for missing price data. Make the request in the form of a loop and start filling out its body:

```
   while(!IsStopped())
     {
      //1. wait for synchronization between the re-built timeseries and intermediate h
      //2. receive the current number of bars in this timeseries
      //    if bars is larger than Max_bars_in_chart, we can exit, work is over
      //3. obtain the start date first_date in the re-built timeseries and compare it
      //    if first_date is lower than start_date, we can exit, work is over
      //4. request from a server a new part of history - 100 bars starting from last a
     }
```

The first three points are implemented by already known means.

```
   while(!IsStopped())
     {
      //--- 1.wait till timeseries re-build process is over
      while(!SeriesInfoInteger(symbol,period,SERIES_SYNCHRONIZED) && !IsStopped())
         Sleep(5);
      //--- 2.request how many bars we have
      int bars=Bars(symbol,period);
      if(bars>0)
        {
         //--- bars more than ones that can be drawn in the chart, exit
         if(bars>=max_bars) return(-2);
         //--- 3. return the current start date in the timeseries
         if(SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date))
            // start date was earlier than that requested, task completed
            if(first_date>0 && first_date<=start_date) return(0);
        }
      //4. Request from a server a new part of history - 100 bars starting from last a
     }
```

The last fourth point is left - requesting history. We can't refer to a server directly, but any Copy-function automatically initiates request sending to a server, if the history in HCC format is not enough. Since the time of the very first start date in the *first_date* variable is the simple and natural criterion to evaluate the request execution degree, then the easiest way is to use the CopyTime() function.

When calling functions that copy any data from timeseries, it should be noted that the *start* parameter (number of the bar, starting from which price data should be copied) must always be within the available terminal history. If you have only 100 bars, it meaningless to try copying 300 bars starting from the bar with the index 500. Such a request will be understood as an erroneous and won't be handled, i.e. no additional history will be loaded from a trade server.

That's why we'll copy bars in groups of 100 starting from the bar with the *bars* index. This will provide the smooth loading of missing history from a trade server. Actually a little more than the requested 100 bars will be loaded, while server sends oversized history.

```
   int copied=CopyTime(symbol,period,bars,100,times);
```

After the copying operation, we should analyze the number of copied elements. If the attempt fails, then value of the *copied* will be equal to null and the value of the fail_cnt counter will be increased by 1. After 100 failing attempts, the operation of the function will be stopped.

```
int fail_cnt=0;
...
   int copied=CopyTime(symbol,period,bars,100,times);
   if(copied>0)
     {
      //--- check data
      if(times[0]<=start_date)  return(0);  // the copied value is smaller, ready
      if(bars+copied>=max_bars) return(-2); // bars are more than can be drawn in the
```

```
      fail_cnt=0;
     }
   else
     {
      //--- no more than 100 failing attempts in succession
      fail_cnt++;
      if(fail_cnt>=100) return(-5);
      Sleep(10);
     }
```

So, not only correct handling of the current situation at each moment of execution is implemented in the function, but also the termination code is returned, that can be handled after calling the CheckLoadHistory() function for getting additional information. For example, this way:

```
   int res=CheckLoadHistory(InpLoadedSymbol,InpLoadedPeriod,InpStartDate);
   switch(res)
     {
      case -1 : Print("Unknown symbol ",InpLoadedSymbol);                      break;
      case -2 : Print("More requested bars than can be drawn in the chart"); break;
      case -3 : Print("Execution stopped by user");                          break;
      case -4 : Print("Indicator mustn't load its own data");               break;
      case -5 : Print("Loading failed");                                    break;
      case  0 : Print("All data loaded");                                   break;
      case  1 : Print("Already available data in timeseries are enough");   break;
      case  2 : Print("Timeseries is built from available terminal data");  break;
      default : Print("Execution result undefined");
     }
```

The full code of the function can be found in the example of a script that shows the correct organization of access to any data with the handling of request's results.

Code:

```

     }
//---
   return("unknown period");
  }
```

SeriesInfoInteger

Returns information about the state of historical data. There are 2 variants of function calls.

Directly returns the property value.

```
long  SeriesInfoInteger(
   string                      symbol_name,      // symbol name
   ENUM_TIMEFRAMES             timeframe,        // period
   ENUM_SERIES_INFO_INTEGER    prop_id,          // property identifier
   );
```

Returns true or false depending on the success of the function run.

```
bool  SeriesInfoInteger(
   string                      symbol_name,      // symbol name
   ENUM_TIMEFRAMES             timeframe,        // period
   ENUM_SERIES_INFO_INTEGER    prop_id,          // property ID
   long&                       long_var          // variable for getting info
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

prop_id

[in] Identifier of the requested property, value of the ENUM_SERIES_INFO_INTEGER enumeration.

long_var

[out] Variable to which the value of the requested property is placed.

Return Value

In the first case, it returns value of the long type.

For the second case, it returns true, if the specified property is available and its value has been placed into long_var variable, otherwise it returns false. For more details about an error, call GetLastError().

Example:

```
void OnStart()
  {
//---
   Print("Total number of bars for the symbol-period at this moment = ",
         SeriesInfoInteger(Symbol(),Period(),SERIES_BARS_COUNT));

   Print("The first date for the symbol-period at this moment = ",
         (datetime)SeriesInfoInteger(Symbol(),Period(),SERIES_FIRSTDATE));
```

```
   Print("The first date in the history for the symbol-period on the server = ",
         (datetime)SeriesInfoInteger(Symbol(),Period(),SERIES_SERVER_FIRSTDATE));

   Print("Symbol data are synchronized = ",
         (bool)SeriesInfoInteger(Symbol(),Period(),SERIES_SYNCHRONIZED));
  }
```

Bars

Returns the number of bars count in the history for a specified symbol and period. There are 2 variants of functions calls.

Request all of the history bars

```
int  Bars(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe         // period
   );
```

Request the history bars for the selected time interval

```
int  Bars(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time         // end date and time
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_time

[in] Bar time corresponding to the first element.

stop_time

[in] Bar time corresponding to the last element.

Return Value

If the start_time and stop_time parameters are defined, the function returns the number of bars in the specified time interval, otherwise it returns the total number of bars.

Note

If data for the timeseries with specified parameters are not formed in the terminal by the time of the Bars() function call, or data of the timeseries are not synchronized with a trade server by the moment of the function call, the function returns a zero value.

When requesting the number of bars in a specified time interval, only bars with an open time falling within the interval are considered. For example, if the current day of the week is Saturday and the request is made for the number of W1 bars with start_time=last_tuesday and stop_time=last_friday, the function will return 0 since the open time of a W1 timeframe is always Sunday and not a single W1 bar falls within the specified interval.

Sample request for the number of all history bars:

```
int bars=Bars(_Symbol,_Period);
if(bars>0)
  {
   Print("Number of bars in the terminal history for the symbol-period at the momer
  }
else  //no available bars
  {
   //--- data on the symbol might be not synchronized with data on the server
   bool synchronized=false;
   //--- loop counter
   int attempts=0;
   // make 5 attempts to wait for synchronization
   while(attempts<5)
     {
      if(SeriesInfoInteger(Symbol(),0,SERIES_SYNCHRONIZED))
        {
         //--- synchronization done, exit
         synchronized=true;
         break;
        }
      //--- increase the counter
      attempts++;
      //--- wait 10 milliseconds till the next iteration
      Sleep(10);
     }
   //--- exit the loop after synchronization
   if(synchronized)
     {
      Print("Number of bars in the terminal history for the symbol-period at the mo
      Print("The first date in the terminal history for the symbol-period at the mo
            (datetime)SeriesInfoInteger(Symbol(),0,SERIES_FIRSTDATE));
      Print("The first date in the history for the symbol on the server = ",
            (datetime)SeriesInfoInteger(Symbol(),0,SERIES_SERVER_FIRSTDATE));
     }
   //--- synchronization of data didn't happen
   else
     {
      Print("Failed to get number of bars for ",_Symbol);
     }
  }
```

Sample request for the number of bars in the specified interval:

```
int n;
datetime date1 = D'2016.09.02 23:55'; // Friday
datetime date2 = D'2016.09.05 00:00'; // Monday
datetime date3 = D'2016.09.08 00:00'; // Thursday
//---
n=Bars(_Symbol,PERIOD_H1,D'2016.09.02 02:05',D'2016.09.02 10:55');
```

```
   Print("Number of bars: ",n); // Output: "Number of bars: 8", H2 bar is considered
   n=Bars(_Symbol,PERIOD_D1,date1,date2);
   Print("Number of bars: ",n); // Output: "Number of bars: 1", since an open time of
   n=Bars(_Symbol,PERIOD_W1,date2,date3);
   Print("Number of bars: ",n); // Output: "Number of bars: 0", since not a single W1
```

Event Handling Functions

BarsCalculated

Returns the number of calculated data for the specified indicator.

```
int  BarsCalculated(
   int       indicator_handle,     // indicator handle
   );
```

Parameters

indicator_handle

[in] The indicator handle, returned by the corresponding indicator function.

Return Value

Returns the amount of calculated data in the indicator buffer or -1 in the case of error (data not calculated yet)

Note

The function is useful when it's necessary to get the indicator data immediately after its creation (indicator handle is available).

Example:

```
void OnStart()
  {
   double Ups[];
//--- set timeseries ordering for the arrays
   ArraySetAsSeries(Ups,true);
//--- create handle for the Fractal Indicator
   int FractalsHandle=iFractals(NULL,0);
//--- reset the error code
   ResetLastError();
//--- try to copy the indicator values
   int i,copied=CopyBuffer(FractalsHandle,0,0,1000,Ups);
   if(copied<=0)
     {
      Sleep(50);
      for(i=0;i<100;i++)
        {
         if(BarsCalculated(FractalsHandle)>0)
            break;
         Sleep(50);
        }
      copied=CopyBuffer(FractalsHandle,0,0,1000,Ups);
      if(copied<=0)
        {
         Print("Failed to copy upper fractals. Error = ",GetLastError(),
         "i = ",i,"    copied = ",copied);
         return;
        }
```

```
      else
        Print("Upper fractals copied",
        "i = ",i,"    copied = ",copied);
    }
  else Print("Upper fractals copied. ArraySize = ",ArraySize(Ups));
}
```

IndicatorCreate

The function returns the handle of a specified technical indicator created based on the array of parameters of MqlParam type.

```
int  IndicatorCreate(
   string           symbol,                          // symbol name
   ENUM_TIMEFRAMES  period,                          // timeframe
   ENUM_INDICATOR   indicator_type,                  // indicator type from the enur
   int              parameters_cnt=0,                // number of parameters
   const MqlParam&  parameters_array[]=NULL,         // array of parameters
   );
```

Parameters

symbol

[in] Name of a symbol, on data of which the indicator is calculated. NULL means the current symbol.

period

[in] The value of the timeframe can be one of values of the ENUM_TIMEFRAMES enumeration, 0 means the current timeframe.

indicator_type

[in] Indicator type, can be one of values of the ENUM_INDICATOR enumeration.

parameters_cnt

[in] The number of parameters passed in the parameters_array[] array. The array elements have a special structure type MqlParam. By default, zero - parameters are not passed. If you specify a non-zero number of parameters, the parameter *parameters_array* is obligatory. You can pass no more than 64 parameters.

parameters_array[]=NULL

[in] An array of MqlParam type, whose elements contain the type and value of each input parameter of a technical indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE.

Note

If the indicator handle of IND_CUSTOM type is created, the *type* field of the first element of the array of input parameters *parameters_array* must have the TYPE_STRING value of the ENUM_DATATYPE enumeration, and the *string_value* field of the first element must contain the name of the custom indicator. The custom indicator must be compiled (file with EX5 extension) and located in the directory MQL5/Indicators of the client terminal or in a subdirectory.

Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter that sets the indicator name) the property #property tester_indicator is required:

```
#property tester_indicator "indicator_name.ex5"
```

If the first form of the call is used in a custom indicator, you can additionally indicate as the last parameter on what data it will be calculated when passing input parameters. If the "Apply to" parameter is not specified explicitly, the default calculation is based on the PRICE_CLOSE values.

Example:

```
void OnStart()
  {
   MqlParam params[];
   int      h_MA,h_MACD;
//--- create iMA("EURUSD",PERIOD_M15,8,0,MODE_EMA,PRICE_CLOSE);
   ArrayResize(params,4);
//--- set ma_period
   params[0].type         =TYPE_INT;
   params[0].integer_value=8;
//--- set ma_shift
   params[1].type         =TYPE_INT;
   params[1].integer_value=0;
//--- set ma_method
   params[2].type         =TYPE_INT;
   params[2].integer_value=MODE_EMA;
//--- set applied_price
   params[3].type         =TYPE_INT;
   params[3].integer_value=PRICE_CLOSE;
//--- create MA
   h_MA=IndicatorCreate("EURUSD",PERIOD_M15,IND_MA,4,params);
//--- create iMACD("EURUSD",PERIOD_M15,12,26,9,h_MA);
   ArrayResize(params,4);
//--- set fast ma_period
   params[0].type         =TYPE_INT;
   params[0].integer_value=12;
//--- set slow ma_period
   params[1].type         =TYPE_INT;
   params[1].integer_value=26;
//--- set smooth period for difference
   params[2].type         =TYPE_INT;
   params[2].integer_value=9;
//--- set indicator handle as applied_price
   params[3].type         =TYPE_INT;
   params[3].integer_value=h_MA;
//--- create MACD based on moving average
   h_MACD=IndicatorCreate("EURUSD",PERIOD_M15,IND_MACD,4,params);
//--- use indicators
//--- . . .
//--- release indicators (first h_MACD)
   IndicatorRelease(h_MACD);
   IndicatorRelease(h_MA);
  }
```

IndicatorParameters

Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters.

```
int  IndicatorParameters(
   int               indicator_handle,     // indicator handle
   ENUM_INDICATOR&   indicator_type,       // a variable for receiving the indicator t
   MqlParam&         parameters[]          // an array for receiving parameters
   );
```

Parameters

indicator_handle

[in] The handle of the indicator, for which you need to know the number of parameters its is calculated on.

indicator_type

[out] A variable if the ENUM_INDICATOR type, into which the indicator type will be written.

parameters[]

[out] A dynamic array for receiving values of the MqlParam type, into which the list of indicator parameters will be written. The array size is returned by the IndicatorParameters() function.

Return Value

The number of input parameters of the indicator with the specified handle. In case of an error returns -1. For more details about the error call the GetLastError() function.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {

//--- The number of windows on the chart (at least one main window is always present)
   int windows=(int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);
//--- Go through the chart windows
   for(int w=0;w<windows;w++)
     {
      //--- The number of indicators in this window/subwindow
      int total=ChartIndicatorsTotal(0,w);
      //--- Take all indicators in the window
      for(int i=0;i<total;i++)
        {
         //--- Get the short name of the indicator
         string name=ChartIndicatorName(0,w,i);
         //--- Get the indicator handle
         int handle=ChartIndicatorGet(0,w,name);
         //--- Add to log
```

```
         PrintFormat("Window=%d,  indicator #%d,  handle=%d",w,i,handle);
         //---
         MqlParam parameters[];
         ENUM_INDICATOR indicator_type;
         int params=IndicatorParameters(handle,indicator_type,parameters);
         //--- The header of the message
         string par_info="Short name "+name+", type "
                         +EnumToString(ENUM_INDICATOR(indicator_type))+"\r\n";
         //---
         for(int p=0;p<params;p++)
           {
            par_info+=StringFormat("parameter %d: type=%s, long_value=%d, double_value
                                   p,
                                   EnumToString((ENUM_DATATYPE)parameters[p].type),
                                   parameters[p].integer_value,
                                   parameters[p].double_value,
                                   parameters[p].string_value
                                   );
           }
         Print(par_info);
        }
      //--- Done for all indicators in the window
     }
//---
  }
```

See also

ChartIndicatorGet()

IndicatorRelease

The function removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else.

```
bool  IndicatorRelease(
   int       indicator_handle     // indicator handle
   );
```

Return Value

Returns true in case of success, otherwise returns false.

Note

The function allows removing an indicator handle, if it's no longer needed, thus saving memory. The handle is removed immediately, the calculation block is deleted in some time (if it's not called anymore).

When working in the strategy tester, the IndicatorRelease() function is not executed.

Example:

```

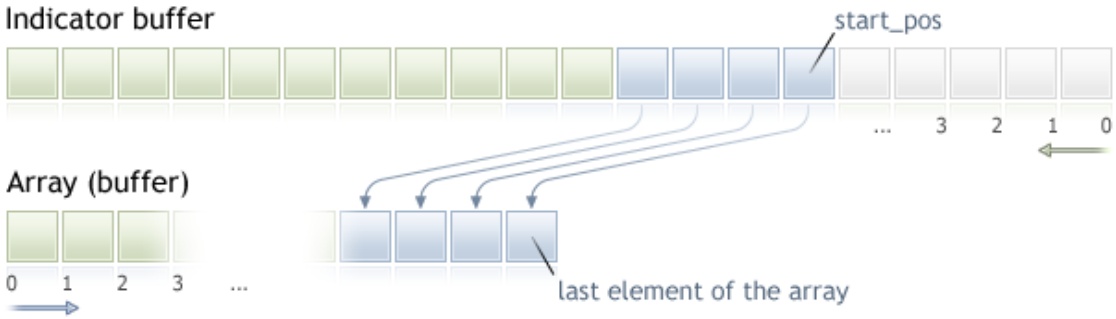
  {
//--- create indicator handle
   MA_handle=iMA(Symbol(),0,MA_Period,MA_shift,MA_smooth,PRICE_CLOSE);
//--- delete global variable
   if(GlobalVariableCheck("MA_value"))
      GlobalVariableDel("MA_value");
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
```

```
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//--- if the global variable value does not exist
   if(!GlobalVariableCheck("MA_value"))
     {
      //--- obtain the indicator value in the last two bars
      if(MA_handle!=INVALID_HANDLE)
        {
         //--- dynamic array for the indicator values
         double values[];
         if(CopyBuffer(MA_handle,0,0,2,values)==2 && values[0]!=EMPTY_VALUE)
           {
            //--- remember in the global variable value on the last but one bar
            if(GlobalVariableSet("MA_value",values[0]))
              {
               //--- free the handle of the indicator
               if(!IndicatorRelease(MA_handle))
                  Print("IndicatorRelease() failed. Error ",GetLastError());
               else MA_handle=INVALID_HANDLE;
              }
            else
               Print("GlobalVariableSet failed. Error ",GetLastError());
           }
        }
     }
//---
  }
```

CopyBuffer

Gets data of a specified buffer of a certain indicator in the necessary quantity.



Counting of elements of copied data (indicator buffer with the index buffer_num) from the starting position is performed from the present to the past, i.e., starting position of 0 means the current bar (indicator value for the current bar).

When copying the yet unknown amount of data, it is recommended to use a dynamic array as a buffer[] recipient buffer, because the CopyBuffer() function tries to allocate the size of the receiving array to the size of the copied data. If an indicator buffer (array that is pre-allocated for storing indicator values by the SetIndexBufer() function) is used as the buffer[] recipient array, partial copying is allowed. An example can be found in the Awesome_Oscillator.mql5 custom indicator in the standard terminal package.

If you need to make a partial copy of the indicator values into another array (non-indicator buffer), you should use an intermediate array, to which the desired number is copied. After that conduct the element-wise copying of the required number of values into the required places of a receiving array from this intermediate one.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyBuffer(
   int       indicator_handle,     // indicator handle
   int       buffer_num,           // indicator buffer number
   int       start_pos,            // start position
   int       count,                // amount to copy
   double    buffer[]              // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyBuffer(
   int       indicator_handle,     // indicator handle
```

```
   int       buffer_num,           // indicator buffer number
   datetime  start_time,           // start date and time
   int       count,                // amount to copy
   double    buffer[]              // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyBuffer(
   int       indicator_handle,     // indicator handle
   int       buffer_num,           // indicator buffer number
   datetime  start_time,           // start date and time
   datetime  stop_time,            // end date and time
   double    buffer[]              // target array to copy
   );
```

Parameters

indicator_handle

[in] The indicator handle, returned by the corresponding indicator function.

buffer_num

[in] The indicator buffer number.

start_pos

[in] The position of the first element to copy.

count

[in] Data count to copy.

start_time

[in] Bar time, corresponding to the first element.

stop_time

[in] Bar time, corresponding to the last element.

buffer[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration.

Example:

```

//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//--- check if all data calculated
   if(BarsCalculated(ma_handle)<rates_total) return(0);
//--- we can copy not all data
   int to_copy;
   if(prev_calculated>rates_total || prev_calculated<=0) to_copy=rates_total;
   else
     {
      to_copy=rates_total-prev_calculated;
      //--- last value is always copied
      to_copy++;
     }
//--- try to copy
   if(CopyBuffer(ma_handle,0,0,to_copy,MABuffer)<=0) return(0);
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

The above example illustrates how an indicator buffer is filled out with the values of another indicator buffer from the indicator on the same symbol/period.

See a detailed example of history requesting data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

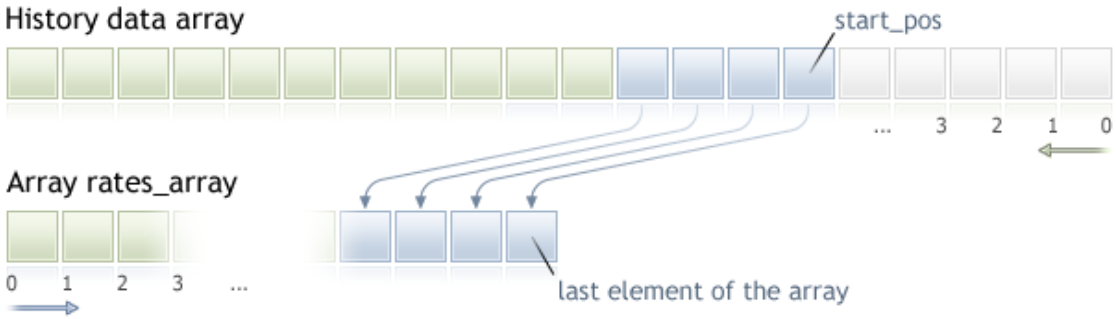
Properties of Custom Indicators, SetIndexBuffer

CopyRates

Gets history data of MqlRates structure of a specified symbol-period in specified quantity into the rates_array array. The elements ordering of the copied data is from present to the past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyRates(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   int               start_pos,         // start position
   int               count,             // data count to copy
   MqlRates          rates_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyRates(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   datetime          start_time,        // start date and time
   int               count,             // data count to copy
   MqlRates          rates_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyRates(
```

```
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   datetime         start_time,        // start date and time
   datetime         stop_time,         // end date and time
   MqlRates         rates_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_time

[in] Bar time for the first element to copy.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

rates_array[]

[out] Array of MqlRates type.

Return Value

Returns the number of copied elements or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
void OnStart()
  {
//---
   MqlRates rates[];
   ArraySetAsSeries(rates,true);
   int copied=CopyRates(Symbol(),0,0,100,rates);
   if(copied>0)
     {
      Print("Bars copied: "+copied);
      string format="open = %G, high = %G, low = %G, close = %G, volume = %d";
      string out;
      int size=fmin(copied,10);
      for(int i=0;i<size;i++)
        {
         out=i+":"+TimeToString(rates[i].time);
         out=out+" "+StringFormat(format,
                                  rates[i].open,
                                  rates[i].high,
                                  rates[i].low,
                                  rates[i].close,
                                  rates[i].tick_volume);
         Print(out);
        }
     }
   else Print("Failed to get history data for the symbol ",Symbol());
  }
```

See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,

- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

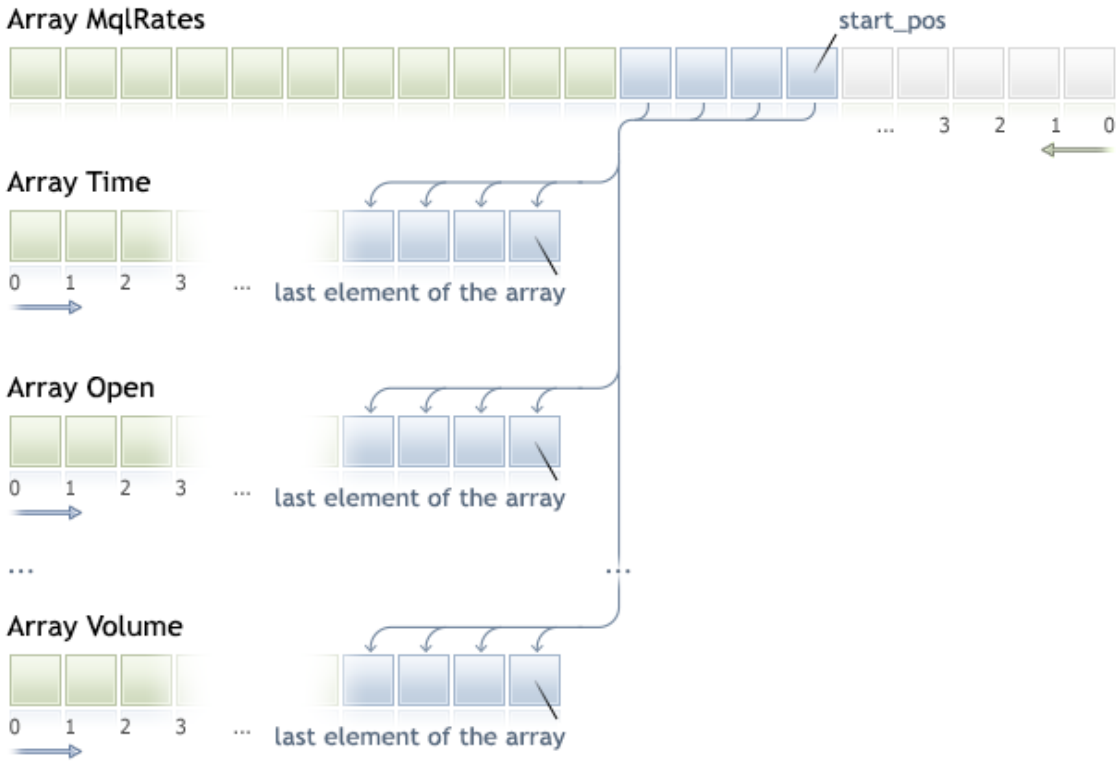
Structures and Classes, TimeToString, StringFormat

CopySeries

Gets the synchronized timeseries from the MqlRates structure for the specified symbol-period and the specified amount. The data is received into the specified set of arrays. Elements are counted down from the present to the past, which means that the starting position equal to 0 means the current bar.



If the data amount to be copied is unknown, it is recommended to use the dynamic array for the receiving arrays, since if the data amount exceeds what an array can contain, this can cause the attempt to redistribute the array to fit all of the requested data.

If you need to copy a predetermined amount of data, it is recommended to use a statistically allocated buffer to avoid unnecessary memory reallocation.

The property of the receiving array — as_series=true or as_series=false — will be ignored: during copying, the oldest timeseries element will be copied to the beginning of the physical memory allocated for the array.

```
int  CopySeries(
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   int              start_pos,         // start position
   int              count,             // amount to copy
   ulong            rates_mask,        // combination of flags to specify the requeste
   void&            array1[],          // array to receive the data of the first copie
   void&            array2[]           // array to receive the data of the second copi
   ...
   );
```

Parameters

symbol_name

[in] Symbol.

timeframe

[in] Period.

start_pos

[in] First copied element index.

count

[in] Number of copied elements.

rates_mask

[in] A combination of flags from the ENUM_COPY_RATES enumeration.

array1, array2,...

[out] Array of the appropriate type to receive the timeseries from the MqlRates structure. The order of the arrays passed to the function must match the order of the fields in the MqlRates structure.

Return Value

The number of copied elements or -1 if error occurs.

Note

If the entire interval of the requested data is beyond the data available on the server, the function returns -1. If the requested data is beyond TERMINAL_MAXBARS (the maximum number of bars on the chart), the function also returns -1.

When requesting data from an indicator, the function immediately returns -1 if requested timeseries are not constructed yet or they should be downloaded from the server. However, this will initiate data download/constructing itself.

When requesting data from an Expert Advisor or a script, download from the server is initiated if the terminal does not have the appropriate data locally, or construction of the necessary timeseries starts if the data can be constructed from the local history but they are not ready yet. The function returns the amount of data that is ready by the time the timeout expires, however the history download continues, and the function returns more data during the next similar request.

Difference between CopySeries and CopyRates

The CopySeries function allows obtaining only the necessary timeseries into different specified arrays during one call, while all of timeseries data will be synchronized. This means that all values in the resulting arrays at a certain index N will belong to the same bar on the specified Symbol/Timeframe pair. Therefore, there is no need for the programmer to ensure the synchronization of all received timeseries by the bar opening time.

Unlike CopyRates, which returns the full set of timeseries as an MqlRates array, the CopySeries function allows the programmer to get only the required timeseries as separate arrays. This can be

done by specifying a combination of flags to select the type of timeseries. The order of the arrays passed to the function must match the order of the fields in the MqlRates structure:

```
struct MqlRates
  {
   datetime time;         // period start time
   double   open;         // open price
   double   high;         // high price for the period
   double   low;          // low price for the period
   double   close;        // close price
   long     tick_volume;  // tick volume
   int      spread;       // spread
   long     real_volume;  // exchange volume
  }
```

Thus, if you need to get the values of the *time*, *close* and *real_volume* timeseries for the last 100 bars of the current Symbol/Timeframe, you should use the following call:

```
datetime time[];
double   close[];
long     volume[];
CopySeries(NULL,0,0,100,COPY_RATES_TIME|COPY_RATES_CLOSE|COPY_RATES_VOLUME_REAL,time,c
```

Mind the order of the arrays "*time*, *close*, *volume*" — it must match the order of the fields in the MqlRates structure. The order of values in the *rates_mask* does not matter. The mask could be as follows:

```
COPY_RATES_VOLUME_REAL|COPY_RATES_TIME|COPY_RATES_CLOSE
```

Example:

```
//--- input parameters
input datetime InpDateFrom=D'2022.01.01 00:00:00';
input datetime InpDateTo  =D'2023.01.01 00:00:00';
input uint     InpCount   =20;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
//--- arrays to get timeseries from the MqlRates price structure
   double   open[];
   double   close[];
   float    closef[];
   datetime time1[], time2[];
//--- request close prices to a double array
   ResetLastError();
   int res1=CopySeries(NULL, PERIOD_CURRENT, 0, InpCount,
                       COPY_RATES_TIME|COPY_RATES_CLOSE, time1, close);
   PrintFormat("1. CopySeries  returns %d values. Error code=%d", res1, GetLastError()
```

```
   ArrayPrint(close);

//--- now also request open prices; use float array for close prices
   ResetLastError();
   int res2=CopySeries(NULL, PERIOD_CURRENT, 0, InpCount,
                       COPY_RATES_TIME|COPY_RATES_CLOSE|COPY_RATES_OPEN, time2, open,
   PrintFormat("2. CopySeries  returns %d values. Error code=%d", res2, GetLastError()
   ArrayPrint(closef);
//--- Compare the received data
   if((res1==res2) && (time1[0]==time2[0]))
     {
      Print("  | Time             |    Open      | Close double | Close float |");
      for(int i=0; i<10; i++)
        {
         PrintFormat("%d | %s |   %.5f    |   %.5f    |   %.5f   |",
                     i, TimeToString(time1[i]), open[i], close[i], closef[i]);
        }

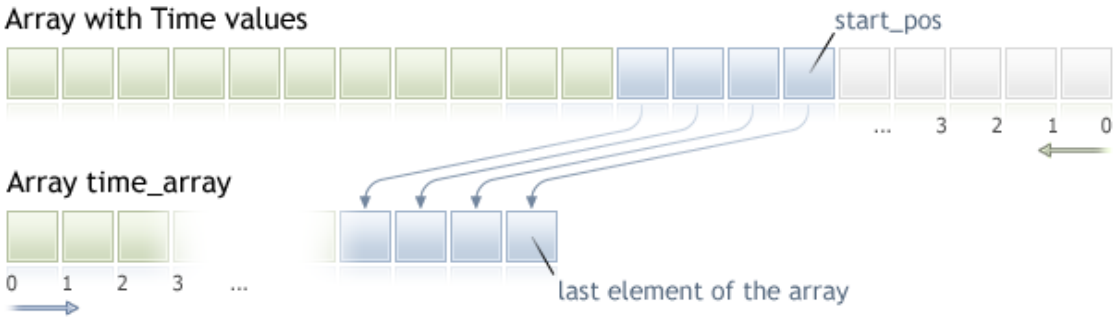
CopyTime

The function gets to time_array history data of bar opening time for the specified symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyTime(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   datetime          time_array[]      // target array to copy open times
   );
```

Call by the start date and the number of required elements

```
int  CopyTime(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   datetime          time_array[]      // target array to copy  open times
   );
```

Call by the start and end dates of a required time interval

```
int  CopyTime(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   datetime         time_array[]      // target array to copy open times
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time corresponding to the last element to copy.

time_array[]

[out] Array of datetime type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

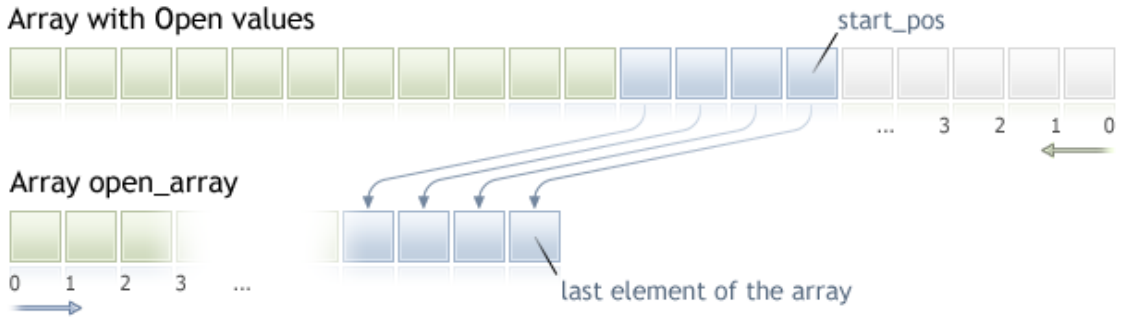
If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyOpen

The function gets into open_array the history data of bar open prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyOpen(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            open_array[]      // target array to copy open prices
   );
```

Call by the start date and the number of required elements

```
int  CopyOpen(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            open_array[]      // target array for bar open prices
   );
```

Call by the start and end dates of a required time interval

```
int  CopyOpen(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           open_array[]      // target array for bar open values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] The start time for the last element to copy.

open_array[]

[out] Array of double type.

Return Value

Returns the number of element in the array or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

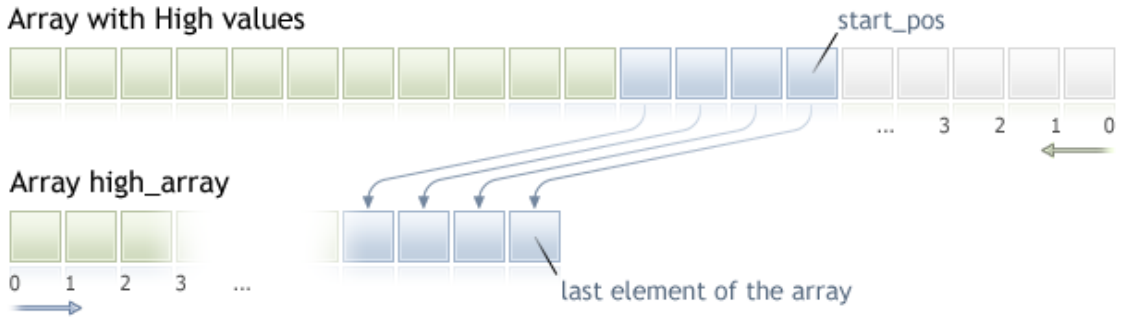
If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyHigh

The function gets into high_array the history data of highest bar prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyHigh(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            high_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyHigh(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            high_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyHigh(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           high_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

high_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

#property description "for a random chosen bars"

double High[],Low[];
//+------------------------------------------------------------------+
//| Get Low for specified bar index                                  |
//+------------------------------------------------------------------+
double iLow(string symbol,ENUM_TIMEFRAMES timeframe,int index)
  {
   double low=0;
   ArraySetAsSeries(Low,true);
   int copied=CopyLow(symbol,timeframe,0,Bars(symbol,timeframe),Low);
   if(copied>0 && index<copied) low=Low[index];
   return(low);
  }
//+------------------------------------------------------------------+
//| Get the High for specified bar index                             |
//+------------------------------------------------------------------+
double iHigh(string symbol,ENUM_TIMEFRAMES timeframe,int index)
  {
   double high=0;
   ArraySetAsSeries(High,true);
   int copied=CopyHigh(symbol,timeframe,0,Bars(symbol,timeframe),High);
   if(copied>0 && index<copied) high=High[index];
   return(high);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
```

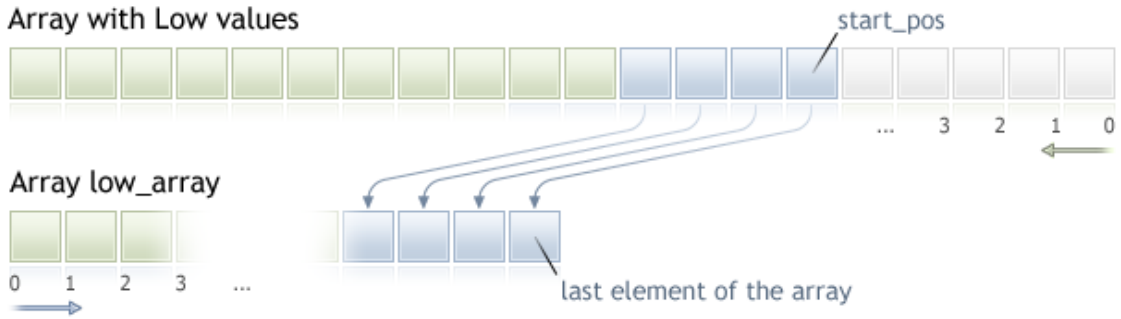
```
//--- on every tick we output the High and Low values for the bar with index,
//--- that is equal to the second, on which tick arrived
   datetime t=TimeCurrent();
   int sec=t%60;
   printf("High[%d] = %G  Low[%d] = %G",
          sec,iHigh(Symbol(),0,sec),
          sec,iLow(Symbol(),0,sec));
  }
```

See a detailed example of requesting history data in the Methods of Object Binding section. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyLow

The function gets into low_array the history data of minimal bar prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyLow(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            low_array[]       // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyLow(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            low_array[]       // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyLow(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           low_array[]       // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] Bar time, corresponding to the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

low_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

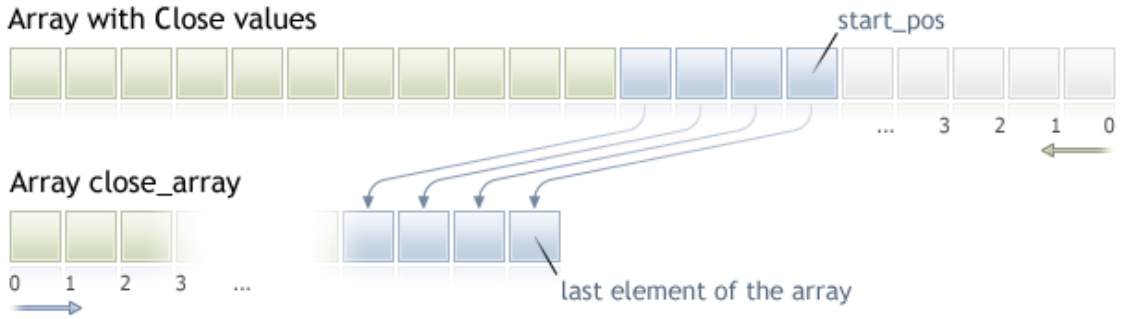
CopyHigh

CopyClose

The function gets into close_array the history data of bar close prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyClose(
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   int              start_pos,         // start position
   int              count,             // data count to copy
   double           close_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyClose(
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   datetime         start_time,        // start date and time
   int              count,             // data count to copy
   double           close_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyClose(
```

```
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   datetime         start_time,        // start date and time
   datetime         stop_time,         // stop date and time
   double           close_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

close_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

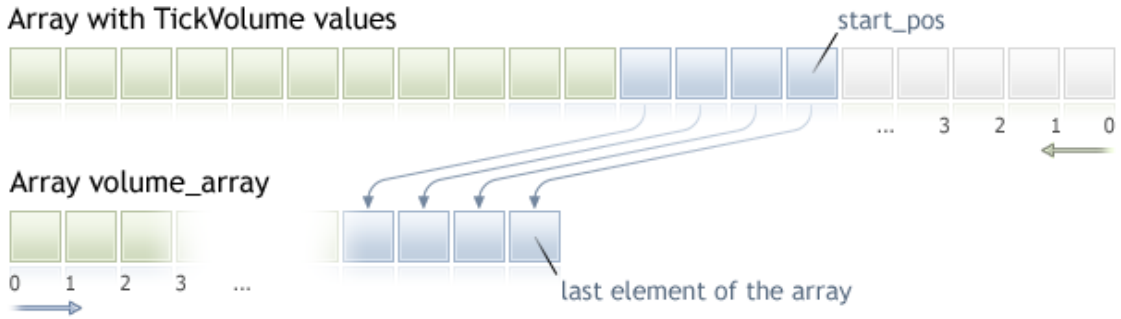
If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

See a detailed example of history data requesting in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyTickVolume

The function gets into volume_array the history data of tick volumes for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyTickVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   int              start_pos,        // start position
   int              count,            // data count to copy
   long             volume_array[]    // target array for tick volumes
   );
```

Call by the start date and the number of required elements

```
int  CopyTickVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   int              count,            // data count to copy
   long             volume_array[]    // target array for tick volumes
   );
```

Call by the start and end dates of a required time interval

```
int  CopyTickVolume(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   long             volume_array[]    // target array for tick volumes
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

volume_array[]

[out] Array of long type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot TickVolume
#property indicator_label1  "TickVolume"
#property indicator_type1   DRAW_HISTOGRAM
#property indicator_color1  C'143,188,139'
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- input parameters
input int      bars=3000;
//--- indicator buffers
double         TickVolumeBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,TickVolumeBuffer,INDICATOR_DATA);
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
```

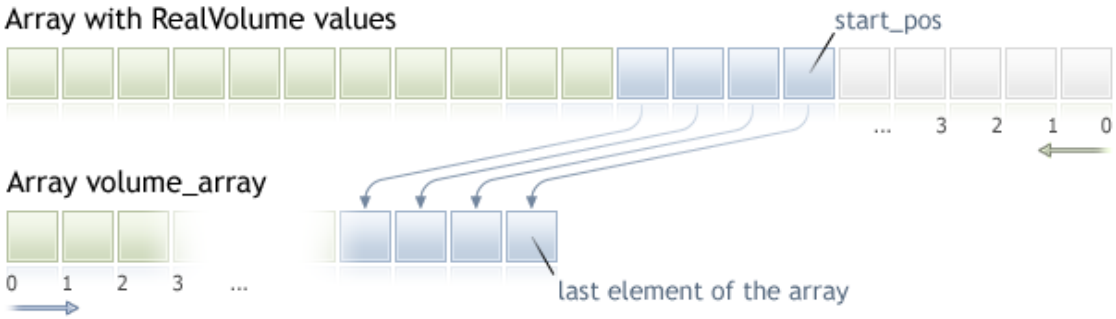
```
                  const int &spread[])
  {
//---
   if(prev_calculated==0)
     {
      long timeseries[];
      ArraySetAsSeries(timeseries,true);
      int prices=CopyTickVolume(Symbol(),0,0,bars,timeseries);
      for(int i=0;i<rates_total-prices;i++) TickVolumeBuffer[i]=0.0;
      for(int i=0;i<prices;i++) TickVolumeBuffer[rates_total-1-i]=timeseries[prices-1-
      Print("We have received the following number of TickVolume values: "+prices);
     }
   else
     {
      long timeseries[];
      int prices=CopyTickVolume(Symbol(),0,0,1,timeseries);
      TickVolumeBuffer[rates_total-1]=timeseries[0];
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

See a detailed example of history data requesting in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyRealVolume

The function gets into volume_array the history data of trade volumes for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyRealVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   int              start_pos,        // start position
   int              count,            // data count to copy
   long             volume_array[]    // target array for volumes values
   );
```

Call by the start date and the number of required elements

```
int  CopyRealVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   int              count,            // data count to copy
   long             volume_array[]    // target array for volumes values
   );
```

Call by the start and end dates of a required time interval

```
int  CopyRealVolume(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   long             volume_array[]    // target array for volumes values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

volume_array[]

[out] Array of long type.

Return Value

Returns the copied data count or -1 in the case of error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

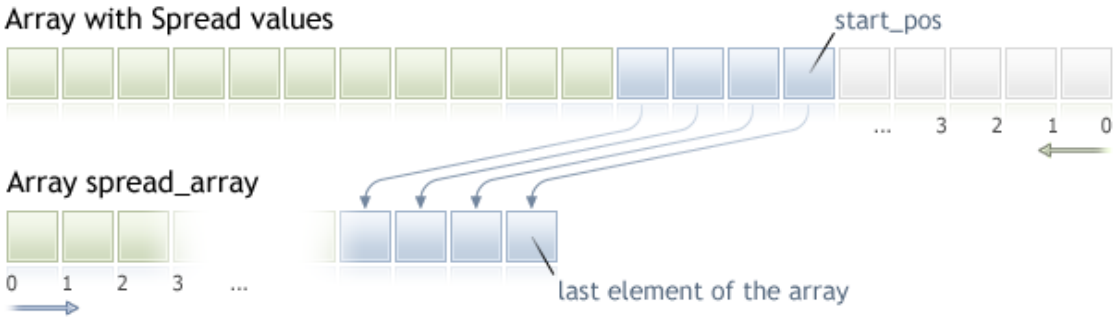
If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

See an example of history data requesting in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopySpread

The function gets into spread_array the history data of spread values for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopySpread(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   int               spread_array[]    // target array for spread values
   );
```

Call by the start date and the number of required elements

```
int  CopySpread(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   int               spread_array[]    // target array for spread values
   );
```

Call by the start and end dates of a required time interval

```
int  CopySpread(
```

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   int              spread_array[]    // target array for spread values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

spread_array[]

[out] Array of int type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot Spread
#property indicator_label1  "Spread"
#property indicator_type1   DRAW_HISTOGRAM
#property indicator_color1  clrRed
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- input parameters
input int      bars=3000;
//--- indicator buffers
double         SpreadBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,SpreadBuffer,INDICATOR_DATA);
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
```

```
                  const int &spread[])
  {
//---
   if(prev_calculated==0)
     {
      int spread_int[];
      ArraySetAsSeries(spread_int,true);
      int spreads=CopySpread(Symbol(),0,0,bars,spread_int);
      Print("We have received the following number of Spread values: ",spreads);
      for (int i=0;i<spreads;i++)
      {
      SpreadBuffer[rates_total-1-i]=spread_int[i];
      if(i<=30) Print("spread["+i+"] = ",spread_int[i]);
      }
     }
   else
     {
      double Ask,Bid;
      Ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
      Bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
      Comment("Ask = ",Ask,"  Bid = ",Bid);
      SpreadBuffer[rates_total-1]=(Ask-Bid)/Point();
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

See an example of history data requesting in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

CopyTicks

The function receives ticks in the MqlTick format into ticks_array. In this case, ticks are indexed from the past to the present, i.e. the 0 indexed tick is the oldest one in the array. For tick analysis, check the *flags* field, which shows what exactly has changed in the tick.

```
int  CopyTicks(
   string           symbol_name,           // Symbol name
   MqlTick&         ticks_array[],         // Tick receiving array
   uint             flags=COPY_TICKS_ALL,  // The flag that determines the type of req
   ulong            from=0,                // The date from which you want to request
   uint             count=0                // The number of ticks that you want to req
   );
```

Parameters

symbol_name

[in] Symbol.

ticks_array

[out] An array of the MqlTick type for receiving ticks.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from

[in] The date from which you want to request ticks. In milliseconds since 1970.01.01. If *from*=0, the last *count* ticks will be returned.

count

[in] The number of requested ticks. If the 'from' and 'count' parameters are not specified, all available recent ticks (but not more than 2000) will be written to ticks_array[].

Returned value

The number of copied tick or -1 in case of an error.

Note

The CopyTicks() function allows requesting and analyzing all received ticks. The first call of CopyTicks() initiates synchronization of the symbol's tick database stored on the hard disk. If the local database does not provide all the requested ticks, then missing ticks will be automatically downloaded from the trade server. Ticks beginning with the ***from*** date specified in CopyTicks() till the current moment will be synchronized. After that, all ticks arriving for this symbol will be added to the tick database thus keeping it in the synchronized state.

If the *from* and *count* parameters are not specified, all available recent ticks (but not more than 2000) will be written to *ticks_array[]*. The *flags* parameter allows specifying the type of required ticks.

COPY_TICKS_INFO - ticks with Bid and/or Ask price changes are returned. Data of other fields will also be added. For example, if only the Bid has changed, the *ask* and *volume* fields will be filled with last known values. To find out exactly what has changed, analyze the *flags* field, which will have the value of TICK_FLAG_BID and/or TICK_FLAG_ASK. If a tick has zero values of the Bid and Ask prices, and the flags show that these data have changed (*flags*=TICK_FLAG_BID|TICK_FLAG_ASK), this means that the order book (Market Depth) is empty. In other words, there are no buy and sell orders.

COPY_TICKS_TRADE - ticks with the Last price and volume changes are returned. Data of other fields will also be added, i.e. last known values of Bid and Ask will be specified in the appropriate fields. To find out exactly what has changed, analyze the *flags* field, which will have the TICK_FLAG_LAST and TICK_FLAG_VOLUME value.

COPY_TICKS_ALL - all ticks with any change are returned. Unchanged fields will be filled with last known values.

Call of CopyTicks() with the COPY_TICKS_ALL flag immediately returns all ticks from the request interval, while calls in other modes require some time to process and select ticks, therefore they do not provide significant speed advantage.

When requesting ticks (either COPY_TICKS_INFO or COPY_TICKS_TRADE), every tick contains full price information as of the time of the tick (*bid, ask, last* and *volume*). This feature is provided for an easier analysis of the trade state at the time of each tick, so there is no need to request a deep tick history and search for the values of other fields.

In indicators, the CopyTicks() function returns the result: when called from an indicator, CopyTick() immediately returns all available ticks of a symbol, and will launch synchronization of the tick database, if available data is not enough. All indicators in one symbol operate in one common thread, so the indicator cannot wait for the completion of synchronization. After synchronization, CopyTicks() will return all requested ticks during the next call. In indicators, the OnCalculate() function is called after the arrival of each tick.

CopyTicks() can wait for the result for 45 seconds in Expert Advisors and scripts: as distinct from indicators, every Expert Advisor and script operate in a separate thread, and therefore can wait 45 seconds till the completion of synchronization. If the required amount of ticks fails to be synchronized during this time, CopyTicks() will return available ticks by timeout and will continue synchronization. OnTick() in Expert Advisor is not a handler of every tick, it only notifies an Expert Advisor about changes in the market. It can be a batch of changes: the terminal can simultaneously make a few ticks, but OnTick() will be called only once to notify the EA of the latest market state.

The rate of data return: the terminal stores in the fast access cache 4,096 last ticks for each instrument (65,536 ticks for symbols with a running Market Depth). If requested ticks for the current trading session are beyond the cache, CopyTicks() calls the ticks stored in the terminal memory. These requests require more time for execution. The slowest requests are those requesting ticks for other days, since the data is read from the disk in this case.

Example:

```

CopyTicksRange

The function receives ticks in the MqlTick format within the specified date range to ticks_array. Indexing goes from the past to the present meaning that a tick with the index 0 is the oldest one in the array. For tick analysis, check the *flags* field, which shows what exactly has changed.

```
int  CopyTicksRange(
   const string      symbol_name,           // symbol name
   MqlTick&          ticks_array[],         // tick receiving array
   uint              flags=COPY_TICKS_ALL,  // flag that defines the type of the ticks
   ulong             from_msc=0,            // date, starting from which ticks are requ
   ulong             to_msc=0               // date, up to which ticks are requested
   );
```

Parameters

symbol_name

[in] Symbol.

ticks_array

[out] MqlTick static or dynamic array for receiving ticks. If the static array cannot hold all the ticks from the requested time interval, the maximum possible amount of ticks is received. In this case, the function generates the error ERR_HISTORY_SMALL_BUFFER (4407) .

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from_msc

[in] The date, from which you want to request ticks. In milliseconds since 1970.01.01. If the *from_msc* parameter is not specified, ticks from the beginning of the history are sent. Ticks with the time >= from_msc are sent.

to_msc

[in] The date, up to which you want to request ticks. In milliseconds since 01.01.1970. Ticks with the time <= to_msc are sent. If the *to_msc* parameter is not specified, all ticks up to the end of the history are sent.

Return Value

The number of copied tick or -1 in case of an error. GetLastError() is able to return the following errors:

- ERR_HISTORY_TIMEOUT - ticks synchronization waiting time is up, the function has sent all it had.
- ERR_HISTORY_SMALL_BUFFER - static buffer is too small. Only the amount the array can store has been sent.
- ERR_NOT_ENOUGH_MEMORY - insufficient memory for receiving a history from the specified range to the dynamic tick array. Failed to allocate enough memory for the tick array.

Note

The CopyTicksRange() function is used for requesting ticks strictly from a specified range, for example, from a certain day in history. At the same time, CopyTicks() allows specifying only a start date, for example – receive all ticks from the beginning of the month till the current moment.

iBars

Returns the number of bars of a corresponding symbol and period, available in history.

```
int  iBars(
   const string           symbol,          // Symbol
   ENUM_TIMEFRAMES        timeframe        // Period
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

Return Value

The number of bars of a corresponding symbol and period, available in history, but no more than allowed by the "Max bars in chart" parameter in platform settings.

Example:

```
  Print("Bar count on the 'EURUSD,H1' is ",iBars("EURUSD",PERIOD_H1));
```

See also

Bars

iBarShift

Search bar by time. The function returns the index of the bar corresponding to the specified time.

```
int  iBarShift(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   datetime             time,            // Time
   bool                 exact=false      // Mode
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. PERIOD_CURRENT means the current chart period.

time

[in] Time value to search for.

exact=false

[in] A return value, in case the bar with the specified time is not found. If *exact=false*, *iBarShift* returns the index of the nearest bar, the Open time of which is less than the specified time (*time_open<time*). If such a bar is not found (history before the specified time is not available), then the function returns -1. If *exact=true*, iBarShift does not search for a nearest bar but immediately returns -1.

Return Value

The index of the bar corresponding to the specified time. If the bar corresponding to the specified time is not found (there is a gap in the history), the function returns -1 or the index of the nearest bar (depending on the *'exact'* parameter).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- The date is on Sunday
   datetime time=D'2002.04.25 12:00';
   string symbol="GBPUSD";
   ENUM_TIMEFRAMES tf=PERIOD_H1;
   bool exact=false;
//--- If there is no bar at the specified time, iBarShift will return the index of the
   int bar_index=iBarShift(symbol,tf,time,exact);
//--- Check the error code after the call of iBarShift()
   int error=GetLastError();
```

```
   if(error!=0)
     {
      PrintFormat("iBarShift(): GetLastError=%d - The requested date %s "+
                  "for %s %s is not found in the available history",
                  error,TimeToString(time),symbol,EnumToString(tf));
      return;
     }
//--- The iBarShift() function was executed successfully, return a result for exact=fa
   PrintFormat("1. %s %s %s(%s): bar index is %d (exact=%s)",
               symbol,EnumToString(tf),TimeToString(time),
               DayOfWeek(time),bar_index,string(exact));
   datetime bar_time=iTime(symbol,tf,bar_index);
   PrintFormat("Time of bar #%d is %s (%s)",
               bar_index,TimeToString(bar_time),DayOfWeek(bar_time));
//--- Request the index of the bar with the specified time; if there is no bar -1 will
   exact=true;
   bar_index=iBarShift(symbol,tf,time,exact);
//--- The iBarShift() function was executed successfully, return a result for exact=tr
   PrintFormat("2. %s %s %s (%s):bar index is %d (exact=%s)",
               symbol,EnumToString(tf),TimeToString(time)
               ,DayOfWeek(time),bar_index,string(exact));
  }
//+------------------------------------------------------------------+
//| Returns the name of the day of the week                          |
//+------------------------------------------------------------------+
string DayOfWeek(const datetime time)
  {
   MqlDateTime dt;
   string day="";
   TimeToStruct(time,dt);
   switch(dt.day_of_week)
     {
      case 0: day=EnumToString(SUNDAY);
      break;
      case 1: day=EnumToString(MONDAY);
      break;
      case 2: day=EnumToString(TUESDAY);
      break;
      case 3: day=EnumToString(WEDNESDAY);
      break;
      case 4: day=EnumToString(THURSDAY);
      break;
      case 5: day=EnumToString(FRIDAY);
      break;
      default:day=EnumToString(SATURDAY);
      break;
     }
//---
   return day;
```

```
   }
//+------------------------------------------------------------------+
/* Execution result
   1. GBPUSD PERIOD_H1 2018.06.10 12:00(SUNDAY): bar index is 64 (exact=false)
   Time of bar #64 is 2018.06.08 23:00 (FRIDAY)
   2. GBPUSD PERIOD_H1 2018.06.10 12:00 (SUNDAY):bar index is -1 (exact=true)
*/
```

iClose

Returns the Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iClose(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

CopyClose, CopyRates

iHigh

Returns the High price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iHigh(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The High price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }

CopyHigh, CopyRates

iHighest

Returns the index of the highest value found on the corresponding chart (shift relative to the current bar).

```
int  iHighest(
   const string        symbol,              // Symbol
   ENUM_TIMEFRAMES     timeframe,           // Period
   ENUM_SERIESMODE     type,                // Timeseries identifier
   int                 count=WHOLE_ARRAY,   // Number of elements
   int                 start=0              // Index
  );
```

Parameters

symbol

[in] The symbol, on which the search will be performed. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

type

[in] The identifier of the timeseries, in which the search will be performed. Can be equal to any value from ENUM_SERIESMODE.

count=WHOLE_ARRAY

[in] The number of elements in the timeseries (from the current bar towards index increasing direction), among which the search should be performed.

start=0

[in] The index (shift relative to the current bar) of the initial bar, from which search for the highest value begins. Negative values are ignored and replaced with a zero value.

Return Value

The index of the highest value found on the corresponding chart (shift relative to the current bar) or -1 in case of an error. For error details, call the GetLastError() function.

Example:

```
   double val;
//--- Calculation of the highest Close value among 20 consecutive bars
//--- From index 4 to index 23 inclusive, on the current timeframe
   int val_index=iHighest(NULL,0,MODE_CLOSE,20,4);
   if(val_index!=-1)
      val=High[val_index];
   else
      PrintFormat("iHighest() call error. Error code=%d",GetLastError());
```

iLow

Returns the Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iLow(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

CopyLow, CopyRates

iLowest

Returns the index of the smallest value found on the corresponding chart (shift relative to the current bar).

```
int  iLowest(
   const string        symbol,              // Symbol
   ENUM_TIMEFRAMES     timeframe,           // Period
   ENUM_SERIESMODE     type,                // Timeseries identifier
   int                 count=WHOLE_ARRAY,   // Number of elements
   int                 start=0              // Index
  );
```

Parameters

symbol

[in] The symbol, on which the search will be performed. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

type

[in] The identifier of the timeseries, in which the search will be performed. Can be equal to any value from ENUM_SERIESMODE.

count=WHOLE_ARRAY

[in] The number of elements in the timeseries (from the current bar towards index increasing direction), among which the search should be performed.

start=0

[in] The index (shift relative to the current bar) of the initial bar, from which search for the lowest value begins. Negative values are ignored and replaced with a zero value.

Return Value

The index of the lowest value found on the corresponding chart (shift relative to the current bar) or -1 in case of an error. For error details, call the GetLastError() function.

Example:

```
   double val;
//--- Search for a bar with the lowest value of the real volume among 15 consecutive b
//--- From index 10 to index 24 inclusive, on the current timeframe
   int val_index=iLowest(NULL,0,MODE_REAL_VOLUME,15,10);
   if(val_index!=-1)
      val=Low[val_index];
   else
      PrintFormat("iLowest() call error. Error code=%d",GetLastError());
```

iOpen

Returns the Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iOpen(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

CopyOpen, CopyRates

iTime

Returns the opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
datetime  iTime(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

iTickVolume

Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
long  iTickVolume(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```

CopyTickVolume, CopyRates

iRealVolume

Returns the real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
long  iRealVolume(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

iVolume

Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
long  iVolume(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

iSpread

Returns the spread value of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
long  iSpread(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Spread value of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);

Custom symbols

Functions for creating and editing the custom symbol properties.

When connecting the terminal to a certain trade server, a user is able to work with time series of the financial symbols provided by a broker. Available financial symbols are displayed as a list in the Market Watch window. A separate group of functions allows receiving data on the symbol properties, trading sessions and market depth updates.

The group of functions described in this section allows creating custom symbols. To do this, users are able to apply the trade server's existing symbols, text files or external data sources.

Function	Action
CustomSymbolCreate	Create a custom symbol with the specified name in the specified group
CustomSymbolDelete	Delete a custom symbol with the specified name
CustomSymbolSetInteger	Set the integer type property value for a custom symbol
CustomSymbolSetDouble	Set the real type property value for a custom symbol
CustomSymbolSetString	Set the string type property value for a custom symbol
CustomSymbolSetMarginRate	Set the margin rates depending on the order type and direction for a custom symbol
CustomSymbolSetSessionQuote	Set the start and end time of the specified quotation session for the specified symbol and week day
CustomSymbolSetSessionTrade	Set the start and end time of the specified trading session for the specified symbol and week day
CustomRatesDelete	Delete all bars from the price history of the custom symbol in the specified time interval
CustomRatesReplace	Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlRates type array
CustomRatesUpdate	Add missing bars to the custom symbol history and replace existing data with the ones from the MqlRates type array
CustomTicksAdd	Adds data from an array of the MqlTick type to the price history of a custom symbol. The custom symbol must be selected in the Market Watch window
CustomTicksDelete	Delete all ticks from the price history of the custom symbol in the specified time interval
CustomTicksReplace	Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlTick type array
CustomBookAdd	Passes the status of the Depth of Market for a custom symbol

CustomSymbolCreate

Creates a custom symbol with the specified name in the specified group.

```
bool  CustomSymbolCreate(
   const string      symbol_name,          // custom symbol name
   const string      symbol_path="",       // name of a group a symbol is to be created
   const string      symbol_origin=NULL    // name of a symbol used as a basis to create
   );
```

Parameters

symbol_name

[in] Custom symbol name. It should not contain groups or subgroups the symbol is located in.

symbol_path=""

[in] The group name a symbol is located in.

symbol_origin=NULL

[in] Name of a symbol the properties of a created custom symbol are to be copied from. After creating a custom symbol, any property value can be changed to a necessary one using the appropriate functions.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

All custom symbols are created in the special Custom section. If a group name is not specified (the *symbol_path* parameter in the CustomSymbolCreate function contains an empty string or NULL), a custom symbol is generated in the Custom section root. Here we can draw an analogy with the file system, where groups and subgroups can be viewed as folders and subfolders

The symbol and group names may only contain Latin letters without punctuation, spaces or special characters (may only contain ".", "_", "&" and "#"). It is not recommended to use characters <, >, :, ", /, |, ?, *.

The custom symbol name should be unique regardless of a group name it is created in. If a symbol with the same name already exists, the CustomSymbolCreate() function returns 'false', while the subsequent GetLastError() call returns the error 5300 (ERR_NOT_CUSTOM_SYMBOL) or 5304 (ERR_CUSTOM_SYMBOL_EXIST).

The length of the symbol name should not exceed 31 characters. Otherwise, CustomSymbolCreate() returns 'false' and the error 5302 - ERR_CUSTOM_SYMBOL_NAME_LONG is activated.

The *symbol_path* parameter can be set in two ways:

- only a group name without a name of the custom symbol, for example - "CFD\\Metals". It is best to use this option to avoid errors.
- or <group> name + groups separator "\\"+<custom symbol name>, for example - "CFD\\Metals\\Platinum". In this case, the group name should end with the exact name of the custom symbol. In case of a mismatch, the custom symbol is still created, but not in the intended group. For example, if *symbol_path*="CFD\\Metals\\Platinum" and *symbol_name*="platinum" (register error),

then a custom symbol named "platinum" is created in the "Custom\CFD\Metals\Platinum" group. The SymbolInfoGetString("platinum",SYMBOL_PATH) function returns the "Custom\CFD\Metals\Platinum\platinum" value.

Note that the SYMBOL_PATH property returns the path with the symbol name at the end. Therefore, it cannot be copied without changes if you want to create a custom symbol in the exact same group. In this case, it is necessary to cut the symbol name in order not to get the result described above.

If a non-existent symbol is set as the *symbol_origin* parameter, then the custom symbol is created empty as if the *symbol_origin* parameter is not set. The error 4301 - ERR_MARKET_UNKNOWN_SYMBOL is activated in that case.

The *symbol_path* parameter length should not exceed 127 characters considering "Custom\\", "\\" groups separators and the symbol name if it is specified at the end.

SymbolName, SymbolSelect, CustomSymbolDelete

CustomSymbolDelete

Deletes a custom symbol with the specified name.

```
bool  CustomSymbolDelete(
   const string      symbol_name          // custom symbol name
   );
```

Parameters

symbol

[in] Custom symbol name. It should not match the name of an already existing symbol.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The custom symbol displayed in the Market Watch or the one a chart is opened for cannot be deleted.

See also

SymbolName, SymbolSelect, CustomSymbolCreate

CustomSymbolSetInteger

Sets the integer type property value for a custom symbol.

```
bool  CustomSymbolSetInteger(
   const string               symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_INTEGER   property_id,      // property ID
   long                       property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_INTEGER enumeration.

property_value

[in] A long type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if any of these properties is changed in the symbol specification:

- SYMBOL_CHART_MODE - price type for constructing bars (Bid or Last)
- SYMBOL_DIGITS - number of digits after the decimal point to display the price

After deleting the custom symbol history, the terminal attempts to create a new history using the updated properties. The same happens when the custom symbol properties are changed manually.

See also

SymbolInfoInteger

CustomSymbolSetDouble

Sets the real type property value for a custom symbol.

```
bool  CustomSymbolSetDouble(
   const string              symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_DOUBLE   property_id,      // property ID
   double                    property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_DOUBLE enumeration.

property_value

[in] A double type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if any of these properties is changed in the symbol specification:

- SYMBOL_POINT - one point value
- SYMBOL_TRADE_TICK_SIZE - value of a tick that specifies the minimum allowable price change
- SYMBOL_TRADE_TICK_VALUE - one-tick price change value for a profitable position

After deleting the custom symbol history, the terminal attempts to create a new history using the updated properties. The same happens when the custom symbol properties are changed manually.

See also

SymbolInfoDouble

CustomSymbolSetString

Sets the string type property value for a custom symbol.

```
bool  CustomSymbolSetString(
   const string               symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_STRING    property_id,      // property ID
   string                     property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_STRING enumeration.

property_value

[in] A string type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if the SYMBOL_FORMULA property (setting the equation for the custom symbol price construction) is changed in the symbol specification. After deleting the custom symbol history, the terminal attempts to create a new history using the new equation. The same happens when the custom symbol equation is changed manually.

See also

SymbolInfoString

CustomSymbolSetMarginRate

Sets the margin rates depending on the order type and direction for a custom symbol.

```
bool  CustomSymbolSetMarginRate(
   const string       symbol_name,              // symbol name
   ENUM_ORDER_TYPE    order_type,               // order type
   double             initial_margin_rate,      // initial margin rate
   double             maintenance_margin_rate   // maintenance margin rate
   );
```

Parameters

symbol_name

[in] Custom symbol name.

order_type

[in] Order type.

initial_margin_rate

[in] A double type variable with an initial margin rate. Initial margin is a security deposit for 1 lot deal in the appropriate direction. Multiplying the rate by the initial margin, we receive the amount of funds to be reserved on the account when placing an order of the specified type.

maintenance_margin_rate

[in] A double type variable with a maintenance margin rate. Maintenance margin is a minimum amount for maintaining an open position of 1 lot in the appropriate direction. Multiplying the rate by the maintenance margin, we receive the amount of funds to be reserved on the account after an order of the specified type is activated.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

See also

SymbolInfoMarginRate

CustomSymbolSetSessionQuote

Sets the start and end time of the specified quotation session for the specified symbol and week day.

```
bool  CustomSymbolSetSessionQuote(
   const string      symbol_name,          // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,          // week day
   uint              session_index,        // session index
   datetime          from,                 // session start time
   datetime          to                    // session end time
   );
```

Parameters

symbol_name

[in] Custom symbol name.

ENUM_DAY_OF_WEEK

[in] Week day, value from the ENUM_DAY_OF_WEEK enumeration.

uint

[in] Index of the session, for which start and end times are to be set. Session indexing starts from 0.

from

[in] Session start time in seconds from 00:00, data value in the variable is ignored.

to

[in] Session end time in seconds from 00:00, data value in the variable is ignored.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

If the session with the specified *session_index* already exists, the function simply edits the beginning and end of the session.

If zero start and end parameters have been passed for the session (*from=0* and *to=0*), the appropriate session with the *session_index* is deleted, while the session indexing is shifted downwards.

Sessions can be added only sequentially. In other words, you can add *session_index=1* only if the session with the index 0 already exists. If this rule is broken, a new session is not created, while the function itself returns 'false'.

See also

SymbolInfoSessionQuote, Symbol info, TimeToStruct, Date structure

CustomSymbolSetSessionTrade

Sets the start and end time of the specified trading session for the specified symbol and week day.

```
bool  CustomSymbolSetSessionTrade(
   const string      symbol_name,          // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,          // week day
   uint              session_index,        // session index
   datetime          from,                 // session start time
   datetime          to                    // session end time
   );
```

Parameters

symbol_name

[in] Custom symbol name.

ENUM_DAY_OF_WEEK

[in] Week day, value from the ENUM_DAY_OF_WEEK enumeration.

uint

[in] Index of the session, for which start and end times are to be set. Session indexing starts from 0.

from

[in] Session start time in seconds from 00:00, data value in the variable is ignored.

to

[in] Session end time in seconds from 00:00, data value in the variable is ignored.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

If the session with the specified *session_index* already exists, the function simply edits the beginning and end of the session.

If zero start and end parameters have been passed for the session (*from=0* and *to=0*), the appropriate session with the *session_index* is deleted, while the session indexing is shifted downwards.

Sessions can be added only sequentially. In other words, you can add *session_index=1* only if the session with the index 0 already exists. If this rule is broken, a new session is not created, while the function itself returns 'false'.

SymbolInfoSessionTrade, Symbol info, TimeToStruct, Date structure

CustomRatesDelete

Deletes all bars from the price history of the custom symbol in the specified time interval.

```
int  CustomRatesDelete(
   const string      symbol,        // symbol name
   datetime          from,          // start date
   datetime          to             // end date
   );
```

Parameters

symbol

[in] Custom symbol name.

from

[in] Time of the first bar in the price history within the specified range to be removed.

to

[in] Time of the last bar in the price history within the specified range to be removed.

Return Value

Number of deleted bars or -1 in case of an error.

See also

CustomRatesReplace, CustomRatesUpdate, CopyRates

CustomRatesReplace

Fully replaces the price history of the custom symbol within the specified time interval with the data from the MqlRates type array.

```
int  CustomRatesReplace(
   const string     symbol,              // symbol name
   datetime         from,                // start date
   datetime         to,                  // end date
   const MqlRates&  rates[],             // array for the data to be applied to a custo
   uint             count=WHOLE_ARRAY    // number of the rates[] array elements to be
   );
```

Parameters

symbol

[in] Custom symbol name.

from

[in] Time of the first bar in the price history within the specified range to be updated.

to

[in] Time of the last bar in the price history within the specified range to be updated.

rates[]

[in] Array of the MqlRates type history data for M1.

count=WHOLE_ARRAY

[in] Number of the *rates[]* array elements to be used for replacement. WHOLE_ARRAY means that all *rates[]* array elements should be used for replacement.

Return Value

Number of updated bars or -1 in case of an error.

Note

If the bar from the *rates[]* array goes beyond the specified range, it is ignored. If such a bar is already present in the price history and enters the given range, it is replaced. All other bars in the current price history outside the specified range remain unchanged. The *rates[]* array data should be correct regarding OHLC prices, while the bars opening time should correspond to the M1 timeframe.

See also

CustomRatesDelete, CustomRatesUpdate, CopyRates

CustomRatesUpdate

Adds missing bars to the custom symbol history and replaces existing data with the ones from the MqlRates type array.

```
int  CustomRatesUpdate(
   const string     symbol,             // custom symbol name
   const MqlRates&  rates[],            // array for the data to be applied to a custo
   uint             count=WHOLE_ARRAY   // number of the rates[] array elements to be
   );
```

Parameters

symbol

[in] Custom symbol name.

rates[]

[in] Array of the MqlRates type history data for M1.

count=WHOLE_ARRAY

[in] Number of the *rates[]* array elements to be used for update. WHOLE_ARRAY means that all *rates[]* array elements should be used.

Return Value

Number of updated bars or -1 in case of an error.

Note

If there is no bar from the *rates[]* array in the current custom symbol history, it is added. If such a bar already exists, it is replaced. All other bars in the current price history remain unchanged. The *rates[]* array data should be correct regarding OHLC prices, while the bars opening time should correspond to the M1 timeframe.

See also

CustomRatesReplace, CustomRatesDelete, CopyRates

CustomTicksAdd

Adds data from an array of the MqlTick type to the price history of a custom symbol. The custom symbol must be selected in the Market Watch window.

```
int  CustomTicksAdd(
   const string     symbol,              // Symbol name
   const MqlTick&   ticks[],             // The array with tick data that should be app
   uint             count=WHOLE_ARRAY    // number of the ticks[] array elements to be
   );
```

Parameters

symbol

[in] The name of the custom symbol.

ticks[]

[in] An array of tick data of the MqlTick type arranged in order of time from earlier data to more recent ones, i.e. ticks[k].time_msc <= ticks[n].time_msc, if k<n.

count=WHOLE_ARRAY

[in] Number of the *ticks[]* array elements to be used for adding. WHOLE_ARRAY means that all *ticks[]* array elements should be used.

Return Value

The number of added ticks or -1 in case of an error.

Further Note

The CustomTicksAdd function only works for custom symbols opened in the Market Watch window. If the symbol is not selected in Market Watch, then you should add ticks using CustomTicksReplace.

The CustomTicksAdd function allows transmitting ticks as if they are delivered from the broker's server. Data are sent to the Market Watch window instead of being written directly to the tick database. The terminal then saves ticks from the Market Watch to a database. If the amount of data transmitted during one function call is large, the behavior of the function changes in order to reduce resource usage. If more than 256 ticks are passed, data is divided into two parts. The first, i.e. the larger part is written directly to the tick database (as it is done in CustomTicksReplace). The second part containing 128 ticks is passed to the Market Watch window, from which the terminal saves the ticks to a database.

The MqlTick structure has two fields with the time value: time (the tick time in seconds) and time_msc (the tick time in milliseconds), which are counted from January 1, 1970. These fields in the added ticks are processed in the following order:

1. If ticks[k].time_msc!=0, we use it to fill the ticks[k].time field, i.e. ticks[k].time=ticks[k].time_msc/1000 (integer division) is set for the tick
2. If ticks[k].time_msc==0 and ticks[k].time!=0, time in milliseconds is obtained by multiplying by 1000, i.e. ticks[k].time_msc=ticks[k].time*1000
3. If ticks[k].time_msc==0 and ticks[k].time==0, the current trade server time up to a millisecond as of the moment of CustomTicksAdd call is written to these fields.

If the value of ticks[k].bid, ticks[k].ask, ticks[k].last or ticks[k].volume is greater than zero, a combination of appropriate flags is written to the ticks[k].flags field:

- TICK_FLAG_BID - the tick has changed the bid price
- TICK_FLAG_ASK - the tick has changed the ask price
- TICK_FLAG_LAST - the tick has changed the last deal price
- TICK_FLAG_VOLUME - the tick has changed the volume

If the value of a field is less than or equal to zero, the corresponding flag is not written to the ticks[k].flags field.

Flags TICK_FLAG_BUY and TICK_FLAG_SELL are not added to the history of a custom symbol.

See also

CustomRatesDelete, CustomRatesUpdate, CustomTicksReplace, CopyTicks, CopyTicksRange

CustomTicksDelete

Deletes all ticks from the price history of the custom symbol in the specified time interval.

```
int  CustomTicksDelete(
   const string      symbol,            // symbol name
   long              from_msc,          // start date
   long              to_msc             // end date
   );
```

Parameters

symbol

[in] Custom symbol name.

from_msc

[in] Time of the first tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

to_msc

[in] Time of the last tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

Return Value

Number of deleted ticks or -1 in case of an error.

See also

CustomRatesDelete, CustomRatesUpdate, CustomTicksReplace, CopyTicks, CopyTicksRange

CustomTicksReplace

Fully replaces the price history of the custom symbol within the specified time interval with the data from the MqlTick type array.

```
int  CustomTicksReplace(
   const string     symbol,            // symbol name
   long             from_msc,          // start date
   long             to_msc,            // end date
   const MqlTick&   ticks[],           // array for the data to be applied to a custor
   uint             count=WHOLE_ARRAY  // number of the ticks[] array elements to be u
   );
```

Parameters

symbol

[in] Custom symbol name.

from_msc

[in] Time of the first tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

to_msc

[in] Time of the last tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

ticks[]

[in] Array of the MqlTick type tick data ordered in time in ascending order.

count=WHOLE_ARRAY

[in] Number of the *ticks[]* array elements to be used for replacement in the specified time interval. WHOLE_ARRAY means that all *ticks[]* array elements should be used.

Return Value

Number of updated ticks or -1 in case of an error.

Note

Since several ticks may often have the same time up to a millisecond in a stream of quotes (accurate tick time is stored in the *time_msc* field of the MqlTick structure), the CustomTicksReplace function does not automatically sort out the *ticks[]* array elements by time. Therefore, the array of ticks must be pre-arranged in time ascending order.

The ticks are replaced consecutively, day after day, until the time specified in *to_msc* or until an error occurs. The first day from the specified range is processed followed by the next one, etc. As soon as the mismatch between the tick time and the ascending (non-descending) order is detected, the tick replacement stops on the current day. All ticks from the previous days are successfully replaced, while the current day (at the moment of a wrong tick) and all the remaining days in the specified interval remain unchanged.

If the *ticks[]* array contains no tick data for any day (generally, any time interval), a "hole" corresponding to the missing data appears in the custom symbol history after the tick data from *ticks[]* are applied. In other words, the call of CustomTicksReplace with missing ticks is

equivalent to deleting part of the tick history, as if CustomTicksDelete with the "hole" interval is called.

If the tick database has no data for the specified time interval, CustomTicksReplace will add to the database ticks form the ticks[] array.

The CustomTicksReplace function works directly with the tick database.

See also

CustomRatesDelete, CustomRatesUpdate, CustomTicksDelete, CopyTicks, CopyTicksRange

CustomBookAdd

Passes the status of the Depth of Market for a custom symbol. The function allows broadcasting the Depth of Market as if the prices arrive from a broker's server.

```
bool  CustomBookAdd(
   const string        symbol,            // symbol name
   const MqlBookInfo&  books[]            // array with descriptions of the Depth of M
   uint                count=WHOLE_ARRAY  // number of elements to be used
   );
```

Parameters

symbol

[in] Custom symbol name.

books[]

[in] The array of MqlBookInfo type data fully describing the Depth of Market status — all buy and sell requests. The passed Depth of Market status completely replaces the previous one.

count=WHOLE_ARRAY

[in] The number of 'books' array elements to be passed to the function. The entire array is used by default.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The CustomBookAdd function works only for custom symbols the Depth of Market is opened for — via the platform interface or the MarketBookAdd function.

When throwing the Depth of Market in, the symbol's Bid and Ask prices are not updated. You should control the change of the best prices and throw in the ticks using CustomTicksAdd.

The function verifies the accuracy of transmitted data: the type, price and volume must be indicated for each element. Furthermore, MqlBookInfo.volume and MqlBookInfo.volume_real must not be zero or negative; if both volumes are negative, this will be considered an error. You can specify any of the volumes or both of them: the one that is indicated or is positive will be used:

```
volume=-1 && volume_real=2 — volume_real=2 will be used,
a volume=3 && volume_real=0 — volume=3 will be used.
```

The MqlBookInfo.volume_real extended accuracy volume has a higher priority over the regular MqlBookInfo.volume. If both values are specified for the Depth of Market element, the volume_real one is used.

The order of the MqlBookInfo elements in the 'books' array does not matter. When saving the data, the terminal sorts them by price on its own.

When saving data, the "Book depth" (SYMBOL_TICKS_BOOKDEPTH) parameter of the recipient custom symbol is checked. If the number of sell requests exceeds this value in the passed Depth of Market, the excess levels are discarded. The same is true for buy requests.

Sample filling of the 'books' array:

Depth of Market status	Filling books[]

	books[0].type=BOOK_TYPE_SELL;
	books[0].price=1.14337;
	books[0].volume=100;
	books[1].type=BOOK_TYPE_SELL;
	books[1].price=1.14330;
	books[1].volume=50;
	books[2].type=BOOK_TYPE_SELL;
	books[2].price=1.14335;
	books[2].volume=40;
	books[3].type=BOOK_TYPE_SELL;
	books[3].price=1.14333;
	books[3].volume=10;
	books[4].type=BOOK_TYPE_BUY;
	books[4].price=1.14322;
	books[4].volume=10;
	books[5].type=BOOK_TYPE_BUY;
	books[5].price=1.14320;
	books[5].volume=90;
	books[6].type=BOOK_TYPE_BUY;
	books[6].price=1.14319;
	books[6].volume=100;
	books[7].type=BOOK_TYPE_BUY;
	books[7].price=1.14318;
	books[7].volume=10;

Example:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- enable the Depth of Market for a symbol we are to retrieve data from
   MarketBookAdd(Symbol());
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
  }
//+------------------------------------------------------------------+
//| Tick function                                                    |
//+------------------------------------------------------------------+
void OnTick(void)
  {
   MqlTick ticks[];
   ArrayResize(ticks,1);
```

```
//--- copy the current prices from the common symbol to the custom one
   if(SymbolInfoTick(Symbol(),ticks[0]))
     {
      string symbol_name=Symbol()+".SYN";
      CustomTicksAdd(symbol_name,ticks);
     }
  }
//+------------------------------------------------------------------+
//| Book function                                                    |
//+------------------------------------------------------------------+
void OnBookEvent(const string &book_symbol)
  {
//--- copy the current Depth of Market status from the common symbol to the custom one
   if(book_symbol==Symbol())
     {
      MqlBookInfo book_array[];
      if(MarketBookGet(Symbol(),book_array))
        {
         string symbol_name=Symbol()+".SYN";
         CustomBookAdd(symbol_name,book_array);
        }
     }
  }
//+------------------------------------------------------------------+
```

Chart Operations

Functions for setting chart properties (ChartSetInteger, ChartSetDouble, ChartSetString) are asynchronous and are used for sending update commands to a chart. If these functions are executed successfully, the command is included in the common queue of the chart events. Chart property changes are implemented along with handling of the events queue of this chart.

Thus, do not expect an immediate update of the chart after calling asynchronous functions. Use the ChartRedraw() function to forcedly update the chart appearance and properties.

Function	Action
ChartApplyTemplate	Applies a specific template from a specified file to the chart
ChartSaveTemplate	Saves current chart settings in a template with a specified name
ChartWindowFind	Returns the number of a subwindow where an indicator is drawn
ChartTimePriceToXY	Converts the coordinates of a chart from the time/price representation to the X and Y coordinates
ChartXYToTimePrice	Converts the X and Y coordinates on a chart to the time and price values
ChartOpen	Opens a new chart with the specified symbol and period
ChartClose	Closes the specified chart
ChartFirst	Returns the ID of the first chart of the client terminal
ChartNext	Returns the chart ID of the chart next to the specified one
ChartSymbol	Returns the symbol name of the specified chart
ChartPeriod	Returns the period value of the specified chart
ChartRedraw	Calls a forced redrawing of a specified chart
ChartSetDouble	Sets the double value for a corresponding property of the specified chart
ChartSetInteger	Sets the integer value (datetime, int, color, bool or char) for a corresponding property of the specified chart
ChartSetString	Sets the string value for a corresponding property of the specified chart
ChartGetDouble	Returns the double value property of the specified chart
ChartGetInteger	Returns the integer value property of the specified chart
ChartGetString	Returns the string value property of the specified chart
ChartNavigate	Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart
ChartID	Returns the ID of the current chart

Function	Action
ChartIndicatorAdd	Adds an indicator with the specified handle into a specified chart window
ChartIndicatorDelete	Removes an indicator with a specified name from the specified chart window
ChartIndicatorGet	Returns the handle of the indicator with the specified short name in the specified chart window
ChartIndicatorName	Returns the short name of the indicator by the number in the indicators list on the specified chart window
ChartIndicatorsTotal	Returns the number of all indicators applied to the specified chart window.
ChartWindowOnDropped	Returns the number (index) of the chart subwindow the Expert Advisor or script has been dropped to
ChartPriceOnDropped	Returns the price coordinate of the chart point the Expert Advisor or script has been dropped to
ChartTimeOnDropped	Returns the time coordinate of the chart point the Expert Advisor or script has been dropped to
ChartXOnDropped	Returns the X coordinate of the chart point the Expert Advisor or script has been dropped to
ChartYOnDropped	Returns the Y coordinate of the chart point the Expert Advisor or script has been dropped to
ChartSetSymbolPeriod	Changes the symbol value and a period of the specified chart
ChartScreenShot	Provides a screenshot of the chart of its current state in a GIF, PNG or BMP format depending on specified extension

ChartApplyTemplate

Applies a specific template from a specified file to the chart. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartApplyTemplate(
   long          chart_id,      // Chart ID
   const string  filename       // Template file name
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] The name of the file containing the template.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The Expert Advisor will be unloaded and will not be able to continue operating in case of successful loading of a new template to the chart it is attached to.

When applying the template to the chart, trade permissions may be limited due to security reasons:

> **Live trading permission cannot be extended for the Expert Advisors launched by applying the template using ChartApplyTemplate() function.**

If the mql5-program calling ChartApplyTemplate() function has no permission to trade, the Expert Advisor launched via the template will also not be able to trade regardless of the template settings.

If the mql5-program calling ChartApplyTemplate() function has permission to trade, while there is no such permission in the template settings, the Expert Advisor launched via the template will not be able to trade.

Using Templates

The resources of the MQL5 language allow setting multiple chart properties, including colors using the ChartSetInteger() function:

- Chart background color;
- Color of the axes, scale and the OHLC line;
- Grid color;
- Color of volumes and position open levels;
- Color of the up bar, shadow and edge of a bullish candlestick;
- Color of the down bar, shadow and edge of a bearish candlestick;
- Color of the chart line and Doji candlesticks;

- Color of the bullish candlestick body;
- Color of the bearish candlestick body;
- Color of the Bid price line;
- Color of the Ask price line;
- Color of the line of the last deal price (Last);
- Color of the stop order levels (Stop Loss and Take Profit).

Besides, there can be multiple graphical objects and indicators on a chart. You may set up a chart with all the necessary indicators once and then save it as a template. Such a template can be applied to any chart.

The ChartApplyTemplate() function is intended for using a previously saved template, and it can be used in any mql5 program. The path to the file that stores the template is passed as the second parameter to ChartApplyTemplate(). The template file is searched according to the following rules:

- if the backslash "\" separator (written as "\\") is placed at the beginning of the path, the template is searched for relative to the path _terminal_data_directory\MQL5,
- if there is no backslash, the template is searched for relative to the executable EX5 file, in which ChartApplyTemplate() is called;
- if a template is not found in the first two variants, the search is performed in the folder terminal_directory\Profiles\Templates\.

Here terminal_directory is the folder from which the MetaTrader 5 Client Terminal is running, and terminal_data_directory is the folder, in which editable files are stored, its location depends on the operating system, user name and computer's security settings. Normally they are different folders, but in some cases they may coincide.

The location of folders terminal_data_directory and terminal_directory can be obtained using the TerminalInfoString() function.

```
//--- directory from which the terminal is started
   string terminal_path=TerminalInfoString(TERMINAL_PATH);
   Print("Terminal directory:",terminal_path);
//--- terminal data directory, in which the MQL5 folder with EAs and indicators is loc
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
   Print("Terminal data directory:",terminal_data_path);
```

For example:

```
//--- search for a template in terminal_data_directory\MQL5\
ChartApplyTemplate(0,"\\first_template.tpl"))
//--- search for a template in directory_of_EX5_file\, then in folder terminal_data_di
ChartApplyTemplate(0,"second_template.tpl"))
//--- search for a template in directory_of_EX5_file\My_templates\, then in folder ter
ChartApplyTemplate(0,"My_templates\\third_template.tpl"))
```

Templates are not resources, they cannot be included into an executable EX5 file.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
```

```
void OnStart()
  {
//--- example of applying template, located in \MQL5\Files
   if(FileIsExist("my_template.tpl"))
     {
      Print("The file my_template.tpl found in \Files'");
      //--- apply template
      if(ChartApplyTemplate(0,"\\Files\\my_template.tpl"))
        {
         Print("The template 'my_template.tpl' applied successfully");
         //--- redraw chart
         ChartRedraw();
        }
      else
         Print("Failed to apply 'my_template.tpl', error code ",GetLastError());
     }
   else
     {
      Print("File 'my_template.tpl' not found in "
            +TerminalInfoString(TERMINAL_PATH)+"\\MQL5\\Files");
     }
  }
```

Resources

ChartSaveTemplate

Saves current chart settings in a template with a specified name.

```
bool  ChartSaveTemplate(
   long          chart_id,     // Chart ID
   const string  filename      // Filename to save the template
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] The filename to save the template. The ".tpl" extension will be added to the filename automatically; there is no need to specify it. The template is saved in **data_folder**\Profiles\Templates\ and can be used for manual application in the terminal. If a template with the same filename already exists, the contents of this file will be overwritten.

Return Value

If successful, the function returns true, otherwise it returns false. To get information about the error, call the GetLastError() function.

Note

Using templates, you can save chart settings with all applied indicators and graphical objects, to then apply it to another chart.

Example:

```
//+------------------------------------------------------------------+
//|                                      Test_ChartSaveTemplate.mq5 |

ChartApplyTemplate(), Resources

ChartWindowFind

The function returns the number of a subwindow where an indicator is drawn. There are 2 variants of the function.

1. The function searches in the indicated chart for the subwindow with the specified "short name" of the indicator (the short name is displayed in the left top part of the subwindow), and it returns the subwindow number in case of success.

```
int  ChartWindowFind(
   long     chart_id,                  // chart identifier
   string   indicator_shortname        // short indicator name, see INDICATOR_SHORTNAM
```

2. The function must be called from a custom indicator. It returns the number of the subwindow where the indicator is working.

```
int  ChartWindowFind();
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

indicator_shortname

[in] Short name of the indicator.

Return Value

Subwindow number in case of success. In case of failure the function returns -1.

Note

If the second variant of the function (without parameters) is called from a script or Expert Advisor, the function returns -1.

Don't mix up the short name of an indicator and a file name, which is specified when an indicator is created using iCustom() and IndicatorCreate() functions. If the indicator's short name is not set explicitly, then the name of the file containing the source code of the indicator, is specified in it during compilation.

It is important to correctly form the short name of an indicator, which is recorded in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name contains values of the indicator's input parameters, because the indicator deleted from a chart in the ChartIndicatorDelete() function is identified by its short name.

Example:

```
#property script_show_inputs
//--- input parameters
input string   shortname="MACD(12,26,9)";
//+------------------------------------------------------------------+
//| Returns number of the chart window with this indicator           |
//+------------------------------------------------------------------+
int GetIndicatorSubWindowNumber(long chartID=0,string short_name="")
```

```
  {
   int window=-1;
//---
   if((ENUM_PROGRAM_TYPE)MQL5InfoInteger(MQL5_PROGRAM_TYPE)==PROGRAM_INDICATOR)
     {
      //--- the function is called from the indicator, name is not required
      window=ChartWindowFind();
     }
   else
     {
      //--- the function is called from an Expert Advisor or script
      window=ChartWindowFind(0,short_name);
      if(window==-1) Print(__FUNCTION__+"(): Error = ",GetLastError());
     }
//---
   return(window);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int window=GetIndicatorSubWindowNumber(0,shortname);
   if(window!=-1)
      Print("Indicator "+shortname+" is in the window #"+(string)window);
   else
      Print("Indicator "+shortname+" is not found. window = "+(string)window);
  }
```

ObjectCreate(), ObjectFind()

ChartTimePriceToXY

Converts the coordinates of a chart from the time/price representation to the X and Y coordinates.

```
bool  ChartTimePriceToXY(
   long           chart_id,      // Chart ID
   int            sub_window,    // The number of the subwindow
   datetime       time,          // Time on the chart
   double         price,         // Price on the chart
   int&           x,             // The X coordinate for the time on the chart
   int&           y              // The Y coordinates for the price on the chart
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart subwindow. 0 means the main chart window.

time

[in] The time value on the chart, for which the value in pixels along the X axis will be received. The origin is in the upper left corner of the main chart window.

price

[in] The price value on the chart, for which the value in pixels along the Y axis will be received. The origin is in the upper left corner of the main chart window.

x

[out] The variable, into which the conversion of time to X will be received.

y

[out] The variable, into which the conversion of price to Y will be received.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

ChartXYToTimePrice()

ChartXYToTimePrice

Converts the X and Y coordinates on a chart to the time and price values.

```
bool  ChartXYToTimePrice(
   long            chart_id,      // Chart ID
   int             x,             // The X coordinate on the chart
   int             y,             // The Y coordinate on the chart
   int&            sub_window,    // The number of the subwindow
   datetime&       time,          // Time on the chart
   double&         price          // Price on the chart
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

x

[in] The X coordinate.

y

[in] The Y coordinate.

sub_window

[out] The variable, into which the chart subwindow number will be written. 0 means the main chart window.

time

[out] The time value on the chart, for which the value in pixels along the X axis will be received. The origin is in the upper left corner of the main chart window.

price

[out] The price value on the chart, for which the value in pixels along the Y axis will be received. The origin is in the upper left corner of the main chart window.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Example:

```
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,
                  const long &lparam,
                  const double &dparam,
                  const string &sparam)
  {
//--- Show the event parameters on the chart
```

```
   Comment(__FUNCTION__,": id=",id," lparam=",lparam," dparam=",dparam," sparam=",spa
//--- If this is an event of a mouse click on the chart
   if(id==CHARTEVENT_CLICK)
     {
      //--- Prepare variables
      int      x     =(int)lparam;
      int      y     =(int)dparam;
      datetime dt    =0;
      double   price =0;
      int      window=0;
      //--- Convert the X and Y coordinates in terms of date/time
      if(ChartXYToTimePrice(0,x,y,window,dt,price))
        {
         PrintFormat("Window=%d X=%d  Y=%d  =>  Time=%s  Price=%G",window,x,y,TimeToSt
         //--- Perform reverse conversion: (X,Y) => (Time,Price)
         if(ChartTimePriceToXY(0,window,dt,price,x,y))
            PrintFormat("Time=%s  Price=%G  =>  X=%d  Y=%d",TimeToString(dt),price,x,y
         else
            Print("ChartTimePriceToXY return error code: ",GetLastError());
         //--- delete lines
         ObjectDelete(0,"V Line");
         ObjectDelete(0,"H Line");
         //--- create horizontal and vertical lines of the crosshair
         ObjectCreate(0,"H Line",OBJ_HLINE,window,dt,price);
         ObjectCreate(0,"V Line",OBJ_VLINE,window,dt,price);
         ChartRedraw(0);
        }
      else
         Print("ChartXYToTimePrice return error code: ",GetLastError());
      Print("+------------------------------------------------------------------+");
     }
  }
```

See also

ChartTimePriceToXY()

ChartOpen

Opens a new chart with the specified symbol and period.

```
long  ChartOpen(
   string           symbol,     // Symbol name
   ENUM_TIMEFRAMES  period      // Period
   );
```

Parameters

symbol

[in] Chart symbol. NULL means the symbol of the current chart (the Expert Advisor is attached to).

period

[in] Chart period (timeframe). Can be one of the ENUM_TIMEFRAMES values. 0 means the current chart period.

Return Value

If successful, it returns the opened chart ID. Otherwise returns 0.

Note

The maximum possible number of simultaneously open charts in the terminal can't exceed the CHARTS_MAX value.

ChartFirst

Returns the ID of the first chart of the client terminal.

```
long  ChartFirst();
```

Return Value

Chart ID.

ChartNext

Returns the chart ID of the chart next to the specified one.

```
long  ChartNext(
   long  chart_id      // Chart ID
   );
```

Parameters

chart_id

[in] Chart ID. 0 does not mean the current chart. 0 means "return the first chart ID".

Return Value

Chart ID. If this is the end of the chart list, it returns -1.

Example:

```
//--- variables for chart ID
   long currChart,prevChart=ChartFirst();
   int i=0,limit=100;
   Print("ChartFirst =",ChartSymbol(prevChart)," ID =",prevChart);
   while(i<limit)// We have certainly not more than 100 open charts
     {
      currChart=ChartNext(prevChart); // Get the new chart ID by using the previous ch
      if(currChart<0) break;          // Have reached the end of the chart list
      Print(i,ChartSymbol(currChart)," ID =",currChart);
      prevChart=currChart;// let's save the current chart ID for the ChartNext()
      i++;// Do not forget to increase the counter
     }
```

ChartClose

Closes the specified chart.

```
bool  ChartClose(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

If successful, returns true, otherwise false.

ChartSymbol

Returns the symbol name for the specified chart.

```
string  ChartSymbol(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

If chart does not exist, the result will be an empty string.

See also

ChartSetSymbolPeriod

ChartPeriod

Returns the timeframe period of specified chart.

```
ENUM_TIMEFRAMES  ChartPeriod(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

The function returns one of the ENUM_TIMEFRAMES values. If chart does not exist, it returns 0.

ChartRedraw

This function calls a forced redrawing of a specified chart.

```
void  ChartRedraw(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Note

Usually it is used after changing the object properties.

See also

Objects functions

ChartSetDouble

Sets a value for a corresponding property of the specified chart. Chart property should be of a double type. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetDouble(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE     prop_id,       // Property ID
   double                         value          // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. Can be one of the ENUM_CHART_PROPERTY_DOUBLE values (except the read-only properties).

value

[in] Property value.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

ChartSetInteger

Sets a value for a corresponding property of the specified chart. Chart property must be datetime, int, color, bool or char. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetInteger(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_INTEGER    prop_id,       // Property ID
   long                           value          // Value
   );
```

Sets a value for a corresponding property of the specified subwindow.

```
bool  ChartSetInteger(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_INTEGER    prop_id,       // Property ID
   int                            sub_window,    // Subwindow number
   long                           value          // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. It can be one of the ENUM_CHART_PROPERTY_INTEGER value (except the read-only properties).

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

value

[in] Property value.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

Example:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- Enabling events of mouse movements on the chart window
   ChartSetInteger(0,CHART_EVENT_MOUSE_MOVE,1);
//--- Forced updating of chart properties ensures readiness for event processing
   ChartRedraw();
  }
//+------------------------------------------------------------------+
//| MouseState                                                       |
//+------------------------------------------------------------------+
string MouseState(uint state)
  {
   string res;
   res+="\nML: "   +(((state& 1)== 1)?"DN":"UP");   // mouse left
   res+="\nMR: "   +(((state& 2)== 2)?"DN":"UP");   // mouse right
   res+="\nMM: "   +(((state&16)==16)?"DN":"UP");   // mouse middle
   res+="\nMX: "   +(((state&32)==32)?"DN":"UP");   // mouse first X key
   res+="\nMY: "   +(((state&64)==64)?"DN":"UP");   // mouse second X key
   res+="\nSHIFT: "+(((state& 4)== 4)?"DN":"UP");   // shift key
   res+="\nCTRL: " +(((state& 8)== 8)?"DN":"UP");   // control key
   return(res);
  }
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,const long &lparam,const double &dparam,const string &s
  {
   if(id==CHARTEVENT_MOUSE_MOVE)
      Comment("POINT: ",(int)lparam,",",(int)dparam,"\n",MouseState((uint)sparam));
  }
```

ChartSetString

Sets a value for a corresponding property of the specified chart. Chart property must be of the string type. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetString(
   long                          chart_id,     // Chart ID
   ENUM_CHART_PROPERTY_STRING    prop_id,      // Property ID
   string                        str_value     // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. Its value can be one of the ENUM_CHART_PROPERTY_STRING values (except the read-only properties).

str_value

[in] Property value string. String length cannot exceed 2045 characters (extra characters will be truncated).

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

ChartSetString can be used for a comment output on the chart instead of the Comment function.

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

Example:

```
void OnTick()
  {
//---
   double Ask,Bid;
```

```
   int Spread;
   Ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   Bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   Spread=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD);
   string comment=StringFormat("Выводим цены:\nAsk = %G\nBid = %G\nSpread = %d",
                               Ask,Bid,Spread);
   ChartSetString(0,CHART_COMMENT,comment);
  }
```

See also

Comment, ChartGetString

ChartGetDouble

Returns the value of a corresponding property of the specified chart. Chart property must be of double type. There are 2 variants of the function calls.

1. Returns the property value directly.

```
double  ChartGetDouble(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE    prop_id,           // Property ID
   int                           sub_window=0       // subwindow number, if necessary
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable double_var passed by reference.

```
bool  ChartGetDouble(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE    prop_id,           // Property ID
   int                           sub_window,      // Subwindow number
   double&                       double_var       // Target variable for the chart prop
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_DOUBLE values.

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

double_var

[out] Target variable of double type for the requested property.

Return Value

The value of double type.

For the second call case it returns true if the specified property is available and its value has been placed into double_var variable, otherwise returns false. To get an additional information about the error, it is necessary to call the function GetLastError().

Note

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
```

```
{
 double priceMin=ChartGetDouble(0,CHART_PRICE_MIN,0);
 double priceMax=ChartGetDouble(0,CHART_PRICE_MAX,0);
 Print("CHART_PRICE_MIN =",priceMin);
 Print("CHART_PRICE_MAX =",priceMax);
}
```

ChartGetInteger

Returns the value of a corresponding property of the specified chart. Chart property must be of datetime, int or bool type. There are 2 variants of the function calls.

1. Returns the property value directly.

```
long  ChartGetInteger(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_INTEGER   prop_id,           // Property ID
   int                           sub_window=0       // subwindow number, if necessary
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable long_var passed by reference.

```
bool  ChartGetInteger(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_INTEGER   prop_id,           // Property ID
   int                           sub_window=0       // subwindow number
   long&                         long_var           // Target variable for the propert
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_INTEGER values.

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

long_var

[out] Target variable of long type for the requested property.

Return Value

The value of long type.

For the second call case it returns true if specified property is available and its value has been stored into long_var variable, otherwise returns false. To get additional information about the error, it is necessary to call the function GetLastError().

Note

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
```

```
{
 int height=ChartGetInteger(0,CHART_HEIGHT_IN_PIXELS,0);
 int width=ChartGetInteger(0,CHART_WIDTH_IN_PIXELS,0);
 Print("CHART_HEIGHT_IN_PIXELS =",height,"pixels");
 Print("CHART_WIDTH_IN_PIXELS =",width,"pixels");
}
```

ChartGetString

Returns the value of a corresponding property of the specified chart. Chart property must be of string type. There are 2 variants of the function call.

1. Returns the property value directly.

```
string  ChartGetString(
   long                        chart_id,         // Chart ID
   ENUM_CHART_PROPERTY_STRING  prop_id           // Property ID
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable string_var passed by reference.

```
bool  ChartGetString(
   long                        chart_id,         // Chart ID
   ENUM_CHART_PROPERTY_STRING  prop_id,          // Property ID
   string&                     string_var        // Target variable for the property
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_STRING values.

string_var

[out] Target variable of string type for the requested property.

Return Value

The value of string type.

For the second call case it returns true if the specified property is available and its value has been stored into string_var variable, otherwise returns false. To get additional information about the error, it is necessary to call the function GetLastError().

Note

ChartGetString can be used for reading comments plotted on the chart using the Comment or ChartSetString functions.

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
  {
   ChartSetString(0,CHART_COMMENT,"Test comment.\nSecond line.\nThird!");
   ChartRedraw();
```

```
   Sleep(1000);
   string comm=ChartGetString(0,CHART_COMMENT);
   Print(comm);
  }
```

See also

Comment, ChartSetString

ChartNavigate

Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart.

```
bool  ChartNavigate(
   long                  chart_id,      // Chart ID
   ENUM_CHART_POSITION   position,      // Position
   int                   shift=0        // Shift value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

position

[in] Chart position to perform a shift. Can be one of the ENUM_CHART_POSITION values.

shift=0

[in] Number of bars to shift the chart. Positive value means the right shift (to the end of chart), negative value means the left shift (to the beginning of chart). The zero shift can be used to navigate to the beginning or end of chart.

Return Value

Returns true if successful, otherwise returns false.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get handle of the current chart
   long handle=ChartID();
   string comm="";
   if(handle>0) // if successful, additionally set up the chart
     {
      //--- disable auto scroll
      ChartSetInteger(handle,CHART_AUTOSCROLL,false);
      //--- set a shift from the right chart border
      ChartSetInteger(handle,CHART_SHIFT,true);
      //--- draw candlesticks
      ChartSetInteger(handle,CHART_MODE,CHART_CANDLES);
      //--- set the display mode for tick volumes
      ChartSetInteger(handle,CHART_SHOW_VOLUMES,CHART_VOLUME_TICK);

      //--- prepare a text to output in Comment()
      comm="Scroll 10 bars to the right of the history start";
      //--- show comment
```

```
   Comment(comm);
   //--- scroll 10 bars to the right of the history start
   ChartNavigate(handle,CHART_BEGIN,10);
   //--- get the number of the first bar visible on the chart (numeration like in t
   long first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   //--- add line feed character
   comm=comm+"\r\n";
   //--- add to comment
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   //--- show comment
   Comment(comm);
   //--- wait 5 seconds to see how the chart moves
   Sleep(5000);

   //--- add to the comment text
   comm=comm+"\r\n"+"Scroll 10 bars to the left of the right chart border";
   Comment(comm);
   //--- scroll 10 bars to the left of the right chart border
   ChartNavigate(handle,CHART_END,-10);
   //--- get the number of the first bar visible on the chart (numeration like in t
   first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   comm=comm+"\r\n";
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   Comment(comm);
   //--- wait 5 seconds to see how the chart moves
   Sleep(5000);

   //--- new block of chart scrolling
   comm=comm+"\r\n"+"Scroll 300 bars to the right of the history start";
   Comment(comm);
   //--- scroll 300 bars to the right of the history start
   ChartNavigate(handle,CHART_BEGIN,300);
   first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   comm=comm+"\r\n";
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   Comment(comm);
   //--- wait 5 seconds to see how the chart moves
   Sleep(5000);

   //--- new block of chart scrolling
   comm=comm+"\r\n"+"Scroll 300 bars to the left of the right chart border";
   Comment(comm);
   //--- scroll 300 bars to the left of the right chart border
   ChartNavigate(handle,CHART_END,-300);
   first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   comm=comm+"\r\n";
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   Comment(comm);
  }
```

```
}
```

ChartID

Returns the ID of the current chart.

```
long  ChartID();
```

Return Value

Value of long type.

ChartIndicatorAdd

Adds an indicator with the specified handle into a specified chart window. Indicator and chart should be generated on the same symbol and time frame.

```
bool  ChartIndicatorAdd(
   long  chart_id,                  // chart ID
   int   sub_window                 // number of the sub-window
   int   indicator_handle           // handle of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart sub-window. 0 means the main chart window. To add an indicator in a new window, the parameter must be one greater than the index of the last existing window, i.e. equal to CHART_WINDOWS_TOTAL. If the value of the parameter is greater than CHART_WINDOWS_TOTAL, a new window will not be created, and the indicator will not be added.

indicator_handle

[in] The handle of the indicator.

Return Value

The function returns true in case of success, otherwise it returns false. In order to obtain information about the error, call the GetLastError() function. Error 4114 means that a chart and an added indicator differ by their symbol or time frame.

Note

If an indicator that should be drawn in a separate subwindow (for example, built-in iMACD or a custom indicator with specified #property indicator_separate_window property) is applied to the main chart window, it may not be visible though it will still be present in the list of indicators. This means that the scale of the indicator is different from the scale of the price chart, and applied indicator's values do not fit in the displayed range of the price chart. In this case, GetLastError() returns zero code indicating the absence of an error. The values of such "invisible" indicator can be seen in Data Window and received from other MQL5 applications.

Example:

```
#property description "Expert Advisor demonstrating the work with ChartIndicatorAdd()
#property description "After launching on the chart (and receiving the error in Journa
#property description "the Expert Advisor's properties and specify correct <symbol> ar
#property description "MACD indicator will be added on the chart."

//--- input parameters
input string          symbol="AUDUSD";     // symbol name
input ENUM_TIMEFRAMES period=PERIOD_M12;   // time frame
input int     fast_ema_period=12;          // fast MACD period
input int     slow_ema_period=26;          // slow MACD period
```

```
input int      signal_period=9;           // signal period

     }
//--- Indicator added successfully
   return(true);
  }
```

See Also

ChartIndicatorDelete(), ChartIndicatorName(), ChartIndicatorsTotal(), iCustom(), IndicatorCreate()

ChartIndicatorDelete

Removes an indicator with a specified name from the specified chart window.

```
bool  ChartIndicatorDelete(
   long           chart_id,              // chart id
   int            sub_window             // number of the subwindow
   const string   indicator_shortname    // short name of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

const indicator_shortname

[in] The short name of the indicator which is set in the INDICATOR_SHORTNAME property with the IndicatorSetString() function. To get the short name of an indicator use the ChartIndicatorName() function.

Return Value

Returns true in case of successful deletion of the indicator. Otherwise it returns false. To get error details use the GetLastError() function.

Note

If two indicators with identical short names exist in the chart subwindow, the first one in a row will be deleted.

If other indicators on this chart are based on the values of the indicator that is being deleted, such indicators will also be deleted.

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions iCustom() and IndicatorCreate(). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

Deletion of an indicator from a chart doesn't mean that its calculation part will be deleted from the terminal memory. To release the indicator handle use the IndicatorRelease() function.

The indicator's short name should be formed correctly. It will be written to the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the ChartIndicatorDelete() function is identified by the short name.

Example of deleting an indicator after initialization has failed:

        }
     }
  }
```

See also

ChartIndicatorAdd(), ChartIndicatorName(), ChartIndicatorsTotal(), iCustom(), IndicatorCreate(), IndicatorSetString()

ChartIndicatorGet

Returns the handle of the indicator with the specified short name in the specified chart window.

```
int  ChartIndicatorGet(
   long           chart_id,              // Chart ID
   int            sub_window             // The number of the subwindow
   const string   indicator_shortname    // Short name of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart subwindow. 0 means the main chart window.

const indicator_shortname

[in] The short name if the indicator, which is set in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. To get the short name of an indicator, use the ChartIndicatorName() function.

Return Value

Returns an indicator handle if successful, otherwise returns INVALID_HANDLE. To get information about the error, call the GetLastError() function.

Note

The indicator handle obtained using the ChartIndicatorGet() function increases the internal indicator usage counter. The terminal runtime system keeps all indicators, whose counter is greater than zero, loaded. Therefore, the indicator handle that is no longer needed should be immediately and explicitly released using IndicatorRelease() in the same program that received it, as shown in the example below. Otherwise, it will be impossible to find the “abandoned” handle and release it from another program correctly.

When creating an indicator, be careful forming its short name, which is written in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that a short name should contain the values of input parameters of the indicator, since the indicator is identified in the ChartIndicatorGet() function based on its short name.

Another way to identify the indicator is to get a list of its parameters for a given handle using the IndicatorParameters() function and then to analyze the obtained values.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   //--- The number of windows on the chart (at least one main window is always preser
   int windows=(int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);
```

```
   //--- Check all windows
   for(int w=0;w<windows;w++)
     {
      //--- the number of indicators in this window/subwindow
      int total=ChartIndicatorsTotal(0,w);
      //--- Go through all indicators in the window
      for(int i=0;i<total;i++)
        {
         //--- get the short name of an indicator
         string name=ChartIndicatorName(0,w,i);
         //--- get the handle of an indicator
         int handle=ChartIndicatorGet(0,w,name);
         //--- Add to log
         PrintFormat("Window=%d,  index=%d,  name=%s,  handle=%d",w,i,name,handle);
         //--- You should obligatorily release the indicator handle when it is no long
         IndicatorRelease(handle);
        }
     }
  }
```

See also

ChartIndicatorAdd(), ChartIndicatorName(), ChartIndicatorsTotal(), IndicatorParameters()

ChartIndicatorName

Returns the short name of the indicator by the number in the indicators list on the specified chart window.

```
string  ChartIndicatorName(
   long  chart_id,       // chart id
   int   sub_window      // number of the subwindow
   int   index           // index of the indicator in the list of indicators added to t
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

index

[in] the index of the indicator in the list of indicators. The numeration of indicators start with zero, i.e. the first indicator in the list has the 0 index. To obtain the number of indicators in the list use the ChartIndicatorsTotal() function.

Return Value

The short name of the indicator which is set in the INDICATOR_SHORTNAME property with the IndicatorSetString() function. To get error details use the GetLastError() function.

Note

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions iCustom() and IndicatorCreate(). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

The indicator's short name should be formed correctly. It will be written to the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the ChartIndicatorDelete() function is identified by the short name.

ChartIndicatorAdd(), ChartIndicatorDelete(), ChartIndicatorsTotal(), iCustom(), IndicatorCreate(), IndicatorSetString()

ChartIndicatorsTotal

Returns the number of all indicators applied to the specified chart window.

```
int  ChartIndicatorsTotal(
   long  chart_id,       // chart id
   int   sub_window      // number of the subwindow
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

Return Value

The number of indicators in the specified chart window. To get error details use the GetLastError() function.

Note

The function allows going searching through all the indicators attached to the chart. The number of all the windows of the chart can be obtained from the CHART_WINDOWS_TOTAL property using the ChartGetInteger() function.

See also

ChartIndicatorAdd(), ChartIndicatorDelete(), iCustom(), IndicatorCreate(), IndicatorSetString()

ChartWindowOnDropped

Returns the number (index) of the chart subwindow the Expert Advisor or script has been dropped to. 0 means the main chart window.

```
int  ChartWindowOnDropped();
```

Return Value

Value of int type.

Example:

```
   int myWindow=ChartWindowOnDropped();
   int windowsTotal=ChartGetInteger(0,CHART_WINDOWS_TOTAL);
   Print("Script is running on the window #"+myWindow+
         ". Total windows on the chart "+ChartSymbol()+":",windowsTotal);
```

See also

ChartPriceOnDropped, ChartTimeOnDropped, ChartXOnDropped, ChartYOnDropped

ChartPriceOnDropped

Returns the price coordinate corresponding to the chart point the Expert Advisor or script has been dropped to.

```
double  ChartPriceOnDropped();
```

Return Value

Value of double type.

Example:

```
   double p=ChartPriceOnDropped();
   Print("ChartPriceOnDropped() = ",p);
```

See also

ChartXOnDropped, ChartYOnDropped

ChartTimeOnDropped

Returns the time coordinate corresponding to the chart point the Expert Advisor or script has been dropped to.

```
datetime  ChartTimeOnDropped();
```

Return Value

Value of datetime type.

Example:

```
   datetime t=ChartTimeOnDropped();
   Print("Script was dropped on the "+t);
```

See also

ChartXOnDropped, ChartYOnDropped

ChartXOnDropped

Returns the X coordinate of the chart point the Expert Advisor or script has been dropped to.

```
int  ChartXOnDropped();
```

Return Value

The X coordinate value.

Note

X axis direction from left to right.

Example:

```
   int X=ChartXOnDropped();
   int Y=ChartYOnDropped();
   Print("(X,Y) = ("+X+","+Y+")");
```

See also

ChartWindowOnDropped, ChartPriceOnDropped, ChartTimeOnDropped

ChartYOnDropped

Returns the Y coordinateof the chart point the Expert Advisor or script has been dropped to.

```
int  ChartYOnDropped();
```

Return Value

The Y coordinate value.

Note

Y axis direction from top to bottom.

See also

ChartWindowOnDropped, ChartPriceOnDropped, ChartTimeOnDropped

ChartSetSymbolPeriod

Changes the symbol and period of the specified chart. The function is asynchronous, i.e. it sends the command and does not wait for its execution completion. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetSymbolPeriod(
   long             chart_id,      // Chart ID
   string           symbol,        // Symbol name
   ENUM_TIMEFRAMES  period         // Period
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

symbol

[in] Chart symbol. NULL value means the current chart symbol (Expert Advisor is attached to)

period

[in] Chart period (timeframe). Can be one of the ENUM_TIMEFRAMES values. 0 means the current chart period.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The symbol/period change leads to the re-initialization of the Expert Advisor attached to a chart.

The call of ChartSetSymbolPeriod with the same symbol and timeframe can be used to update the chart (similar to the terminal's Refresh command). In its turn, the chart update triggers re-calculation of the indicators attached to it. Thus, you are able to calculate an indicator on the chart even if there are no ticks (e.g., on weekends).

See also

ChartSymbol, ChartPeriod

ChartScreenShot

The function provides a screenshot of the chart in its current state in the GIF, PNG or BMP format depending on specified extension.

```
bool  ChartScreenShot(
   long             chart_id,                  // Chart ID
   string           filename,                  // Symbol name
   int              width,                     // Width
   int              height,                    // Height
   ENUM_ALIGN_MODE  align_mode=ALIGN_RIGHT     // Alignment type
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] Screenshot file name. Cannot exceed 63 characters. Screenshot files are placed in the \Files directory.

width

[in] Screenshot width in pixels.

height

[in] Screenshot height in pixels.

align_mode=ALIGN_RIGHT

[in] Output mode of a narrow screenshot. A value of the ENUM_ALIGN_MODE enumeration. ALIGN_RIGHT means align to the right margin (the output from the end). ALIGN_LEFT means Left justify.

Return Value

Returns true if successful, otherwise false.

Note

If you need to take a screenshot from a chart from a certain position, first it's necessary to position the graph using the ChartNavigate() function. If the horizontal size of the screenshot is smaller than the chart window, either the right part of the chart window, or its left part is output, depending on the align_mode settings.

Example:

```
#property description "The Expert Advisor demonstrates how to create a series of scree
#property description "chart using the ChartScreenShot() function. For convenience, th
#property description "shown on the chart. The height and width of images is defined t

#define        WIDTH  800     // Image width to call ChartScreenShot()
#define        HEIGHT 600     // Image height to call ChartScreenShot()

Trade Functions

This is the group of functions intended for managing trading activities.

Before you proceed to study the trade functions of the platform, you must have a clear understanding of the basic terms: order, deal and position:

- An order is an instruction given to a broker to buy or sell a financial instrument. There are two main types of orders: Market and Pending. In addition, there are special Take Profit and Stop Loss levels.
- A deal is the commercial exchange (buying or selling) of a financial security. Buying is executed at the demand price (Ask), and Sell is performed at the supply price (Bid). A deal can be opened as a result of market order execution or pending order triggering. Note that in some cases, execution of an order can result in several deals.
- A position is a trade obligation, i.e. the number of bought or sold contracts of a financial instrument. A long position is financial security bought expecting the security price go higher. A short position is an obligation to supply a security expecting the price will fall in future.

General information about trading operations is available in the client terminal help.

Trading functions can be used in Expert Advisors and scripts. Trading functions can be called only if in the properties of the Expert Advisor or script the "Allow live trading" checkbox is enabled.

Trading can be allowed or prohibited depending on various factors described in the Trade Permission section.

Function	Action
OrderCalcMargin	Calculates the margin required for the specified order type, in the deposit currency
OrderCalcProfit	Calculates the profit based on the parameters passed, in the deposit currency
OrderCheck	Checks if there are enough funds to execute the required trade operation.
OrderSend	Sends trade requests to a server
OrderSendAsync	Asynchronously sends trade requests without waiting for the trade response of the trade server
PositionsTotal	Returns the number of open positions
PositionGetSymbol	Returns the symbol corresponding to the open position
PositionSelect	Chooses an open position for further working with it
PositionSelectByTicket	Selects a position to work with by the ticket number specified in it
PositionGetDouble	Returns the requested property of an open position (double)
PositionGetInteger	Returns the requested property of an open position (datetime or int)
PositionGetString	Returns the requested property of an open position (string)

Function	Action
PositionGetTicket	Returns the ticket of the position with the specified index in the list of open positions
OrdersTotal	Returns the number of orders
OrderGetTicket	Return the ticket of a corresponding order
OrderSelect	Selects a order for further working with it
OrderGetDouble	Returns the requested property of the order (double)
OrderGetInteger	Returns the requested property of the order (datetime or int)
OrderGetString	Returns the requested property of the order (string)
HistorySelect	Retrieves the history of transactions and orders for the specified period of the server time
HistorySelectByPosition	Requests the history of deals with a specified position identifier.
HistoryOrderSelect	Selects an order in the history for further working with it
HistoryOrdersTotal	Returns the number of orders in the history
HistoryOrderGetTicket	Return order ticket of a corresponding order in the history
HistoryOrderGetDouble	Returns the requested property of an order in the history (double)
HistoryOrderGetInteger	Returns the requested property of an order in the history (datetime or int)
HistoryOrderGetString	Returns the requested property of an order in the history (string)
HistoryDealSelect	Selects a deal in the history for further calling it through appropriate functions
HistoryDealsTotal	Returns the number of deals in the history
HistoryDealGetTicket	Returns a ticket of a corresponding deal in the history
HistoryDealGetDouble	Returns the requested property of a deal in the history (double)
HistoryDealGetInteger	Returns the requested property of a deal in the history (datetime or int)
HistoryDealGetString	Returns the requested property of a deal in the history (string)

OrderCalcMargin

The function calculates the margin required for the specified order type, on the current account, in the current market environment not taking into account current pending orders and open positions. It allows the evaluation of margin for the trade operation planned. The value is returned in the account currency.

```
bool  OrderCalcMargin(
   ENUM_ORDER_TYPE       action,           // type of order
   string                symbol,           // symbol name
   double                volume,           // volume
   double                price,            // open price
   double&               margin            // variable for obtaining the margin value
   );
```

Parameters

action

[in] The order type, can be one of the values of the ENUM_ORDER_TYPE enumeration.

symbol

[in] Symbol name.

volume

[in] Volume of the trade operation.

price

[in] Open price.

margin

[out] The variable, to which the value of the required margin will be written in case the function is successfully executed. The calculation is performed as if there were no pending orders and open positions on the current account. The margin value depends on many factors, and can differ in different market environments.

Return Value

The function returns true in case of success; otherwise it returns false. In order to obtain information about the error, call the GetLastError() function.

See also

OrderSend(), Order Properties, Trade Operation Types

OrderCalcProfit

The function calculates the profit for the current account, in the current market conditions, based on the parameters passed. The function is used for pre-evaluation of the result of a trade operation. The value is returned in the account currency.

```
bool  OrderCalcProfit(
   ENUM_ORDER_TYPE       action,          // type of the order (ORDER_TYPE_BUY or ORI
   string                symbol,          // symbol name
   double                volume,          // volume
   double                price_open,      // open price
   double                price_close,     // close price
   double&               profit           // variable for obtaining the profit value
   );
```

Parameters

action

[in] Type of the order, can be one of the two values of the ENUM_ORDER_TYPE enumeration: ORDER_TYPE_BUY or ORDER_TYPE_SELL.

symbol

[in] Symbol name.

volume

[in] Volume of the trade operation.

price_open

[in] Open price.

price_close

[in] Close price.

profit

[out] The variable, to which the calculated value of the profit will be written in case the function is successfully executed. The estimated profit value depends on many factors, and can differ in different market environments.

Return Value

The function returns true in case of success; otherwise it returns false. If an invalid order type is specified, the function will return false. In order to obtain information about the error, call GetLastError().

OrderSend(), Order Properties, Trade Operation Types

OrderCheck

The OrderCheck() function checks if there are enough money to execute a required trade operation. The check results are placed to the fields of the MqlTradeCheckResult structure.

```
bool  OrderCheck(
   MqlTradeRequest&        request,      // request structure
   MqlTradeCheckResult&    result        // result structure
   );
```

Parameters

request

[in] Pointer to the structure of the MqlTradeRequest type, which describes the required trade action.

result

[in,out] Pointer to the structure of the MqlTradeCheckResult type, to which the check result will be placed.

Return Value

If funds are not enough for the operation, or parameters are filled out incorrectly, the function returns false. In case of a successful basic check of structures (check of pointers), it returns true. **However, this is not an indication that the requested trade operation is sure to be successfully executed**. For a more detailed description of the function execution result, analyze the fields of the *result* structure.

In order to obtain information about the error, call the GetLastError() function.

OrderSend(), Trade Operation Types, Trade Request Structure, Structure of Request Check Results, Structure of a Trade Request Result

OrderSend

The OrderSend() function is used for executing trade operations by sending requests to a trade server.

```
bool  OrderSend(
   MqlTradeRequest&   request,      // query structure
   MqlTradeResult&    result        // structure of the answer
   );
```

Parameters

request

[in] Pointer to a structure of MqlTradeRequest type describing the trade activity of the client.

result

[in,out] Pointer to a structure of MqlTradeResult type describing the result of trade operation in case of a successful completion (if true is returned).

Return Value

In case of a successful basic check of structures (index checking) returns true. **However, this is not a sign of successful execution of a trade operation**. For a more detailed description of the function execution result, analyze the fields of *result* structure.

Note

The trade requests go through several stages of checking on a trade server. First of all, it checks if all the required fields of the *request* parameter are filled out correctly. If there are no errors, the server accepts the order for further processing. If the order is successfully accepted by the trade server, the OrderSend() function returns true.

It is recommended to check the request before sending it to a trade server. To check requests, use the OrderCheck() function. It checks if there are enough funds to execute the trade operation, and returns many useful parameters in the results of trade request checking:

- return code containing information about errors in the checked request;
- balance value that will appear after the trade operation is executed;
- equity value that will appear after the trade operation is executed;
- floating point value that will appear after the trade operation is executed;
- margin required for the trade operation;
- amount of free equity that will remain after the execution of the trade operation;
- the margin level that will be set after the trade operation is executed;
- comment to the reply code, error description.

When sending a market order (MqlTradeRequest.action=TRADE_ACTION_DEAL), the successful result of the OrderSend() function does not mean that the order has been executed (appropriate trades have been performed). In this case, 'true' means only that the order has been successfully placed in the trading system for further execution. The trade server can fill in the *deal or order* field values *in the returned* result structure, if it is aware of these data when forming a response to an OrderSend() call. Generally, event(s) of executing trades corresponding to an order may happen after sending a response to the OrderSend() call. Therefore, for any type of a trade request, when receiving the OrderSend() execution result, we should first check the *retcode* trade server response code and the

retcode_external external system response code (if necessary) available in the obtained result structure.

Each accepted order is stored on the trade server awaiting processing until one of the conditions for its execution occurs:

- expiration,
- appearance of an opposite request,
- order execution when the execution price appears,
- a request to cancel the order is received.

At the moment of the order processing, the trade server sends to the terminal a message about the occurrence of the Trade event, which can be processed by the OnTrade() function.

The result of executing the trade request on a server sent by OrderSend() function can be tracked by OnTradeTransaction handler. It should be noted that OnTradeTransaction handler will be called several times when executing one trade request.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. OnTradeTransaction function will be called for each of these events.

Example:

```
//--- value for ORDER_MAGIC
input long order_magic=55555;
//+------------------------------------------------------------------+
//| Script program start function                                    |

OrderSendAsync

The OrderSendAsync() function is used for conducting asynchronous trade operations without waiting for the trade server's response to a sent request. The function is designed for high-frequency trading, when under the terms of the trading algorithm it is unacceptable to waste time waiting for a response from the server.

```
bool  OrderSendAsync(
   MqlTradeRequest&  request,      // Request structure
   MqlTradeResult&   result        // Response structure
   );
```

Parameters

request

[in] A pointer to a structure of the MqlTradeRequest type that describes the trade action of the client.

result

[in,out] A pointer to a structure of the MqlTradeResult type that describes the result of a trade operation in case of successful execution of the function (if true is returned).

Return Value

Returns true if the request is sent to a trade server. In case the request is not sent, it returns false. In case the request is sent, in the *result* variable the response code contains TRADE_RETCODE_PLACED value (code 10008) - "order placed". Successful execution means only the fact of sending, but does not give any guarantee that the request has reached the trade server and has been accepted for processing. When processing the received request, a trade server sends a reply to a client terminal notifying of change in the current state of positions, orders and deals, which leads to the generation of the Trade event.

The result of executing the trade request on a server sent by OrderSendAsync() function can be tracked by OnTradeTransaction handler. It should be noted that OnTradeTransaction handler will be called several times when executing one trade request.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. OnTradeTransaction function will be called for each of these events. To get such a data, the function parameters should be analyzed:

- **trans** - this parameter gets MqlTradeTransaction structure describing a trade transaction applied to a trade account;
- **request** - this parameter gets MqlTradeRequest structure describing the trade request resulted in a trade transaction;
- **result** - this parameter gets MqlTradeResult structure describing a trade request execution result.

Note

In terms of purposes and parameters, the function is similar to OrderSend(), but unlike it, it is asynchronous, i.e. does not hold the program operation while waiting for the function execution result. You can compare the rate of trade operations of these two functions using the sample Expert Advisor.

Example:

```
#property description "Expert Advisor for sending trade requests "
                      " using OrderSendAsync() function.\r\n"
#property description "Handling trading events using"

12:52:52   ExpertAdvisor (EURUSD,H1)
```

PositionsTotal

Returns the number of open positions.

```
int  PositionsTotal();
```

Return Value

Value of int type.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

See also

PositionGetSymbol(), PositionSelect(), Position Properties

PositionGetSymbol

Returns the symbol corresponding to the open position and automatically selects the position for further working with it using functions PositionGetDouble, PositionGetInteger, PositionGetString.

```
string  PositionGetSymbol(
   int  index      // Number in the list of positions
   );
```

Parameters

index

[in] Number of the position in the list of open positions.

Return Value

Value of the string type. If the position was not found, an empty string will be returned. To get an error code, call the GetLastError() function.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

See also

PositionsTotal(), PositionSelect(), Position Properties

PositionSelect

Chooses an open position for further working with it. Returns true if the function is successfully completed. Returns false in case of failure. To obtain information about the error, call GetLastError().

```
bool  PositionSelect(
   string  symbol      // Symbol name
   );
```

Parameters

symbol

[in] Name of the financial security.

Return Value

Value of the bool type.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol. In this case, PositionSelect will select a position with the lowest ticket.

Function PositionSelect() copies data about a position into the program environment, and further calls of PositionGetDouble(), PositionGetInteger() and PositionGetString() return the earlier copied data. This means that the position itself may no longer exist (or its volume, direction, etc. has changed), but data of this position still can be obtained. To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

See also

PositionGetSymbol(), PositionsTotal(), Position Properties

PositionSelectByTicket

Selects an open position to work with based on the ticket number specified in the position. If successful, returns true. Returns false if the function failed. Call GetLastError() for error details.

```
bool  PositionSelectByTicket(
   ulong   ticket     // Position ticket
   );
```

Parameters

ticket

[in] Position ticket.

Return Value

A value of the bool type.

Note

The PositionSelectByTicket() function copies position data to the program environment. Further calls of PositionGetDouble(), PositionGetInteger() and PositionGetString() return the previously copied data. Even if a position does not exist already (or its size, direction etc. has changed), the data may still be received sometimes. To make sure that you receive valid position data, it is recommended to call PositionSelectByTicket() before you access the data.

See also

PositionGetSymbol(), PositionsTotal(), Position Properties

PositionGetDouble

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  PositionGetDouble(
   ENUM_POSITION_PROPERTY_DOUBLE  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variable passed by reference by the last parameter.

```
bool  PositionGetDouble(
   ENUM_POSITION_PROPERTY_DOUBLE  property_id,     // Property identifier
   double&                        double_var       // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type, accepting the value of the requested property.

Return Value

Value of the double type. If the function fails, 0 is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

PositionGetSymbol(), PositionSelect(), Position Properties

PositionGetInteger

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property should be of datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  PositionGetInteger(
   ENUM_POSITION_PROPERTY_INTEGER  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variables passed by reference by the last parameter.

```
bool  PositionGetInteger(
   ENUM_POSITION_PROPERTY_INTEGER  property_id,     // Property identifier
   long&                           long_var         // Here we accept the property val
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type accepting the value of the requested property.

Return Value

Value of the long type. If the function fails, 0 is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

void OnTrade()
  {
//--- check if a position is present and display the time of its changing
```

```
   if(PositionSelect(_Symbol))
     {
//--- receive position ID for further work
      ulong position_ID=PositionGetInteger(POSITION_IDENTIFIER);
      Print(_Symbol," position #",position_ID);
//--- receive the time of position forming in milliseconds since 01.01.1970
      long create_time_msc=PositionGetInteger(POSITION_TIME_MSC);
      PrintFormat("Position #%d  POSITION_TIME_MSC = %i64 milliseconds => %s",positior
                  create_time_msc,TimeToString(create_time_msc/1000));
//--- receive the time of the position's last change in seconds since 01.01.1970
      long update_time_sec=PositionGetInteger(POSITION_TIME_UPDATE);
      PrintFormat("Position #%d  POSITION_TIME_UPDATE = %i64 seconds => %s",
                  position_ID,update_time_sec,TimeToString(update_time_sec));
//--- receive the time of the position's last change in milliseconds since 01.01.1970
      long update_time_msc=PositionGetInteger(POSITION_TIME_UPDATE_MSC);
      PrintFormat("Position #%d  POSITION_TIME_UPDATE_MSC = %i64 milliseconds => %s",
                  position_ID,update_time_msc,TimeToString(update_time_msc/1000));
     }
//---
  }
```

PositionGetSymbol(), PositionSelect(), Position Properties

PositionGetString

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property should be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  PositionGetString(
   ENUM_POSITION_PROPERTY_STRING  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variables passed by reference by the last parameter.

```
bool  PositionGetString(
   ENUM_POSITION_PROPERTY_STRING  property_id,     // Property identifier
   string&                        string_var       // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type accepting the value of the requested property.

Return Value

Value of the string type. If the function fails, an empty string is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

See also

PositionGetSymbol(), PositionSelect(), Position Properties

PositionGetTicket

The function returns the ticket of a position with the specified index in the list of open positions and automatically selects the position to work with using functions PositionGetDouble, PositionGetInteger, PositionGetString.

```
ulong  PositionGetTicket(
   int  index      // The number of a position in the list
   );
```

Parameters

index

[in] The index of a position in the list of open positions, numeration starts with 0.

Return Value

The ticket of the position. Returns 0 if the function fails.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

See also

PositionGetSymbol(), PositionSelect(), Position Properties

OrdersTotal

Returns the number of current orders.

```
int  OrdersTotal();
```

Return Value

Value of the int type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal. An order is a request to conduct a transaction, while a position is a result of one or more deals.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

OrderSelect(), OrderGetTicket(), Order Properties

OrderGetTicket

Returns ticket of a corresponding order and automatically selects the order for further working with it using functions.

```
ulong  OrderGetTicket(
   int  index      // Number in the list of orders
   );
```

Parameters

index

[in] Number of an order in the list of current orders.

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal. An order is a request to conduct a transaction, while a position is a result of one or more deals.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Function OrderGetTicket() copies data about an order into the program environment, and further calls of OrderGetDouble(), OrderGetInteger(), OrderGetString() return the earlier copied data. This means that the order itself may no longer exist (or its open price, Stop Loss/Take Profit levels or expiration has changed), but data of this order still can be obtained. To ensure receipt of fresh data about an order, it is recommended to call OrderGetTicket() right before referring to them.

Example:

```
void OnStart()
  {
//--- variables for returning values from order properties
   ulong    ticket;
   double   open_price;
   double   initial_volume;
   datetime time_setup;
   string   symbol;
   string   type;
   long     order_magic;
   long     positionID;
//--- number of current pending orders
   uint     total=OrdersTotal();
```

```
//--- go through orders in a loop
   for(uint i=0;i<total;i++)
     {
      //--- return order ticket by its position in the list
      if((ticket=OrderGetTicket(i))>0)
        {
         //--- return order properties
         open_price    =OrderGetDouble(ORDER_PRICE_OPEN);
         time_setup    =(datetime)OrderGetInteger(ORDER_TIME_SETUP);
         symbol        =OrderGetString(ORDER_SYMBOL);
         order_magic   =OrderGetInteger(ORDER_MAGIC);
         positionID    =OrderGetInteger(ORDER_POSITION_ID);
         initial_volume=OrderGetDouble(ORDER_VOLUME_INITIAL);
         type          =EnumToString(ENUM_ORDER_TYPE(OrderGetInteger(ORDER_TYPE)));
         //--- prepare and show information about the order
         printf("#ticket %d %s %G %s at %G was set up at %s",
                ticket,                  // order ticket
                type,                    // type
                initial_volume,          // placed volume
                symbol,                  // symbol
                open_price,              // specified open price
                TimeToString(time_setup)// time of order placing
                );
        }
     }
//---
  }
```

See also

OrdersTotal(), OrderSelect(), OrderGetInteger()

OrderSelect

Selects an order to work with. Returns true if the function has been successfully completed. Returns false if the function completion has failed. For more information about an error call GetLastError().

```
bool  OrderSelect(
   ulong   ticket      // Order ticket
   );
```

Parameters

ticket

[in] Order ticket.

Return Value

Value of the bool type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Function OrderSelect() copies data about an order into the program environment, and further calls of OrderGetDouble(), OrderGetInteger(), OrderGetString() return the earlier copied data. This means that the order itself may no longer exist (or its open price, Stop Loss/Take Profit levels or expiration has changed), but data of this order still can be obtained. To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

OrderGetInteger(), OrderGetDouble(), OrderGetString(), OrderCalcProfit(), OrderGetTicket(), Order Properties

OrderGetDouble

Returns the requested property of an order, pre-selected using OrderGetTicket or OrderSelect. The order property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  OrderGetDouble(
   ENUM_ORDER_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable passed by reference by the last parameter.

```
bool  OrderGetDouble(
   ENUM_ORDER_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                     double_var         // Here we accept the property va
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

OrdersTotal(), OrderGetTicket(), Order Properties

OrderGetInteger

Returns the requested order property, pre-selected using OrderGetTicket or OrderSelect. Order property must be of the datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  OrderGetInteger(
   ENUM_ORDER_PROPERTY_INTEGER  property_id        // Property identifier
   );
```

2. Returns true or false depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  OrderGetInteger(
   ENUM_ORDER_PROPERTY_INTEGER  property_id,       // Property identifier
   long&                        long_var           // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

OrdersTotal(), OrderGetTicket(), Order Properties

OrderGetString

Returns the requested order property, pre-selected using OrderGetTicket or OrderSelect. The order property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  OrderGetString(
   ENUM_ORDER_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  OrderGetString(
   ENUM_ORDER_PROPERTY_STRING  property_id,       // Property identifier
   string&                     string_var        // Here we accept the property value
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type that accepts the value of the requested property.

Return Value

Value of the string type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

OrdersTotal(), OrderGetTicket(), Order Properties

HistorySelect

Retrieves the history of deals and orders for the specified period of server time.

```
bool  HistorySelect(
   datetime  from_date,      // From date
   datetime  to_date         // To date
   );
```

Parameters

from_date

[in] Start date of the request.

to_date

[in] End date of the request.

Return Value

It returns true if successful, otherwise returns false.

Note

HistorySelect() creates a list of orders and a list of trades in a mql5-program, for further referring to the list elements using corresponding functions. The deals list size can be returned using the HistoryDealsTotal() function; the size of the list of orders in the history can be obtained using HistoryOrdersTotal(). Selection in the list of orders should be better performed by HistoryOrderGetTicket(), for items in the list of deals HistoryDealGetTicket() suits better.

After using HistoryOrderSelect(), the list of history orders available to the mql5 program is reset and filled again by the found order, if the search of an order by the ticket has been completed successfully. The same applies to the list of deals available to the mql5 program - it is reset by HistoryDealSelect() and filled again in case of a successful receipt of a deal by ticket number.

Example:

```
void OnStart()
  {
   color BuyColor =clrBlue;
   color SellColor=clrRed;
//--- request trade history
   HistorySelect(0,TimeCurrent());
//--- create objects
   string   name;
   uint     total=HistoryDealsTotal();
   ulong    ticket=0;
   double   price;
   double   profit;
   datetime time;
   string   symbol;
   long     type;
   long     entry;
//--- for all deals
```

```
   for(uint i=0;i<total;i++)
     {
      //--- try to get deals ticket
      if((ticket=HistoryDealGetTicket(i))>0)
        {
         //--- get deals properties
         price =HistoryDealGetDouble(ticket,DEAL_PRICE);
         time  =(datetime)HistoryDealGetInteger(ticket,DEAL_TIME);
         symbol=HistoryDealGetString(ticket,DEAL_SYMBOL);
         type  =HistoryDealGetInteger(ticket,DEAL_TYPE);
         entry =HistoryDealGetInteger(ticket,DEAL_ENTRY);
         profit=HistoryDealGetDouble(ticket,DEAL_PROFIT);
         //--- only for current symbol
         if(price && time && symbol==Symbol())
           {
            //--- create price object
            name="TradeHistory_Deal_"+string(ticket);
            if(entry) ObjectCreate(0,name,OBJ_ARROW_RIGHT_PRICE,0,time,price,0,0);
            else      ObjectCreate(0,name,OBJ_ARROW_LEFT_PRICE,0,time,price,0,0);
            //--- set object properties
            ObjectSetInteger(0,name,OBJPROP_SELECTABLE,0);
            ObjectSetInteger(0,name,OBJPROP_BACK,0);
            ObjectSetInteger(0,name,OBJPROP_COLOR,type?BuyColor:SellColor);
            if(profit!=0) ObjectSetString(0,name,OBJPROP_TEXT,"Profit: "+string(profit
           }
        }
     }
//--- apply on chart
   ChartRedraw();
  }
```

See also

HistoryOrderSelect(), HistoryDealSelect()

HistorySelectByPosition

Retrieves the history of deals and orders having the specified position identifier.

```
bool  HistorySelectByPosition(
   long   position_id     // position identifier - POSITION_IDENTIFIER
   );
```

Parameters

position_id

[in] Position identifier that is set to every executed order and every deal.

Return Value

It returns true if successful, otherwise returns false.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistorySelectByPosition() creates in a mql5 program a list of orders and a list of deals with a specified position identifier for further reference to the elements of the list using the appropriate functions. To know the size of the list of deals, use function HistoryDealsTotal(), the size of the list of orders in the history can be obtained using HistoryOrdersTotal(). To run through elements of the orders list, use HistoryOrderGetTicket(), for elements of the deals list - HistoryDealGetTicket().

After using HistoryOrderSelect(), list of history orders available to the mql5 program is reset and filled again with the found order, if search of an order by its ticket was successful. The same refers to the list of deals available to the mql5 program - it is reset by function HistoryDealSelect() and is filled out again if a deal was found successfully by the ticket number.

See also

HistorySelect(), HistoryOrderGetTicket(), Order Properties

HistoryOrderSelect

Selects an order from the history for further calling it through appropriate functions. It returns true if the function has been successfully completed. Returns false if the function has failed. For more details on error call GetLastError().

```
bool  HistoryOrderSelect(
   ulong  ticket      // Order ticket
   );
```

Parameters

ticket

[in] Order ticket.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistoryOrderSelect() clears in a mql5-program the list of orders from a history, available for calls, and copies to it a single order, if the execution of HistoryOrderSelect () has been completed successfully. If you need to go through all orders selected by HistorySelect(), you should better use HistoryOrderGetTicket().

See also

HistorySelect(), HistoryOrderGetTicket(), Order Properties

HistoryOrdersTotal

Returns the number of orders in the history. Prior to calling HistoryOrdersTotal(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
int  HistoryOrdersTotal();
```

Return Value

Value of the int type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

See also

HistorySelect(), HistoryOrderSelect(), HistoryOrderGetTicket(), Order Properties

HistoryOrderGetTicket

Return the ticket of a corresponding order in the history. Prior to calling HistoryOrderGetTicket(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
ulong  HistoryOrderGetTicket(
   int  index      // Number in the list of orders
   );
```

Parameters

index

[in] Number of the order in the list of orders.

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
void OnStart()
  {
   datetime from=0;
   datetime to=TimeCurrent();
//--- request the entire history
   HistorySelect(from,to);
//--- variables for returning values from order properties
   ulong    ticket;
   double   open_price;
   double   initial_volume;
   datetime time_setup;
   datetime time_done;
   string   symbol;
   string   type;
   long     order_magic;
   long     positionID;
//--- number of current pending orders
   uint     total=HistoryOrdersTotal();
//--- go through orders in a loop
   for(uint i=0;i<total;i++)
     {
      //--- return order ticket by its position in the list
      if((ticket=HistoryOrderGetTicket(i))>0)
        {
         //--- return order properties
```

```
         open_price    =HistoryOrderGetDouble(ticket,ORDER_PRICE_OPEN);
         time_setup    =(datetime)HistoryOrderGetInteger(ticket,ORDER_TIME_SETUP);
         time_done     =(datetime)HistoryOrderGetInteger(ticket,ORDER_TIME_DONE);
         symbol        =HistoryOrderGetString(ticket,ORDER_SYMBOL);
         order_magic   =HistoryOrderGetInteger(ticket,ORDER_MAGIC);
         positionID    =HistoryOrderGetInteger(ticket,ORDER_POSITION_ID);
         initial_volume=HistoryOrderGetDouble(ticket,ORDER_VOLUME_INITIAL);
         type          =GetOrderType(HistoryOrderGetInteger(ticket,ORDER_TYPE));
         //--- prepare and show information about the order
         printf("#ticket %d %s %G %s at %G was set up at %s => done at %s, pos ID=%d",
                ticket,                   // order ticket
                type,                     // type
                initial_volume,           // placed volume
                symbol,                   // symbol
                open_price,               // specified open price
                TimeToString(time_setup),// time of order placing
                TimeToString(time_done), // time of order execution or deletion
                positionID                // ID of a position , to which the deal of th
                );
        }
     }
//---
  }
//+------------------------------------------------------------------+
//| Returns the string name of the order type                        |
//+------------------------------------------------------------------+
string GetOrderType(long type)
  {
   string str_type="unknown operation";
   switch(type)
     {
      case (ORDER_TYPE_BUY):             return("buy");
      case (ORDER_TYPE_SELL):            return("sell");
      case (ORDER_TYPE_BUY_LIMIT):       return("buy limit");
      case (ORDER_TYPE_SELL_LIMIT):      return("sell limit");
      case (ORDER_TYPE_BUY_STOP):        return("buy stop");
      case (ORDER_TYPE_SELL_STOP):       return("sell stop");
      case (ORDER_TYPE_BUY_STOP_LIMIT): return("buy stop limit");
      case (ORDER_TYPE_SELL_STOP_LIMIT):return("sell stop limit");
     }
   return(str_type);
  }
```

HistorySelect(), HistoryOrdersTotal(), HistoryOrderSelect(), Order Properties

HistoryOrderGetDouble

Returns the requested order property. The order property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  HistoryOrderGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                    double_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistorySelect(), HistoryOrdersTotal(), HistoryOrderSelect(), Order Properties

HistoryOrderGetInteger

Returns the requested property of an order. The order property must be of datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  HistoryOrderGetInteger(
   ulong                          ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_INTEGER    property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetInteger(
   ulong                          ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_INTEGER    property_id,       // Property identifier
   long&                          long_var           // Here we accept the property valu
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
//+------------------------------------------------------------------+
//| Trade function                                                   |
//+------------------------------------------------------------------+
void OnTrade()
  {
//--- receive the last order's ticket from week's trading history
   ulong last_order=GetLastOrderTicket();
   if(HistoryOrderSelect(last_order))
```

```
     {
      //--- time of placing an order in milliseconds since 01.01.1970
      long time_setup_msc=HistoryOrderGetInteger(last_order,ORDER_TIME_SETUP_MSC);
      PrintFormat("Order #%d ORDER_TIME_SETUP_MSC=%i64 => %s",
                  last_order,time_setup_msc,TimeToString(time_setup_msc/1000));
      //--- order execution/cancellation time in milliseconds since 01.01.1970
      long  time_done_msc=HistoryOrderGetInteger(last_order,ORDER_TIME_DONE_MSC);
      PrintFormat("Order #%d ORDER_TIME_DONE_MSC=%i64 => %s",
                  last_order,time_done_msc,TimeToString(time_done_msc/1000));
     }
   else // notify on failure
      PrintFormat("HistoryOrderSelect() failed for #%d. Eror code=%d",
                  last_order,GetLastError());

//---
  }
//+------------------------------------------------------------------+
//| Returns the last order ticket in history or -1                   |
//+------------------------------------------------------------------+
ulong GetLastOrderTicket()
  {
//--- request history for the last 7 days
   if(!GetTradeHistory(7))
     {
      //--- notify on unsuccessful call and return -1
      Print(__FUNCTION__," HistorySelect() returned false");
      return -1;
     }
//---
   ulong first_order,last_order,orders=HistoryOrdersTotal();
//--- work with orders if there are any
   if(orders>0)
     {
      Print("Orders = ",orders);
      first_order=HistoryOrderGetTicket(0);
      PrintFormat("first_order = %d",first_order);
      if(orders>1)
        {
         last_order=HistoryOrderGetTicket((int)orders-1);
         PrintFormat("last_order = %d",last_order);
         return last_order;
        }
      return first_order;
     }
//--- no order found, return -1
   return -1;
  }
//+------------------------------------------------------------------------+
//| Requests history for the last days and returns false in case of failure  |
```

```
//+------------------------------------------------------------------------------+
bool GetTradeHistory(int days)
  {
//--- set a week period to request trade history
   datetime to=TimeCurrent();
   datetime from=to-days*PeriodSeconds(PERIOD_D1);
   ResetLastError();
//--- make a request and check the result
   if(!HistorySelect(from,to))
     {
      Print(__FUNCTION__," HistorySelect=false. Error code=",GetLastError());
      return false;
     }
//--- history received successfully
   return true;
  }
```

HistorySelect(), HistoryOrdersTotal(), HistoryOrderSelect(), Order Properties

HistoryOrderGetString

Returns the requested property of an order. The order property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  HistoryOrderGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_STRING  property_id,       // Property identifier
   string&                    string_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type.

Return Value

Value of the string type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistorySelect(), HistoryOrdersTotal(), HistoryOrderSelect(), Order Properties

HistoryDealSelect

Selects a deal in the history for further calling it through appropriate functions. It returns true if the function has been successfully completed. Returns false if the function has failed. For more details on error call GetLastError().

```
bool  HistoryDealSelect(
   ulong  ticket      // Deal ticket
   );
```

Parameters

ticket

[in] Deal ticket.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

HistoryDealSelect() clears in a mql5-program the list of deals available for reference, and copies the single deal, if the execution of HistoryDealSelect() has been completed successfully. If you need to go through all deals selected by the HistorySelect() function, you should better use HistoryDealGetTicket().

See also

HistorySelect(), HistoryDealGetTicket(), Deal Properties

HistoryDealsTotal

Returns the number of deal in history. Prior to calling HistoryDealsTotal(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
int  HistoryDealsTotal();
```

Return Value

Value of the int type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

See also

HistorySelect(), HistoryDealGetTicket(), Deal Properties

HistoryDealGetTicket

The function selects a deal for further processing and returns the deal ticket in history. Prior to calling HistoryDealGetTicket(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
ulong  HistoryDealGetTicket(
   int  index      // ticket deal
   );
```

Parameters

index

[in] Number of a deal in the list of deals

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
void OnStart()
  {
   ulong deal_ticket;            // deal ticket
   ulong order_ticket;           // ticket of the order the deal was executed on
   datetime transaction_time;    // time of a deal execution
   long deal_type ;              // type of a trade operation
   long position_ID;             // position ID
   string deal_description;      // operation description
   double volume;                // operation volume
   string symbol;                // symbol of the deal
//--- set the start and end date to request the history of deals
   datetime from_date=0;         // from the very beginning
   datetime to_date=TimeCurrent();// till the current moment
//--- request the history of deals in the specified period
   HistorySelect(from_date,to_date);
//--- total number in the list of deals
   int deals=HistoryDealsTotal();
//--- now process each trade
   for(int i=0;i<deals;i++)
     {
      deal_ticket=               HistoryDealGetTicket(i);
      volume=                    HistoryDealGetDouble(deal_ticket,DEAL_VOLUME);
      transaction_time=(datetime)HistoryDealGetInteger(deal_ticket,DEAL_TIME);
      order_ticket=              HistoryDealGetInteger(deal_ticket,DEAL_ORDER);
      deal_type=                 HistoryDealGetInteger(deal_ticket,DEAL_TYPE);
      symbol=                    HistoryDealGetString(deal_ticket,DEAL_SYMBOL);
```

```
      position_ID=              HistoryDealGetInteger(deal_ticket,DEAL_POSITION_ID);
      deal_description=         GetDealDescription(deal_type,volume,symbol,order_tic
      //--- perform fine formatting for the deal number
      string print_index=StringFormat("% 3d",i);
      //--- show information on the deal
      Print(print_index+": deal #",deal_ticket," at ",transaction_time,deal_descriptio
     }
  }
//+------------------------------------------------------------------+
//| Returns the string description of the operation                  |

HistoryDealGetDouble

Returns the requested property of a deal. The deal property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  HistoryDealGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                    double_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Deal ticket.

property_id

[in] Identifier of a deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

HistorySelect(), HistoryDealsTotal(), HistoryDealGetTicket(), Deal Properties

HistoryDealGetInteger

Returns the requested property of a deal. The deal property must be of the datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  HistoryDealGetInteger(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_INTEGER property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetInteger(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_INTEGER property_id,       // Property identifier
   long&                      long_var           // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Trade ticket.

property_id

[in] Identifier of the deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
//+------------------------------------------------------------------+
//| Trade function                                                   |
//+------------------------------------------------------------------+
void OnTrade()
  {
//--- receive the last deal's ticket from week's trading history
   ulong last_deal=GetLastDealTicket();
   if(HistoryDealSelect(last_deal))
     {
```

```
      //--- time of deal execution in milliseconds since 01.01.1970
      long deal_time_msc=HistoryDealGetInteger(last_deal,DEAL_TIME_MSC);
      PrintFormat("Deal #%d DEAL_TIME_MSC=%i64 => %s",
                  last_deal,deal_time_msc,TimeToString(deal_time_msc/1000));
     }
   else
      PrintFormat("HistoryDealSelect() failed for #%d. Eror code=%d",
                  last_deal,GetLastError());
//---
  }
//+------------------------------------------------------------------+
//| Returns the last deal ticket in history or -1                    |
//+------------------------------------------------------------------+
ulong GetLastDealTicket()
  {
//--- request history for the last 7 days

HistoryDealGetString

Returns the requested property of a deal. The deal property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  HistoryDealGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_STRING  property_id,       // Property identifier
   string&                    string_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Deal ticket.

property_id

[in] Identifier of the deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type that accepts the value of the requested property.

Return Value

Value of the string type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Trade Signals

This is the group of functions intended for managing trade signals. The functions allow:

- get information about trade signals, available for copying,
- get and set the signal copy settings,
- subscribe and unsubscribe to the signal copying using MQL5 language functions.

Function	Action
SignalBaseGetDouble	Returns the value of double type property for selected signal
SignalBaseGetInteger	Returns the value of integer type property for selected signal
SignalBaseGetString	Returns the value of string type property for selected signal
SignalBaseSelect	Selects a signal from signals, available in terminal for further working with it
SignalBaseTotal	Returns the total amount of signals, available in terminal
SignalInfoGetDouble	Returns the value of double type property of signal copy settings
SignalInfoGetInteger	Returns the value of integer type property of signal copy settings
SignalInfoGetString	Returns the value of string type property of signal copy settings
SignalInfoSetDouble	Sets the value of double type property of signal copy settings
SignalInfoSetInteger	Sets the value of integer type property of signal copy settings
SignalSubscribe	Subscribes to the trading signal
SignalUnsubscribe	Cancels subscription

SignalBaseGetDouble

Returns the value of double type property for selected signal.

```
double  SignalBaseGetDouble(
   ENUM_SIGNAL_BASE_DOUBLE     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_DOUBLE enumeration.

Return Value

The value of double type property of the selected signal.

SignalBaseGetInteger

Returns the value of integer type property for selected signal.

```
long  SignalBaseGetInteger(
   ENUM_SIGNAL_BASE_INTEGER     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_INTEGER enumeration.

Return Value

The value of integer type property of the selected signal.

SignalBaseGetString

Returns the value of string type property for selected signal.

```
string  SignalBaseGetString(
   ENUM_SIGNAL_BASE_STRING     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_STRING enumeration.

Return Value

The value of string type property of the selected signal.

SignalBaseSelect

Selects a signal from signals, available in terminal for further working with it.

```
bool  SignalBaseSelect(
   int      index     // signal index
   );
```

Parameters

index

[in] Signal index in base of trading signals.

Return Value

Returns true if successful, otherwise returns false. To read more about the error call GetLastError().

Example:

```
void OnStart()
  {
//--- get total amount of signals in the terminal
   int total=SignalBaseTotal();
//--- process all signals
   for(int i=0;i<total;i++)
     {
      //--- select the signal by index
      if(SignalBaseSelect(i))
        {
         //--- get signal properties
         long   id    =SignalBaseGetInteger(SIGNAL_BASE_ID);           // signal id
         long   pips  =SignalBaseGetInteger(SIGNAL_BASE_PIPS);         // profit in pi
         long   subscr=SignalBaseGetInteger(SIGNAL_BASE_SUBSCRIBERS); // number of su
         string name  =SignalBaseGetString(SIGNAL_BASE_NAME);          // signal name
         double price =SignalBaseGetDouble(SIGNAL_BASE_PRICE);         // signal price
         string curr  =SignalBaseGetString(SIGNAL_BASE_CURRENCY);      // signal curre
         //--- print all profitable free signals with subscribers
         if(price==0.0 && pips>0 && subscr>0)
            PrintFormat("id=%d, name=\"%s\", currency=%s, pips=%d, subscribers=%d",id,
        }
      else PrintFormat("Error in call of SignalBaseSelect. Error code=%d",GetLastErro
     }
  }
```

SignalBaseTotal

Returns the total amount of signals, available in terminal.

```
int  SignalBaseTotal();
```

Return Value

The total amount of signals, available in terminal.

SignalInfoGetDouble

Returns the value of double type property of signal copy settings.

```
double  SignalInfoGetDouble(
   ENUM_SIGNAL_INFO_DOUBLE     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_DOUBLE enumeration.

Return Value

The value of double type property of signal copy settings.

SignalInfoGetInteger

Returns the value of integer type property of signal copy settings.

```
long  SignalInfoGetInteger(
   ENUM_SIGNAL_INFO_INTEGER     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_INTEGER enumeration.

Return Value

The value of integer type property of signal copy settings.

SignalInfoGetString

Returns the value of string type property of signal copy settings.

```
string  SignalInfoGetString(
   ENUM_SIGNAL_INFO_STRING     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_STRING enumeration.

Return Value

The value of string type property of signal copy settings.

SignalInfoSetDouble

Sets the value of double type property of signal copy settings.

```
bool  SignalInfoSetDouble(
   ENUM_SIGNAL_INFO_DOUBLE      property_id,      // property identifier
   double                       value             // new value
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_DOUBLE enumeration.

value

[in] The value of signal copy settings property.

Return Value

Returns true if property has been changed, otherwise returns false. To read more about the error call GetLastError().

SignalInfoSetInteger

Sets the value of integer type property of signal copy settings.

```
bool  SignalInfoSetInteger(
   ENUM_SIGNAL_INFO_INTEGER     property_id,     // property identifier
   long                         value            // new value
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_INTEGER enumeration.

value

[in] The value of signal copy settings property.

Return Value

Returns true if property has been changed, otherwise returns false. To read more about the error call GetLastError().

SignalSubscribe

Subscribes to the trading signal.

```
bool  SignalSubscribe(
   long     signal_id     // signal id
   );
```

Parameters

signal_id

[in] Signal identifier.

Return Value

Returns true if subscription was successful, otherwise returns false. To read more about the error call GetLastError().

SignalUnsubscribe

Cancels subscription.

```
bool  SignalUnsubscribe();
```

Return Value

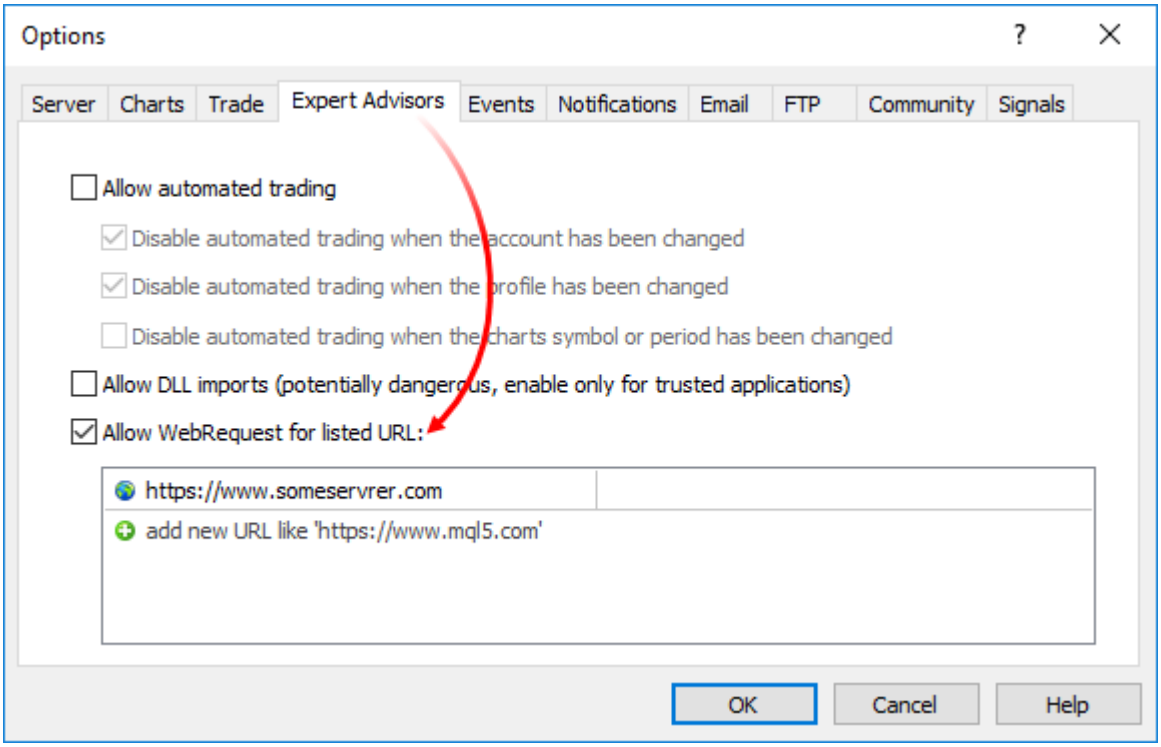
Returns true if subscription has been canceled successfully, otherwise returns false. To read more about the error call GetLastError().

Network functions

MQL5 programs can exchange data with remote servers, as well as send push notifications, emails and data via FTP.

- The Socket* group of functions allows establishing a TCP connection (including a secure TLS) with a remote host via system sockets. The operation principle is simple: create a socket, connect to the server and start reading and writing data.
- The WebRequest function is designed to work with web resources and allows sending HTTP requests (including GET and POST) easily.
- SendFTP, SendMail and SendNotification are more simple functions for sending files, emails and mobile notifications.

For end-user security, the list of allowed IP addresses is implemented on the client terminal side. The list contains IP addresses the MQL5 program is allowed to connect to via the Socket* and WebRequest functions. For example, if the program needs to connect to https://www.someserver.com, this address should be explicitly indicated by a terminal user in the list. An address cannot be added programmatically.



Add an explicit message to the MQL5 program to notify a user of the need for additional configuration. You can do that via #property description, Alert or Print.

Function	Action
SocketCreate	Create a socket with specified flags and return its handle
SocketClose	Close a socket
SocketConnect	Connect to the server with timeout control
SocketIsConnected	Checks if the socket is currently connected

Function	Action
SocketIsReadable	Get a number of bytes that can be read from a socket
SocketIsWritable	Check whether data can be written to a socket at the current time
SocketTimeouts	Set timeouts for receiving and sending data for a socket system object
SocketRead	Read data from a socket
SocketSend	Write data to a socket
SocketTlsHandshake	Initiate secure TLS (SSL) connection to a specified host via TLS Handshake protocol
SocketTlsCertificate	Get data on the certificate used to secure network connection
SocketTlsRead	Read data from secure TLS connection
SocketTlsReadAvailable	Read all available data from secure TLS connection
SocketTlsSend	Send data via secure TLS connection
WebRequest	Send an HTTP request to a specified server
SendFTP	Send a file to an address specified on the FTP tab
SendMail	Send an email to an address specified in the Email tab of the options window
SendNotification	Send push notifications to mobile terminals whose MetaQuotes IDs are specified in the Notifications tab

SocketCreate

Create a socket with specified flags and return its handle.

```
int  SocketCreate(
   uint     flags          // flags
   );
```

Parameters

flags

[in] Combination of flags defining the mode of working with a socket. Currently, only one flag is supported — SOCKET_DEFAULT.

Return Value

In case of a successful socket creation, return its handle, otherwise INVALID_HANDLE.

Notes

To free up computer memory from an unused socket, call SocketClose for it.

You can create a maximum of 128 sockets from one MQL5 program. If the limit is exceeded, the error 5271 (ERR_NETSOCKET_TOO_MANY_OPENED) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

         if(HTTPSend(socket,"GET / HTTP/1.1\r\nHost: www.mql5.com\r\nUser-Agent: MT5\r
           {
            Print("GET request sent");
            //--- read the response
            if(!HTTPRecv(socket,1000))
               Print("Failed to get a response, error ",GetLastError());
           }
         else
            Print("Failed to send GET request, error ",GetLastError());
        }
      else
        {
         Print("Connection to ",Address,":",Port," failed, error ",GetLastError());
        }
      //--- close a socket after using
      SocketClose(socket);
     }
   else
      Print("Failed to create a socket, error ",GetLastError());
  }
//+------------------------------------------------------------------+
```

SocketClose

Close a socket.

```
bool  SocketClose(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Handle of a socket to be closed. The handle is returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

Return Value

Returns true if successful, otherwise false.

Note

If a connection via SocketConnect was previously created for a socket, it is discontinued.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketExample.mq5 |

         //--- send GET request to the server
         if(HTTPSend(socket,"GET / HTTP/1.1\r\nHost: www.mql5.com\r\nUser-Agent: MT5\r
           {
            Print("GET request sent");
            //--- read the response
            if(!HTTPRecv(socket,1000))
               Print("Failed to get a response, error ",GetLastError());
           }
         else
            Print("Failed to send GET request, error ",GetLastError());
        }
      else
        {
         Print("Connection to ",Address,":",Port," failed, error ",GetLastError());
        }
      //--- close a socket after using
      SocketClose(socket);
     }
   else
      Print("Failed to create a socket, error ",GetLastError());
  }
//+------------------------------------------------------------------+
```

SocketConnect

Connect to the server with timeout control.

```
bool  SocketConnect(
   int           socket,               // socket
   const string  server,               // connection address
   uint          port,                 // connection port
   uint          timeout_receive_ms    // connection timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

server

[in] Domain name of the server you want to connect to or its IP address.

port

[in] Connection port number.

timeout_receive_ms

[in] Connection timeout in milliseconds. If connection is not established within that time interval, attempts are stopped.

Return Value

If connection is successful, return true, otherwise false.

Note

Connection address should be added to the list of allowed ones on the client terminal side (Tools \ Options \ Expert Advisors).

If connection fails, error 5272 (ERR_NETSOCKET_CANNOT_CONNECT) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

       SocketClose(socket);
      }
    else
       Print("Failed to create a socket, error ",GetLastError());
  }
//+------------------------------------------------------------------+
```

SocketIsConnected

Checks if the socket is currently connected.

```
bool  SocketIsConnected(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate() function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

Return Value

Returns true if the socket is connected, otherwise - false.

Note

The SocketIsConnected() function allows checking the current socket connection status.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

See also

SocketConnect, SocketIsWritable, SocketCreate, SocketClose

SocketIsReadable

Get a number of bytes that can be read from a socket.

```
uint  SocketIsReadable(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

Return Value

Number of bytes that can be read. In case of an error, 0 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

Before calling SocketRead, check if the socket features data for reading. Otherwise, if there are no data, the SocketRead function waits for data within timeout_ms delaying the program execution.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketExample.mq5 |

      SocketClose(socket);
     }
   else
      Print("Failed to create a socket, error ",GetLastError());
  }
//+------------------------------------------------------------------+
```

SocketIsWritable

Check whether data can be written to a socket at the current time.

```
bool  SocketIsWritable(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

Return Value

Return true if writing is possible, otherwise false.

Note

This function allows you to check whether it is possible to write data to a socket right now.

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts

Set timeouts for receiving and sending data for a socket system object.

```
bool  SocketTimeouts(
   int           socket,               // socket
   uint          timeout_send_ms,      // data sending timeout
   uint          timeout_receive_ms    // data obtaining timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

timeout_send_ms

[in] Data sending timeout in milliseconds.

timeout_receive_ms

[in] Data obtaining timeout in milliseconds.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse system object timeouts with the ones set when reading data via SocketRead. SocketTimeout sets timeouts once for a socket object in the operating system. These timeouts are to be applied to all functions for reading and sending data via this socket. In SocketRead, the timeout is set for a certain data reading operation.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketRead

Read data from a socket.

```
int  SocketRead(
   int           socket,              // socket
   uchar&        buffer[],            // buffer for reading data from socket
   uint          buffer_maxlen,       // number of bytes to read
   uint          timeout_ms           // reading timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the *buffer[]* array. Data not fitting into the array remain in the socket. They can be received by the next SocketRead call. *buffer_maxlen* cannot exceed INT_MAX (2147483647).

timeout_ms

[in] Data reading timeout in milliseconds. If data is not obtained within this time, attempts are stopped and the function returns -1.

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts, MathSwap

SocketSend

Write data to a socket.

```
int  SocketSend(
   int           socket,              // socket
   const uchar&  buffer[],            // data buffer
   uint          buffer_len           // buffer size
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

buffer

[in] Reference to the uchar type array with the data to be sent to the socket.

buffer_len

[in] 'buffer' array size.

Return Value

If successful, return the number of bytes written to a socket. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data writing error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts, MathSwap, StringToCharArray

SocketTlsHandshake

Initiate secure TLS (SSL) connection to a specified host via TLS Handshake protocol. During Handshake, a client and a server agree on connection parameters: applied protocol version and data encryption method.

```
bool  SocketTlsHandshake(
   int           socket,               // socket
   const string  host                  // host address
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

host

[in] Address of a host a secure connection is established with.

Return Value

Returns true if successful, otherwise false.

Notes

Before a secure connection, the program should establish a standard TCP connection with the host using SocketConnect.

If secure connection fails, the error 5274 (ERR_NETSOCKET_HANDSHAKE_FAILED) is written to _LastError.

There is no need to call the function when connecting to the port 443. This is a standard TCP port used for secure TLS (SSL) connections.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTlsCertificate

Get data on the certificate used to secure network connection.

```
int  SocketTlsCertificate(
   int           socket,              // socket
   string&       subject,             // certificate owner
   string&       issuer,              // certificate issuer
   string&       serial,              // certificate serial number
   string&       thumbprint,          // certificate print
   datetime&     expiration           // certificate expiration
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

subject

[in] Certificate owner name. Corresponds to the Subject field.

issuer

[in] Certificate issuer name. Corresponds to the Issuer field.

serial

[in] Certificate serial number. Corresponds to the SerialNumber field.

thumbprint

[in] Certificate print. Corresponds to the SHA-1 hash from the entire certificate file (all fields including the issuer signature).

expiration

[in] Certificate expiration date in the datetime format.

Return Value

Returns true if successful, otherwise false.

Note

Certificate data can be requested only after establishing a secure connection using SocketTlsHandshake.

In case of a certificate obtaining error, the error 5275 (ERR_NETSOCKET_NO_CERTIFICATE) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
```

```
//|                                                  SocketExample.mq5 |

     }
   else
      Print("Failed to create a socket, error ",GetLastError());
  }
//+------------------------------------------------------------------+
```

SocketTlsRead

Read data from secure TLS connection.

```
int  SocketTlsRead(
   int           socket,              // socket
   uchar&        buffer[],            // buffer for reading data from socket
   uint          buffer_maxlen        // number of bytes to read
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the *buffer[]* array. Data not fitting into the array remain in the socket. They can be received by the next SocketTLSRead call. *buffer_maxlen* cannot exceed INT_MAX (2147483647).

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

The function is executed till it receives the specified amount of data or the timeout is reached (SocketTimeouts).

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts, MathSwap

SocketTlsReadAvailable

Read all available data from secure TLS connection.

```
int  SocketTlsReadAvailable(
   int           socket,               // socket
   uchar&        buffer[],             // buffer for reading data from socket
   const uint    buffer_maxlen         // number of bytes to read
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the buffer[] array. Data not fitting into the array remain in the socket. They can be received by the next SocketTlsReadAvailable or SocketTlsRead call. buffer_maxlen cannot exceed INT_MAX (2147483647).

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts, MathSwap

SocketTlsSend

Send data via secure TLS connection.

```
int  SocketTlsSend(
   int           socket,              // socket
   const uchar&  buffer[],            // data buffer
   uint          buffer_len           // buffer size
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

buffer

[in] Reference to the uchar type array with the data to be sent.

buffer_len

[in] 'buffer' array size.

Return Value

If successful, return the number of bytes written to a socket. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data writing error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTimeouts, MathSwap, StringToCharArray

WebRequest

The function sends an HTTP request to a specified server. The function has two versions:

1. **Sending simple requests** of type "key=value" using the header Content-Type: application/x-www-form-urlencoded.

```
int  WebRequest(
   const string      method,           // HTTP method
   const string      url,              // URL
   const string      cookie,           // cookie
   const string      referer,          // referer
   int               timeout,          // timeout
   const char        &data[],          // the array of the HTTP message body
   int               data_size,        // data[] array size in bytes
   char              &result[],        // an array containing server response data
   string            &result_headers   // headers of server response
   );
```

2. **Sending a request of any type** specifying the custom set of headers for a more flexible interaction with various Web services.

```
int  WebRequest(
   const string      method,           // HTTP method
   const string      url,              // URL
   const string      headers,          // headers
   int               timeout,          // timeout
   const char        &data[],          // the array of the HTTP message body
   char              &result[],        // an array containing server response data
   string            &result_headers   // headers of server response
   );
```

Parameters

method

[in] HTTP method.

url

[in] URL.

headers

[in] Request headers of type "key: value", separated by a line break "\r\n".

cookie

[in] Cookie value.

referer

[in] Value of the Referer header of the HTTP request.

timeout

[in] Timeout in milliseconds.

data[]

[in] Data array of the HTTP message body.

data_size

[in] Size of the data[] array.

result[]

[out] An array containing server response data.

result_headers

[out] Server response headers.

Return Value

HTTP server response code or -1 for an error.

Note

To use the WebRequest() function, add the addresses of the required servers in the list of allowed URLs in the "Expert Advisors" tab of the "Options" window. Server port is automatically selected on the basis of the specified protocol - 80 for "http://" and 443 for "https://".

The WebRequest() function is synchronous, which means its breaks the program execution and waits for the response from the requested server. Since the delays in receiving a response can be large, the function is not available for calls from indicators, because indicators run in a common thread shared by all indicators and charts on one symbol. Indicator performance delay on one of the charts of a symbol may stop updating of all charts of the same symbol.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If you try to call the function from an indicator, GetLastError() will return error 4014 - "Function is not allowed for call".

WebRequest() cannot be executed in the Strategy Tester.

Example:

```
void OnStart()
  {
   string cookie=NULL,headers;
   char   post[],result[];
   string url="https://finance.yahoo.com";
//--- To enable access to the server, you should add URL "https://finance.yahoo.com"
//--- to the list of allowed URLs (Main Menu->Tools->Options, tab "Expert Advisors"):
//--- Resetting the last error code
   ResetLastError();
//--- Downloading a html page from Yahoo Finance
   int res=WebRequest("GET",url,cookie,NULL,500,post,0,result,headers);
   if(res==-1)
     {
      Print("Error in WebRequest. Error code  =",GetLastError());
      //--- Perhaps the URL is not listed, display a message about the necessity to ad
      MessageBox("Add the address '"+url+"' to the list of allowed URLs on tab 'Expert
     }
```

```
   else
     {
      if(res==200)
        {
         //--- Successful download
         PrintFormat("The file has been successfully downloaded, File size %d byte.",A
         //PrintFormat("Server headers: %s",headers);
         //--- Saving the data to a file
         int filehandle=FileOpen("url.htm",FILE_WRITE|FILE_BIN);
         if(filehandle!=INVALID_HANDLE)
           {
            //--- Saving the contents of the result[] array to a file
            FileWriteArray(filehandle,result,0,ArraySize(result));
            //--- Closing the file
            FileClose(filehandle);
           }
         else
            Print("Error in FileOpen. Error code =",GetLastError());
        }
      else
         PrintFormat("Downloading '%s' failed, error code %d",url,res);
     }
  }
```

SendFTP

Sends a file at the address, specified in the setting window of the "FTP" tab.

```
bool  SendFTP(
   string  filename,           // file to be send by ftp
   string  ftp_path=NULL       // ftp catalog
   );
```

Parameters

filename

[in] Name of sent file.

ftp_path=NULL

[in] FTP catalog. If a directory is not specified, directory described in settings is used.

Return Value

In case of failure returns 'false'.

Note

Sent file must be located in the folder *terminal_directory\MQL5\files* or its subfolders. Sending isn't performed if FTP address and/or access password are not specified in settings.

SendFTP() function does not work in the Strategy Tester.

SendMail

Sends an email at the address specified in the settings window of the "Email" tab.

```
bool  SendMail(
   string  subject,        // header
   string  some_text       // email text
   );
```

Parameters

subject

[in] Email header.

some_text

[in] Email body.

Return Value

true - if an email is put into the send queue, otherwise - false.

Note

Sending can be prohibited in settings, email address can be omitted as well. For the error information call GetLastError().

SendMail() function does not work in the Strategy Tester.

SendNotification

Sends push notifications to the mobile terminals, whose MetaQuotes IDs are specified in the "Notifications" tab.

```
bool  SendNotification(
   string  text          // Text of the notification
   );
```

Parameters

text

[in] The text of the notification. The message length should not exceed 255 characters.

Return Value

true if a notification has been successfully sent from the terminal; in case of failure returns false. When checking after a failed push of notification, GetLastError () may return one of the following errors:

- 4515 - ERR_NOTIFICATION_SEND_FAILED,
- 4516 - ERR_NOTIFICATION_WRONG_PARAMETER,
- 4517 - ERR_NOTIFICATION_WRONG_SETTINGS,
- 4518 - ERR_NOTIFICATION_TOO_FREQUENT.

Note

Strict use restrictions are set for the SendNotification() function: no more than 2 calls per second and not more than 10 calls per minute. Monitoring the frequency of use is dynamic. The function can be disabled in case of the restriction violation.

SendNotification() function does not work in the Strategy Tester.

Global Variables of the Client Terminal

There is a group set of functions for working with global variables.

Global variables of the client terminal should not be mixed up with variables declared in the global scope of the mql5 program.

Global variables are kept in the client terminal for 4 weeks since the last access, then they will be deleted automatically. An access to a global variable is not only setting of a new value, but reading of the global variable value, as well.

Global variables of the client terminal are accessible simultaneously from all mql5 programs launched in the client terminal.

Function	Action
GlobalVariableCheck	Checks the existence of a global variable with the specified name
GlobalVariableTime	Returns time of the last accessing the global variable
GlobalVariableDel	Deletes a global variable
GlobalVariableGet	Returns the value of a global variable
GlobalVariableName	Returns the name of a global variable by its ordinal number in the list of global variables
GlobalVariableSet	Sets the new value to a global variable
GlobalVariablesFlush	Forcibly saves contents of all global variables to a disk
GlobalVariableTemp	Sets the new value to a global variable, that exists only in the current session of the terminal
GlobalVariableSetOnCondition	Sets the new value of the existing global variable by condition
GlobalVariablesDeleteAll	Deletes global variables with the specified prefix in their names
GlobalVariablesTotal	Returns the total number of global variables

GlobalVariableCheck

Checks the existence of a global variable with the specified name

```
bool  GlobalVariableCheck(
   string  name      // Global variable name
   );
```

Parameters

name

[in] Global variable name.

Return Value

Returns true, if the global variable exists, otherwise returns false.

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

See also

GlobalVariableTime()

GlobalVariableTime

Returns the time when the global variable was last accessed.

```
datetime  GlobalVariableTime(
   string  name      // name
   );
```

Parameters

name

[in] Name of the global variable.

Return Value

The function returns time of last accessing the specified global variable. Addressing a variable for its value, for example using the GlobalVariableGet() and GlobalVariableCheck() functions, also modifies the time of last access. In order to obtain error details, call the GetLastError() function.

Note

Global variables exist in the client terminal during 4 weeks since they were called last. After that they are automatically deleted.

See also

GlobalVariableCheck()

GlobalVariableDel

Deletes a global variable from the client terminal.

```
bool  GlobalVariableDel(
   string  name      // Global variable name
   );
```

Parameters

name

[in] Global variable name.

Return Value

If successful, the function returns true, otherwise it returns false. To obtain an information about the error it is necessary to call the function GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

GlobalVariableGet

Returns the value of an existing global variable of the client terminal. There are 2 variants of the function.

1. Immediately returns the value of the global variable.

```
double  GlobalVariableGet(
   string  name      // Global variable name
   );
```

2. Returns true or false depending on the success of the function run. If successful, the global variable of the client terminal is placed in a variable passed by reference in the second parameter.

```
bool  GlobalVariableGet(
   string  name,              // Global variable name
   double& double_var         // This variable will contain the value of the global va
   );
```

Parameters

name

[in] Global variable name.

double_var

[out] Target variable of the double type, which accepts the value stored in a the global variable of the client terminal.

Return Value

The value of the existing global variable or 0 in case of an error. For more details about the error, call GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

GlobalVariableName

Returns the name of a global variable by its ordinal number.

```
string  GlobalVariableName(
   int  index      // Global variable number in the list of global variables
   );
```

Parameters

index

[in] Sequence number in the list of global variables. It should be greater than or equal to 0 and less than GlobalVariablesTotal().

Return Value

Global variable name by its ordinal number in the list of global variables. For more details about the error, call GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

GlobalVariableSet

Sets a new value for a global variable. If the variable does not exist, the system creates a new global variable.

```
datetime  GlobalVariableSet(
   string  name,      // Global variable name
   double  value      // Value to set
   );
```

Parameters

name

[in] Global variable name.

value

[in] The new numerical value.

Return Value

If successful, the function returns the last modification time, otherwise 0. For more details about the error, call GetLastError().

Note

A global variable name should not exceed 63 characters. Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

GlobalVariablesFlush

Forcibly saves contents of all global variables to a disk.

```
void  GlobalVariablesFlush();
```

Return Value

No return value.

Note

The terminal writes all the global variables when the work is over, but data can be lost at a sudden computer operation failure. This function allows independently controlling the process of saving global variables in case of contingency.

GlobalVariableTemp

The function attempts to create a temporary global variable. If the variable doesn't exist, the system creates a new temporary global variable.

```
bool  GlobalVariableTemp(
   string  name      // Global variable name
   );
```

Parameters

name

[in] The name of a temporary global variable.

Return Value

If successful, the function returns true, otherwise - false. To get details about the error, you should call the GetLastError() function.

Note

Temporary global variables exist only while the client terminal is running; after the terminal shutdown they are automatically deleted. Note that during the execution of GlobalVariablesFlush() temporary global variables are not written to a disk.

After a temporary global variable has been created, it can be accessed and modified the same as global variable of the client terminal.

GlobalVariableSetOnCondition

Sets the new value of the existing global variable if the current value equals to the third parameter check_value. If there is no global variable, the function will generate an error ERR_GLOBALVARIABLE_NOT_FOUND (4501) and return false.

```
bool  GlobalVariableSetOnCondition(
   string  name,             // Global variable name
   double  value,            // New value for variable if condition is true
   double  check_value       // Check value condition
   );
```

Parameters

name

[in] The name of a global variable.

value

[in] New value.

check_value

[in] The value to check the current value of the global variable.

Return Value

If successful, the function returns true, otherwise it returns false. For details about the error call GetLastError(). If the current value of the global variable is different from check_value, the function returns false.

Note

Function provides atomic access to the global variable, so it can be used for providing of a mutex at interaction of several Expert Advisors working simultaneously within one client terminal.

GlobalVariablesDeleteAll

Deletes global variables of the client terminal.

```
int  GlobalVariablesDeleteAll(
   string     prefix_name=NULL,     // All global variables with names beginning with
   datetime   limit_data=0          // All global variables that were changed before t
   );
```

Parameters

prefix_name=NULL

[in] Name prefix global variables to remove. If you specify a prefix NULL or empty string, then all variables that meet the data criterion will be deleted.

limit_data=0

[in] Date to select global variables by the time of their last modification. The function removes global variables, which were changed before this date. If the parameter is zero, then all variables that meet the first criterion (prefix) are deleted.

Return Value

The number of deleted variables.

Note

If both options are equal to zero (prefix_name = NULL and limit_data = 0), then function deletes all global variables of the terminal. If both parameters are specified, then it deletes global variables corresponding to both parameters.

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

GlobalVariablesTotal

Returns the total number of global variables of the client terminal.

```
int  GlobalVariablesTotal();
```

Return Value

Number of global variables.

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted. Call of a global variable is not only setting a new value, but also reading the value of the global variable.

File Functions

This is a group of functions for working with files.

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means cannot be outside the file sandbox.

There are two directories (with subdirectories) in which working files can be located:

- terminal_data_folder\MQL5\FILES\ (in the terminal menu select to view "File" - "Open the data directory");
- the common folder for all the terminals installed on a computer - usually located in the directory C:\Documents and Settings\All Users\Application Data\MetaQuotes\Terminal\Common\Files.

There is a program method to obtain names of these catalogs using the TerminalInfoString() function, using the ENUM_TERMINAL_INFO_STRING enumeration:

```
//--- Folder that stores the terminal data
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
//--- Common folder for all client terminals
   string common_data_path=TerminalInfoString(TERMINAL_COMMONDATA_PATH);
```

Work with files from other directories is prohibited.

If the file is opened for writing using FileOpen(), all subfolders specified in the path will be created if there are no such ones.

File functions allow working with so-called "named pipes". To do this, simply call FileOpen() function with appropriate parameters.

Function	Action
FileSelectDialog	Create a file or folder opening/creation dialog
FileFindFirst	Starts the search of files in a directory in accordance with the specified filter
FileFindNext	Continues the search started by the FileFindFirst() function
FileFindClose	Closes search handle
FileOpen	Opens a file with a specified name and flag
FileDelete	Deletes a specified file
FileFlush	Writes to a disk all data remaining in the input/output file buffer
FileGetInteger	Gets an integer property of a file
FileIsEnding	Defines the end of a file in the process of reading
FileIsLineEnding	Defines the end of a line in a text file in the process of reading
FileClose	Closes a previously opened file
FileIsExist	Checks the existence of a file

Function	Action
FileCopy	Copies the original file from a local or shared folder to another file
FileMove	Moves or renames a file
FileReadArray	Reads arrays of any type except for string from the file of the BIN type
FileReadBool	Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string to a value of bool type
FileReadDatetime	Reads from the file of the CSV type a string of one of the formats: "YYYY.MM.DD HH:MM:SS", "YYYY.MM.DD" or "HH:MM:SS" - and converts it into a datetime value
FileReadDouble	Reads a double value from the current position of the file pointer
FileReadFloat	Reads a float value from the current position of the file pointer
FileReadInteger	Reads int, short or char value from the current position of the file pointer
FileReadLong	Reads a long type value from the current position of the file pointer
FileReadNumber	Reads from the file of the CSV type a string from the current position till a delimiter (or til the end of a text line) and converts the read string into double value
FileReadString	Reads a string from the current position of a file pointer from a file
FileReadStruct	Reads the contents from a binary file into a structure passed as a parameter, from the current position of the file pointer
FileSeek	Moves the position of the file pointer by a specified number of bytes relative to the specified position
FileSize	Returns the size of a corresponding open file
FileTell	Returns the current position of the file pointer of a corresponding open file
FileWrite	Writes data to a file of CSV or TXT type
FileWriteArray	Writes arrays of any type except for string into a file of BIN type
FileWriteDouble	Writes value of the double type from the current position of a file pointer into a binary file
FileWriteFloat	Writes value of the float type from the current position of a file pointer into a binary file
FileWriteInteger	Writes value of the int type from the current position of a file pointer into a binary file
FileWriteLong	Writes value of the long type from the current position of a file pointer into a binary file

Function	Action
FileWriteString	Writes the value of a string parameter into a BIN or TXT file starting from the current position of the file pointer
FileWriteStruct	Writes the contents of a structure passed as a parameter into a binary file, starting from the current position of the file pointer
FileLoad	Reads all data of a specified binary file into a passed array of numeric types or simple structures
FileSave	Writes to a binary file all elements of an array passed as a parameter
FolderCreate	Creates a folder in the Files directory
FolderDelete	Removes a selected directory. If the folder is not empty, then it can't be removed
FolderClean	Deletes all files in the specified folder

FileSelectDialog

Create a file or folder opening/creation dialog.

```
int  FileSelectDialog(
   string   caption,              // window header
   string   initial_dir,          // initial directory
   string   filter,               // extension filter
   uint     flags,                // combination of flags
   string&  filenames[],          // array with file names
   string   default_filename      // default file name
   );
```

Parameters

caption

[in] Dialog window header.

initial_dir

[in] Initial directory name relative to MQL5\Files, the contents of which is to be displayed in the dialog box. If the value is NULL, MQL5\Files is displayed in the dialog.

filter

[in] Extension filter of the files to be displayed in the selection dialog window. Files of other formats are hidden.

flags

[in] Combination of flags defining the dialog window mode. The flags are defined as follows:
FSD_WRITE_FILE - file open dialog;
FSD_SELECT_FOLDER - allow selection of folders only;
FSD_ALLOW_MULTISELECT - allow selection of multiple files;
FSD_FILE_MUST_EXIST - selected files should exist;
FSD_COMMON_FOLDER - file is located in the common folder of all client terminals \Terminal\Common\Files.

filenames[]

[out] Array of strings the names of selected files/folders are placed to.

default_filename

[in] Default file/folder name. If specified, a name is automatically added to the open dialog and returned in the *filenames[]* array when testing.

Return Value

In case of a successful completion, the function returns the number of selected files whose names can be obtained in *filenames[]*. If a user closes the dialog without selecting a file, the function returns 0. In case of unsuccessful execution, a value less than 0 is returned. The error code can be obtained using GetLastError().

Note

For reasons of security, working with files is strictly controlled in MQL5 language. Files used in file operations by means of MQL5 language cannot be located outside the file sandbox (namely, outside the MQL5\Files directory).

The *initial_dir* name is searched in the client terminal's directory in MQL5\Files (or testing_agent_directory\MQL5\Files in case of testing). If FSD_COMMON_FOLDER is set among the flags, the search for the initial directory is performed in the common folder of all client terminals \Terminal\Common\Files.

The *filter* parameter indicates valid files and should be set in the "<description 1>|<extension 1>|<description 2>|<extension 2>..." format, for example, "Text files (*.txt)|*.txt|All files (*.*)|*.*". The first extension "Text files (*.txt)|*.txt" is selected as a default file type.

If *filter*=NULL, the mask of file selection in the dialog window is "All Files (*.*)|*.*|"

If the *default_filename* parameter is set, calling FileSelectDialog() returns 1, while the *default_filename* value itself is copied to the *filenames[]* array during the non-visualized testing.

The function cannot be used in custom indicators since calling FileSelectDialog() suspends the thread of execution for the whole time while waiting for the user's response. Since all indicators for each symbol are executed in a single thread, such suspension makes the operation of all charts on all timeframes for this symbol impossible.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the names of text files for downloading from the common folder of the client
   string filenames[];
   if(FileSelectDialog("Select files to download", NULL,
                       "Text files (*.txt)|*.txt|All files (*.*)|*.*",
                       FSD_ALLOW_MULTISELECT|FSD_COMMON_FOLDER, filenames, "data.txt")
     {
      //--- display the name of each selected file
      int total=ArraySize(filenames);
      for(int i=0; i<total; i++)
         Print(i, ": ", filenames[i]);
     }
   else
     {
     Print("Files not selected");
     }
//---
  }
```

See also

FileOpen, FileIsExist, FileDelete, FileMove, FolderCreate, FolderDelete, FolderClean, Flags of opening files

FileFindFirst

The function starts the search of files or subdirectories in a directory in accordance with the specified filter.

```
long  FileFindFirst(
   const string   file_filter,          // String - search filter
   string&        returned_filename,    // Name of the file or subdirectory found
   int            common_flag=0         // Defines the search
   );
```

Parameters

file_filter

[in] Search filter. A subdirectory (or sequence of nested subdirectories) relative to the \Files directory, in which files should be searched for, can be specified in the filter.

returned_filename

[out] The returned parameter, where, in case of success, the name of the first found file or subdirectory is placed. Only the file name is returned (including the extension), the directories and subdirectories are not included no matter if they are specified or not in the search filter.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

Returns handle of the object searched, which should be used for further sorting of files and subdirectories by the FileFindNext() function, or INVALID_HANDLE when there is no file and subdirectory corresponding to the filter (in the particular case - when the directory is empty). After searching, the handle must be closed using the FileFindClose() function.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="Dir1\\*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   string int_dir="";
   int    i=1,pos=0,last_pos=-1;
//--- search for the last backslash
   while(!IsStopped())
     {
      pos=StringFind(InpFilter,"\\",pos+1);
      if(pos>=0)
         last_pos=pos;
      else
         break;
     }
//--- the filter contains the folder name
   if(last_pos>=0)
      int_dir=StringSubstr(InpFilter,0,last_pos+1);
//--- get the search handle in the root of the local folder
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if the FileFindFirst() is executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- in a loop, check if the passed strings are the names of files or director
      do
        {
         ResetLastError();
         //--- if it's a file, the function returns true, and if it's a directory, it
         FileIsExist(int_dir+file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==ERR_FILE_IS_DIRECTORY ? "Di
         i++;
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
      Print("Files not found!");
  }
```

See also

FileFindNext, FileFindClose

FileFindNext

The function continues the search started by FileFindFirst().

```
bool  FileFindNext(
   long      search_handle,          // Search handle
   string&   returned_filename       // Name of the file or subdirectory found
   );
```

Parameters

search_handle

[in] Search handle, retrieved by FileFindFirst().

returned_filename

[out] The name of the next file or subdirectory found. Only the file name is returned (including the extension), the directories and subdirectories are not included no matter if they are specified or not in the search filter.

Return Value

If successful returns true, otherwise false.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   int    i=1;
//--- receive search handle in local folder's root
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if FileFindFirst() function executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- check if the passed strings are file or directory names in the loop
      do
        {
         ResetLastError();
         //--- if this is a file, the function will return true, if it is a directory,
         FileIsExist(file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==ERR_FILE_IS_DIRECTORY ? "Di
         i++;
        }
      while(FileFindNext(search_handle,file_name));
```

```
      //--- close search handle
      FileFindClose(search_handle);
     }
   else
      Print("Files not found!");
  }
```

See also

FileFindFirst, FileFindClose

FileFindClose

The function closes the search handle.

```
void  FileFindClose(
   long  search_handle      //  Search handle
   );
```

Parameters

search_handle

[in] Search handle, retrieved by FileFindFirst().

Return Value

No value returned.

Note

Function must be called to free up system resources.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   int    i=1;
//--- receive search handle in local folder's root
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if FileFindFirst() function executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- check if the passed strings are file or directory names in the loop
      do
        {
         ResetLastError();
         //--- if this is a file, the function will return true, if it is a directory,
         FileIsExist(file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==5018 ? "Directory" : "File"
         i++;
        }
      while(FileFindNext(search_handle,file_name));
      //--- close search handle
      FileFindClose(search_handle);
     }
```

```
   else
      Print("Files not found!");
  }
```

See also

FileFindFirst, FileFindNext

FileIsExist

Checks the existence of a file.

```
bool  FileIsExist(
   const string  file_name,        // File name
   int           common_flag=0     // Search area
   );
```

Parameters

file_name

[in] The name of the file being checked

common_flag=0

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

Returns true, if the specified file exists.

Note

Checked file can turn out to be a subdirectory. In this case, FileIsExist() function will return false, while error 5018 will be logged in _LastError variable - "This is a directory, not a file" (see example for FileFindFirst function).

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If common_flag = FILE_COMMON, then the function looks for the file in a shared folder for all client terminals \Terminal\Common\Files, otherwise the function looks for a file in a local folder (MQL5\Files or MQL5\Tester\Files in the case of testing).

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- date for old files
input datetime InpFilesDate=D'2013.01.01 00:00';
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;       // variable for storing file names
   string   filter="*.txt"; // filter for searching the files
   datetime create_date;     // file creation date
   string   files[];         // list of file names
   int      def_size=25;     // array size by default
   int      size=0;          // number of files
```

```
//--- allocate memory for the array
   ArrayResize(files,def_size);
//--- receive the search handle in the local folder's root
   long search_handle=FileFindFirst(filter,file_name);
//--- check if FileFindFirst() executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- searching files in the loop
      do
        {
         files[size]=file_name;
         //--- increase the array size
         size++;
         if(size==def_size)
           {
            def_size+=25;
            ArrayResize(files,def_size);
           }
         //--- reset the error value
         ResetLastError();
         //--- receive the file creation date
         create_date=(datetime)FileGetInteger(file_name,FILE_CREATE_DATE,false);
         //--- check if the file is old
         if(create_date<InpFilesDate)
           {
            PrintFormat("%s file deleted!",file_name);
            //--- delete the old file
            FileDelete(file_name);
           }
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
     {
      Print("Files not found!");
      return;
     }
//--- check what files have remained
   PrintFormat("Results:");
   for(int i=0;i<size;i++)
     {
      if(FileIsExist(files[i]))
         PrintFormat("%s file exists!",files[i]);
      else
         PrintFormat("%s file deleted!",files[i]);
     }
  }
```

See also

FileFindFirst

FileOpen

The function opens the file with the specified name and flag.

```
int  FileOpen(
   string  file_name,           // File name
   int     open_flags,          // Combination of flags
   short   delimiter='\t',      // Delimiter
   uint    codepage=CP_ACP      // Code page
   );
```

Parameters

file_name

[in] The name of the file can contain subfolders. If the file is opened for writing, these subfolders will be created if there are no such ones.

open_flags

[in] combination of flags determining the operation mode for the file. The flags are defined as follows:
FILE_READ file is opened for reading
FILE_WRITE file is opened for writing
FILE_BIN binary read-write mode (no conversion from a string and to a string)
FILE_CSV file of csv type (all recorded items are converted to the strings of unicode or ansi type, and are separated by a delimiter)
FILE_TXT a simple text file (the same as csv, but the delimiter is not taken into account)
FILE_ANSI lines of ANSI type (single-byte symbols)
FILE_UNICODE lines of UNICODE type (double-byte characters)
FILE_SHARE_READ shared reading from several programs
FILE_SHARE_WRITE shared writing from several programs
FILE_COMMON location of the file in a shared folder for all client terminals \Terminal\Common\Files

delimiter='\t'

[in] value to be used as a separator in txt or csv-file. If the csv-file delimiter is not specified, it defaults to a tab. If the txt-file delimiter is not specified, then no separator is used. If the separator is clearly set to 0, then no separator is used.

codepage=CP_ACP

[in] The value of the code page. For the most-used code pages provide appropriate constants.

Return Value

If a file has been opened successfully, the function returns the file handle, which is then used to access the file data. In case of failure returns INVALID_HANDLE.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Make sure to set the FILE_ANSI flag if the file should be read in a specific encoding (the codepage parameter with a code page value is specified). If there is no specified FILE_ANSI flag, the text file is read in Unicode without any conversion.

The file is opened in the folder of the client terminal in the subfolder MQL5\files (or testing_agent_directory\MQL5\files in case of testing). If FILE_COMMON is specified among flags, the file is opened in a shared folder for all MetaTrader 5 client terminals.

"Named pipes" can be opened according to the following rules:

- Pipe name is a string, which should have the following look: "\\servername\pipe\pipename", where servername - server name in the network, while pipename is a pipe name. If the pipes are used on the same computer, the server name can be omitted but a point should be inserted instead of it: "\\.\pipe\pipename". A client trying to connect the pipe should know its name.
- FileFlush() and FileSeek() should be called to the beginning of a file between sequential operations of reading from the pipe and writing to it.

A special symbol '\' is used in shown strings. Therefore, '\' should be doubled when writing a name in MQL5 application. It means that the above example should have the following look in the code: "\\\\servername\\pipe\\pipename".

More information about working with named pipes can be found in the article "Communicating With MetaTrader 5 Using Named Pipes Without Using DLLs".

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- incorrect file opening method
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
   string filename=terminal_data_path+"\\MQL5\\Files\\"+"fractals.csv";
   int filehandle=FileOpen(filename,FILE_WRITE|FILE_CSV);
   if(filehandle<0)
     {
      Print("Failed to open the file by the absolute path ");
      Print("Error code ",GetLastError());
     }

//--- correct way of working in the "file sandbox"
   ResetLastError();
   filehandle=FileOpen("fractals.csv",FILE_WRITE|FILE_CSV);
   if(filehandle!=INVALID_HANDLE)
     {
      FileWrite(filehandle,TimeCurrent(),Symbol(), EnumToString(_Period));
      FileClose(filehandle);
      Print("FileOpen OK");
     }
   else Print("Operation FileOpen failed, error ",GetLastError());
//--- another example with the creation of an enclosed directory in MQL5\Files\
```

```
   string subfolder="Research";
   filehandle=FileOpen(subfolder+"\\fractals.txt",FILE_WRITE|FILE_CSV);
      if(filehandle!=INVALID_HANDLE)
     {
      FileWrite(filehandle,TimeCurrent(),Symbol(), EnumToString(_Period));
      FileClose(filehandle);
      Print("The file must be created in the folder "+terminal_data_path+"\\"+subfolde
     }
   else Print("File open failed, error ",GetLastError());
  }
```

Use of a Codepage, FileFindFirst, FolderCreate, File opening flags

FileClose

Close the file previously opened by FileOpen().

```
void  FileClose(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

No value returned.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="file.txt";     // file name
input string InpDirectoryName="Data";    // directory name
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the path to the file we are going to use
   PrintFormat("Working %s\\Files\\ folder",TerminalInfoString(TERMINAL_DATA_PATH));
//--- reset the error value
   ResetLastError();
//--- open the file for reading (if the file does not exist, the error will occur)
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_TXT|InpEr
   if(file_handle!=INVALID_HANDLE)
     {
      //--- print the file contents
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      //--- close the file
      FileClose(file_handle);
     }
   else
      PrintFormat("Error, code = %d",GetLastError());
  }
```

FileCopy

The function copies the original file from a local or shared folder to another file.

```
bool  FileCopy(
   const string  src_file_name,     // Name of a source file
   int           common_flag,       // Location
   const string  dst_file_name,     // Name of the destination file
   int           mode_flags         // Access mode
   );
```

Parameters

src_file_name

[in] File name to copy.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder (for example, *common_flag=0*).

dst_file_name

[in] Result file name.

mode_flags

[in] Access flags. The parameter can contain only 2 flags: FILE_REWRITE and/or FILE_COMMON - other flags are ignored. If the file already exists, and the FILE_REWRITE flag hasn't been specified, then the file will not be rewritten, and the function will return false.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the new file already exists, the copy will be made depending on the availability of the FILE_REWRITE flag in the mode_flags parameter.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpSrc="source.txt";       // source
input string InpDst="destination.txt";  // copy
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

```
  {
//--- display the source contents (it must exist)
   if(!FileDisplay(InpSrc))
      return;
//--- check if the copy file already exists (may not be created)
   if(!FileDisplay(InpDst))
     {
      //--- the copy file does not exist, copying without FILE_REWRITE flag (correct c
      if(FileCopy(InpSrc,0,InpDst,0))
         Print("File is copied!");
      else
         Print("File is not copied!");
     }
   else
     {
      //--- the copy file already exists, try to copy without FILE_REWRITE flag (inco
      if(FileCopy(InpSrc,0,InpDst,0))
         Print("File is copied!");
      else
         Print("File is not copied!");
      //--- InpDst file's contents remains the same
      FileDisplay(InpDst);
      //--- copy once more with FILE_REWRITE flag (correct copying if the file exists)
      if(FileCopy(InpSrc,0,InpDst,FILE_REWRITE))
         Print("File is copied!");
      else
         Print("File is not copied!");
     }
//--- receive InpSrc file copy
   FileDisplay(InpDst);
  }
//+------------------------------------------------------------------+
//| Read the file contents                                           |
//+------------------------------------------------------------------+
bool FileDisplay(const string file_name)
  {
//--- reset the error value
   ResetLastError();
//--- open the file
   int file_handle=FileOpen(file_name,FILE_READ|FILE_TXT|InpEncodingType);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- display the file contents in the loop
      Print("+----------------------+");
      PrintFormat("File name = %s",file_name);
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      Print("+----------------------+");
      //--- close the file
```

```
      FileClose(file_handle);
      return(true);
     }
//--- failed to open the file
   PrintFormat("%s is not opened, error = %d",file_name,GetLastError());
   return(false);
  }
```

FileDelete

Deletes the specified file in a local folder of the client terminal.

```
bool  FileDelete(
   const string  file_name,     // File name to delete
   int           common_flag=0  // Location of the file to delete
   );
```

Parameters

file_name

[in] File name.

common_flag=0

[in] Flag determining the file location. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Deletes the specified file from a local folder of the client terminal (MQL5\Files or MQL5\Tester\Files in case of testing). If common_flag = FILE_COMMON, then the function removes the file from the shared folder for all client terminals \Terminal\Common\Files.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- date for old files
input datetime InpFilesDate=D'2013.01.01 00:00';
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;      // variable for storing file names
   string   filter="*.txt"; // filter for searching the files
   datetime create_date;    // file creation date
   string   files[];        // list of file names
   int      def_size=25;    // array size by default
   int      size=0;         // number of files
//--- allocate memory for the array
   ArrayResize(files,def_size);
//--- receive the search handle in the local folder's root
   long search_handle=FileFindFirst(filter,file_name);
```

```
//--- check if FileFindFirst() executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- searching files in the loop
      do
        {
         files[size]=file_name;
         //--- increase the array size
         size++;
         if(size==def_size)
           {
            def_size+=25;
            ArrayResize(files,def_size);
           }
         //--- reset the error value
         ResetLastError();
         //--- receive the file creation date
         create_date=(datetime)FileGetInteger(file_name,FILE_CREATE_DATE,false);
         //--- check if the file is old
         if(create_date<InpFilesDate)
           {
            PrintFormat("%s file deleted!",file_name);
            //--- delete the old file
            FileDelete(file_name);
           }
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
     {
      Print("Files not found!");
      return;
     }
//--- check what files have remained
   PrintFormat("Results:");
   for(int i=0;i<size;i++)
     {
      if(FileIsExist(files[i]))
         PrintFormat("%s file exists!",files[i]);
      else
         PrintFormat("%s file deleted!",files[i]);
     }
  }
```

FileMove

Moves a file from a local or shared folder to another folder.

```
bool  FileMove(
   const string  src_file_name,     // File name for the move operation
   int           common_flag,       // Location
   const string  dst_file_name,     // Name of the destination file
   int           mode_flags         // Access mode
   );
```

Parameters

src_file_name

[in] File name to move/rename.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder (*common_flag=0*).

dst_file_name

[in] File name after operation

mode_flags

[in] Access flags. The parameter can contain only 2 flags: FILE_REWRITE and/or FILE_COMMON - other flags are ignored. If the file already exists and the FILE_REWRITE flag isn't specified, the file will not be rewritten, and the function will return false.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the new file already exists, the copy will be made depending on the availability of the FILE_REWRITE flag in the mode_flags parameter.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpSrcName="data.txt";
input string InpDstName="newdata.txt";
input string InpSrcDirectory="SomeFolder";
input string InpDstDirectory="OtherFolder";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
```

```
void OnStart()
  {
   string local=TerminalInfoString(TERMINAL_DATA_PATH);
   string common=TerminalInfoString(TERMINAL_COMMONDATA_PATH);
//--- receive file paths
   string src_path;
   string dst_path;
   StringConcatenate(src_path,InpSrcDirectory,"//",InpSrcName);
   StringConcatenate(dst_path,InpDstDirectory,"//",InpDstName);
//--- check if the source file exists (if not - exit)
   if(FileIsExist(src_path))
      PrintFormat("%s file exists in the %s\\Files\\%s folder",InpSrcName,local,InpSrc
   else
     {
      PrintFormat("Error, %s source file not found",InpSrcName);
      return;
     }
//--- check if the result file already exists
   if(FileIsExist(dst_path,FILE_COMMON))
     {
      PrintFormat("%s file exists in the %s\\Files\\%s folder",InpDstName,common,InpDs
      //--- file exists, moving should be performed with FILE_REWRITE flag
      ResetLastError();
      if(FileMove(src_path,0,dst_path,FILE_COMMON|FILE_REWRITE))
         PrintFormat("%s file moved",InpSrcName);
      else
         PrintFormat("Error! Code = %d",GetLastError());
     }
   else
     {
      PrintFormat("%s file does not exist in the %s\\Files\\%s folder",InpDstName,comm
      //--- the file does not exist, moving should be performed without FILE_REWRITE f
      ResetLastError();
      if(FileMove(src_path,0,dst_path,FILE_COMMON))
         PrintFormat("%s file moved",InpSrcName);
      else
         PrintFormat("Error! Code = %d",GetLastError());
     }
//--- the file is moved; let's check it out
   if(FileIsExist(dst_path,FILE_COMMON) && !FileIsExist(src_path,0))
      Print("Success!");
   else
      Print("Error!");
  }
```

See also

FileIsExist

FileFlush

Writes to a disk all data remaining in the input/output file buffer.

```
void  FileFlush(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

No value returned.

Note

When writing to a file, the data may be actually found there only after some time. To save the data in the file instantly, use FileFlush() function. If the function is not used, part of the data that has not been stored in the disk yet, will be forcibly written there only when the file is closed using FileClose() function.

The function should be used when written data is of a certain value. It should be kept in mind that frequent function call may affect the program operation speed.

Function FileFlush () must be called between the operations of reading from a file and writing to it.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- file name for writing
input string InpFileName="example.csv"; // file name
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- reset error value
   ResetLastError();
//--- open the file
   int file_handle=FileOpen(InpFileName,FILE_READ|FILE_WRITE|FILE_CSV);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- write data to the file
      for(int i=0;i<1000;i++)
        {
         //--- call write function
         FileWrite(file_handle,TimeCurrent(),SymbolInfoDouble(Symbol(),SYMBOL_BID),Sy
         //--- save data on the disk at each 128th iteration
         if((i & 127)==127)
```

```
            {
             //--- now, data will be located in the file and will not be lost in case o
             FileFlush(file_handle);
             PrintFormat("i = %d, OK",i);
            }
          //--- 0.01 second pause
          Sleep(10);
         }
       //--- close the file
       FileClose(file_handle);
      }
    else
       PrintFormat("Error, code = %d",GetLastError());
  }
```

See also

FileClose

FileGetInteger

Gets an integer property of a file. There are two variants of the function.

1. Get a property by the handle of a file.

```
long  FileGetInteger(
   int                          file_handle,    // File handle
   ENUM_FILE_PROPERTY_INTEGER   property_id     // Property ID
   );
```

2. Get a property by the file name.

```
long  FileGetInteger(
   const string                 file_name,             // File name
   ENUM_FILE_PROPERTY_INTEGER   property_id,           // Property ID
   bool                         common_folder=false    // The file is viewed in a local
   );                                                  // or a common folder of all terr
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

file_name

[in] File name.

property_id

[in] File property ID. The value can be one of the values of the ENUM_FILE_PROPERTY_INTEGER enumeration. If the second variant of the function is used, you can receive only the values of the following properties: FILE_EXISTS, FILE_CREATE_DATE, FILE_MODIFY_DATE, FILE_ACCESS_DATE and FILE_SIZE.

common_folder=false

[in] Points to the file location. If the parameter is false, terminal data folder is viewed. Otherwise it is assumed that the file is in the shared folder of all terminals \Terminal\Common\Files (FILE_COMMON).

Return Value

The value of the property. In case of an error, -1 is returned. To get an error code use the GetLastError() function.

If a folder is specified when getting properties by the name, the function will have error 5018 (ERR_MQL_FILE_IS_DIRECTORY) in any case, though the return value will be correct.

Note

The function always changes the error code. In case of successful completion the error code is reset to NULL.

Example:

```
//--- display the window of input parameters when launching the script
```

```
#property script_show_inputs
//--- input parameters
input string InpFileName="data.csv";
input string InpDirectoryName="SomeFolder";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string path=InpDirectoryName+"//"+InpFileName;
   long   l=0;
//--- open the file
   ResetLastError();
   int handle=FileOpen(path,FILE_READ|FILE_CSV);
   if(handle!=INVALID_HANDLE)
     {
      //--- print all information about the file
      Print(InpFileName," file info:");
      FileInfo(handle,FILE_EXISTS,l,"bool");
      FileInfo(handle,FILE_CREATE_DATE,l,"date");
      FileInfo(handle,FILE_MODIFY_DATE,l,"date");
      FileInfo(handle,FILE_ACCESS_DATE,l,"date");
      FileInfo(handle,FILE_SIZE,l,"other");
      FileInfo(handle,FILE_POSITION,l,"other");
      FileInfo(handle,FILE_END,l,"bool");
      FileInfo(handle,FILE_IS_COMMON,l,"bool");
      FileInfo(handle,FILE_IS_TEXT,l,"bool");
      FileInfo(handle,FILE_IS_BINARY,l,"bool");
      FileInfo(handle,FILE_IS_CSV,l,"bool");
      FileInfo(handle,FILE_IS_ANSI,l,"bool");
      FileInfo(handle,FILE_IS_READABLE,l,"bool");
      FileInfo(handle,FILE_IS_WRITABLE,l,"bool");
      //--- close the file
      FileClose(handle);
     }
   else
      PrintFormat("%s file is not opened, ErrorCode = %d",InpFileName,GetLastError());
  }
//+------------------------------------------------------------------+
//| Display the value of the file property                           |
//+------------------------------------------------------------------+
void FileInfo(const int handle,const ENUM_FILE_PROPERTY_INTEGER id,
              long l,const string type)
  {
//--- receive the property value
   ResetLastError();
   if((l=FileGetInteger(handle,id))!=-1)
     {
      //--- the value received, display it in the correct format
```

```
      if(!StringCompare(type,"bool"))
         Print(EnumToString(id)," = ",l ? "true" : "false");
      if(!StringCompare(type,"date"))
         Print(EnumToString(id)," = ",(datetime)l);
      if(!StringCompare(type,"other"))
         Print(EnumToString(id)," = ",l);
     }
   else
      Print("Error, Code = ",GetLastError());
  }
```

File Operations, File Properties

FileIsEnding

Defines the end of a file in the process of reading.

```
bool  FileIsEnding(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The function returns true if the file end has been reached in the process of reading or moving of the file pointer.

Note

To define the end of the file, the function tries to read the next string from it. If the string does not exist, the function returns true, otherwise it returns false.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="file.txt";     // file name
input string InpDirectoryName="Data";    // directory name
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the path to the file we are going to use
   PrintFormat("Working %s\\Files\\ folder",TerminalInfoString(TERMINAL_DATA_PATH));
//--- reset the error value
   ResetLastError();
//--- open the file for reading (if the file does not exist, the error will occur)
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_TXT|InpEr
   if(file_handle!=INVALID_HANDLE)
     {
      //--- print the file contents
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      //--- close the file
      FileClose(file_handle);
     }
   else
      PrintFormat("Error, code = %d",GetLastError());
```

```
}
```

FileIsLineEnding

Defines the line end in a text file in the process of reading.

```
bool  FileIsLineEnding(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Returns true if in the process of reading txt or csv-file reached the end of the line (the characters CR-LF).

Example (the file obtained during the execution of an example for FileWriteString function is used here)

```

FileWriteString

FileReadArray

Reads from a file of BIN type arrays of any type except string (may be an array of structures, not containing strings, and dynamic arrays).

```
uint  FileReadArray(
   int     file_handle,               // File handle
   void&   array[],                   // Array to record
   int     start=0,                   // start array position to write
   int     count=WHOLE_ARRAY          // count to read
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

array[]

[out] An array where the data will be loaded.

start=0

[in] Start position to read from the array.

count=WHOLE_ARRAY

[in] Number of elements to read. By default, reads the entire array (count=WHOLE_ARRAY).

Return Value

Number of elements read.

Note

String array can be read only from the file of TXT type. If necessary, the function tries to increase the size of the array.

Example (the file obtained after execution of the example for FileWriteArray function is used here)

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="data.bin";
input string InpDirectoryName="SomeFolder";
//+------------------------------------------------------------------+
//| Structure for storing price data                                 |
//+------------------------------------------------------------------+
struct prices
  {
   datetime          date; // date
   double            bid;  // bid price
   double            ask;  // ask price
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
```

```
//+------------------------------------------------------------------+
void OnStart()
  {
//--- structure array
   prices arr[];
//--- file path
   string path=InpDirectoryName+"//"+InpFileName;
//--- open the file
   ResetLastError();
   int file_handle=FileOpen(path,FILE_READ|FILE_BIN);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- read all data from the file to the array
      FileReadArray(file_handle,arr);
      //--- receive the array size
      int size=ArraySize(arr);
      //--- print data from the array
      for(int i=0;i<size;i++)
         Print("Date = ",arr[i].date," Bid = ",arr[i].bid," Ask = ",arr[i].ask);
      Print("Total data = ",size);
      //--- close the file
      FileClose(file_handle);
     }
   else
      Print("File open failed, error ",GetLastError());
  }
```

Variables, FileWriteArray

FileReadBool

Reads from the file of CSV type string from the current position to a delimiter (or till the end of the text line) and converts the read string to a bool type value.

```
bool  FileReadBool(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Line read may be set to "true", "false" or the symbolic representation of integers "0" or "1". A nonzero value is converted to a logical true. The function returns the converted value.

Example (the file obtained after executing the example for FileWrite function is used here)

Type bool, FileWrite

FileReadDatetime

Reads from the file of CSV type a string of one of the formats: "YYYY.MM.DD HH:MI:SS", "YYYY.MM.DD" or "HH:MI:SS" - and converts it into a value of datetime type.

```
datetime  FileReadDatetime(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of datetime type.

Example (the file obtained after executing the example for FileWrite function is used here)

```

FileReadDouble

Reads a double-precision floating point number (double) from the current position of the binary file.

```
double  FileReadDouble(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of double type.

Note

For more details about the error, call GetLastError().

Example (the file obtained after executing the example for FileWriteDouble function is used here)

```

See also

Real types (double, float), FileReadDouble, FileWriteFloat

FileReadInteger

The function reads int, short or char value from the current position of the file pointer depending on the length specified in bytes.

```
int  FileReadInteger(
   int  file_handle,         // File handle
   int  size=INT_VALUE       // Size of an integer in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

size=INT_VALUE

[in] Number of bytes (up to 4 inclusive) that should be read. The corresponding constants are provided: CHAR_VALUE = 1, SHORT_VALUE = 2 and INT_VALUE = 4, so the function can read the whole value of char, short or int type.

Return Value

A value of the int type. The result of this function must be explicitly cast to a target type, i.e. to the type of data that you need to read. Since a value of the int type is returned, it can be easily converted to any integer value. The file pointer is shifted by the number of bytes read.

Note

When reading less than 4 bytes, the received result is always positive. If one or two bytes are read, the sign of the number can be determined by explicit casting to type char (1 byte) or short (2 bytes). Getting the sign for a three-byte number is not trivial, since there is no corresponding underlying type.

FileReadLong

The function reads an integer of long type (8 bytes) from the current position of the binary file.

```
long  FileReadLong(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of long type.

Integer types, FileReadInteger, FileWriteLong

FileReadNumber

The function reads from the CSV file a string from the current position till a separator (or till the end of a text string) and converts the read string to a value of double type.

```
double  FileReadNumber(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of double type.

Example (the file obtained during the execution of an example for FileWriteString function is used here)

```

FileWriteString

FileReadString

The function reads a string from the current position of a file pointer in a file.

```
string  FileReadString(
   int  file_handle,     // File handle
   int  length=-1        // Length of the string
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

length=-1

[in] Number of characters to read.

Return Value

Line read (string).

Note

When reading from a bin-file. the length of a string to read must be specified. When reading from a txt-file the string length is not required, and the string will be read from the current position to the line feed character "\r\n". When reading from a csv-file, the string length isn't required also, the string will be read from the current position till the nearest delimiter or till the text string end character.

If the file is opened with FILE_ANSI flag, then the line read is converted to Unicode.

Example (the file obtained after executing the example for FileWriteInteger function is used here)

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- parameters for data reading
input string InpFileName="Trend.bin"; // file name
input string InpDirectoryName="Data"; // directory name
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- open the file
   ResetLastError();
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_BIN|FILE_
   if(file_handle!=INVALID_HANDLE)
     {
      PrintFormat("%s file is available for reading",InpFileName);
      PrintFormat("File path: %s\\Files\\",TerminalInfoString(TERMINAL_DATA_PATH));
      //--- additional variables
      int    str_size;
      string str;
```

```
      //--- read data from the file
      while(!FileIsEnding(file_handle))
        {
         //--- find out how many symbols are used for writing the time
         str_size=FileReadInteger(file_handle,INT_VALUE);
         //--- read the string
         str=FileReadString(file_handle,str_size);
         //--- print the string
         PrintFormat(str);
        }
      //--- close the file
      FileClose(file_handle);
      PrintFormat("Data is read, %s file is closed",InpFileName);
     }
   else
      PrintFormat("Failed to open %s file, Error code = %d",InpFileName,GetLastError()
  }
```

String Type, Conversion Functions, FileWriteInteger

FileReadStruct

The function reads contents into a structure passed as a parameter from a binary-file, starting with the current position of the file pointer.

```
uint  FileReadStruct(
   int           file_handle,        // file handle
   const void&   struct_object,      // target structure to which the contents are read
   int           size=-1             // structure size in bytes
   );
```

Parameters

file_handle

[in] File descriptor of an open bin-file.

struct_object

[out] The object of this structure. The structure should not contain strings, dynamic arrays or virtual functions.

size=-1

[in] Number of bytes that should be read. If size is not specified or the indicated value is greater than the size of the structure, the exact size of the specified structure is used.

Return Value

If successful the function returns the number of bytes read. File pointer is moved by the same number of bytes.

Example (the file obtained after using the example for FileWriteStruct function is used here)

Structures and classes, FileWriteStruct

FileSeek

The function moves the position of the file pointer by a specified number of bytes relative to the specified position.

```
bool  FileSeek(
   int                  file_handle,     // File handle
   long                 offset,          // In bytes
   ENUM_FILE_POSITION   origin           // Position for reference
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

offset

[in] The shift in bytes (may take a negative value).

origin

[in] The starting point for the displacement. Can be one of values of ENUM_FILE_POSITION.

Return Value

If successful the function returns true, otherwise false. To obtain information about the error call the GetLastError() function.

Note

If the execution of the FileSeek() function results in a negative shift (going beyond the "level boundary" of the file), the file pointer will be set to the file beginning.

If a position is set beyond the "right boundary" of the file (larger than the file size), the next writing to the file will be performed not from the end of the file, but from the position set. In this case indefinite values will be written for the previous file end and the position set.

Example:

```

      else
         break; // end of the file, exit
     }
//--- define the actual size of the array
   ArrayResize(arr,i);
  }
```

FileSize

The function returns the file size in bytes.

```
ulong  FileSize(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of type int.

Note

To obtain information about the error call GetLastError().

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input ulong  InpThresholdSize=20;        // file threshold size in kilobytes
input string InpBigFolderName="big";     // folder for large files
input string InpSmallFolderName="small"; // folder for small files
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;      // variable for storing file names
   string   filter="*.csv"; // filter for searching the files

       FileFindClose(search_handle);
      }
    else
       Print("Files not found!");
  }
```

FileTell

The file returns the current position of the file pointer of an open file.

```
ulong  FileTell(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Current position of the file descriptor in bytes from the beginning of the file.

Note

To obtain information about the error call GetLastError().

         break; // end of the file, exit
     }
//--- define the actual size of the array
   ArrayResize(arr,i);
  }
```

FileWrite

The function is intended for writing of data into a CSV file, delimiter being inserted automatically unless it is equal to 0. After writing into the file, the line end character "\r\n" will be added.

```
uint  FileWrite(
   int  file_handle,    // File handle
   ...                  // List of recorded parameters
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

...

[in] The list of parameters separated by commas, to write to the file. The number of written parameters can be up to 63.

Return Value

Number of bytes written.

Note

Numbers will be converted into a text at output (see the Print() function). Data of the double type are output with the accuracy of 16 digits after the decimal point, and the data can be displayed either in traditional or in scientific format - depending on which format will be the most compact. The data of the float type are shown with 5 digits after the decimal point. To output real numbers with different precision or in a clearly specified format, use DoubleToString().

Numbers of the bool type are displayed as "true" or "false" strings. Numbers of the datetime type are displayed as "YYYY.MM.DD HH:MI:SS".

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FileWrite.mq5 |

Comment, Print, StringFormat

FileWriteArray

The function writes arrays of any type except for string to a BIN file (can be an array of structures not containing strings or dynamic arrays).

```
uint  FileWriteArray(
   int           file_handle,          // File handle
   const void&   array[],              // Array
   int           start=0,              // Start index in the array
   int           count=WHOLE_ARRAY     // Number of elements
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

array[]

[out] Array for recording.

start=0

[in] Initial index in the array (number of the first recorded element).

count=WHOLE_ARRAY

[in] Number of items to write (WHOLE_ARRAY means that all items starting with the number start until the end of the array will be written).

Return Value

Number of recorded items.

Note

String array can be recorded in a TXT file. In this case, strings are automatically ended by the line end characters "\r\n". Depending on the file type ANSI or UNICODE, strings are either converted to ansi-encoding or not.

Example:

Variables, FileSeek

FileWriteDouble

The function writes the value of a double parameter to a a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteDouble(
   int     file_handle,     // File handle
   double  value            // Value to write
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] The value of double type.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(double)=8). The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                        Demo_FileWriteDouble.mq5 |

Real types (double, float)

FileWriteFloat

The function writes the value of the float parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteFloat(
   int    file_handle,     // File handle
   float  value            // Value to be written
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] The value of float type.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(float)=4). The file pointer is shifted by the same number of bytes.

Example:

```

Real types (double, float), FileWriteDouble

FileWriteInteger

The function writes the value of the int parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteInteger(
   int  file_handle,         // File handle
   int  value,               // Value to be written
   int  size=INT_VALUE       // Size in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] Integer value.

size=INT_VALUE

[in] Number of bytes (up to 4 inclusive), that should be written. The corresponding constants are provided: CHAR_VALUE=1, SHORT_VALUE=2 and INT_VALUE=4, so the function can write the integer value of char, uchar, short, ushort, int, or uint type.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                        Demo_FileWriteInteger.mq5 |

FileWriteLong

The function writes the value of the long-type parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteLong(
   int   file_handle,     // File handle
   long  value            // Value to be written
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] Value of type long.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(long)=8). The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                          Demo_FileWriteLong.mq5 |

Integer types, FileWriteInteger

FileWriteString

The function writes the value of a string-type parameter into a BIN, CSV or TXT file starting from the current position of the file pointer. When writing to a CSV or TXT file: if there is a symbol in the string '\n' (LF) without previous character '\r' (CR), then before '\n' the missing '\r' is added.

```
uint  FileWriteString(
   int           file_handle,     // File handle
   const string  text_string,     // string to write
   int           length=-1        // number of symbols
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

text_string

[in] String.

length=-1

[in] The number of characters that you want to write. This option is needed for writing a string into a BIN file. If the size is not specified, then the entire string without the trailer 0 is written. If you specify a size smaller than the length of the string, then a part of the string without the trailer 0 is written. If you specify a size greater than the length of the string, the string is filled by the appropriate number of zeros. For files of CSV and TXT type, this parameter is ignored and the string is written entirely.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Note

Note that when writing to a file opened by the FILE_UNICODE flag (or without a flag FILE_ANSI), then the number of bytes written will be twice as large as the number of string characters written. When recording to a file opened with the FILE_ANSI flag, the number of bytes written will coincide with the number of string characters written.

Example:

String Type, StringFormat

FileWriteStruct

The function writes into a bin-file contents of a structure passed as a parameter, starting from the current position of the file pointer.

```
uint  FileWriteStruct(
   int          file_handle,       // File handle
   const void&  struct_object,     // link to an object
   int          size=-1            // size to be written in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

struct_object

[in] Reference to the object of this structure. The structure should not contain strings, dynamic arrays or virtual functions.

size=-1

[in] Number of bytes that you want to record. If size is not specified or the specified number of bytes is greater than the size of the structure, the entire structure is written.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+

Structures and classes

FileLoad

Reads all data of a specified binary file into a passed array of numeric types or simple structures. The function allows you to quickly read data of a known type into the appropriate array.

```
long  FileLoad(
   const string  file_name,          // File name
   void&         buffer[],           // An array of numeric types or simple structures
   int           common_flag=0       // A file flag, is searched in <data_folder>\MQL5\
   );
```

Parameters

file_name

[in] The name of the file from which data will be read.

buffer

[out] An array of numeric types or simple structures.

common_flag=0

[in] A file flag indicating the operation mode. If the parameter is not specified, the file is searched in the subfolder MQL5\Files (or in <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

The number of elements read or -1 in case of an error.

Note

The FileLoad() function reads from a file the number of bytes multiple of the array element size. Suppose the file size is 10 bytes, and the function reads data into an array of type double (sizeof(double)=8). In this case the function will read only 8 bytes, the remaining 2 bytes at the end of the file will be dropped, and the function FileLoad() will return 1 (1 element read).

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FileLoad.mq5 |

FileSave

Writes to a binary file all elements of an array passed as a parameter. The function allows you to quickly write arrays of numeric types or simple structures as one string.

```
bool  FileSave(
   const string  file_name,          // File name
   void&         buffer[],           // An array of numeric types or simple structures
   int           common_flag=0       // A file flag, by default files are written to <
   );
```

Parameters

file_name

[in] The name of the file, to the data array will be written.

buffer

[in] An array of numeric types or simple structures.

common_flag=0

[in] A file flag indicating the operation mode. If the parameter is not specified, the file will be written to the subfolder MQL5\Files (or to <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

In case of failure returns false.

Example:

```
//+------------------------------------------------------------------+
//|                                                 Demo_FileSave.mq5 |

Structures and Classes, FileWriteArray, FileWriteStruct, FileLoad, FileWrite

FolderCreate

Creates a directory in the Files folder (depending on the common_flag value)

```
bool  FolderCreate(
   string  folder_name,       // line with the created folder name
   int     common_flag=0      // action area
   );
```

Parameters

folder_name

[in] Name of the directory to be created. Contains the relative path to the folder.

common_flag=0

[in] Flag defining the directory location. If common_flag=FILE_COMMON, the directory is located in the common folder of all client terminals \Terminal\Common\Files. Otherwise, the directory is in the local folder (MQL5\Files or MQL5\Tester\Files when testing).

Return Value

Returns true if successful, otherwise false.

Note

For reasons of security, working with files is strictly controlled in MQL5 language. Files used in file operations by means of MQL5 language cannot be located outside the file sandbox.

Example:

```
#property copyright "Copyright 2000-2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com"
#property version   "1.00"
//--- description

   if(CreateFolder(root_folder,common_folder))
     {
      //--- create the Child_Folder_B1 sub-folder in it
```

```
      string folder_B1="Child_Folder_B1";
      string path=root_folder+"\\"+folder_B1;          // create the folder name consi
      if(CreateFolder(path,common_folder))
        {
         //--- create 3 more sub-directories in this folder
         string folder_C11="Child_Folder_C11";
         string child_path=root_folder+"\\"+folder_C11;// create the folder name consi
         CreateFolder(child_path,common_folder);
         //--- second sub-directory
         string folder_C12="Child_Folder_C12";
         child_path=root_folder+"\\"+folder_C12;
         CreateFolder(child_path,common_folder);

         //--- third sub-directory
         string folder_C13="Child_Folder_C13";
         child_path=root_folder+"\\"+folder_C13;
         CreateFolder(child_path,common_folder);
        }
     }
//---
  }
//+------------------------------------------------------------------+
//| Try creating a folder and display a message about that           |
//+------------------------------------------------------------------+
bool CreateFolder(string folder_path,bool common_flag)
  {
   int flag=common_flag?FILE_COMMON:0;
   string working_folder;
//--- define the full path depending on the common_flag parameter
   if(common_flag)
      working_folder=TerminalInfoString(TERMINAL_COMMONDATA_PATH)+"\\MQL5\\Files";
   else
      working_folder=TerminalInfoString(TERMINAL_DATA_PATH)+"\\MQL5\\Files";
//--- debugging message
   PrintFormat("folder_path=%s",folder_path);
//--- attempt to create a folder relative to the MQL5\Files path
   if(FolderCreate(folder_path,flag))
     {
      //--- display the full path for the created folder
      PrintFormat("Created the folder %s",working_folder+"\\"+folder_path);
      //--- reset the error code
      ResetLastError();
      //--- successful execution
      return true;
     }
   else
      PrintFormat("Failed to create the folder %s. Error code %d",working_folder+folde
//--- execution failed
   return false;
```

```
}
```

See also

FileOpen(), FolderClean(), FileCopy()

FolderDelete

The function removes the specified directory. If the folder is not empty, then it can't be removed.

```
bool  FolderDelete(
   string  folder_name,       // String with the name of the folder to delete
   int     common_flag=0      // Scope
   );
```

Parameters

folder_name

[in] The name of the directory you want to delete. Contains the full path to the folder.

common_flag=0

[in] Flag determining the location of the directory. If common_flag=FILE_COMMON, then the directory is in the shared folder for all client terminals \Terminal\Common\Files. Otherwise, the directory is in a local folder (MQL5\Files or MQL5\Tester\Files in the case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the directory contains at least one file and/or subdirectory, then this directory can't be deleted, it must be cleared first. FolderClean() is used to clear a folder of all its files or subfolders.

Example:

```
//+------------------------------------------------------------------+
//|                                              Demo_FolderDelete.mq5 |

FolderClean

The function deletes all files in a specified folder.

```
bool  FolderClean(
   string  folder_name,       // String with the name of the deleted folder
   int     common_flag=0      // Scope
   );
```

Parameters

folder_name

[in] The name of the directory where you want to delete all files. Contains the full path to the folder.

common_flag=0

[in] Flag determining the location of the directory. If common_flag = FILE_COMMON, then the directory is in the shared folder for all client terminals \Terminal\Common\Files. Otherwise, the directory is in a local folder(MQL5\Files or MQL5\Tester\Files in case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

This function should be used with caution, since all the files and all subdirectories are deleted irretrievably.

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FolderClean.mq5 |

Custom Indicators

This is the group functions used in the creation of custom indicators. These functions can't be used when writing Expert Advisors and Scripts.

Function	Action
SetIndexBuffer	Binds the specified indicator buffer with one-dimensional dynamic array of the double type
IndicatorSetDouble	Sets the value of an indicator property of the double type
IndicatorSetInteger	Sets the value of an indicator property of the int type
IndicatorSetString	Sets the value of an indicator property of the string type
PlotIndexSetDouble	Sets the value of an indicator line property of the type double
PlotIndexSetInteger	Sets the value of an indicator line property of the int type
PlotIndexSetString	Sets the value of an indicator line property of the string type
PlotIndexGetInteger	Returns the value of an indicator line property of the integer type

Indicator properties can be set using the compiler directives or using functions. To better understand this, it is recommended that you study indicator styles in examples.

All the necessary calculations of a custom indicator must be placed in the predetermined function OnCalculate(). If you use a short form of the OnCalculate() function call, like

```
int OnCalculate (const int rates_total, const int prev_calculated, const int begin, co
```

then the *rates_total* variable contains the value of the total number of elements of the price[] array, passed as an input parameter for calculating indicator values.

Parameter *prev_calculated* is the result of the execution of OnCalculate() at the previous call; it allows organizing a saving algorithm for calculating indicator values. For example, if the current value rates_total = 1000, prev_calculated = 999, then perhaps it's enough to make calculations only for one value of each indicator buffer.

If the information about the size of the input array price would have been unavailable, then it would lead to the necessity to make calculations for 1000 values of each indicator buffer. At the first call of OnCalculate() value prev_calculated = 0. If the price[] array has changed somehow, then in this case prev_calculated is also equal to 0.

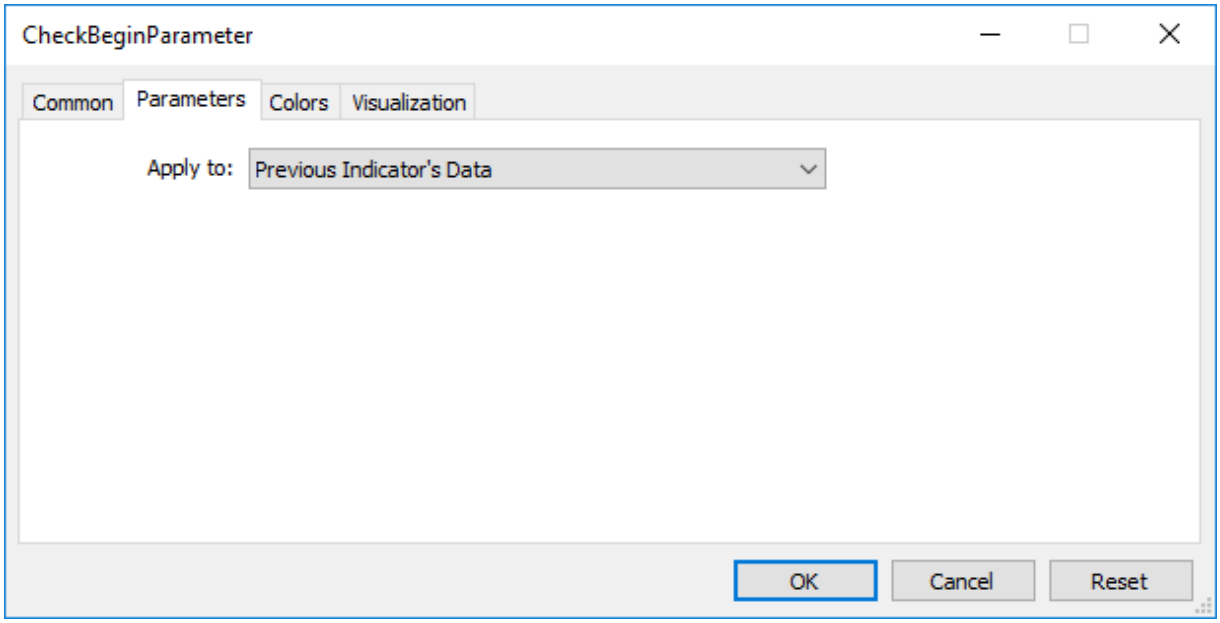
The *begin* parameter shows the number of initial values of the price array, which don't contain data for calculation. For example, if values of Accelerator Oscillator (for which the first 37 values aren't calculated) were used as an input parameter, then begin = 37. For example, let's consider a simple indicator:

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot Label1
#property indicator_label1  "Label1"
```

```
#property indicator_type1   DRAW_LINE
#property indicator_color1  clrRed
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- indicator buffers
double         Label1Buffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,Label1Buffer,INDICATOR_DATA);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])

  {
//---
   Print("begin = ",begin,"  prev_calculated = ",prev_calculated,"  rates_total = ",ra
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Drag it from the "Navigator" window to the window of the Accelerator Oscillator indicator and we indicate that calculations will be made based on the values of the previous indicator:



As a result, the first call of OnCalculate() the value of prev_calculated will be equal to zero, and in further calls it will be equal to the rates_total value (until the number of bars on the price chart increases).

The value of the begin parameter will be exactly equal to the number of initial bars, for which the values of the Accelerator indicator aren't calculated according to the logic of this indicator. If we look at the source code of the custom indicator Accelerator.mq5, we'll see the following lines in the OnInit() function:

```
//--- sets first bar from which index will be drawn
   PlotIndexSetInteger(0,PLOT_DRAW_BEGIN,37);
```

Using the function PlotIndexSetInteger(0, PLOT_DRAW_BEGIN, empty_first_values), we set the number of non-existing first values in the zero indicator array of a custom indicator, which we don't need to accept for calculation (empty_first_values). Thus, we have mechanisms to:

1. set the number of initial values of an indicator, which shouldn't be used for calculations in another custom indicator;
2. get information on the number of first values to be ignored when you call another custom indicator, without going into the logic of its calculations.

Indicator Styles in Examples

The MetaTrader 5 Client Terminal includes 38 technical indicators that can be used in MQL5 programs using appropriate functions. But the main advantage of the MQL5 language is the ability to create custom indicators, which can then be used in Expert Advisors or simply applied on price charts for the purpose of technical analysis.

The entire set of indicators can be derived from several base drawing styles, known as plotting. Plotting denotes a way of displaying data, which the indicator calculates, stores and provides on request. There are seven such basic plotting types:

1. A line
2. A section (segment)
3. Histogram
4. Arrow (symbol)
5. A painted area (filled channel)
6. Bars
7. Japanese candlesticks

Each plotting requires one to five arrays of the double type, in which indicator values are stored. For the purpose of convenience, these arrays are associated with the indicator buffers. The number of buffers in an indicator must be declared in advance using compiler directives, for example:

```
#property indicator_buffers 3 // Number of buffers
#property indicator_plots   2 // number of plots
```

The number of buffers in the indicator is always greater than or equal to the number of plots in the indicator.

Since each basic plotting type can have color variation or construction specifics, the actual number of plotting types in the MQL5 is 18:

Plotting	Description	Value buffers	Color buffers
DRAW_NONE	Is not visually displayed in the chart, but the values of the corresponding buffer can be viewed in the Data Window	1	-

Plotting	Description	Value buffers	Color buffers
DRAW_LINE	A line is plotted on the values of the corresponding buffer (empty values in the buffer are undesirable)	1	-
DRAW_SECTION	Is drawn as line segments between the values of the corresponding buffer (usually has a lot of empty values)	1	-
DRAW_HISTOGRAM	Is drawn as a histogram from the zero line to the values of the corresponding buffer (may have empty values)	1	-

Plotting	Description	Value buffers	Color buffers
DRAW_HISTOGRAM2	Is drawn as a histogram based on two indicator buffers (may have empty values)	2	-
DRAW_ARROW	Is drawn as symbols (may have empty values)	1	-
DRAW_ZIGZAG	Similar to the style DRAW_SECTION, but unlike it, can plot vertical segments on one bar	2	-
DRAW_FILLING	Color fill between two lines. 2 values of the corresponding buffers are shown in the Data Window	2	-
DRAW_BARS	Is drawn as bars. 4 values	4	-

Plotting	Description	Value buffers	Color buffers
	of the corresponding buffers are shown in the Data Window		
DRAW_CANDLES	Drawn as Japanese candlesticks. 4 values of the corresponding buffers are shown in the Data Window	4	-
DRAW_COLOR_LINE	A line for which you can alternate colors on different bars or change its color at any time	1	1
DRAW_COLOR_SECTION	Similar to the style DRAW_SECTION, but the color of each section can be set individually; color can also	1	1

Plotting	Description	Value buffers	Color buffers
	be set dynamically		
DRAW_COLOR_HISTOGRAM	Similar to the style DRAW_HISTOGRAM, but each strip may have a different color, you can set the color dynamically	1	1
DRAW_COLOR_HISTOGRAM2	Similar to the style DRAW_HISTOGRAM2, but each strip may have a different color, you can set the color dynamically	2	1
DRAW_COLOR_ARROW	Similar to the style DRAW_ARROW, but each symbol can have its color. Color can be	1	1

Plotting	Description	Value buffers	Color buffers
	changed dynamically		
DRAW_COLOR_ZIGZAG	The DRAW_ZIGZAG style with the options of individual coloring of sections and dynamic color changing	2	1
DRAW_COLOR_BARS	The DRAW_BARS style with the options of individual coloring of bars and dynamic color changing	4	1
DRAW_COLOR_CANDLES	The DRAW_CANDLES style with the options of individual coloring of candlesticks and dynamic color changing	4	1

The difference between an indicator buffer and an array

In each indicator, on its global level, you should declare one or more arrays of the double type, which then must be used as an indicator buffer using the SetIndexBuffer() function. To draw indicator plots, only the values of the indicator buffers are used, any other arrays cannot be used for this purpose. In addition, buffer values are displayed in the Data Window.

An indicator buffer should be dynamic and does not require specification of the size - the size of the array used as the indicator buffer is set by the terminal execution subsystem automatically.

After the array is bound to the indicator buffer, the indexing direction is set by default like in ordinary arrays, but you can use the ArraySetAsSeries() function to change the way of access to the array elements. By default, the indicator buffer is used to store data used for plotting (INDICATOR_DATA).

If the calculation of indicator values requires holding intermediate calculations and storing the additional values for each bar, then such an array can be declared as a calculation buffer during binding (INDICATOR_CALCULATIONS). For the intermediate values, you can also use a regular array, but in this case, the programmer has to manage the size of the array.

Some plots allow setting a color for each bar. To store the information about color, color buffers are used (INDICATOR_COLOR_INDEX). The color is an integer type color, but all indicator buffers must be of type double. Values of color and auxiliary (INDICATOR_CALCULATIONS) buffers cannot be obtained by using CopyBuffer().

The number of indicator buffers must be specified using the compiler directive #property indicator_buffers number_of_buffers:

```
#property indicator_buffers 3  //  the indicator has 3 buffers
```

The maximum allowed number of buffers in one indicator is 512.

Relevance of Indicator Buffers and Plotting

Each plotting is based on one or more indicator buffers. So, for displaying simple candlesticks, four values are required - Open, High, Low and Close prices. Accordingly, to display an indicator in the form of candlesticks, it is necessary to declare 4 indicator buffers and 4 arrays of the double type for them. For example:

```
//--- The indicator has four indicator buffers
#property indicator_buffers 4
//--- The indicator has one plotting
#property indicator_plots   1
//--- Graphical plotting number 1 will appear as candlesticks
#property indicator_type1   DRAW_CANDLES
//--- Candlestick will be drawn in clrDodgerBlue
#property indicator_color1  clrDodgerBlue
//--- 4 arrays for the indicator buffers
double OBuffer[];
```

```
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

Graphical plots automatically use indicator buffers in accordance with the plot number. Numbering of plots starts with 1, numbering of buffers starts with zero. If the first plotting requires 4 indicator buffers, then the first 4 indicator buffers will be used to draw it. These four buffers should be linked with the appropriate arrays with correct indexing using the SetIndexBuffer() function.

```
//--- Binding arrays with indicator buffers
   SetIndexBuffer(0,OBuffer,INDICATOR_DATA);  // The first buffer corresponds to the
   SetIndexBuffer(1,HBuffer,INDICATOR_DATA);  // The second buffer corresponds to inde
   SetIndexBuffer(2,LBuffer,INDICATOR_DATA);  // The third buffer corresponds to index
   SetIndexBuffer(3,CBuffer,INDICATOR_DATA);  // The fourth buffer corresponds to inde
```

The plotting candlesticks, the indicator will use just the first four buffers, because plotting of "candlesticks" was announced under the first number.

Change the example, and add plotting of a simple line - DRAW_LINE. Now suppose that the line is numbered 1, and the candlesticks are number 2. The number of buffers and the number of plots has increased.

```
//--- The indicator has 5 indicator buffers
#property indicator_buffers 5
//--- The indicator has 2 plots
#property indicator_plots   2
//--- Plot 1 is a line
#property indicator_type1   DRAW_LINE
//--- The color of the line is clrDodgerRed
#property indicator_color1  clrDodgerRed
//--- Plot 2 is drawn as Japanese candlesticks
#property indicator_type2   DRAW_CANDLES
//--- The color of the candlesticks is clrDodgerBlue
#property indicator_color2  clrDodgerBlue
//--- 5 arrays for indicator buffers
double LineBuffer[];
double OBuffer[];
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

The order of the plots has changed, and now the line comes first, followed by Japanese candlesticks. Therefore, the order of the buffers is appropriate - first we announce a buffer for the line with the zero index, and then four buffers for the candlesticks.

```
   SetIndexBuffer(0,LineBuffer,INDICATOR_DATA);  // The first buffer corresponds to in
//--- Binding arrays with indicator buffers for the candlesticks
   SetIndexBuffer(1,OBuffer,INDICATOR_DATA);     // The second buffer corresponds to
   SetIndexBuffer(2,HBuffer,INDICATOR_DATA);     // The third buffer corresponds to in
   SetIndexBuffer(3,LBuffer,INDICATOR_DATA);     // The fourth buffer corresponds to
```

```
   SetIndexBuffer(4,CBuffer,INDICATOR_DATA);     // The fifth buffer corresponds to ir
```

The number of buffers and plots can be set only by using compiler directives, it is impossible to change these properties dynamically using functions.

Color Versions of Styles

As can be seen in the table, the styles are divided into two groups. The first group includes styles in whose name there is no word **COLOR**, we call these styles basic:

- DRAW_LINE
- DRAW_SECTION
- DRAW_HISTOGRAM
- DRAW_HISTOGRAM2
- DRAW_ARROW
- DRAW_ZIGZAG
- DRAW_FILLING
- DRAW_BARS
- DRAW_CANDLES

In the second group, the style names contain the word **COLOR**, let's call them color versions:

- DRAW_COLOR_LINE
- DRAW_COLOR_SECTION
- DRAW_COLOR_HISTOGRAM
- DRAW_COLOR_HISTOGRAM2
- DRAW_COLOR_ARROW
- DRAW_COLOR_ZIGZAG
- DRAW_COLOR_BARS
- DRAW_COLOR_CANDLES

All color versions of styles differ from the basic ones in that they allow specifying a color for each part of the plotting. The minimal part of plotting is a bar, so we can say that the color versions allow setting the color on each bar.

Exceptions are styles DRAW_NONE and DRAW_FILLING, they do not have color versions.

To set the plotting color on each bar, an additional buffer for storing the color index has been added to the color version. These indices indicate the number of a color in a special array, which contains a predefined set of colors. The size of the array of colors is 64. This means that each color version of a style allows painting a plot in 64 different colors.

The set and the number of colors in the special array of colors can be set via a compiler directive #property indicator_color, where you can specify all the necessary colors separated by commas. For example, such an entry in an indicator:

```
//--- Define 8 colors for coloring candlesticks (they are stored in the special array)
#property indicator_color1  clrRed,clrBlue,clrGreen,clrYellow,clrMagenta,clrCyan,clrL
```

It states that for plotting 1, 8 colors are set, which will be placed in a special array. Further in the program we will not specify the color of the plotting, but only its index. If we want to set red color for the bar number K, the color index value from an array should be set in the color buffer of the indicator. The red color is specified first in the directive, it corresponds to the index number 0.

```
   //--- set the candlestick color clrRed
   col_buffer[buffer_index]=0;
```

The set of colors is not given once and for all, it can be changed dynamically using PlotIndexSetInteger(). Example:

```
      //--- Set the color for each index as the property PLOT_LINE_COLOR
      PlotIndexSetInteger(0,                    //  The number of a graphical style
                          PLOT_LINE_COLOR,      //  Property identifier
                          plot_color_ind,       //  The index of the color, where we w
                          color_array[i]);      //  A new color
```

Properties of the indicator and plotting

For indicator plots, properties can be set by means of compiler directives and using the appropriate functions. Read more information about this in Connection between Indicator Properties and Functions. Dynamic change of indicator properties using special functions allows creating more flexible custom indicators.

Start of Indicator Drawing on the Chart

In many cases, according to the conditions of the algorithm, it is impossible to start calculating the indicator values immediately with the current bar, since it is necessary to provide a minimum number of previous bars available in history. For example, many types of smoothing imply using an array of prices over the previous N bars, and on the basis of these values, the indicator value on the current bar is calculated.

In such cases, either there is no way to calculate the indicator values for the first N bars, or these values are not intended to be displayed on the chart and are only subsidiary for calculating further values. To avoid plotting of the indicator on the first N bars of the history, set the N value to the PLOT_DRAW_BEGIN property for the corresponding plot:

```
//--- Binding arrays with indicator buffers for the candlesticks
PlotIndexSetInteger(number_of_plot,PLOT_DRAW_BEGIN,N);
```

Here:

- number_of_plot – a value from zero to indicator_plots-1 (numbering of plots starts with zero).
- N - the number of first bars in the history, on which the indicator should not be displayed on the chart.

DRAW_NONE

The DRAW_NONE style is designed for use in cases where it is necessary to calculate the values of a buffer and show them in the Data Window, but plotting on the chart is not required. To set up the accuracy use the expression IndicatorSetInteger(INDICATOR_DIGITS,num_chars) in the OnInit() function:

```
int OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,InvisibleBuffer,INDICATOR_DATA);
//--- Set the accuracy of values to be displayed in the Data Window
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
   return(INIT_SUCCEEDED);
  }
```

The number of buffers required for plotting DRAW_NONE is 1.

An example of the indicator that shows the number of the bar on which the mouse currently hovers in the Data Window. The numbering corresponds to the timeseries, meaning the current unfinished bar has the zero index, and the oldest bar has the largest index.

Note that despite the fact that, for red color is set plotting **#1**, the indicator does not draw anything on the chart.

  }
```

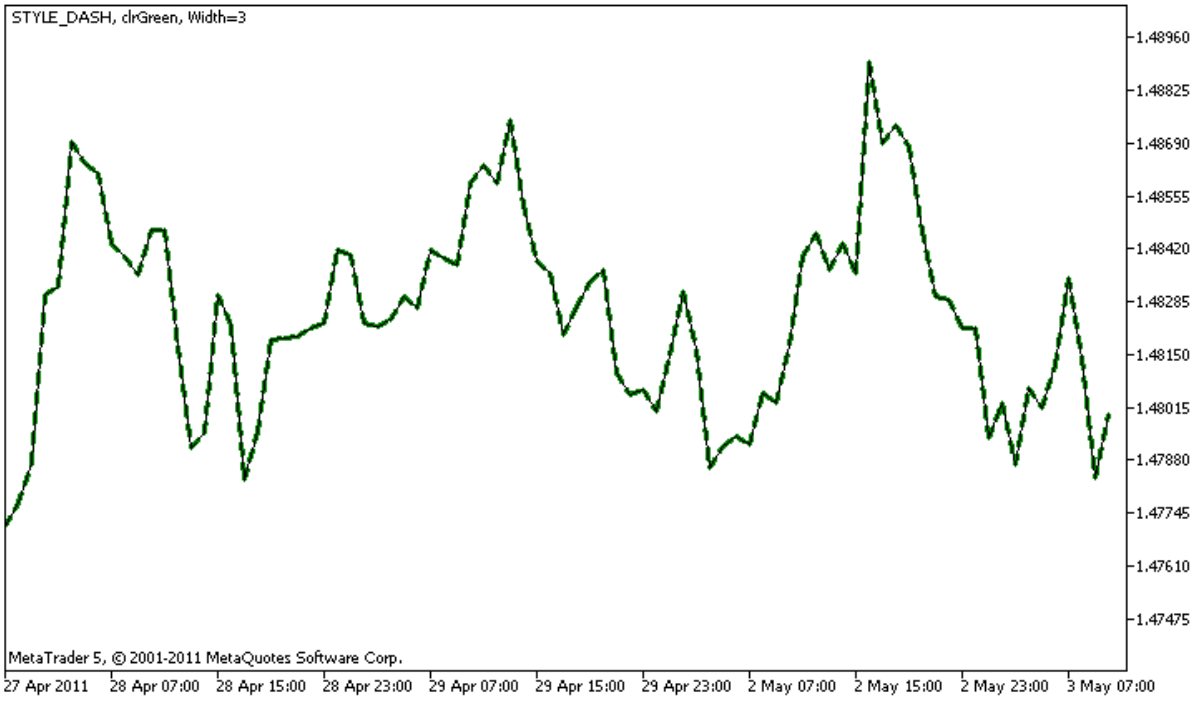
DRAW_LINE

DRAW_LINE draws a line of the specified color by the values of the indicator buffer. The width, style and color of the line can be set using the compiler directives and dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The number of buffers required for plotting DRAW_LINE is 1.

An example of the indicator that draws a line using Close prices of bars. The line color, width and style change randomly every N=5 ticks.



Note that initially for **plot1** with DRAW_LINE the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

//--- Show the information on the chart using a comment
   Comment(comm);
  }
```

DRAW_SECTION

DRAW_SECTION draws sections of the specified color by the values of the indicator buffer. The width, color and style of the line can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

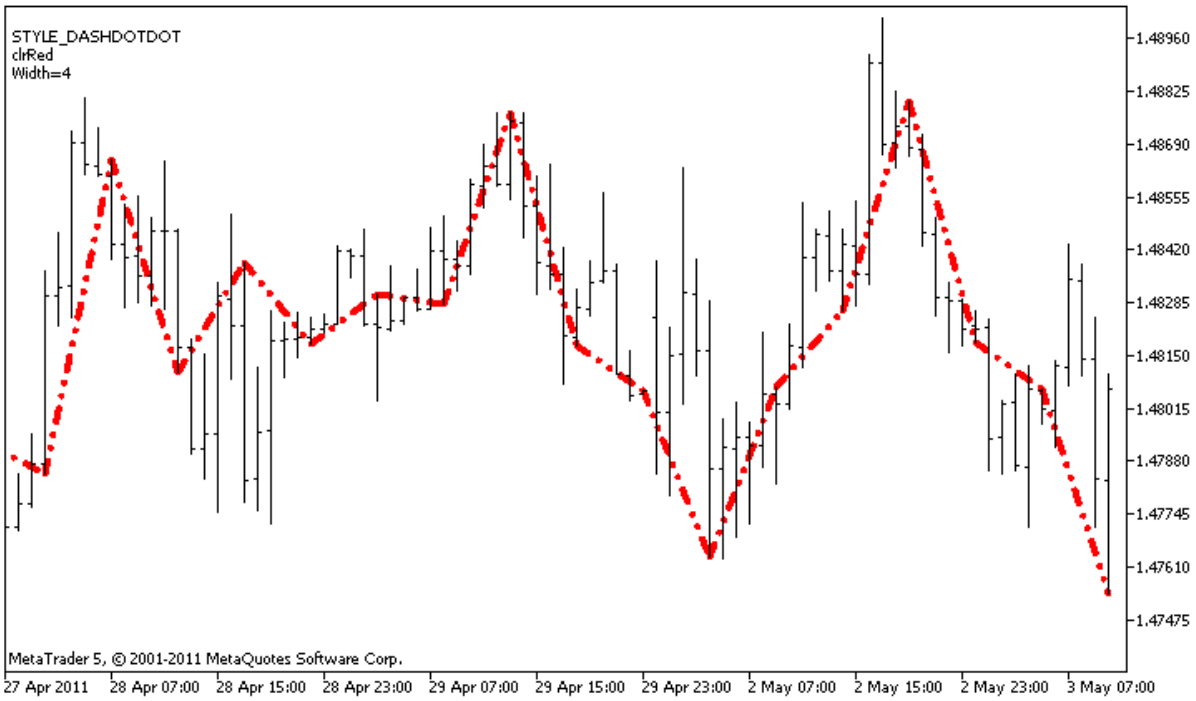
Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

The number of buffers required for plotting DRAW_SECTION is 1.

An example of the indicator that draws sections between the High and Low prices. The color, width and style of **all** sections change randomly every **N** ticks.



Note that initially for **plot1** with DRAW_SECTION the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

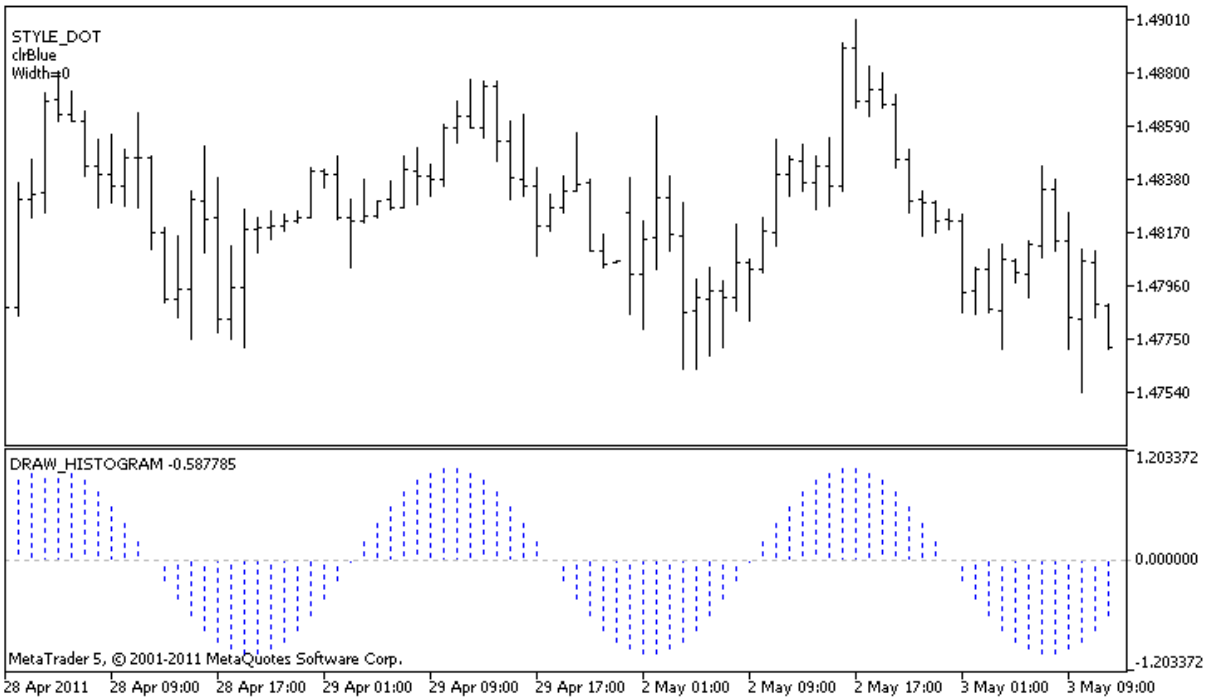
DRAW_HISTOGRAM

The DRAW_HISTOGRAM style draws a histogram as a sequence of columns of a specified color from zero to a specified value. Values are taken from the indicator buffer. The width, color and style of the column can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

Since a column from the zero level is drawn on each bar, DRAW_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, Bears Power or OsMA. For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_HISTOGRAM is 1.

An example of the indicator that draws a sinusoid of a specified color based on the MathSin() function. The color, width and style of **all** histogram columns change randomly each **N** ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.



Note that initially for **plot1** with DRAW_HISTOGRAM the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_HISTOGRAM2

The DRAW_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. The width, color and style of the segments can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with a zero value.

The number of buffers required for plotting DRAW_HISTOGRAM2 is 2.

An example of the indicator that plots a vertical segment of the specified color and width between the Open and Close prices of each bar. The color, width and style of **all** histogram columns change randomly each **N** ticks. During the start of the indicator, in the OnInit() function, the number of the day of week for which the histogram will not be drawn - invisible_day - is set randomly. For this purpose an empty value is set PLOT_EMPTY_VALUE=0:

```
//--- Set an empty value
   PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Note that initially for **plot1** with DRAW_HISTOGRAM2 the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

  }
```

DRAW_ARROW

The DRAW_ARROW style draws arrows of the specified color (symbols of the set Wingdings) based on the value of the indicator buffer. The width and color of the symbols can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the PLOT_ARROW property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW
   PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels
   PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

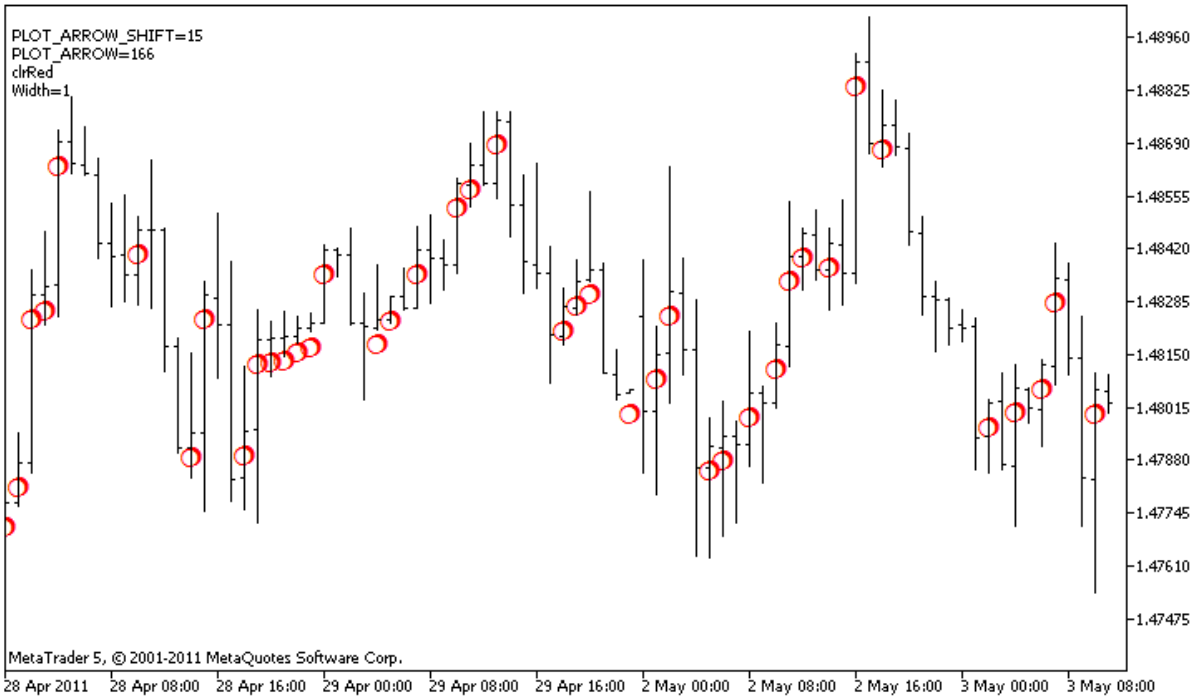
A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

The DRAW_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

```
//--- Set an empty value
   PlotIndexSetDouble(index_of_plot_DRAW_ARROW,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_ARROW is 1.

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The color, width, shift and symbol code of **all** arrows are changed randomly every **N** ticks.



In the example, for **plot1** with the DRAW_ARROW style, the properties, color and size are specified using the compiler directive #property, and then in the OnCalculate() function the properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

```

DRAW_ZIGZAG

The DRAW_ZIGZAG style draws segments of a specified color based on the values of two indicator buffers. This style is very similar to DRAW_SECTION, but unlike the latter, it allows drawing vertical segments within one bar, if values of both indicator buffers are set for this bar. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the DRAW_SECTION style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

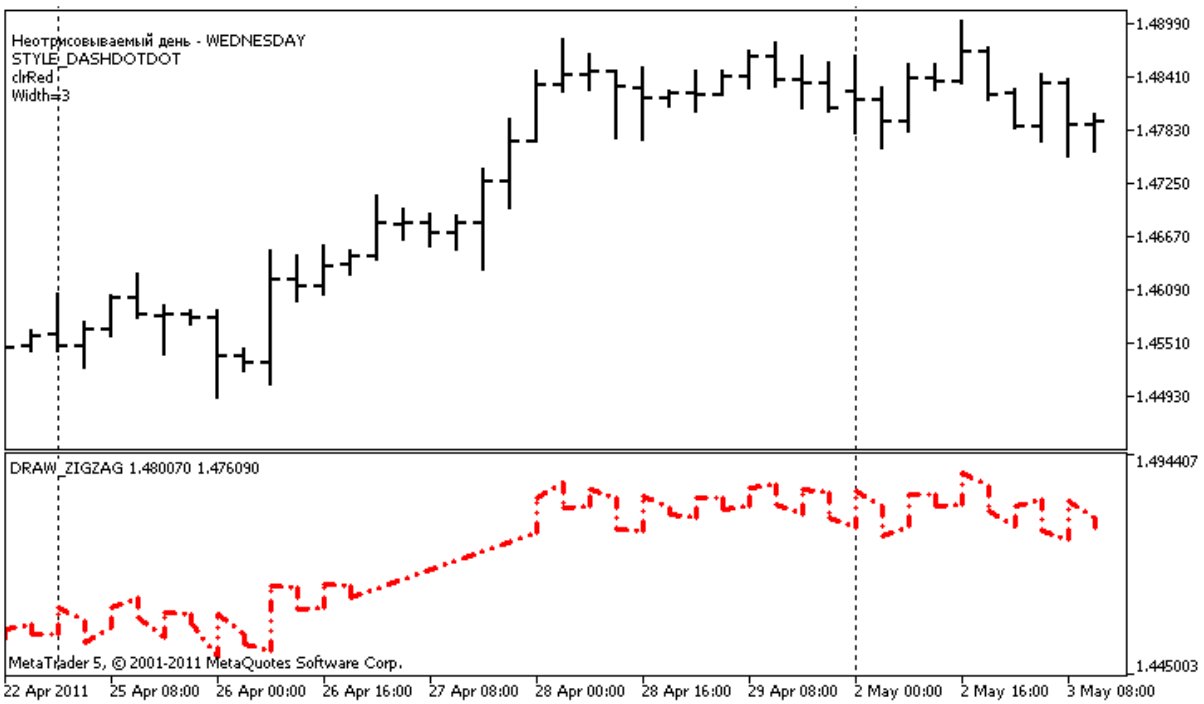
Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_ZIGZAG,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_ZIGZAG is 2.

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every **N** ticks.



Note that initially for **plot1** with DRAW_ZIGZAG the properties are set using the compiler directive #property, and then in the OnCalculate() function these properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

//--- Show the information on the chart using a comment
   Comment(comm);
  }
```

DRAW_FILLING

The DRAW_FILLING style plots a colored area between the values of two indicator buffers. In fact, this style draws two lines and fills the space between them with one of two specified colors. It is used for creating indicators that draw channels. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set two fill colors:

- the first color is used for the areas where values in the first buffer are greater than the values in the second indicator buffer;
- the second color is used for the areas where values in the second buffer are greater than the values in the first indicator buffer.

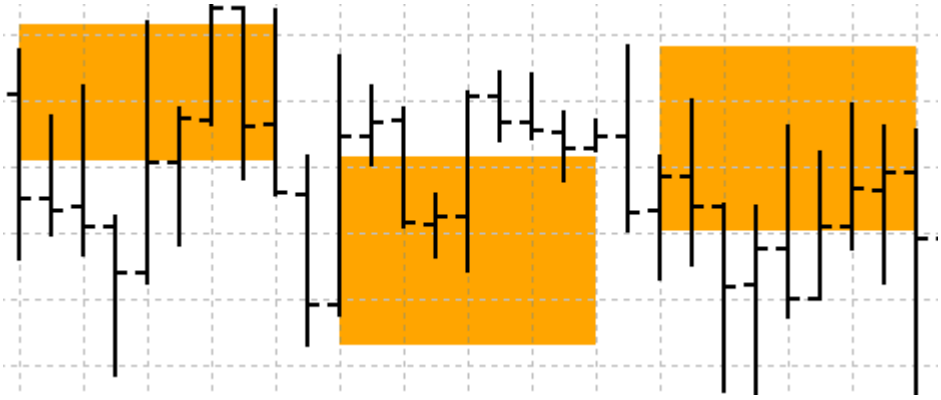
The fill color can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is calculated for all bars, for which the values of the both indicator buffers are equal neither to 0 nor to the empty value. To specify what value should be considered as "empty", set this value in PLOT_EMPTY_VALUE property:

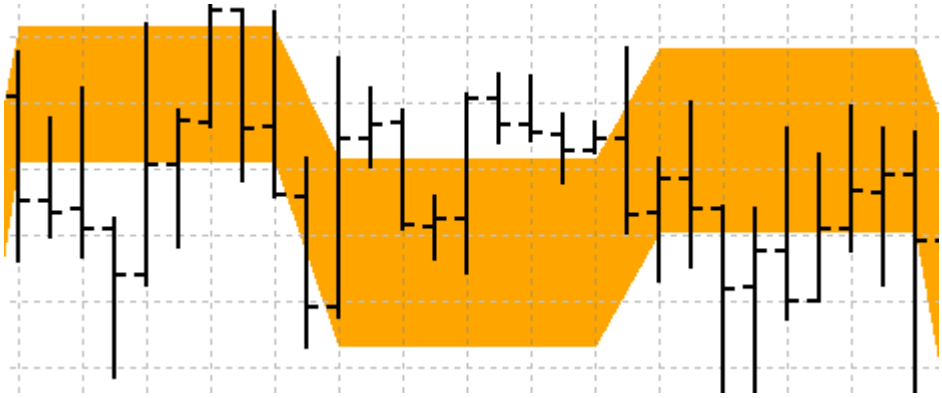
```
   #define INDICATOR_EMPTY_VALUE -1.0
   ...
//--- INDICATOR_EMPTY_VALUE (empty value) will not participate in calculation of
   PlotIndexSetDouble (DRAW_FILLING_creation_index,PLOT_EMPTY_VALUE,INDICATOR_EMPTY_VA
```

Drawing on the bars that do not participate in the indicator calculation will depend on the values in the indicator buffers:

- Bars, for which the values of both indicator buffers are equal to 0, do not participate in drawing the indicator. It means that the area with zero values is not filled out.



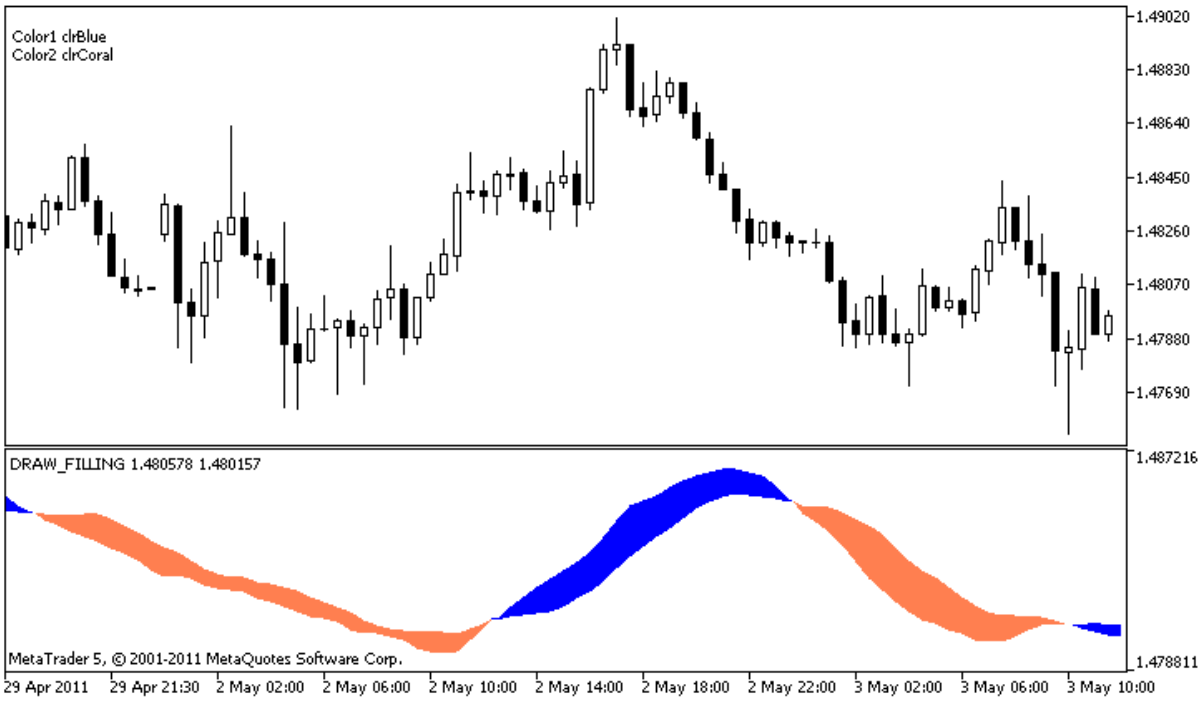
- Bars, for which the values of the indicator buffers are equal to the "empty value", participate in drawing the indicator. The area with empty values will be filled out so that to connect the areas with significant values.



It should be noted that if the "empty value" is equal to zero, the bars that do not participate in the indicator calculation are also filled out.

The number of buffers required for plotting DRAW_FILLING is 2.

An example of the indicator that draws a channel between two MAs with different averaging periods in a separate window. The change of the colors at the crossing of moving averages visually shows the change of the upward and downward trends. The colors change randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).



Note that initially for **plot1** with DRAW_FILLING the properties are set using the compiler directive #property, and then in the OnCalculate() function new colors are set randomly.

```

DRAW_BARS

The DRAW_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_BARS,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_BARS is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for **plot1** with the DRAW_BARS style, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

```

DRAW_CANDLES

The DRAW_CANDLES style draws candlesticks on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The color of candlesticks can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_CANDLES,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_CANDLES is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set up to three colors for the DRAW_CANDLES style affecting the candle look. If only one color is set, it is applied to all candles on a chart.

```
//--- identical candles with a single color applied to them
#property indicator_label1  "One color candles"
#property indicator_type1   DRAW_CANDLES
//--- only one color is specified, therefore all candles are of the same color
#property indicator_color1  clrGreen
```

If two comma-separated colors are specified, the first one is applied to candle outlines, while the second one is applied to the body.

```
//--- different colors for candles and wicks
#property indicator_label1  "Two color candles"
#property indicator_type1   DRAW_CANDLES
//--- green is applied to wicks and outlines, while white is applied to the body
#property indicator_color1  clrGreen,clrWhite
```

Specify three comma-separated colors so that rising and falling candles are displayed differently. In that case, the first color is applied to the candle outlines, while the second and third ones - to bullish and bearish candles.

```
//--- different colors for candles and wicks
#property indicator_label1  "One color candles"
#property indicator_type1   DRAW_CANDLES
//--- wicks and outlines are green, bullish candle body is white, while bearish candle
#property indicator_color1  clrGreen,clrWhite,clrRed
```

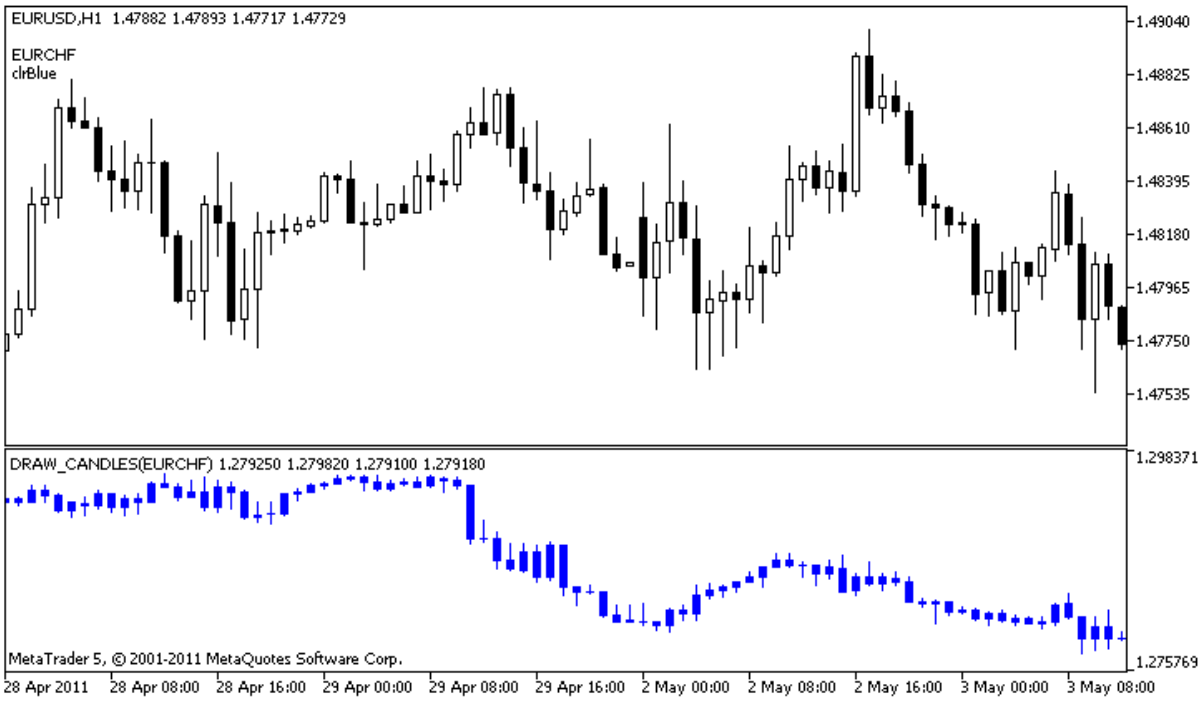
Thus, the DRAW_CANDLES style allows you to create custom candle coloring options. Besides, all colors can be changed dynamically during the indicator operation using the PlotIndexSetInteger function

(composition_index_DRAW_CANDLES, PLOT_LINE_COLOR, modifier_index, color), where modifier_index may have the following values:

- 0 - colors of outlines and wicks
- 1- bullish candle body color
- 2 - bearish candle body color

```
//--- set the color of outlines and wicks
PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrBlue);
//--- set the bullish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrGreen);
//--- set the bearish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrRed);
```

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).



Please note that for **plot1**, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

    comm="\r\n"+symbol+comm;
//--- Show the information on the chart using a comment
    Comment(comm);
   }
```

DRAW_COLOR_LINE

The DRAW_COLOR_LINE value is a colored variant of the DRAW_LINE style; it also draws a line using the values of the indicator buffer. But this style, like all color styles with the word **COLOR** in their title has an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each line segment can be defined by specifying the color index of the index to draw the line at this bar.

The width, style and colors of lines can be set using the compiler directives and dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

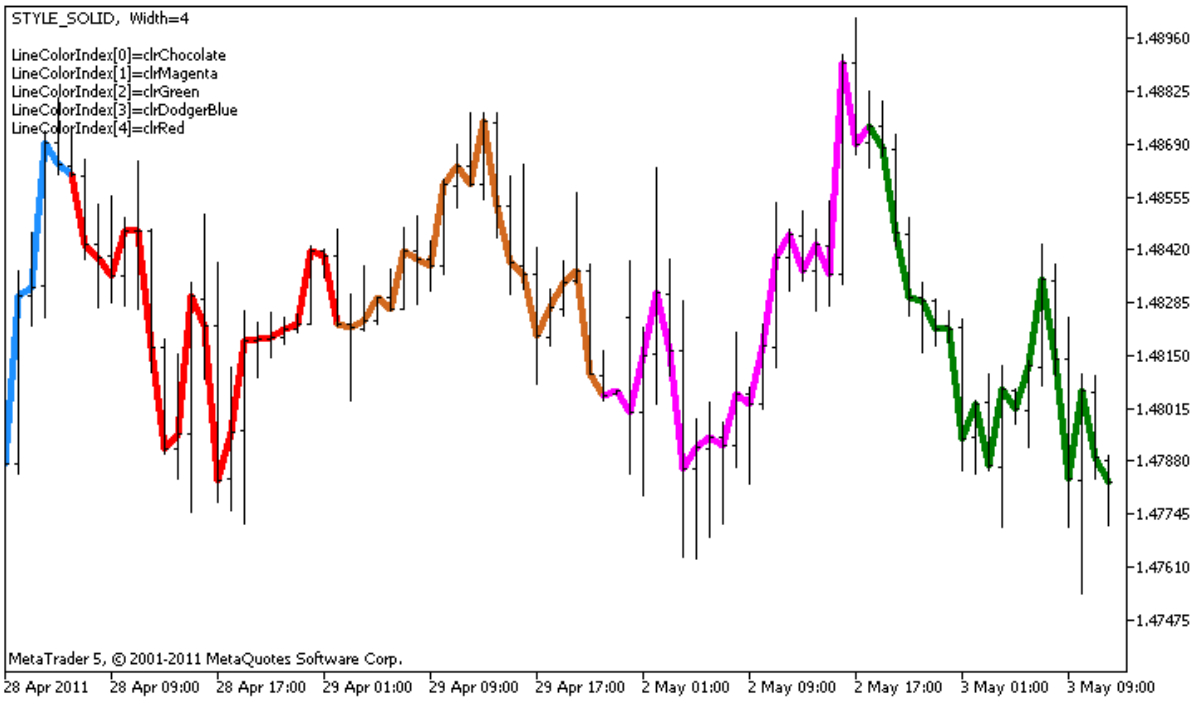
The number of buffers required for plotting DRAW_COLOR_LINE is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the index of the color of the line on each bar.

Colors can be specified by the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

```
//--- Define 5 colors for coloring each bar (they are stored in the special array)
#property indicator_color1  clrRed,clrBlue,clrGreen,clrOrange,clrDeepPink // (Up to 6
```

An example of the indicator that draws a line using Close prices of bars. The line width and style change randomly every N=5 ticks.



The colors of the line segments also change randomly in the custom function ChangeColors().

```
//+------------------------------------------------------------------+
//| Changes the color of line segments                               |
//+------------------------------------------------------------------+
void  ChangeColors(color  &cols[],int plot_colors)
```

```
  {
//--- The number of colors
   int size=ArraySize(cols);
//---
   string comm=ChartGetString(0,CHART_COMMENT)+"\r\n\r\n";

//--- For each color index define a new color randomly
   for(int plot_color_ind=0;plot_color_ind<plot_colors;plot_color_ind++)
     {
      //--- Get a random value
      int number=MathRand();
      //--- Get an index in the col[] array as a remainder of the integer devision
      int i=number%size;
      //--- Set the color for each index as the property PLOT_LINE_COLOR
      PlotIndexSetInteger(0,                    //  The number of a graphical style
                          PLOT_LINE_COLOR,      //  Property identifier
                          plot_color_ind,       //  The index of the color, where we w
                          cols[i]);             //  A new color
      //--- Write the colors
      comm=comm+StringFormat("LineColorIndex[%d]=%s \r\n",plot_color_ind,ColorToString
      ChartSetString(0,CHART_COMMENT,comm);
     }
//---
  }
```

The example shows the feature of the "color" versions of indicators - to change the color of a line segment, you do not need to change values in the ColorLineColors[] buffer (which contains the color indexes). All you need to do is set new colors in a special array. This allows you to quickly change the color once for the entire plotting, changing only a small array of colors using the PlotIndexSetInteger() function.

Note that initially for **plot1** with DRAW_COLOR_LINE the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly.

The N and Length (the length of color segments in bars) parameters are set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_SECTION

The DRAW_COLOR_SECTION style is a color version of DRAW_SECTION, but unlike the latter, it allows drawing sections of different colors. The DRAW_COLOR_SECTION style, like all color styles with the word **COLOR** in their title, contains an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each section can be defined by specifying the color index of the index of the bar that corresponds to the section end.

The width, color and style of the sections can be specified like for the DRAW_SECTION style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_SECTION,PLOT_EMPTY_VALUE,0);
```

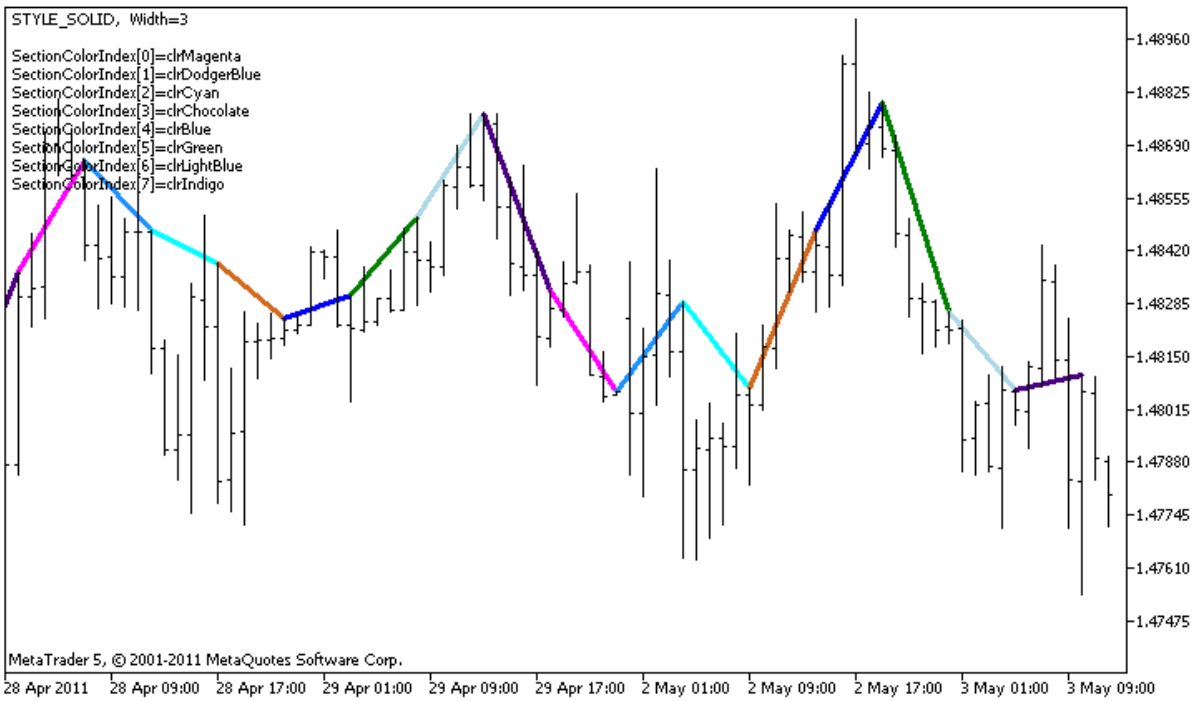
Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

The number of buffers required for plotting DRAW_COLOR_SECTION is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified by the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws colored sections each 5 bars long, using the High price values. The color, width and style of sections change randomly every **N** ticks.



Note that initially for **plot1** with DRAW_COLOR_SECTION 8 colors are set using the compiler directive #property. Then in the OnCalculate() function, colors are set randomly from the array of colors colors[].

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

DRAW_COLOR_HISTOGRAM

The DRAW_COLOR_HISTOGRAM style draws a histogram as a sequence of colored columns from zero to a specified value. Values are taken from the indicator buffer. Each column can have its own color from a predefined set of colors.

The width, color and style of the histogram can be specified like for the DRAW_HISTOGRAM style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

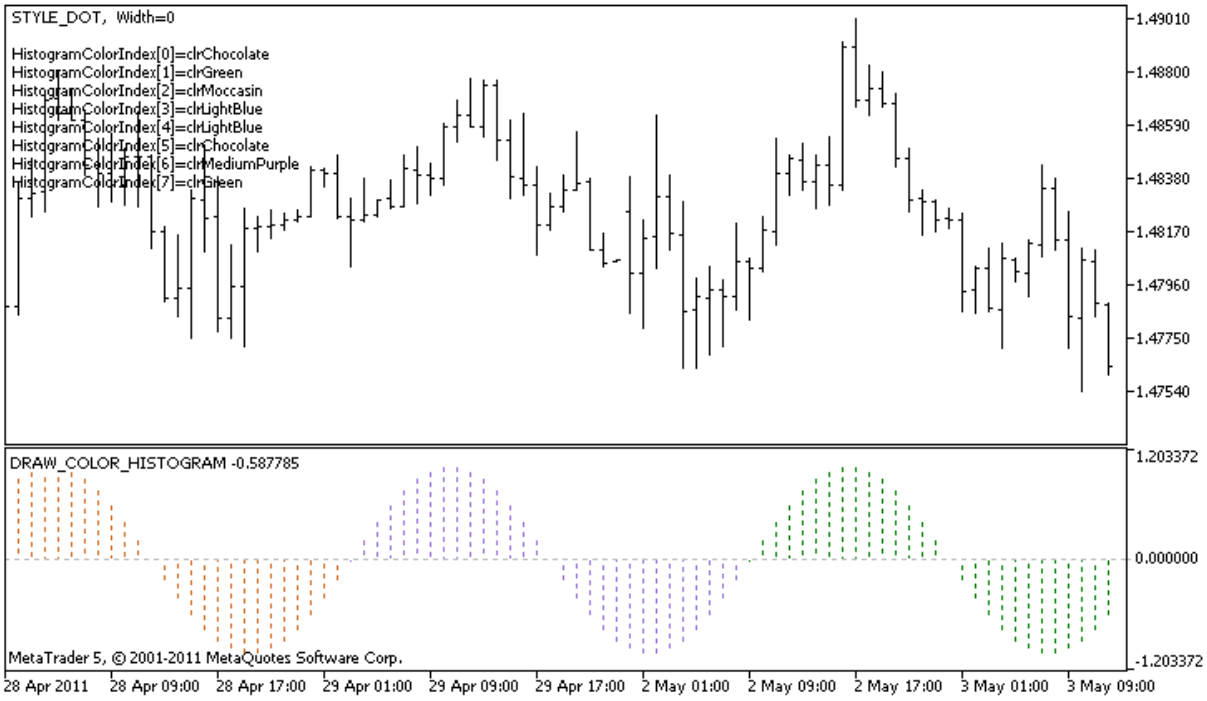
Since a column from the zero level is drawn on each bar, DRAW_COLOR_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, Awesome Oscillator or Market Facilitation Index. For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM is 2.

- one buffer for storing a non-zero value of the vertical segment on each bar, the second end of the segment is always on the zero line of the indicator;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified using the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws a sinusoid of a specified color based on the MathSin() function. The color, width and style of **all** histogram columns change randomly each **N** ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.



Please note that for **plot1** with the DRAW_COLOR_HISTOGRAM style, 5 colors are set using the compiler directive #property, and then in the OnCalculate() function the colors are selected randomly

from the 14 colors stored in the colors[] array. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_HISTOGRAM2

The DRAW_COLOR_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. But unlike the one-color DRAW_HISTOGRAM2, in this style each column of the histogram can have its own color from a predefined set. The values of all the segments are taken from the indicator buffer.

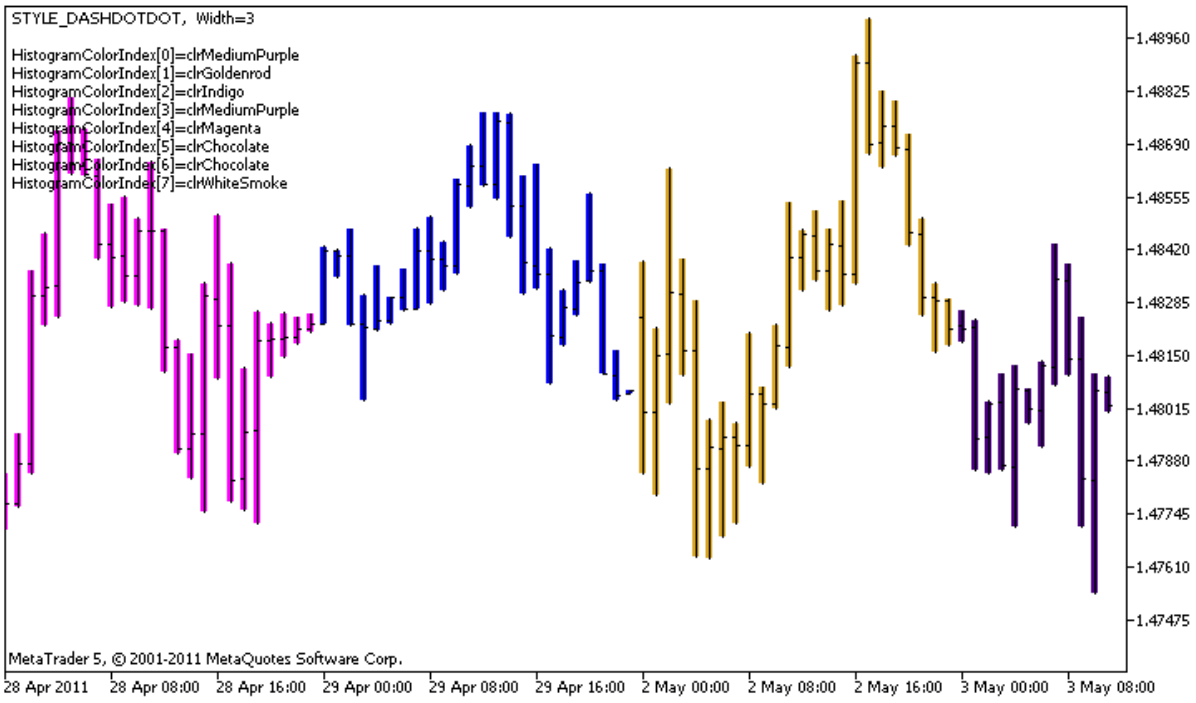
The width, style and color of the histogram can be specified like for theDRAW_HISTOGRAM2 style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_COLOR_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with empty values.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM2 is 3:

- two buffers to store the upper and lower end of the vertical segment on each bar;
- one buffer to store the color index, which is used to draw the segment (it makes sense to set only non-empty values).

An example of the indicator that draws a histogram of a specified color between the High and Low prices. For each day of week, the histogram lines have a different color. The color of the day, width and style of the histogram change randomly each **N** ticks.



Please note that for **plot1** with the DRAW_COLOR_HISTOGRAM2 style, 5 colors are set using the compiler directive #property, and then in the OnCalculate() function the colors are selected randomly from the 14 colors stored in the colors[] array.

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

DRAW_COLOR_ARROW

The DRAW_COLOR_ARROW style draws colored arrows (symbols of the set Wingdings) based on the value of the indicator buffer. In contrast to DRAW_ARROW, in this style it is possible to set a color from a predefined set of colors specified by the indicator_color1 property for each symbol.

The width and color of the symbols can be specified like for theDRAW_ARROW style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the PLOT_ARROW property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW
   PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels
   PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

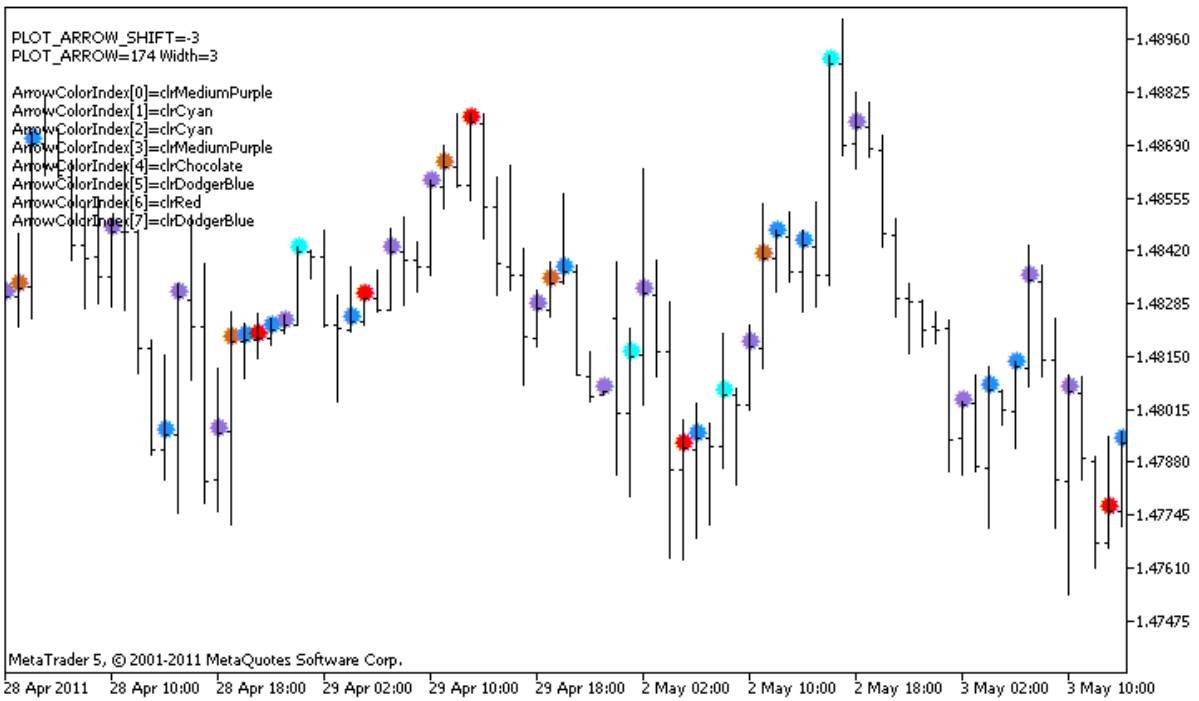
The DRAW_COLOR_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

```
//--- Set an empty value
   PlotIndexSetDouble(DRAW_COLOR_ARROW_plot_index,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_COLOR_ARROW is 2.

- a buffer to store the value of the price which is used to draw the symbol (plus a shift in pixels, given in the PLOT_ARROW_SHIFT property);
- a buffer to store the color index, which is used to draw an arrow (it makes sense to set only non-empty values).

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The width, shift and symbol code of **all** arrows are changed randomly every **N** ticks. The color of the symbol depends on the number of the bar on which it is drawn.



In the example, for **plot1** with the DRAW_COLOR_ARROW style, the properties, color and size are specified using the compiler directive #property, and then in the OnCalculate() function the properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that initially 8 colors are set using the compiler directive #property, and then in the OnCalculate() function, the color is set randomly from the 14 colors that are stored in the colors[] array.

```

DRAW_COLOR_ZIGZAG

The DRAW_COLOR_ZIGZAG style draws segments of different colors, using the values of two indicator buffers. This style is a colored version of DRAW_ZIGZAG, i.e. allows specifying for each segment an individual color from the predefined set of colors. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the DRAW_ZIGZAG style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

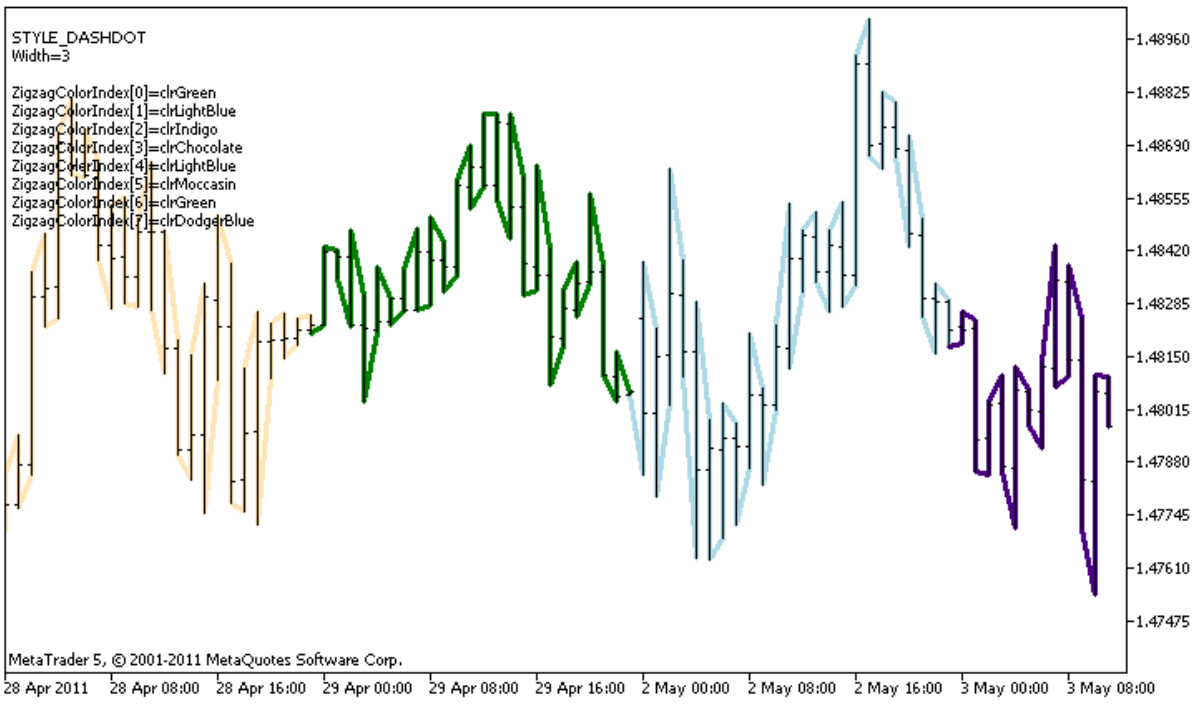
```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_ZIGZAG,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_COLOR_ZIGZAG is 3:

- two buffers to store the values of ends of the zigzag sections;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every N ticks.



Please note that for **plot1** with the DRAW_COLOR_ZIGZAG style, 8 colors are set using the compiler directive #property, and then in the OnCalculate() function the color is selected randomly from the 14 colors stored in the colors[] array.

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_BARS

The DRAW_COLOR_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. This style is an advanced version of DRAW_BARS and allows specifying for each bar an individual color from the predefined set of colors. It used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_BARS,PLOT_EMPTY_VALUE,0);
```

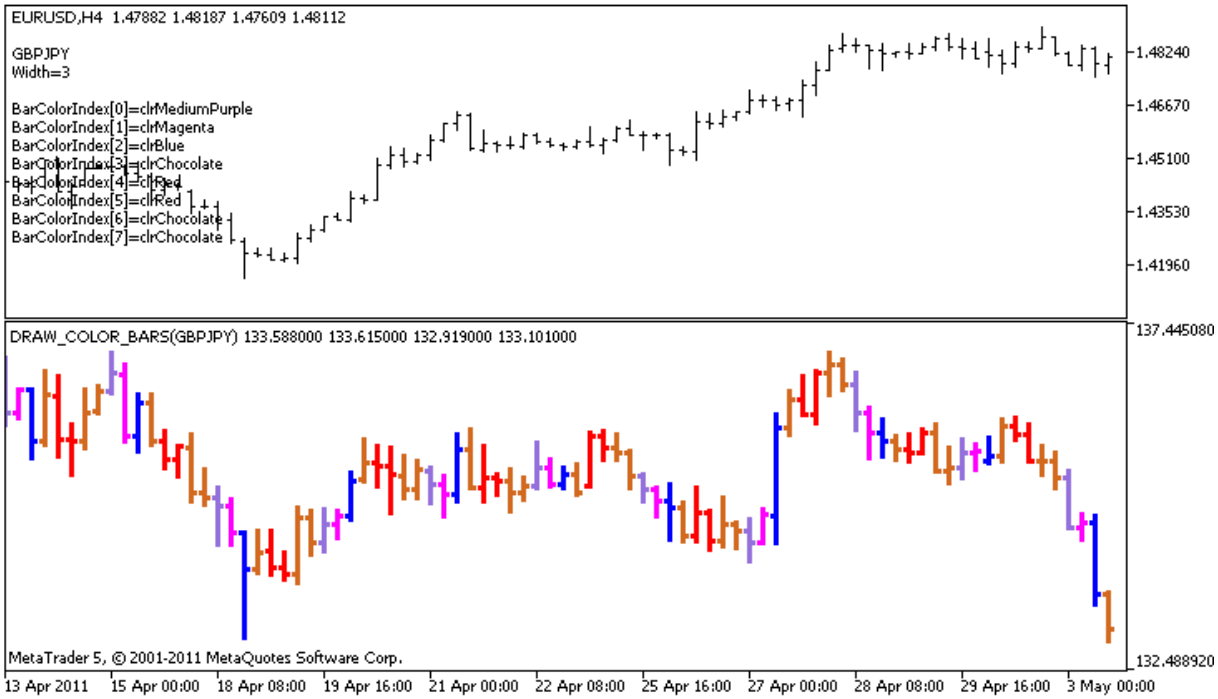
Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_COLOR_BARS is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a bar (it makes sense to set it only for the bars that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only null values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).



Please note that for **plot1** with the DRAW_COLOR_BARS style, 8 colors are set using the compiler directive #property, and then in the OnCalculate() function the color is selected randomly from the 14 colors stored in the colors[] array.

DRAW_COLOR_CANDLES

The DRAW_COLOR_CANDLES style, like DRAW_CANDLES, draws candlesticks using the values of four indicator buffers, which contain Open, High, Low and Close prices. In addition, it allows specifying a color for each candlestick from a given set. For this purpose, the style has a special color buffer that stores color indexes for each bar. It used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The number of colors of candlesticks can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of four price buffers of the indicator are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_CANDLES,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_COLOR_CANDLES is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a candlestick (it makes sense to set it only for the candlesticks that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for **plot1**, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

```

Connection between Indicator Properties and Corresponding Functions

Every custom indicator has numerous properties, some of which are obligatory and are always positioned at the beginning of description. They are the following properties:

- indication of a window to plot the indicator – indicator_separate_window or indicator_chart_window;
- number of indicator buffers – indicator_buffers;
- number of plots of the indicator – indicator_plots.

Also there are other properties that can be set both through preprocessor directives and through functions intended for custom indicator creation. These properties and corresponding functions are described in the following table.

Directives for properties of indicator subwindow	Functions of IndicatorSet...() type	Description of the adjusted property of the subwindow
indicator_height	IndicatorSetInteger (INDICATOR_INDICATOR_HEIGHT, nHeight)	The fixed value of the subwindow height
indicator_minimum	IndicatorSetDouble (INDICATOR_MINIMUM, dMaxValue)	Minimal value of the vertical axis
indicator_maximum	IndicatorSetDouble (INDICATOR_MAXIMUM, dMinValue)	Maximal value of the vertical axis
indicator_levelN	IndicatorSetDouble (INDICATOR_LEVELVALUE, N-1, nLevelValue)	Vertical axis value for N level
no preprocessor directive	IndicatorSetString (INDICATOR_LEVELTEXT, N-1, sLevelName)	Name of a displayed level
indicator_levelcolor	IndicatorSetInteger (INDICATOR_LEVELCOLOR, N-1, nLevelColor)	Color of N level
indicator_levelwidth	IndicatorSetInteger (INDICATOR_LEVELWIDTH, N-1, nLevelWidth)	Line width for N level
indicator_levelstyle	IndicatorSetInteger (INDICATOR_LEVELSTYLE, N-1, nLevelStyle)	Line style for N level
Directives for plotting properties	**Functions of PlotIndexSet...() type**	**Description of the adjusted property of a plot**
indicator_labelN	PlotIndexSetString(N-1,PLOT_LABEL,sLabel)	Short name of the number N plot. It is displayed in

Directives for properties of indicator subwindow	Functions of IndicatorSet...() type	Description of the adjusted property of the subwindow
		DataWindow and in the pop-up tooltip when pointing the mouse cursor over it
indicator_colorN	PlotIndexSetInteger(N-1, PLOT_LINE_COLOR, nColor)	Line color for N plot
indicator_styleN	PlotIndexSetInteger(N-1, PLOT_LINE_STYLE, nType)	Line style for N plot
indicator_typeN	PlotIndexSetInteger(N-1, PLOT_DRAW_TYPE, nType)	Line type for N plot
indicator_widthN	PlotIndexSetInteger(N-1, PLOT_LINE_WIDTH, nWidth)	Line width for N plot
Common indicator properties	**Functions of IndicatorSet...() type**	**Description**
no preprocessor directive	IndicatorSetString (INDICATOR_SHORTNAME, sShortName)	Sets the convenient short name of the indicator that will be displayed in the list of indicators (opened in the terminal by pressing **Ctrl+I**).
no preprocessor directive	IndicatorSetInteger (INDICATOR_DIGITS, nDigits)	Sets required accuracy of display of indicator values - number of decimal places
no preprocessor directive	IndicatorSetInteger (INDICATOR_LEVELS, nLevels)	Sets number of levels in the indicator window
indicator_applied_price	No function, the property can be set only by the preprocessor directive.	Default price type used for the indicator calculation. It is specified when necessary, only if OnCalculate() of the first type is used. The property value can also be set from the dialog of indicator properties in the "Parameters" tab - "Apply to".

It should be noted that numeration of levels and plots in preprocessor terms starts with one, while numeration of the same properties at using functions starts with zero, i.e. the indicated value must be by 1 less than that indicated for #property.

There are several directives, for which there are no corresponding functions:

Directive	Description
indicator_chart_window	Indicator is displayed in the main window

Directive	Description
indicator_separate_window	Indicator is displayed in a separate subwindow
indicator_buffers	Number of required indicator buffers
indicator_plots	Number of plots in the indicator

SetIndexBuffer

The function binds a specified indicator buffer with one-dimensional dynamic array of the double type.

```
bool  SetIndexBuffer(
   int                   index,          // buffer index
   double                buffer[],       // array
   ENUM_INDEXBUFFER_TYPE  data_type      // what will be stored
   );
```

Parameters

index

[in] Number of the indicator buffer. The numbering starts with 0. The number must be less than the value declared in #property indicator_buffers.

buffer[]

[in] An array declared in the custom indicator program.

data_type

[in] Type of data stored in the indicator array. By default it is INDICATOR_DATA (values of the calculated indicator). It may also take the value of INDICATOR_COLOR_INDEX; in this case this buffer is used for storing color indexes for the previous indicator buffer. You can specify up to 64 colors in the #property indicator_colorN line. The INDICATOR_CALCULATIONS value means that the buffer is used in intermediate calculations of the indicator and is not intended for drawing.

Return Value

If successful, returns true, otherwise - false.

Note

After binding, the dynamic array buffer[] will be indexed as in common arrays, even if the indexing of timeseries is pre-installed for the bound array. If you want to change the order of access to elements of the indicator array, use the ArraySetAsSeries() function **after binding the array using the SetIndexBuffer() function**. Please note that you can't change the size for dynamic arrays set as indicator buffers by the function SetIndexBuffer(). For indicator buffers, all operations of size changes are performed by the executing sub-system of the terminal.

Example:

```
//+------------------------------------------------------------------+
//|                                              TestCopyBuffer1.mq5 |

Custom Indicator Properties, Access to timeseries and indicators

IndicatorSetDouble

The function sets the value of the corresponding indicator property. Indicator property must be of the double type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetDouble(
   int     prop_id,           // identifier
   double  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetDouble(
   int     prop_id,           // identifier
   int     prop_modifier,     // modifier
   double  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier. Numbering of levels starts from 0. It means that in order to set property for the second level you need to specify 1 (1 less than when using compiler directive).

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

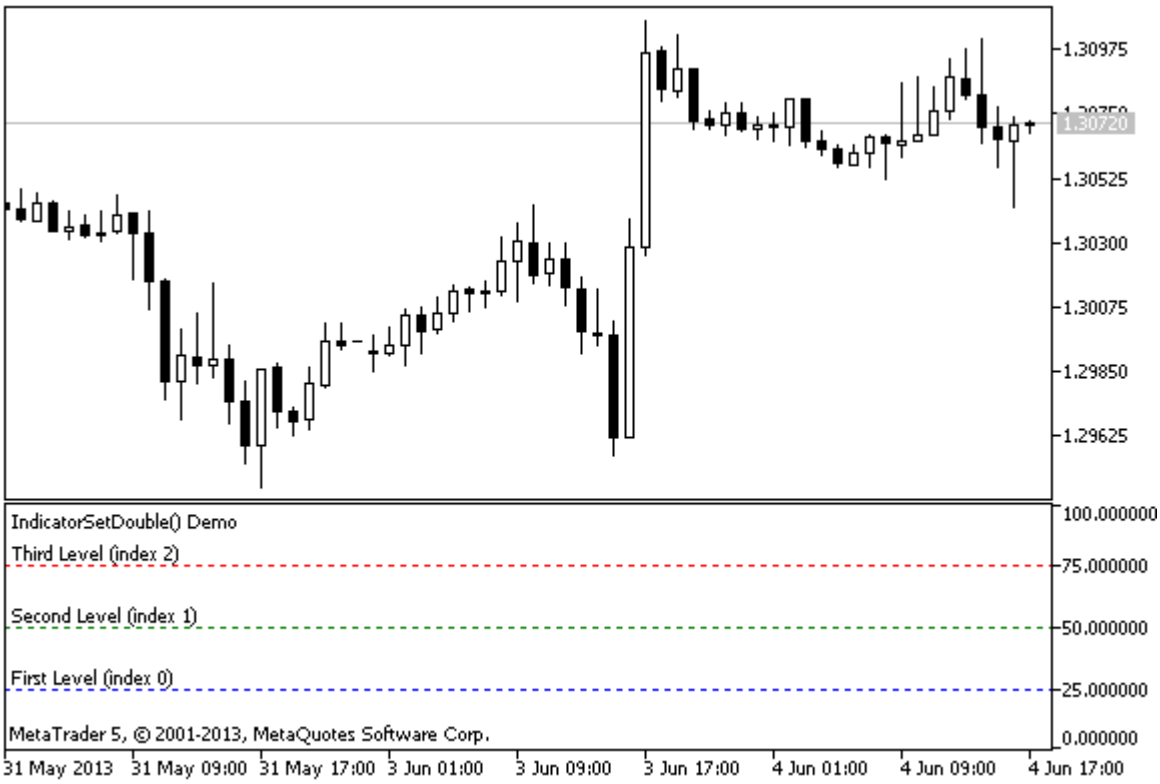
Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, the first level value for the indicator in a separate subwindow can be set in two ways:

- property indicator_level**1** 50 - the value of 1 is used for specifying the level number,
- IndicatorSetDouble(INDICATOR_LEVELVALUE, **0**, 50) - 0 is used for specifying the first level.

Example: indicator that turns upside down the maximum and minimum values of the indicator window and values of levels on which the horizontal lines are placed.



```
#property indicator_separate_window
//--- set the maximum and minimum values for the indicator window
#property indicator_minimum  0
#property indicator_maximum  100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 25
#property indicator_level2 50
#property indicator_level3 75
//--- set thickness of horizontal levels
#property indicator_levelwidth 1
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_DOT
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- set descriptions of horizontal levels
   IndicatorSetString(INDICATOR_LEVELTEXT,0,"First Level (index 0)");
   IndicatorSetString(INDICATOR_LEVELTEXT,1,"Second Level (index 1)");
   IndicatorSetString(INDICATOR_LEVELTEXT,2,"Third Level (index 2)");
//--- set the short name for indicator
   IndicatorSetString(INDICATOR_SHORTNAME,"IndicatorSetDouble() Demo");
//--- set color for each level
   IndicatorSetInteger(INDICATOR_LEVELCOLOR,0,clrBlue);
   IndicatorSetInteger(INDICATOR_LEVELCOLOR,1,clrGreen);
   IndicatorSetInteger(INDICATOR_LEVELCOLOR,2,clrRed);
```

```
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {

Indicator Styles in Examples, Connection between Indicator Properties and Functions, Drawing Styles

IndicatorSetInteger

The function sets the value of the corresponding indicator property. Indicator property must be of the int or color type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetInteger(
   int  prop_id,           // identifier
   int  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetInteger(
   int  prop_id,           // identifier
   int  prop_modifier,     // modifier
   int  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

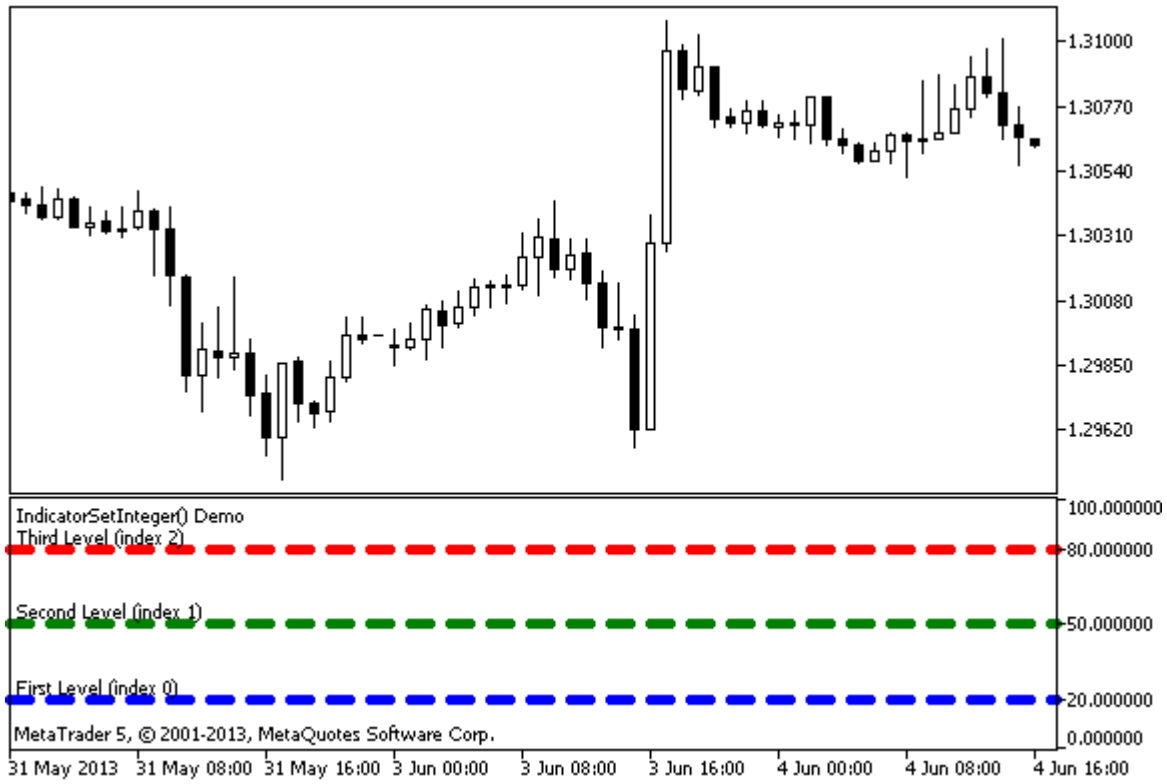
Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, in order to set thickness of the first horizontal line use zeroth index:

- IndicatorSetInteger(INDICATOR_LEVELWIDTH, **0**, 5) - index 0 is used to set thickness of the first level.

Example: indicator that sets color, style and thickness of the indicator horizontal lines.



```
#property indicator_separate_window
#property indicator_minimum 0
#property indicator_maximum 100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 20
#property indicator_level2 50
#property indicator_level3 80
//--- set thickness of horizontal levels
#property indicator_levelwidth 5
//--- set color of horizontal levels
#property indicator_levelcolor clrAliceBlue
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_DOT
//+------------------------------------------------------------------+

IndicatorSetString

The function sets the value of the corresponding indicator property. Indicator property must be of the string type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetString(
   int     prop_id,           // identifier
   string  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetString(
   int     prop_id,           // identifier
   int     prop_modifier,     // modifier
   string  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, in order to set description of the first horizontal line use zeroth index:

- IndicatorSetString(INDICATOR_LEVELTEXT, **0**, "First Level") - index 0 is used to set text description of the first level.

Example: indicator that sets text labels to the indicator horizontal lines.

```
#property indicator_separate_window
#property indicator_minimum 0
#property indicator_maximum 100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 30
#property indicator_level2 50
#property indicator_level3 70
//--- set color of horizontal levels
#property indicator_levelcolor clrRed
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_SOLID
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- set descriptions of horizontal levels
   IndicatorSetString(INDICATOR_LEVELTEXT,0,"First Level (index 0)");
   IndicatorSetString(INDICATOR_LEVELTEXT,1,"Second Level (index 1)");
   IndicatorSetString(INDICATOR_LEVELTEXT,2,"Third Level (index 2)");
//--- set the short name for indicator
   IndicatorSetString(INDICATOR_SHORTNAME,"IndicatorSetString() Demo");
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
```

```
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//---

//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Custom Indicator Properties, Program Properties (#property)

PlotIndexSetDouble

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the double type.

```
bool  PlotIndexSetDouble(
   int     plot_index,     // plotting style index
   int     prop_id,        // property identifier
   double  prop_value      // value to be set
   );
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_DOUBLE enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

PlotIndexSetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, char, bool or color type. There are 2 variants of the function.

Call indicating identifier of the property.

```
bool  PlotIndexSetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   int  prop_value          // value to be set
   );
```

Call indicating the identifier and modifier of the property.

```
bool  PlotIndexSetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   int  prop_modifier,      // property modifier
   int  prop_value          // value to be set
   )
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

Example: an indicator that draws a three-color line. The color scheme changes every 5 ticks.

```
#property indicator_chart_window
#property indicator_buffers 2
#property indicator_plots   1
//---- plot ColorLine
#property indicator_label1  "ColorLine"

               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrGreen);
               Print("Color scheme "+modified);
               break;
            case 1:// second color scheme
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrYellow);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrPink);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLightSlateGray);
               Print("Color scheme "+modified);
               break;
            default:// third color scheme
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrLightGoldenrod);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrOrchid);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLimeGreen);
               Print("Color scheme "+modified);
           }
        }
      else
        {
         //--- set start position
         limit=prev_calculated-1;
         //--- now we set line color for every bar
         for(int i=limit;i<rates_total;i++)
            ColorBuffer[i]=getIndexOfColor(i);
        }
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

PlotIndexSetString

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the string type.

```
bool  PlotIndexSetString(
   int     plot_index,     // plotting style index
   int     prop_id,        // property identifier
   string  prop_value      // value to be set
   );
```

Parameters

plot_index

[in] Index of graphical plot

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_STRING enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

PlotIndexGetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, color, bool or char type. There are 2 variants of the function.

Call indicating identifier of the property.

```
int  PlotIndexGetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   );
```

Call indicating the identifier and modifier of the property.

```
int  PlotIndexGetInteger(
   int  plot_index,         // plotting index
   int  prop_id,            // property identifier
   int  prop_modifier       // property modifier
   )
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

Note

Function is designed to extract the settings of drawing of the appropriate indicator line. The function works in tandem with the function PlotIndexSetInteger to copy the drawing properties of one line to another.

Example: an indicator that colors candles depending on the day of the week. Colors for each day are set in a programmatically.

```
#property indicator_separate_window
#property indicator_buffers 5
#property indicator_plots   1
//---- plot ColorCandles
#property indicator_label1  "ColorCandles"
#property indicator_type1   DRAW_COLOR_CANDLES
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- indicator buffers
double         OpenBuffer[];
double         HighBuffer[];
double         LowBuffer[];
double         CloseBuffer[];
double         ColorCandlesColors[];
color          ColorOfDay[6]={CLR_NONE,clrMediumSlateBlue,
                              clrDarkGoldenrod,clrForestGreen,clrBlueViolet,clrRed};
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,OpenBuffer,INDICATOR_DATA);
   SetIndexBuffer(1,HighBuffer,INDICATOR_DATA);
   SetIndexBuffer(2,LowBuffer,INDICATOR_DATA);
   SetIndexBuffer(3,CloseBuffer,INDICATOR_DATA);
   SetIndexBuffer(4,ColorCandlesColors,INDICATOR_COLOR_INDEX);
//--- set number of colors in color buffer
```

```
   PlotIndexSetInteger(0,PLOT_COLOR_INDEXES,6);
//--- set colors for color buffer
   for(int i=1;i<6;i++)
      PlotIndexSetInteger(0,PLOT_LINE_COLOR,i,ColorOfDay[i]);
//--- set accuracy
   IndicatorSetInteger(INDICATOR_DIGITS,_Digits);
   printf("We have %u colors of days",PlotIndexGetInteger(0,PLOT_COLOR_INDEXES));
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],

      LowBuffer[i]=low[i];
      CloseBuffer[i]=close[i];
      //--- set color for every candle
      TimeToStruct(time[i],t);
      ColorCandlesColors[i]=t.day_of_week;
      //---
      i++;
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

Object Functions

This is the group of functions intended for working with graphic objects relating to any specified chart.

The functions defining the properties of graphical objects, as well as ObjectCreate() and ObjectMove() operations for creating and moving objects along the chart are actually used for sending commands to the chart. If these functions are executed successfully, the command is included in the common queue of the chart events. Visual changes in the properties of graphical objects are implemented when handling the queue of the chart events.

Thus, do not expect an immediate visual update of graphical objects after calling these functions. Generally, the graphical objects on the chart are updated automatically by the terminal following the change events - a new quote arrival, resizing the chart window, etc. Use ChartRedraw() function to forcefully update the graphical objects.

Function	Action
ObjectCreate	Creates an object of the specified type in a specified chart
ObjectName	Returns the name of an object of the corresponding type in the specified chart (specified chart subwindow)
ObjectDelete	Removes the object with the specified name from the specified chart (from the specified chart subwindow)
ObjectsDeleteAll	Removes all objects of the specified type from the specified chart (from the specified chart subwindow)
ObjectFind	Searches for an object with the specified ID by the name
ObjectGetTimeByValue	Returns the time value for the specified object price value
ObjectGetValueByTime	Returns the price value of an object for the specified time
ObjectMove	Changes the coordinates of the specified object anchor point
ObjectsTotal	Returns the number of objects of the specified type in the specified chart (specified chart subwindow)
ObjectGetDouble	Returns the double value of the corresponding object property
ObjectGetInteger	Returns the integer value of the corresponding object property
ObjectGetString	Returns the string value of the corresponding object property
ObjectSetDouble	Sets the value of the corresponding object property
ObjectSetInteger	Sets the value of the corresponding object property
ObjectSetString	Sets the value of the corresponding object property
TextSetFont	Sets the font for displaying the text using drawing methods (Arial 20 used by default)
TextOut	Transfers the text to the custom array (buffer) designed for creation of a graphical resource

Function	Action
TextGetSize	Returns the string's width and height at the current font settings

Every graphical object should have a name unique within one chart, including its subwindows. Changing of a name of a graphic object generates two events: event of deletion of an object with the old name, and event of creation of an object with a new name.

After an object is created or an object property is modified it is recommended to call the ChartRedraw() function, which commands the client terminal to forcibly draw a chart (and all visible objects in it).

ObjectCreate

The function creates an object with the specified name, type, and the initial coordinates in the specified chart subwindow. During creation up to 30 coordinates can be specified.

```
bool  ObjectCreate(
   long          chart_id,      // chart identifier
   string        name,          // object name
   ENUM_OBJECT   type,          // object type
   sub_window    nwin,          // window index
   datetime      time1,         // time of the first anchor point
   double        price1,        // price of the first anchor point
   ...
   datetime      timeN=0,       // time of the N-th anchor point
   double        priceN=0,      // price of the N-th anchor point
   ...
   datetime      time30=0,      // time of the 30th anchor point
   double        price30=0      // price of the 30th anchor point
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object. The name must be unique within a chart, including its subwindows.

type

[in] Object type. The value can be one of the values of the ENUM_OBJECT enumeration.

sub_window

[in] Number of the chart subwindow. 0 means the main chart window. The specified subwindow must exist, otherwise the function returns false.

time1

[in] The time coordinate of the first anchor.

price1

[in] The price coordinate of the first anchor point.

timeN=0

[in] The time coordinate of the N-th anchor point.

priceN=0

[in] The price coordinate of the N-th anchor point.

time30=0

[in] The time coordinate of the thirtieth anchor point.

price30=0

[in] The price coordinate of the thirtieth anchor point.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise. If an object has already been created, an attempt is made to change its coordinates.

Note

An asynchronous call is always used for ObjectCreate(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use the ObjectFind() function or any other function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object name should not exceed 63 characters.

The numbering of the chart subwindows (if there are subwindows with indicators in the chart) starts with 1. The main chart window of the chart is and always has index 0.

The large number of anchor points (up to 30) is implemented for future use. At the same time, the limit of 30 possible anchor points for graphical objects is determined by the limit on the number of parameters (not more than 64) that can be used when calling a function.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

There is a certain number of anchor points that must be specified when creating each object type:

ID	Description	Anchor Points
OBJ_VLINE	Vertical Line	One anchor point. Actually only the time coordinate is used.
OBJ_HLINE	Horizontal Line	One anchor point. Actually only the price coordinate is used.
OBJ_TREND	Trend Line	Two anchor points.
OBJ_TRENDBYANGLE	Trend Line By Angle	Two anchor points.
OBJ_CYCLES	Cycle Lines	Two anchor points.
OBJ_ARROWED_LINE	Arrowed Line	Two anchor points.
OBJ_CHANNEL	Equidistant Channel	Three anchor points.
OBJ_STDDEVCHANNEL	Standard Deviation Channel	Two anchor points.
OBJ_REGRESSION	Linear Regression Channel	Two anchor points.

ID	Description	Anchor Points
OBJ_PITCHFORK	Andrews' Pitchfork	Three anchor points.
OBJ_GANNLINE	Gann Line	Two anchor points.
OBJ_GANNFAN	Gann Fan	Two anchor points.
OBJ_GANNGRID	Gann Grid	Two anchor points.
OBJ_FIBO	Fibonacci Retracement	Two anchor points.
OBJ_FIBOTIMES	Fibonacci Time Zones	Two anchor points.
OBJ_FIBOFAN	Fibonacci Fan	Two anchor points.
OBJ_FIBOARC	Fibonacci Arcs	Two anchor points.
OBJ_FIBOCHANNEL	Fibonacci Channel	Three anchor points.
OBJ_EXPANSION	Fibonacci Expansion	Three anchor points.
OBJ_ELLIOTWAVE5	Elliott Motive Wave	Five anchor points.
OBJ_ELLIOTWAVE3	Elliott Correction Wave	Three anchor points.
OBJ_RECTANGLE	Rectangle	Two anchor points.
OBJ_TRIANGLE	Triangle	Three anchor points.
OBJ_ELLIPSE	Ellipse	Three anchor points.
OBJ_ARROW_THUMB_UP	Thumbs Up	One anchor point.
OBJ_ARROW_THUMB_DOWN	Thumbs Down	One anchor point.
OBJ_ARROW_UP	Arrow Up	One anchor point.
OBJ_ARROW_DOWN	Arrow Down	One anchor point.
OBJ_ARROW_STOP	Stop Sign	One anchor point.
OBJ_ARROW_CHECK	Check Sign	One anchor point.
OBJ_ARROW_LEFT_PRICE	Left Price Label	One anchor point.
OBJ_ARROW_RIGHT_PRICE	Right Price Label	One anchor point.
OBJ_ARROW_BUY	Buy Sign	One anchor point.
OBJ_ARROW_SELL	Sell Sign	One anchor point.
OBJ_ARROW	Arrow	One anchor point.
OBJ_TEXT	Text	One anchor point.
OBJ_LABEL	Label	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.

ID	Description	Anchor Points
OBJ_BUTTON	Button	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_CHART	Chart	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_BITMAP	Bitmap	One anchor point.
OBJ_BITMAP_LABEL	Bitmap Label	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_EDIT	Edit	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_EVENT	The "Event" object corresponding to an event in the economic calendar	One anchor point. Actually only the time coordinate is used.
OBJ_RECTANGLE_LABEL	The "Rectangle label" object for creating and designing the custom graphical interface.	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.

ObjectName

The function returns the name of the corresponding object in the specified chart, in the specified subwindow, of the specified type.

```
string  ObjectName(
   long  chart_id,           // chart identifier
   int   pos,                // number in the list of objects
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

pos

[in] Ordinal number of the object according to the specified filter by the number and type of the subwindow.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

Name of the object is returned in case of success.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectDelete

The function removes the object with the specified name from the specified chart.

```
bool  ObjectDelete(
   long    chart_id,      // chart identifier
   string  name           // object name
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of object to be deleted.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise.

Note

An asynchronous call is always used for ObjectDelete(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use the ObjectFind() function or any other function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectsDeleteAll

Removes all objects from the specified chart, specified chart subwindow, of the specified type.

```
int  ObjectsDeleteAll(
   long  chart_id,           // chart identifier
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Removes all objects of the specified type using prefix in object names.

```
int  ObjectsDeleteAll(
   long           chart_id,    // chart ID
   const string     prefix,    // prefix in object name
   int        sub_window=-1,   // window index
   int      object_type=-1     // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

prefix

[in] Prefix in object names. All objects whose names start with this set of characters will be removed from chart. You can specify prefix as 'name' or 'name*' - both variants will work the same. If an empty string is specified as the prefix, objects with all possible names will be removed.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

Returns the number of deleted objects. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

ObjectFind

The function searches for an object with the specified name in the chart with the specified ID.

```
int  ObjectFind(
   long    chart_id,      // chart identifier
   string  name           // object name
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] The name of the searched object.

Return Value

If successful the function returns the number of the subwindow (0 means the main window of the chart), in which the object is found. If the object is not found, the function returns a negative number. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectGetTimeByValue

The function returns the time value for the specified price value of the specified object.

```
datetime  ObjectGetTimeByValue(
   long     chart_id,      // chart identifier
   string   name,          // object name
   double   value,         // Price
   int      line_id        // Line number
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

value

[in] Price value.

line_id

[in] Line identifier.

Return Value

The time value for the specified price value of the specified object.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLINE)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

See also

Object Types

ObjectGetValueByTime

The function returns the price value for the specified time value of the specified object.

```
double  ObjectGetValueByTime(
   long      chart_id,     // chart identifier
   string    name,         // object name
   datetime  time,         // Time
   int       line_id       // Line number
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

time

[in] Time value.

line_id

[in] Line ID.

Return Value

The price value for the specified time value of the specified object.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLINE)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

See also

Object Types

ObjectMove

The function changes coordinates of the specified anchor point of the object.

```
bool  ObjectMove(
   long      chart_id,         // chart identifier
   string    name,             // object name
   int       point_index,      // anchor point number
   datetime  time,             // Time
   double    price             // Price
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

point_index

[in] Index of the anchor point. The number of anchor points depends on the type of object.

time

[in] Time coordinate of the selected anchor point.

price

[in] Price coordinate of the selected anchor point.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise.

Note

An asynchronous call is always used for ObjectMove(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use a function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

ObjectsTotal

The function returns the number of objects in the specified chart, specified subwindow, of the specified type.

```
int  ObjectsTotal(
   long  chart_id,           // chart identifier
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

The number of objects.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

ObjectSetDouble

The function sets the value of the corresponding object property. The object property must be of the double type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property
   double                        prop_value         // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property
   int                           prop_modifier,     // modifier
   double                        prop_value         // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

The function uses an asynchronous call, which means that the function does not wait for the execution of the command that has been added to the queue of the specified chart. Instead, it immediately returns control.

To check the command execution result, you can use a function that requests the specified object property. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result, and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

Example of creating a Fibonacci object and adding a new level in it

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- auxiliary arrays
   double high[],low[],price1,price2;
   datetime time[],time1,time2;
//--- Copy the open prices - 100 latest bars are enough
   int copied=CopyHigh(Symbol(),0,0,100,high);
   if(copied<=0)
     {
      Print("Failed to copy the values of the High price series");
      return;
     }
//--- Copy the close price - 100 latest bars are enough
   copied=CopyLow(Symbol(),0,0,100,low);
   if(copied<=0)
     {
      Print("Failed to copy the values of the Low price series");
      return;
     }
//--- Copy the open time for the last 100 bars
   copied=CopyTime(Symbol(),0,0,100,time);
   if(copied<=0)
     {
      Print("Failed to copy the values of the price series of Time");
      return;
     }
//--- Organize access to the copied data as to timeseries - backwards
   ArraySetAsSeries(high,true);
   ArraySetAsSeries(low,true);
   ArraySetAsSeries(time,true);

//--- Coordinates of the first anchor point of the Fibo object
   price1=high[70];
   time1=time[70];
//--- Coordinates of the second anchor point of the Fibo object
   price2=low[50];
```

```
   time2=time[50];

//--- Time to create the Fibo object
   bool created=ObjectCreate(0,"Fibo",OBJ_FIBO,0,time1,price1,time2,price2);
   if(created) // If the object is created successfully
     {
      //--- set the color of Fibo levels
      ObjectSetInteger(0,"Fibo",OBJPROP_LEVELCOLOR,Blue);
      //--- by the way, how much Fibo levels do we have?
      int levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
      Print("Fibo levels before = ",levels);
      //---output to the Journal => number of level:value level_desription
      for(int i=0;i<levels;i++)
        {
         Print(i,": ",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
               "  ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
        }
      //--- Try to increase the number of levels per unit
      bool modified=ObjectSetInteger(0,"Fibo",OBJPROP_LEVELS,levels+1);
      if(!modified) // failed to change the number of levels
        {
         Print("Failed to change the number of levels of Fibo, error ",GetLastError())
        }
      //--- just inform
      Print("Fibo levels after = ",ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS));
      //--- set a value for a newly created level
      bool added=ObjectSetDouble(0,"Fibo",OBJPROP_LEVELVALUE,levels,133);
      if(added) // managed to set a value for the level
        {
         Print("Successfully set one more Fibo level");
         //--- Also do not forget to set the level description
         ObjectSetString(0,"Fibo",OBJPROP_LEVELTEXT,levels,"my level");
         ChartRedraw(0);
         //--- Get the actual value of the number of levels in the Fibo object
         levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
         Print("Fibo levels after adding = ",levels);
         //--- once again output all levels - just to make sure
         for(int i=0;i<levels;i++)
           {
            Print(i,":",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
                  "  ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
           }
        }
      else // Fails if you try to increase the number of levels in the Fibo object
        {
         Print("Failed to set one more Fibo level. Error ",GetLastError());
        }
     }
  }
```

Object Types, Object Properties

ObjectSetInteger

The function sets the value of the corresponding object property. The object property must be of the datetime, int, color, bool or char type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetInteger(
   long                          chart_id,       // chart identifier
   string                        name,           // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,        // property
   long                          prop_value      // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetInteger(
   long                          chart_id,       // chart identifier
   string                        name,           // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,        // property
   int                           prop_modifier,  // modifier
   long                          prop_value      // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

The function uses an asynchronous call, which means that the function does not wait for the execution of the command that has been added to the queue of the specified chart. Instead, it immediately returns control.

To check the command execution result, you can use a function that requests the specified object property. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result, and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An example of how to create a table of Web colors

```
//+------------------------------------------------------------------+
//|                                              Table of Web Colors|

Object Types, Object Properties

ObjectSetString

The function sets the value of the corresponding object property. The object property must be of the string type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property
   string                        prop_value         // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property
   int                           prop_modifier,     // modifier
   string                        prop_value         // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

The function uses an asynchronous call, which means that the function does not wait for the execution of the command that has been added to the queue of the specified chart. Instead, it immediately returns control.

To check the command execution result, you can use a function that requests the specified object property. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result, and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectGetDouble

The function returns the value of the corresponding object property. The object property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  ObjectGetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if require
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   double&                       double_var         // here we accept the property v
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

double_var

[out] Variable of the double type that received the value of the requested property.

Return Value

Value of the double type for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the double_var variable, otherwise returns false. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

ObjectGetInteger

The function returns the value of the corresponding object property. The object property must be of the datetime, int, color, bool or char type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  ObjectGetInteger(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if requi
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetInteger(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   long&                         long_var           // here we accept the property
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

long_var

[out] Variable of the long type that receives the value of the requested property.

Return Value

The long value for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the long_var variable, otherwise returns false. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

ObjectGetString

The function returns the value of the corresponding object property. The object property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  ObjectGetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if require
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   string&                       string_var         // here we accept the property v
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

string_var

[out] Variable of the string type that receives the value of the requested properties.

Return Value

String value for the first version of the call.

For the second version of the call returns true, if this property is maintained and the value has been placed into the string_var variable, otherwise returns false. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

TextSetFont

The function sets the font for displaying the text using drawing methods and returns the result of that operation. Arial font with the size -120 (12 pt) is used by default.

```
bool  TextSetFont(
   const string  name,            // font name or path to font file on the disk
   int           size,            // font size
   uint          flags,           // combination of flags
   int           orientation=0    // text slope angle
   );
```

Parameters

name

[in] Font name in the system or the name of the resource containing the font or the path to font file on the disk.

size

[in] The font size that can be set using positive and negative values. In case of positive values, the size of a displayed text does not depend on the operating system's font size settings. In case of negative values, the value is set in tenths of a point and the text size depends on the operating system settings ("standard scale" or "large scale"). See the Note below for more information about the differences between the modes.

flags

[in] Combination of flags describing font style.

orientation

[in] Text's horizontal inclination to X axis, the unit of measurement is 0.1 degrees. It means that *orientation=450* stands for inclination equal to 45 degrees.

Return Value

Returns true if the current font is successfully installed, otherwise false. Possible code errors:

- ERR_INVALID_PARAMETER(4003) - *name* presents NULL or "" (empty string),
- ERR_INTERNAL_ERROR(4001) - operating system error (for example, an attempt to create a non-existent font).

Note

If "::" is used in font name, the font is downloaded from EX5 resource. If *name* font name is specified with an extension, the font is downloaded from the file, if the path starts from "\" or "/", the file is searched relative to MQL5 directory. Otherwise, it is searched relative to the path of EX5 file which called TextSetFont() function.

The font size is set using positive or negative values. This fact defines the dependence of the text size from the operating system settings (size scale).

- If the size is specified using a positive number, this size is transformed into physical measurement units of a device (pixels) when changing a logical font into a physical one, and this size corresponds to the height of the symbol glyphs picked from the available fonts. This case is not recommended when the texts displayed by TextOut() function and the ones displayed by OBJ_LABEL ("Label") graphical object are to be used together on the chart.

- If the size is specified using a negative number, this number is supposed to be set in tenths of a logical point and is divided by 10 (for example, -350 is equal to 35 logical points). An obtained value is then transformed into physical measurement units of a device (pixels) and corresponds to the absolute value of the height of a symbol picked from the available fonts. Multiply the font size specified in the object properties by -10 to make the size of a text on the screen similar to the one in OBJ_LABEL object.

The flags can be used as the combination of style flags with one of the flags specifying the font width. Flag names are shown below.

Flags for specifying font style

Flag	Description
FONT_ITALIC	Italic
FONT_UNDERLINE	Underline
FONT_STRIKEOUT	Strikeout

Flags for specifying font width

Flag
FW_DONTCARE
FW_THIN
FW_EXTRALIGHT
FW_ULTRALIGHT
FW_LIGHT
FW_NORMAL
FW_REGULAR
FW_MEDIUM
FW_SEMIBOLD
FW_DEMIBOLD
FW_BOLD
FW_EXTRABOLD
FW_ULTRABOLD
FW_HEAVY
FW_BLACK

See also

Resources, ResourceCreate(), ResourceSave(), TextOut()

TextOut

The function displays a text in a custom array (buffer) and returns the result of that operation. The array is designed to create the graphical resource.

```
bool  TextOut(
   const string       text,          // displayed text
   int                x,             // X coordinate
   int                y,             // Y coordinate
   uint               anchor,        // anchor type
   uint               &data[],       // output buffer
   uint               width,         // buffer width in pixels
   uint               height,        // buffer height in pixels
   uint               color,         // text color
   ENUM_COLOR_FORMAT  color_format   // color format for output
   );
```

Parameters

text

[in] Displayed text that will be written to the buffer. Only one-lined text is displayed.

x

[in] X coordinate of the anchor point of the displayed text.

y

[in] Y coordinate of the anchor point of the displayed text.

anchor

[in] The value out of the 9 pre-defined methods of the displayed text's anchor point location. The value is set by a combination of two flags - flags of horizontal and vertical text align. Flag names are listed in the Note below.

data[]

[in] Buffer, in which text is displayed. The buffer is used to create the graphical resource.

width

[in] Buffer width in pixels.

height

[in] Buffer height in pixels.

color

[in] Text color.

color_format

[in] Color format is set by ENUM_COLOR_FORMAT enumeration value.

Return Value

Returns true if successful, otherwise false.

Note

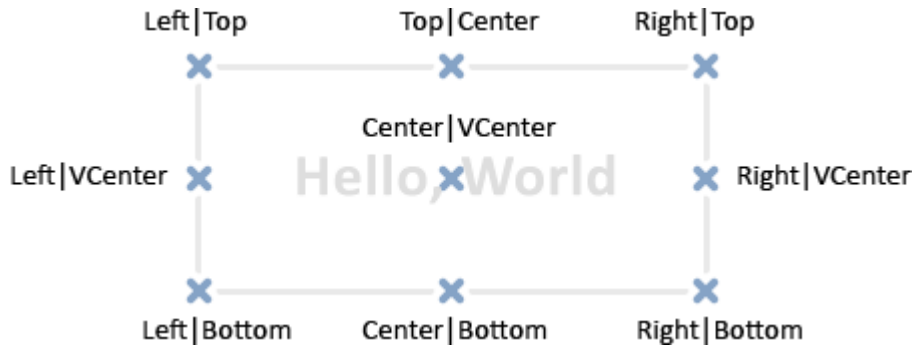
Anchor point specified by *anchor* is a combination of two flags of horizontal and vertical text align.
Horizontal text align flags:

- TA_LEFT - anchor point on the left side of the bounding box
- TA_CENTER - horizontal anchor point is located at the center of the bounding box
- TA_RIGHT - anchor point on the right side of the bounding box

Vertical text align flags:

- TA_TOP - anchor point at the upper side of the bounding box
- TA_VCENTER - vertical anchor point is located at the center of the bounding box
- TA_BOTTOM - anchor point at the lower side of the bounding box

Possible combinations of flags and specified anchor points are shown in the image.



Example:

```
//--- width and height of the canvas (used for drawing)
#define IMG_WIDTH  200
#define IMG_HEIGHT 200
//--- display the parameter window before launching the script
#property script_show_inputs
//--- enable to set color format
input ENUM_COLOR_FORMAT clr_format=COLOR_FORMAT_XRGB_NOALPHA;
//--- drawing array (buffer)
uint ExtImg[IMG_WIDTH*IMG_HEIGHT];
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create OBJ_BITMAP_LABEL object for drawing
   ObjectCreate(0,"CLOCK",OBJ_BITMAP_LABEL,0,0,0);
//--- specify the name of the graphical resource for writing in CLOCK object
   ObjectSetString(0,"CLOCK",OBJPROP_BMPFILE,"::IMG");

//--- auxiliary variables
   double a;            // arrow corner
   uint   nm=2700;      // minute corner
   uint   nh=2700*12;   // hour counter
   uint   w,h;          // variables for receiving text string sizes
```

```
   int    x,y;          // variables for calculation of the current coordinates of te

//--- rotate clock hands in an infinite loop, till the script is stopped
   while(!IsStopped())
     {
      //--- clear the clock drawing buffer array
      ArrayFill(ExtImg,0,IMG_WIDTH*IMG_HEIGHT,0);
      //--- set the font for drawing digits for the clock-face
      TextSetFont("Arial",-200,FW_EXTRABOLD,0);
      //--- draw the clock-face
      for(int i=1;i<=12;i++)
        {
         //--- receive the size of the current hour on the clock-face
         TextGetSize(string(i),w,h);
         //--- calculate the coordinates of the current hour on the clock-face
         a=-((i*300)%3600*M_PI)/1800.0;
         x=IMG_WIDTH/2-int(sin(a)*80+0.5+w/2);
         y=IMG_HEIGHT/2-int(cos(a)*80+0.5+h/2);
         //--- output the hour on the clock-face to ExtImg[] buffer
         TextOut(string(i),x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,
        }
      //--- now, specify the font for drawing the minute hand
      TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nm%3600));
      //--- receive the size of the minute hand
      TextGetSize("----->",w,h);
      //--- calculate the coordinates of the minute hand on the clock-face
      a=-(nm%3600*M_PI)/1800.0;
      x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
      y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
      //--- output of the minute hand to the clock-face in ExtImg[]buffer
      TextOut("----->",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_

      //--- now, set the font for drawing the minute hand
      TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nh/12%3600));
      TextGetSize("==>",w,h);
      //--- calculate the coordinates of the hour hand on the clock-face
      a=-(nh/12%3600*M_PI)/1800.0;
      x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
      y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
      //--- output of the hour hand on the clock-face to ExtImg[] buffer
      TextOut("==>",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_forn

      //--- update the graphical resource
      ResourceCreate("::IMG",ExtImg,IMG_WIDTH,IMG_HEIGHT,0,0,IMG_WIDTH,clr_format);
      //--- forced chart update
      ChartRedraw();

      //--- increase hour and minute counters
      nm+=60;
      nh+=60;
```

```
      //--- keeping a short pause between the frames
      Sleep(10);
     }
//--- delete CLOCK object when completing the script's operation
   ObjectDelete(0,"CLOCK");
//---
  }
```

Resources, ResourceCreate(), ResourceSave(), TextGetSize(), TextSetFont()

TextGetSize

The function returns the line width and height at the current font settings.

```
bool  TextGetSize(
   const string       text,          // text string
   uint&               width,        // buffer width in pixels
   uint&               height        // buffer height in pixels
   );
```

Parameters

text

[in] String, for which length and width should be obtained.

width

[out] Input parameter for receiving width.

height

[out] Input parameter for receiving height.

Return Value

Returns true if successful, otherwise false. Possible code errors:

- ERR_INTERNAL_ERROR(4001) - operating system error.

Technical Indicator Functions

All functions like iMA, iAC, iMACD, iIchimoku etc. create a copy of the corresponding technical indicator in the global cache of the client terminal. If a copy of the indicator with such parameters already exists, the new copy is not created, and the counter of references to the existing copy increases.

These functions return the handle of the appropriate copy of the indicator. Further, using this handle, you can receive data calculated by the corresponding indicator. The corresponding buffer data (technical indicators contain calculated data in their internal buffers, which can vary from 1 to 5, depending on the indicator) can be copied to a mql5-program using the CopyBuffer() function.

You can't refer to the indicator data right after it has been created, because calculation of indicator values requires some time, so it's better to create indicator handles in OnInit(). Function iCustom() creates the corresponding custom indicator, and returns its handle in case it is successfully create. Custom indicators can contain up to 512 indicator buffers, the contents of which can also be obtained by the CopyBuffer() function, using the obtained handle.

There is a universal method for creating any technical indicator using the IndicatorCreate() function. This function accepts the following data as input parameters:

- symbol name;
- timeframe;
- type of the indicator to create;
- number of input parameters of the indicator;
- an array of MqlParam type containing all the necessary input parameters.

The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note. Repeated call of the indicator function with the same parameters within one mql5-program does not lead to a multiple increase of the reference counter; the counter will be increased only once by 1. However, it's recommended to get the indicators handles in function OnInit() or in the class constructor, and further use these handles in other functions. The reference counter decreases when a mql5-program is deinitialized.

All indicator functions have at least 2 parameters - symbol and period. The NULL value of the symbol means the current symbol, the 0 value of the period means the current timeframe.

Function	Returns the handle of the indicator:
iAC	Accelerator Oscillator
iAD	Accumulation/Distribution
iADX	Average Directional Index
iADXWilder	Average Directional Index by Welles Wilder
iAlligator	Alligator
iAMA	Adaptive Moving Average

Function	Returns the handle of the indicator:
iAO	Awesome Oscillator
iATR	Average True Range
iBearsPower	Bears Power
iBands	Bollinger Bands®
iBullsPower	Bulls Power
iCCI	Commodity Channel Index
iChaikin	Chaikin Oscillator
iCustom	Custom indicator
iDEMA	Double Exponential Moving Average
iDeMarker	DeMarker
iEnvelopes	Envelopes
iForce	Force Index
iFractals	Fractals
iFrAMA	Fractal Adaptive Moving Average
iGator	Gator Oscillator
iIchimoku	Ichimoku Kinko Hyo
iBWMFI	Market Facilitation Index by Bill Williams
iMomentum	Momentum
iMFI	Money Flow Index
iMA	Moving Average
iOsMA	Moving Average of Oscillator (MACD histogram)
iMACD	Moving Averages Convergence-Divergence
iOBV	On Balance Volume
iSAR	Parabolic Stop And Reverse System
iRSI	Relative Strength Index
iRVI	Relative Vigor Index
iStdDev	Standard Deviation
iStochastic	Stochastic Oscillator
iTEMA	Triple Exponential Moving Average
iTriX	Triple Exponential Moving Averages Oscillator

Function	Returns the handle of the indicator:
iWPR	Williams' Percent Range
iVIDyA	Variable Index Dynamic Average
iVolumes	Volumes

iAC

The function creates Accelerator Oscillator in a global cache of the client terminal and returns its handle. It has only one buffer.

```
int  iAC(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period      // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES enumeration values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iAD

The function returns the handle of the Accumulation/Distribution indicator. It has only one buffer.

```
int  iAD(
   string               symbol,             // symbol name
   ENUM_TIMEFRAMES      period,             // period
   ENUM_APPLIED_VOLUME  applied_volume      // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES enumeration values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iADX

The function returns the handle of the Average Directional Movement Index indicator.

```
int  iADX(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              adx_period       // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

Example:

```
//+------------------------------------------------------------------+

iADXWilder

The function returns the handle of Average Directional Movement Index by Welles Wilder.

```
int  iADXWilder(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              adx_period       // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

Example:

```

iAlligator

The function returns the handle of the Alligator indicator.

```
int  iAlligator(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  jaw_period,        // period for the calculation of jaws
   int                  jaw_shift,         // horizontal shift of jaws
   int                  teeth_period,      // period for the calculation of teeth
   int                  teeth_shift,       // horizontal shift of teeth
   int                  lips_period,       // period for the calculation of lips
   int                  lips_shift,        // horizontal shift of lips
   ENUM_MA_METHOD       ma_method,         // type of smoothing
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw)

jaw_shift

[in] The shift of the blue line relative to the price chart.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price chart.

ma_method

[in] The method of averaging. Can be any of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - GATORJAW_LINE, 1 - GATORTEETH_LINE, 2 - GATORLIPS_LINE.

iAMA

The function returns the handle of the Adaptive Moving Average indicator. It has only one buffer.

```
int  iAMA(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  ama_period,          // average period for AMA
   int                  fast_ma_period,      // fast MA period
   int                  slow_ma_period,      // slow MA period
   int                  ama_shift,           // horizontal shift of the indicator
   ENUM_APPLIED_PRICE   applied_price        // type of the price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ama_period

[in] The calculation period, on which the efficiency coefficient is calculated.

fast_ma_period

[in] Fast period for the smoothing coefficient calculation for a rapid market.

slow_ma_period

[in] Slow period for the smoothing coefficient calculation in the absence of trend.

ama_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iAO

The function returns the handle of the Awesome Oscillator indicator. It has only one buffer.

```
int  iAO(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period      // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

```

iATR

The function returns the handle of the Average True Range indicator. It has only one buffer.

```
int  iATR(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The value of the averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iBearsPower

The function returns the handle of the Bears Power indicator. It has only one buffer.

```
int  iBearsPower(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The value of the averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iBands

The function returns the handle of the Bollinger Bands® indicator.

```
int  iBands(
   string               symbol,           // symbol name
   ENUM_TIMEFRAMES      period,           // period
   int                  bands_period,     // period for average line calculation
   int                  bands_shift,      // horizontal shift of the indicator
   double               deviation,        // number of standard deviations
   ENUM_APPLIED_PRICE   applied_price     // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

bands_period

[in] The averaging period of the main line of the indicator.

bands_shift

[in] The shift the indicator relative to the price chart.

deviation

[in] Deviation from the main line.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - BASE_LINE, 1 - UPPER_BAND, 2 - LOWER_BAND

Example:

iBullsPower

The function returns the handle of the Bulls Power indicator. It has only one buffer.

```
int  iBullsPower(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iCCI

The function returns the handle of the Commodity Channel Index indicator. It has only one buffer.

```
int  iCCI(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iChaikin

The function returns the handle of the Chaikin Oscillator indicator. It has only one buffer.

```
int  iChaikin(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ma_period,      // fast period
   int                  slow_ma_period,      // slow period
   ENUM_MA_METHOD       ma_method,           // smoothing type
   ENUM_APPLIED_VOLUME  applied_volume       // type of volume
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ma_period

[in] Fast averaging period for calculations.

slow_ma_period

[in] Slow averaging period for calculations.

ma_method

[in] Smoothing type. Can be one of the averaging constants of ENUM_MA_METHOD.

applied_volume

[in] The volume used. Can be one of the constants of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

```

iCustom

The function returns the handle of a specified custom indicator.

```
int  iCustom(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period,     // period
   string           name        // folder/custom_indicator_name
   ...                          // list of indicator input parameters
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

name

[in] Custom indicator name. If the name starts with the reverse slash '\', the EX5 indicator file is searched for relative to the MQL5\Indicators indicator root directory. Thus, when calling iCustom(Symbol(), Period(), "\FirstIndicator"...), the indicator is downloaded as MQL5\Indicators\FirstIndicator.ex5. If the path contains no file, the error 4802 (ERR_INDICATOR_CANNOT_CREATE) occurs.

If the path does not start with '\', the indicator is searched and downloaded as follows:

- First, the indicator EX5 file is searched for in the folder where the EX5 file of the calling program is located. For example, the CrossMA.EX5 EA is located in MQL5\Experts\MyExperts and contains the iCustom call (Symbol(), Period(), "SecondIndicator"...). In this case, the indicator is searched for in MQL5\Experts\MyExperts\SecondIndicator.ex5.
- If the indicator is not found in the same directory, the search is performed relative to the MQL5\Indicators indicator root directory. In other words, the search for the MQL5\Indicators\SecondIndicator.ex5 file is performed. If the indicator is still not found, the function returns INVALID_HANDLE and the error 4802 (ERR_INDICATOR_CANNOT_CREATE) is triggered.

If the path to the indicator is set in the subdirectory (for example, MyIndicators\ThirdIndicator), the search is first performed in the calling program folder (the EA is located in MQL5\Experts\MyExperts) in MQL5\Experts\MyExperts\MyIndicators\ThirdIndicator.ex5. If unsuccessful, the search for the MQL5\Indicators\MyIndicators\ThirdIndicator.ex5 file is performed. Make sure to use the double reverse slash '\\' as a separator in the path, for example iCustom(Symbol(), Period(), "MyIndicators\\ThirdIndicator"...)

...

[in] input-parameters of a custom indicator, separated by commas. Type and order of parameters must match. If there is no parameters specified, then default values will be used.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

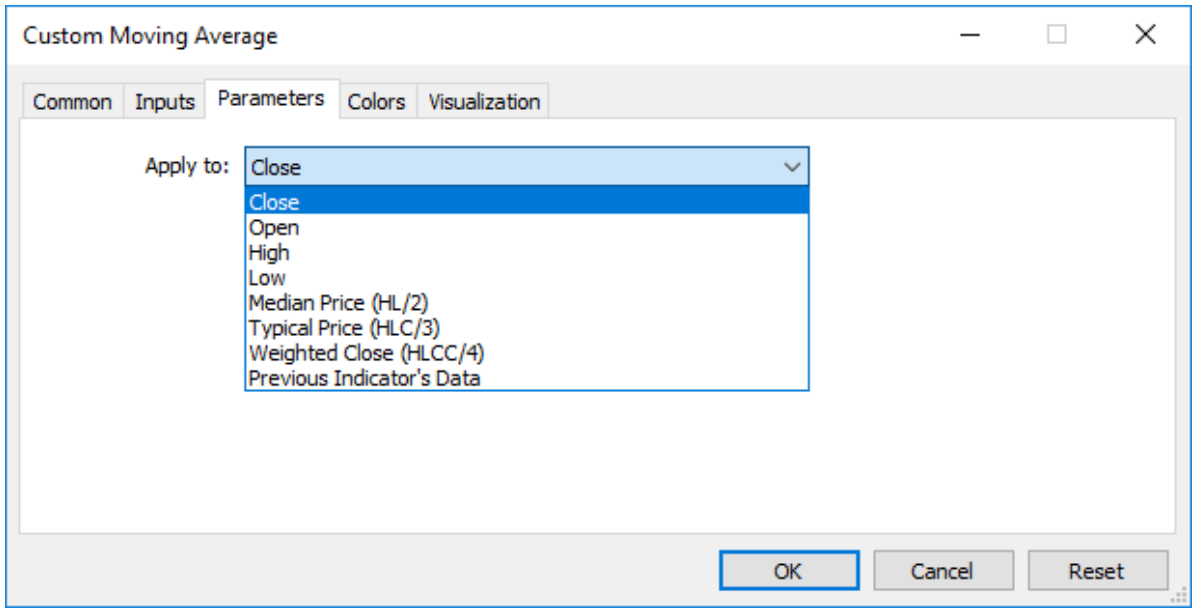
Note

A custom indicator must be compiled (with extension EX5) and located in the directory MQL5/Indicators of the client terminal or its subdirectory.

Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter that sets the indicator name) the property #property tester_indicator is required:

```
#property tester_indicator "indicator_name.ex5"
```

If the first call form is used in the indicator, then at the custom indicator start you can additionally indicate data for calculation in its "Parameters" tab. If the "Apply to" parameter is not selected explicitly, the default calculation is based on the values of "Close" prices.



When you call a custom indicator from mql5-program, the Applied_Price parameter or a handle of another indicator should be passed last, after all input variables of the custom indicator.

```
int  iDEMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

iDeMarker

The function returns the handle of the DeMarker indicator. It has only one buffer.

```
int  iDeMarker(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iEnvelopes

The function returns the handle of the Envelopes indicator.

```
int  iEnvelopes(
   string               symbol,           // symbol name
   ENUM_TIMEFRAMES      period,           // period
   int                  ma_period,        // period for the average line calculation
   int                  ma_shift,         // horizontal shift of the indicator
   ENUM_MA_METHOD       ma_method,        // type of smoothing
   ENUM_APPLIED_PRICE   applied_price,    // type of price or handle
   double               deviation         // deviation of boundaries from the midline
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the main line.

ma_shift

[in] The shift of the indicator relative to the price chart.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

deviation

[in] The deviation from the main line (in percents).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - UPPER_LINE, 1 - LOWER_LINE.

iForce

The function returns the handle of the Force Index indicator. It has only one buffer.

```
int  iForce(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_MA_METHOD       ma_method,         // smoothing type
   ENUM_APPLIED_VOLUME  applied_volume     // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

applied_volume

[in] The volume used. Can be one of the values of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

```

iFractals

The function returns the handle of the Fractals indicator.

```
int  iFractals(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period      // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - UPPER_LINE, 1 - LOWER_LINE.

Example:

```

```

iFrAMA

The function returns the handle of the Fractal Adaptive Moving Average indicator. It has only one buffer.

```
int  iFrAMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift on the chart
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Period (bars count) for the indicator calculations.

ma_shift

[in] Shift of the indicator in the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

iGator

The function returns the handle of the Gator indicator. The Oscillator shows the difference between the blue and red lines of Alligator (upper histogram) and difference between red and green lines (lower histogram).

```
int  iGator(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  jaw_period,        // period for the calculation of the jaws
   int                  jaw_shift,         // jaws horizontal shift
   int                  teeth_period,      // period for the calculation of the teeth
   int                  teeth_shift,       // teeth horizontal shift
   int                  lips_period,       // period for the calculation of the lips
   int                  lips_shift,        // lips horizontal shift
   ENUM_MA_METHOD       ma_method,         // type of smoothing
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw).

jaw_shift

[in] The shift of the blue line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price charts. It isn't directly connected with the visual shift of the indicator histogram.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

Buffer numbers: 0 - UPPER_HISTOGRAM, 1 - color buffer of the upper histogram, 2 - LOWER_HISTOGRAM, 3 - color buffer of the lower histogram.

iIchimoku

The function returns the handle of the Ichimoku Kinko Hyo indicator.

```
int  iIchimoku(
   string           symbol,           // symbol name
   ENUM_TIMEFRAMES  period,           // period
   int              tenkan_sen,       // period of Tenkan-sen
   int              kijun_sen,        // period of Kijun-sen
   int              senkou_span_b     // period of Senkou Span B
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

tenkan_sen

[in] Averaging period for Tenkan Sen.

kijun_sen

[in] Averaging period for Kijun Sen.

senkou_span_b

[in] Averaging period for Senkou Span B.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - TENKANSEN_LINE, 1 - KIJUNSEN_LINE, 2 - SENKOUSPANA_LINE, 3 - SENKOUSPANB_LINE, 4 - CHIKOUSPAN_LINE.

```

iBWMFI

The function returns the handle of the Market Facilitation Index indicator. It has only one buffer.

```
int  iBWMFI(
   string               symbol,             // symbol name
   ENUM_TIMEFRAMES      period,             // period
   ENUM_APPLIED_VOLUME  applied_volume      // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be one of the constants of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iMomentum

The function returns the handle of the Momentum indicator. It has only one buffer.

```
int  iMomentum(
   string                symbol,            // symbol name
   ENUM_TIMEFRAMES       period,            // period
   int                   mom_period,        // averaging period
   ENUM_APPLIED_PRICE    applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

mom_period

[in] Averaging period (bars count) for the calculation of the price change.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iMFI

The function returns the handle of the Money Flow Index indicator.

```
int  iMFI(
   string                symbol,              // symbol name
   ENUM_TIMEFRAMES       period,              // period
   int                   ma_period,           // averaging period
   ENUM_APPLIED_VOLUME   applied_volume       // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for the calculation.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iMA

The function returns the handle of the Moving Average indicator. It has only one buffer.

```
int  iMA(
   string                symbol,            // symbol name
   ENUM_TIMEFRAMES       period,            // period
   int                   ma_period,         // averaging period
   int                   ma_shift,          // horizontal shift
   ENUM_MA_METHOD        ma_method,         // smoothing type
   ENUM_APPLIED_PRICE    applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the calculation of the moving average.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Smoothing type. Can be one of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iOsMA

The function returns the handle of the Moving Average of Oscillator indicator. The OsMA oscillator shows the difference between values of MACD and its signal line. It has only one buffer.

```
int  iOsMA(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ema_period,     // period for Fast Moving Average
   int                  slow_ema_period,     // period for Slow Moving Average
   int                  signal_period,       // averaging period for their difference
   ENUM_APPLIED_PRICE   applied_price        // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Averaging period for signal line calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

In some systems this oscillator is also known as MACD histogram.

```

iMACD

The function returns the handle of the Moving Averages Convergence/Divergence indicator. In systems where OsMA is called MACD Histogram, this indicator is shown as two lines. In the client terminal the Moving Averages Convergence/Divergence looks like a histogram.

```
int  iMACD(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ema_period,     // period for Fast average calculation
   int                  slow_ema_period,     // period for Slow average calculation
   int                  signal_period,       // period for their difference averaging
   ENUM_APPLIED_PRICE   applied_price        // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Period for Signal line calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

Example:

iOBV

The function returns the handle of the On Balance Volume indicator. It has only one buffer.

```
int  iOBV(
   string                symbol,             // symbol name
   ENUM_TIMEFRAMES       period,             // period
   ENUM_APPLIED_VOLUME   applied_volume      // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iSAR

The function returns the handle of the Parabolic Stop and Reverse system indicator. It has only one buffer.

```
int  iSAR(
   string           symbol,      // symbol name
   ENUM_TIMEFRAMES  period,      // period
   double           step,        // price increment step - acceleration factor
   double           maximum      // maximum value of step
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

step

[in] The step of price increment, usually 0.02.

maximum

[in] The maximum step, usually 0.2.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iRSI

The function returns the handle of the Relative Strength Index indicator. It has only one buffer.

```
int  iRSI(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RSI calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iRVI

The function returns the handle of the Relative Vigor Index indicator.

```
int  iRVI(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RVI calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

Example:

```

iStdDev

The function returns the handle of the Standard Deviation indicator. It has only one buffer.

```
int  iStdDev(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift
   ENUM_MA_METHOD       ma_method,         // smoothing type
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Type of averaging. Can be any of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iStochastic

The function returns the handle of the Stochastic Oscillator indicator.

```
int  iStochastic(
   string            symbol,          // symbol name
   ENUM_TIMEFRAMES   period,          // period
   int               Kperiod,         // K-period (number of bars for calculations)
   int               Dperiod,         // D-period (period of first smoothing)
   int               slowing,         // final smoothing
   ENUM_MA_METHOD    ma_method,       // type of smoothing
   ENUM_STO_PRICE    price_field      // stochastic calculation method
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Kperiod

[in] Averaging period (bars count) for the %K line calculation.

Dperiod

[in] Averaging period (bars count) for the %D line calculation.

slowing

[in] Slowing value.

ma_method

[in] Type of averaging. Can be any of the ENUM_MA_METHOD values.

price_field

[in] Parameter of price selection for calculations. Can be one of the ENUM_STO_PRICE values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

iTEMA

The function returns the handle of the Triple Exponential Moving Average indicator. It has only one buffer.

```
int  iTEMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift of indicator
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculation.

ma_shift

[in] Shift of indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iTriX

The function returns the handle of the Triple Exponential Moving Averages Oscillator indicator. It has only one buffer.

```
int  iTriX(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

  }
```

iWPR

The function returns the handle of the Larry Williams' Percent Range indicator. It has only one buffer.

```
int  iWPR(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              calc_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

calc_period

[in] Period (bars count) for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iVIDyA

The function returns the handle of the Variable Index Dynamic Average indicator. It has only one buffer.

```
int  iVIDyA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  cmo_period,        // period for Chande Momentum
   int                  ema_period,        // EMA smoothing period
   int                  ma_shift,          // horizontal shift on the price chart
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

cmo_period

[in] Period (bars count) for the Chande Momentum Oscillator calculation.

ema_period

[in] EMA period (bars count) for smoothing factor calculation.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iVolumes

The function returns the handle of the Volumes indicator. It has an only one buffer.

```
int  iVolumes(
   string                symbol,              // symbol name
   ENUM_TIMEFRAMES       period,              // period
   ENUM_APPLIED_VOLUME   applied_volume       // volume type for calculation
   )
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

Working with Optimization Results

Functions for organizing custom processing of the optimization results in the strategy tester. They can be called during optimization in testing agents, as well as locally in Expert Advisors and scripts.

When you run an Expert Advisor in the strategy tester, you can create your own data array based on the simple types or simple structures (they do not contain strings, class objects or objects of dynamic arrays). This data set can be saved using the FrameAdd() function in a special structure called a frame. During the optimization of an Expert Advisor, each agent can send a series of frames to the terminal. All the received frames are written in the *.MQD file named as the Expert Advisor in the terminal_directory\MQL5\Files\Tester folder. They are written in the order they are received from the agents. Receipt of a frame in the client terminal from a testing agent generates the TesterPass event.

Frames can be stored in the computer memory and in a file with the specified name. The MQL5 language sets no limitations on the number of frames.

Memory and disk space limits in MQL5 Cloud Network

The following limitation applies to optimizations run in the MQL5 Cloud Network: the Expert Advisor must not write to disk more than 4GB of information or use more than 4GB of RAM. If the limit is exceeded, the network agent will not be able to complete the calculation correctly, and you will not receive the result. However, you will be charged for all the time spent on the calculations.

If you need to get information from each optimization pass, send frames without writing to disk. To avoid using file operations in Expert Advisors during calculations in the MQL5 Cloud Network, you can use the following check:

```
int handle=INVALID_HANDLE;
bool file_operations_allowed=true;
if(MQLInfoInteger(MQL_OPTIMIZATION) || MQLInfoInteger(MQL_FORWARD))
   file_operations_allowed=false;

if(file_operations_allowed)
  {
   ...
   handle=FileOpen(...);
   ...
  }
```

Function	Action
FrameFirst	Moves a pointer of frame reading to the beginning and resets the previously set filter
FrameFilter	Sets the frame reading filter and moves the pointer to the beginning
FrameNext	Reads a frame and moves the pointer to the next one
FrameInputs	Receives input parameters, on which the frame is formed
FrameAdd	Adds a frame with data

Function	Action
ParameterGetRange	Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester
ParameterSetRange	Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values

Testing Statistics, Properties of a Running MQL5 Program

FrameFirst

Moves a pointer of frame reading to the beginning and resets a set filter.

```
bool  FrameFirst();
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

FrameFilter

Sets the frame reading filter and moves the pointer to the beginning.

```
bool  FrameFilter(
   const string  name,          // Public name/label
   long          id             // Public ID
   );
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

If an empty string is passed as the first parameter, the filter will work only with a numeric parameter, i.e. only frames with the specified id will be viewed. If the value of the second parameter is ULONG_MAX, only a text filter works.

Call of FrameFilter("", ULONG_MAX) is equivalent to calling FrameFirst(), i.e. equal to not using any filter.

FrameNext

Reads a frame and moves the pointer to the next one. There are two variants of the function.

1. Calling to receive one numeric value

```
bool  FrameNext(
   ulong&   pass,      // The number of a pass in the optimization, during which the
   string&  name,      // Public name/label
   long&    id,        // Public ID
   double&  value      // Value
   );
```

2. Calling to receive all the data of a frame

```
bool  FrameNext(
   ulong&   pass,      // The number of a pass in the optimization, during which the
   string&  name,      // Public name/label
   long&    id,        // Public ID
   double&  value,     // Value
   void&    data[]     // Array of any type
   );
```

Parameters

pass

[out] The number of a pass during optimization in the strategy tester.

name

[out] The name of the identifier.

id

[out] The value of the identifier.

value

[out] A single numeric value.

data

[out] An array of any type.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

In the second version of the call, you must correctly handle the received data in the *data[]* array.

FrameInputs

Receives input parameters, on which the frame with the specified pass number is formed.

```
bool  FrameInputs(
   ulong    pass,                // The number of a pass in the optimization
   string&  parameters[],        // An array of strings of form "parameterN=valueN"
   uint&    parameters_count     // The total number of parameters
   );
```

Parameters

pass

[in] The number of a pass during optimization in the strategy tester.

parameters

[out] A string array with the description of names and parameter values

parameters_count

[out] The number of elements in the array *parameters[]*.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

Having obtained the number of strings *parameters_count* in the *parameters[]* array, you can organize a loop to go through all records. This will help you find the values of input parameters of an Expert Advisor for the specified pass number.

FrameAdd

Adds a frame with data. There are two variants of the function.

1. Adding data from a file

```
bool  FrameAdd(
   const string  name,         // Public name/label
   long          id,           // Public ID
   double        value,        // Value
   const string  filename      // Name of a data file
   );
```

2. Adding data from an array of any type

```
bool  FrameAdd(
   const string  name,         // Public name/label
   long          id,           // Public ID
   double        value,        // Value
   const void&   data[]        // Array of any type
   );
```

Parameters

name

[in] Public frame label. It can be used for a filter in the FrameFilter() function.

id

[in] A public identifier of the frame. It can be used for a filter in the FrameFilter() function.

value

[in] A numeric value to write into the frame. It is used to transmit a single pass result like in the OnTester() function.

filename

[in] The name of the file that contains data to add to the frame. The file must be locate in the folder MQL5/Files.

data

[in] An array of any type to write into the frame. Passed by reference.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

ParameterGetRange

Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester. There are 2 variants of the function.

1. Receiving data for the integer type input parameter

```
bool  ParameterGetRange(
   const string  name,           // parameter (input variable) name
   bool&         enable,         // parameter optimization enabled
   long&         value,          // parameter value
   long&         start,          // initial value
   long&         step,           // change step
   long&         stop            // final value
   );
```

2. Receiving data for the real type input parameter

```
bool  ParameterGetRange(
   const string  name,           // parameter (input variable) name
   bool&         enable,         // parameter optimization enabled
   double&       value,          // parameter value
   double&       start,          // initial value
   double&       step,           // change step
   double&       stop            // final value
   );
```

Parameters

name

[in] input variable ID. These variables are external parameters of an application. Their values can be specified when launching on a chart or during a single test.

enable

[out] Flag that this parameter can be used to enumerate the values during the optimization in the Strategy Tester.

value

[out] Parameter value.

start

[out] Initial parameter value during the optimization.

step

[out] Parameter change step when enumerating its values.

stop

[out] Final parameter value during the optimization.

Return Value

Returns true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

The function can be called only from OnTesterInit(), OnTesterPass() and OnTesterDeinit() handlers. It has been introduced to receive Expert Advisor input parameters' values and variation ranges during the optimization in the Strategy Tester.

When called in OnTesterInit(), the obtained data can be used to redefine the rules for enumeration of any input variable using ParameterSetRange() function. Therefore, new Start, Stop and Step values can be set and the input parameter can even be completely excluded from optimization regardless of the Strategy Tester settings. This allows you to manage the area of the input parameters during the optimization by excluding some parameters from the optimization depending on the Expert Advisor's key parameters' values.

Example:

```
#property description "Expert Advisor for ParameterGetRange() function demonstration."
#property description "Should be launched in the optimization mode of the Strategy Tes
//--- input parameters
input int                  Input1=1;
input double               Input2=2.0;
input bool                 Input3=false;
input ENUM_DAY_OF_WEEK     Input4=SUNDAY;

//+------------------------------------------------------------------+
//| Expert initialization function                                   |

  {
//--- example for long type input parameter
   string name="Input1";
   bool enable;
   long par1,par1_start,par1_step,par1_stop;
   ParameterGetRange(name,enable,par1,par1_start,par1_step,par1_stop);
```

```
   Print("First parameter");
   PrintFormat("%s=%d  enable=%s  from %d to %d with step=%d",
               name,par1,(string)enable,par1_start,par1_stop,par1_step);
//--- example for double type input parameter
   name="Input2";
   double par2,par2_start,par2_step,par2_stop;
   ParameterGetRange(name,enable,par2,par2_start,par2_step,par2_stop);
   Print("Second parameter");
   PrintFormat("%s=%G  enable=%s  from %G to %G with step=%G",
               name,par2,(string)enable,par2_start,par2_stop,par2_step);

//--- example for bool type input parameter
   name="Input3";
   long par3,par3_start,par3_step,par3_stop;
   ParameterGetRange(name,enable,par3,par3_start,par3_step,par3_stop);
   Print("Third parameter");
   PrintFormat("%s=%s  enable=%s  from %s to %s",
               name,(string)par3,(string)enable,
               (string)par3_start,(string)par3_stop);
//--- example for enumeration type input parameter
   name="Input4";
   long par4,par4_start,par4_step,par4_stop;
   ParameterGetRange(name,enable,par4,par4_start,par4_step,par4_stop);
   Print("Fourth parameter");
   PrintFormat("%s=%s  enable=%s  from %s to %s",
               name,EnumToString((ENUM_DAY_OF_WEEK)par4),(string)enable,
               EnumToString((ENUM_DAY_OF_WEEK)par4_start),
               EnumToString((ENUM_DAY_OF_WEEK)par4_stop));
  }
//+------------------------------------------------------------------+
//| TesterDeinit function                                            |
//+------------------------------------------------------------------+
void OnTesterDeinit()
  {
//--- this message will be shown after optimization is complete
   Print(__FUNCTION__," Optimization completed");
  }
```

ParameterSetRange

Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values. There are 2 variants of the function.

1. Specifying the values for the integer type input parameter

```
bool  ParameterSetRange(
   const string  name,          // parameter (input variable) name
   bool          enable,        // parameter optimization enabled
   long          value,         // parameter value
   long          start,         // initial value
   long          step,          // change step
   long          stop           // final value
   );
```

2. Specifying the values for the real type input parameter

```
bool  ParameterSetRange(
   const string  name,          // parameter (input variable) name
   bool          enable,        // parameter optimization enabled
   double        value,         // parameter value
   double        start,         // initial value
   double        step,          // change step
   double        stop           // final value
   );
```

Parameters

name

[in] input or sinput variable ID. These variables are external parameters of an application. Their values can be specified when launching the program.

enable

[in] Enable this parameter to enumerate the values during the optimization in the Strategy Tester.

value

[in] Parameter value.

start

[in] Initial parameter value during the optimization.

step

[in] Parameter change step when enumerating its values.

stop

[in] Final parameter value during the optimization.

Return Value

Returns true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

The function can be called only from OnTesterInit() handler when launching optimization from the Strategy Tester. It is designed for specifying the parameter's range and change step. The parameter can be completely excluded from optimization regardless of the Strategy Tester settings. It also allows using the variables declared with sinput modifier in the optimization process.

ParameterSetRange() function allows you to manage an Expert Advisor optimization in the Strategy Tester depending on its key parameters' values by including or excluding required input parameters from the optimization and setting the required range and the change step.

Event Functions

This group contains functions for working with custom events and timer events. Besides this group, there are special functions for handling predefined events.

Function	Action
EventSetMillisecondTimer	Launches event generator of the high-resolution timer with a period less than 1 second for the current chart
EventSetTimer	Starts the timer event generator with the specified periodicity for the current chart
EventKillTimer	Stops the generation of events by the timer in the current chart
EventChartCustom	Generates a custom event for the specified chart

See also

Types of Chart Events

EventSetMillisecondTimer

The function indicates to the client terminal that timer events should be generated at intervals less than one second for this Expert Advisor or indicator.

```
bool  EventSetMillisecondTimer(
   int  milliseconds      // number of milliseconds
   );
```

Parameters

milliseconds

[in] Number of milliseconds defining the frequency of timer events.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, GetLastError() function should be called.

Note

This feature is designed for the cases when high-resolution timer is required. In other words, timer events should be received more frequently than once per second. If a conventional timer with the period of more than one second is enough for you, use EventSetTimer().

In general, when the timer period is reduced, the testing time is increased, as the handler of timer events is called more often. When working in real-time mode, timer events are generated no more than 1 time in 10-16 milliseconds due to hardware limitations.

Usually, this function should be called from OnInit() function or in class constructor. To handle events coming from the timer, an Expert Advisor or an indicator should have OnTimer() function.

Each Expert Advisor and each indicator work with its own timer receiving events solely from this timer. During mql5 application shutdown, the timer is forcibly destroyed in case it has been created but has not been disabled by EventKillTimer() function.

Only one timer can be launched for each program. Each mql5 application and chart have their own queue of events where all newly arrived events are placed. If the queue already contains Timer event or this event is in the processing stage, then the new Timer event is not added to mql5 application queue.

EventSetTimer

The function indicates to the client terminal, that for this indicator or Expert Advisor, events from the timer must be generated with the specified periodicity.

```
bool  EventSetTimer(
   int  seconds      // number of seconds
   );
```

Parameters

seconds

[in] Number of seconds that determine the frequency of the timer event occurrence.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Note

Normally, this function must be called from the OnInit() function or from a class constructor. In order to handle events coming from the timer, the Expert Advisor must have the OnTimer() function.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the EventKillTimer() function.

For each program no more than one timer can be run. Each mql5 program and each chart has its own queue of events, in which all the newly received events are placed. If the Timer event is present in the queue or is being processed, the new Timer event will not be placed in the queue of the mql5 program.

EventKillTimer

Specifies the client terminal that is necessary to stop the generation of events from Timer.

```
void  EventKillTimer();
```

Return Value

No return value.

Note

Typically, this function must be called from a function OnDeinit(), if the EventSetTimer() function has been called from OnInit(). This function can also be called form the class destructor, if the EventSetTimer() function has been called in the constructor of this class.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the EventKillTimer() function

EventChartCustom

The function generates a custom event for the specified chart.

```
bool  EventChartCustom(
   long    chart_id,            // identifier of the event receiving chart
   ushort  custom_event_id,     // event identifier
   long    lparam,              // parameter of type long
   double  dparam,              // parameter of type double
   string  sparam               // string parameter of the event
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

custom_event_id

[in] ID of the user events. This identifier is automatically added to the value CHARTEVENT_CUSTOM and converted to the integer type.

lparam

[in] Event parameter of the long type passed to the OnChartEvent function.

dparam

[in] Event parameter of the double type passed to the OnChartEvent function.

sparam

[in] Event parameter of the string type passed to the OnChartEvent function. If the string is longer than 63 characters, it is truncated.

Return Value

Returns true if a custom event has been successfully placed in the events queue of the chart that receives the events. In case of failure, it returns false. Use GetLastError() to get an error code.

Note

An Expert Advisor or indicator attached to the specified chart handles the event using the function OnChartEvent(int event_id, long& lparam, double& dparam, string& sparam).

For each type of event, the input parameters of the OnChartEvent() function have definite values that are required for the processing of this event. The events and values passed through this parameters are listed in the below table.

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
Event of a keystroke	CHARTEVENT_KEYDOWN	code of a pressed key	Repeat count (the number of times the keystroke is	The string value of a bit mask describing the

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
			repeated as a result of the user holding down the key)	status of keyboard buttons
Mouse event (if property CHART_EVENT_MOUSE_MOVE=true is set for the chart)	CHARTEVENT_MOUSE_MOVE	the X coordinate	the Y coordinate	The string value of a bit mask describing the status of mouse buttons
Event of graphical object creation (if CHART_EVENT_OBJECT_CREATE=true is set for the chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of the created graphical object
Event of change of an object property via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of the modified graphical object
Event of graphical object deletion (if CHART_EVENT_OBJECT_DELETE=true is set for the chart)	CHARTEVENT_OBJECT_DELETE	—	—	Name of the deleted graphical object
Event of a mouse click on the chart	CHARTEVENT_CLICK	the X coordinate	the Y coordinate	—
Event of a mouse click in a graphical object belonging to the chart	CHARTEVENT_OBJECT_CLICK	the X coordinate	the Y coordinate	Name of the graphical object, on which the event occurred
Event of a graphical object dragging using the mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of the moved graphical object
Event of the finished text	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the LabelEdit

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
editing in the entry box of the LabelEdit graphical object				graphical object, in which text editing has completed
Event of changes on a chart	CHARTEVENT_CHART_CHANGE	—	—	—
ID of the user event under the N number	CHARTEVENT_CUSTOM+N	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function

Working with OpenCL

OpenCL programs are used for performing computations on video cards that support OpenCL 1.1 or higher. Modern video cards contain hundreds of small specialized processors that can simultaneously perform simple mathematical operations with incoming data streams. The OpenCL language organizes parallel computing and provides greater speed for a certain class of tasks.

In some graphic cards working with the double type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: #pragma OPENCL EXTENSION cl_khr_fp64 : enable. However if a graphic card doesn't support double, enabling this directive won't be of help.

It is recommended to write the source code for OpenCL in separate CL files, which can later be included in the MQL5 program using the resource variables.

Handling errors in OpenCL programs

To get information about the last error in an OpenCL program, use the CLGetInfoInteger and CLGetInfoStringfunctions that allow getting the error code and text description.

OpenCL last error code: To get the latest OpenCL error, call CLGetInfoInteger, while the*handle*parameter is ignored (can be set to zero). Description of errors: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS.

For an unknown error code, the"unknown OpenCL error N" string is returned where N is an error code. Example:

```
//--- the first 'handle' parameter is ignored when getting the last error code
intcode= (int)CLGetInfoInteger(0,CL_LAST_ERROR);
```

Text description of the OpenCL error: To get the latest OpenCL error, call CLGetInfoString. The error code should be passed as the*handle*parameter.

Description of errors: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS. If CL_LAST_ERROR is passed instead of the error code, then the function returns the description of the last error. For example:

```
//--- get the code of the last OpenCL error
int   code= (int)CLGetInfoInteger(0,CL_LAST_ERROR);
stringdesc;// to get an error text description

//--- use the error code to get an error text description
if(!CLGetInfoString(code,CL_ERROR_DESCRIPTION,desc))
 desc="cannot get OpenCL error description,"+ (string)GetLastError();
Print(desc);

//--- in order to get the description of the last OpenCL error without getting the co
if(!CLGetInfoString(CL_LAST_ERROR,CL_ERROR_DESCRIPTION,desc))
 desc="cannot get OpenCL error description,"+ (string)GetLastError();
Print(desc);;
```

So far, the name of the internal enumeration is given as an error description. You can find its decoding here: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS. For example, the CL_INVALID_KERNEL_ARGS value means "Returned when enqueuing a kernel when some kernel arguments have not been set or are invalid."

Functions for running programs in OpenCL:

Function	Action
CLHandleType	Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration
CLGetInfoInteger	Returns the value of an integer property for an OpenCL object or device
CLContextCreate	Creates an OpenCL context
CLContextFree	Removes an OpenCL context
CLGetDeviceInfo	Receives device property from OpenCL driver
CLProgramCreate	Creates an OpenCL program from a source code
CLProgramFree	Removes an OpenCL program
CLKernelCreate	Creates an OpenCL start function
CLKernelFree	Removes an OpenCL start function
CLSetKernelArg	Sets a parameter for the OpenCL function
CLSetKernelArgMem	Sets an OpenCL buffer as a parameter of the OpenCL function
CLSetKernelArgMemLocal	Sets the local buffer as an argument of the kernel function
CLBufferCreate	Creates an OpenCL buffer
CLBufferFree	Deletes an OpenCL buffer
CLBufferWrite	Writes an array into an OpenCL buffer
CLBufferRead	Reads an OpenCL buffer into an array
CLExecute	Runs an OpenCL program
CLExecutionStatus	Returns the OpenCL program execution status

OpenCL, Resources

CLHandleType

Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration.

```
ENUM_OPENCL_HANDLE_TYPE  CLHandleType(
   int  handle     // Handle of an OpenCL object
   );
```

Parameters

handle

[in] A handle to an OpenCL object: a context, a kernel or an OpenCL program.

Return Value

The type of the OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration.

ENUM_OPENCL_HANDLE_TYPE

Identifier	Description
OPENCL_INVALID	Incorrect handle
OPENCL_CONTEXT	A handle of the OpenCL context
OPENCL_PROGRAM	A handle of the OpenCL program
OPENCL_KERNEL	A handle of the OpenCL kernel
OPENCL_BUFFER	A handle of the OpenCL buffer

CLGetInfoInteger

Returns the value of an integer property for an OpenCL object or device.

```
long  CLGetInfoInteger(
   int  handle,                          // The handle of the OpenCL object or the nu
   ENUM_OPENCL_PROPERTY_INTEGER  prop    // Requested property
   );
```

Parameters

handle

[in] A handle to the OpenCL object or number of the OpenCL device. Numbering of OpenCL devices starts with zero.

prop

[in] The type of a requested property from the ENUM_OPENCL_PROPERTY_INTEGER enumeration, the value of which you want to obtain.

Return Value

The value of the property if successful or -1 in case of an error. For information about the error, use the GetLastError() function.

ENUM_OPENCL_PROPERTY_INTEGER

Identifier	Description	Type
CL_DEVICE_COUNT	The number of devices with OpenCL support. This property does not require specification of the first parameter, i.e. you can pass a zero value for the *handle* parameter.	int
CL_DEVICE_TYPE	Type of device	ENUM_CL_DEVICE_TYPE
CL_DEVICE_VENDOR_ID	Unique vendor identifier	uint
CL_DEVICE_MAX_COMPUTE_UNITS	Number of parallel calculated tasks in OpenCL device. One working group solves one computational task. The lowest value is 1	uint
CL_DEVICE_MAX_CLOCK_FREQUENCY	Highest set frequency of the device in MHz.	uint
CL_DEVICE_GLOBAL_MEM_SIZE	Size of the global memory of the device in bytes	ulong
CL_DEVICE_LOCAL_MEM_SIZE	Size of the processed data (scene) local memory in bytes	uint

Identifier	Description	Type
CL_BUFFER_SIZE	Actual size of the OpenCL buffer in bytes	ulong
CL_DEVICE_MAX_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL device.	ulong
CL_KERNEL_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL program.	ulong
CL_KERNEL_LOCAL_MEM_SIZE	Size of the local memory (in bytes) used by an OpenCL program for solving all parallel tasks in a group. Use CL_DEVICE_LOCAL_MEM_SIZE to receive the maximum available value	ulong
CL_KERNEL_PRIVATE_MEM_SIZE	The minimum size of the private memory (in bytes) used by each task in the OpenCL program kernel.	ulong
CL_LAST_ERROR	The value of the last OpenCL error	int

The ENUM_CL_DEVICE_TYPE enumeration contains possible types of devices supporting OpenCL. You can receive the type of device by its number or the handle of the OpenCL object by calling CLGetInfoInteger(handle_or_deviceN, CL_DEVICE_TYPE).

ENUM_CL_DEVICE_TYPE

Identifier	Description
CL_DEVICE_ACCELERATOR	Dedicated OpenCL accelerators (for example, the IBM CELL Blade). These devices communicate with the host processor using a peripheral interconnect such as PCIe.
CL_DEVICE_CPU	An OpenCL device that is the host processor. The host processor runs the OpenCL implementations and is a single or multi-core CPU.
CL_DEVICE_GPU	An OpenCL device that is a GPU.
CL_DEVICE_DEFAULT	The default OpenCL device in the system. The default device cannot be a CL_DEVICE_TYPE_CUSTOM device.

Identifier	Description
CL_DEVICE_CUSTOM	Dedicated accelerators that do not support programs written in OpenCL C.

Example:

```
void OnStart()
  {
   int cl_ctx;
//--- initialize OpenCL context
   if((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY))==INVALID_HANDLE)
     {
      Print("OpenCL not found");
      return;
     }
//--- Display general information about OpenCL device
   Print("OpenCL type: ",EnumToString((ENUM_CL_DEVICE_TYPE)CLGetInfoInteger(cl_ctx,CL_
   Print("OpenCL vendor ID: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_VENDOR_ID));
   Print("OpenCL units: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_COMPUTE_UNITS));
   Print("OpenCL freq: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_CLOCK_FREQUENCY)," MHz"
   Print("OpenCL global mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_GLOBAL_MEM_SIZE)," by
   Print("OpenCL local mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_LOCAL_MEM_SIZE)," byte
//--- free OpenCL context
   CLContextFree(cl_ctx);
  }
```

CLGetInfoString

Returns string value of a property for OpenCL object or device.

```
bool  CLGetInfoString(
   int  handle,                          // OpenCL object handle or OpenCL device nu
   ENUM_OPENCL_PROPERTY_STRING  prop,    // requested property
   string&  value                        // referenced string
   );
```

Parameters

handle

[in] OpenCL object handle or OpenCL device number. The numbering of OpenCL devices starts with zero.

prop

[in] Type of requested property from ENUM_OPENCL_PROPERTY_STRING enumeration, the value of which should be obtained.

value

[out] String for receiving the property value.

Return Value

true if successful, otherwise false. For information about the error, use the GetLastError() function.

ENUM_OPENCL_PROPERTY_STRING

Identifier	Description
CL_PLATFORM_PROFILE	CL_PLATFORM_PROFILE - OpenCL Profile. Profile name may be one of the following values: • FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support); • EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_PLATFORM_VERSION	OpenCL version
CL_PLATFORM_VENDOR	Platform vendor name
CL_PLATFORM_EXTENSIONS	List of extensions supported by the platform. Extension names should be supported by all devices related to this platform
CL_DEVICE_NAME	Device name
CL_DEVICE_VENDOR	Vendor name

Identifier	Description
CL_DRIVER_VERSION	OpenCL driver version in major_number.minor_number format
CL_DEVICE_PROFILE	OpenCL device profile. Profile name may be one of the following values: • FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support); • EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_DEVICE_VERSION	OpenCL version in "OpenCL<space><major_version.minor_version><space><vendor-specific information>" format
CL_DEVICE_EXTENSIONS	List of extensions supported by the device. The list may contain extensions supported by the vendor, as well as one or more approved names: cl_khr_int64_base_atomics cl_khr_int64_extended_atomics cl_khr_fp16 cl_khr_gl_sharing cl_khr_gl_event cl_khr_d3d10_sharing cl_khr_dx9_media_sharing cl_khr_d3d11_sharing
CL_DEVICE_BUILT_IN_KERNELS	The list of supported kernels separated by ";".
CL_DEVICE_OPENCL_C_VERSION	The maximum version supported by the compiler for this device. Version format: "OpenCL<space>C<space><major_version.minor_version><space><vendor-specific information> "
CL_ERROR_DESCRIPTION	Text description of an OpenCL error

Example:

```
void OnStart()
  {
   int cl_ctx;
   string str;
//--- initialize OpenCL context
   if((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY))==INVALID_HANDLE)
     {
      Print("OpenCL not found");
      return;
     }
```

```
//--- Display information about the platform
   if(CLGetInfoString(cl_ctx,CL_PLATFORM_NAME,str))
      Print("OpenCL platform name: ",str);
   if(CLGetInfoString(cl_ctx,CL_PLATFORM_VENDOR,str))
      Print("OpenCL platform vendor: ",str);
   if(CLGetInfoString(cl_ctx,CL_PLATFORM_VERSION,str))
      Print("OpenCL platform ver: ",str);
   if(CLGetInfoString(cl_ctx,CL_PLATFORM_PROFILE,str))
      Print("OpenCL platform profile: ",str);
   if(CLGetInfoString(cl_ctx,CL_PLATFORM_EXTENSIONS,str))
      Print("OpenCL platform ext: ",str);
//--- Display information about the device
   if(CLGetInfoString(cl_ctx,CL_DEVICE_NAME,str))
      Print("OpenCL device name: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_PROFILE,str))
      Print("OpenCL device profile: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_BUILT_IN_KERNELS,str))
      Print("OpenCL device kernels: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_EXTENSIONS,str))
      Print("OpenCL device ext: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_VENDOR,str))
      Print("OpenCL device vendor: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_VERSION,str))
      Print("OpenCL device ver: ",str);
   if(CLGetInfoString(cl_ctx,CL_DEVICE_OPENCL_C_VERSION,str))
      Print("OpenCL open c ver: ",str);
//--- Display general information about the OpenCL device
   Print("OpenCL type: ",EnumToString((ENUM_CL_DEVICE_TYPE)CLGetInfoInteger(cl_ctx,CL_
   Print("OpenCL vendor ID: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_VENDOR_ID));
   Print("OpenCL units: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_COMPUTE_UNITS));
   Print("OpenCL freq: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_CLOCK_FREQUENCY));
   Print("OpenCL global mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_GLOBAL_MEM_SIZE));
   Print("OpenCL local mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_LOCAL_MEM_SIZE));
//--- free OpenCL context
   CLContextFree(cl_ctx);
  }
```

CLContextCreate

Creates an OpenCL context and returns its handle.

```
int  CLContextCreate(
   int  device=CL_USE_ANY     // Serial number of the OpenCL device or macro
   );
```

Parameter

device

[in] The ordinal number of the OpenCL-device in the system. Instead of a specific number, you can specify one of the following values:

- CL_USE_ANY - any available device with OpenCL support is allowed;
- CL_USE_CPU_ONLY - only OpenCL emulation on CPU is allowed;
- CL_USE_GPU_ONLY - OpenCL emulation is prohibited and only specialized devices with OpenCL support (video cards) can be used;
- CL_USE_GPU_DOUBLE_ONLY - only the GPUs that support type double are allowed.

Return Value

A handle to the OpenCL context if successful, otherwise -1. For information about the error, use the GetLastError() function.

CLContextFree

Removes an OpenCL context.

```
void  CLContextFree(
   int  context     // Handle to an OpenCL context
   );
```

Parameters

context

[in] Handle of the OpenCL context.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

CLGetDeviceInfo

The function receives device property from OpenCL driver.

```
bool  CLGetDeviceInfo(
   int     handle,          // OpenCL device handle
   int     property_id,     // requested property ID
   uchar&  data[],          // array for receiving data
   uint&   size             // shift in the array elements, default value is 0
   );
```

Parameters

handle

[in] OpenCL device index or OpenCL handle created by CLContextCreate() function.

property_id

[in] ID of the OpenCL device property that should be received. The values can be of one of the predetermined ones listed in the table below.

data[]

[out] The array for receiving data on the requested property.

size

[out] Size of the received data in the array *data[]*.

Return Value

true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

For one-dimensional arrays, the number of the element, from which data reading for OpenCL buffer starts, is calculated considering AS_SERIES flag.

The list of available IDs of OpenCL device properties

Exact description of the property and its functions can be found at the official OpenCL web site.

Identifier	Value

//  2013.07.24 10:50:48     opencl (EURUSD,H1)      0: GeForce GTX 580
```

CLProgramCreate

Creates an OpenCL program from a source code.

```
int  CLProgramCreate(
   int           context,     // Handle to an OpenCL context
   const string  source       // Source code
   );
```

An overloaded function version creates an OpenCL program and writes compiler messages into the passed string.

```
int  CLProgramCreate(
   int           context,     // Handle to an OpenCL context
   const string  source,      // Source code
   string       &build_log    // A string for receiving the compilation log
   );
```

Parameters

context

[in] Handle of the OpenCL context.

source

[in] String with the source code of the OpenCL program.

&build_log

[in] A string for receiving the OpenCL compiler messages.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to the context OpenCL.
- ERR_INVALID_PARAMETER - invalid string parameter.
- ERR_NOT_ENOUGH_MEMORY - not enough memory to complete operation.
- ERR_OPENCL_PROGRAM_CREATE - internal error of OpenCL or compilation error.

In some graphic cards working with the double type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: #pragma OPENCL EXTENSION cl_khr_fp64 : enable. However if a graphic card doesn't support double, enabling this directive won't be of help.

Example:

```
//+------------------------------------------------------------------+
//| OpenCL kernel                                                    |
//+------------------------------------------------------------------+
const string
```

```
cl_src=
       //--- by default some GPU doesn't support doubles
       //--- cl_khr_fp64 directive is used to enable work with doubles
       "#pragma OPENCL EXTENSION cl_khr_fp64 : enable      \r\n"
       //--- OpenCL kernel function
       "__kernel void Test_GPU(__global double *data,      \r\n"
       "                       const    int N,             \r\n"
       "                       const    int total_arrays)  \r\n"
       "  {                                                \r\n"
       "   uint kernel_index=get_global_id(0);             \r\n"
       "   if (kernel_index>total_arrays) return;          \r\n"
       "   uint local_start_offset=kernel_index*N;         \r\n"
       "   for(int i=0; i<N; i++)                          \r\n"
       "     {                                             \r\n"
       "       data[i+local_start_offset] *= 2.0;          \r\n"
       "     }                                             \r\n"
       "  }                                                \r\n";
//+------------------------------------------------------------------+
//| Test_CPU                                                         |
//+------------------------------------------------------------------+

   CLContextFree(cl_ctx);
```

```
//---
   return(0);
  }
```

CLProgramFree

Removes an OpenCL program.

```
void  CLProgramFree(
   int  program     // Handle to an OpenCL object
   );
```

Parameters

program

[in] Handle of the OpenCL object.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

CLKernelCreate

Creates the OpenCL program kernel and returns its handle.

```
int  CLKernelCreate(
   int           program,        // Handle to an OpenCL object
   const string  kernel_name     // Kernel name
   );
```

Parameters

program

[in] Handle to an object of the OpenCL program.

kernel_name

[in] The name of the kernel function in the appropriate OpenCL program, in which execution begins.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL program.
- ERR_INVALID_PARAMETER - invalid string parameter.
- ERR_OPENCL_TOO_LONG_KERNEL_NAME - kernel name contains more than 127 characters.
- ERR_OPENCL_KERNEL_CREATE - internal error occurred while creating an OpenCL object.

CLKernelFree

Removes an OpenCL start function.

```
void  CLKernelFree(
   int  kernel     // Handle to the kernel of an OpenCL program
   );
```

Parameters

kernel_name

[in] Handle of the kernel object.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

CLSetKernelArg

Sets a parameter for the OpenCL function.

```
bool  CLSetKernelArg(
   int   kernel,        // Handle to the kernel of an OpenCL program
   uint  arg_index,     // The number of the argument of the OpenCL function
   void  arg_value      // Source code
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

arg_value

[in] The value of the function argument.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_INVALID_PARAMETER,
- ERR_OPENCL_INVALID_HANDLE - invalid handle to the OpenCL kernel.
- ERR_OPENCL_SET_KERNEL_PARAMETER - internal error of OpenCL.

CLSetKernelArgMem

Sets an OpenCL buffer as a parameter of the OpenCL function.

```
bool  CLSetKernelArgMem(
   int   kernel,           // Handle to the kernel of an OpenCL program
   uint  arg_index,        // The number of the argument of the OpenCL function
   int   cl_mem_handle     // Handle to OpenCL buffer
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

cl_mem_handle

[in] A handle to an OpenCL buffer.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

CLSetKernelArgMemLocal

Sets the local buffer as an argument of the kernel function.

```
bool  CLSetKernelArgMemLocal(
   int    kernel,           // handle to a kernel of an OpenCL program
   uint   arg_index,        // number of the OpenCL function argument
   ulong  local_mem_size    // buffer size
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

local_mem_size

[in] Buffer size in bytes.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

CLBufferCreate

Creates an OpenCL buffer and returns its handle.

```
int  CLBufferCreate(
   int   context,     // Handle to an OpenCL context
   uint  size,        // Buffer size
   uint  flags        // Flags combination which specify properties of OpenCL buffer
   );
```

Parameters

context

[in] A handle to context OpenCL.

size

[in] Buffer size in bytes.

flags

[in] Buffer properties that are set using a combination of flags: CL_MEM_READ_WRITE, CL_MEM_WRITE_ONLY, CL_MEM_READ_ONLY, CL_MEM_ALLOC_HOST_PTR.

Return Value

A handle to an OpenCL buffer if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL context.
- ERR_NOT_ENOUGH_MEMORY - insufficient memory.
- ERR_OPENCL_BUFFER_CREATE - internal error creating buffers.

CLBufferFree

Deletes an OpenCL buffer.

```
void  CLBufferFree(
   int   buffer     // Handle to an OpenCL buffer
   );
```

Parameters

buffer

[in] A handle to an OpenCL buffer.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

CLBufferWrite

Writes into the OpenCL buffer and returns the number of written elements.

```
uint  CLBufferWrite(
   int           buffer,                    // A handle to the OpenCL buffer
   const void&   data[],                    // An array of values
   uint          buffer_offset=0,           // An offset in the OpenCL buffer in bytes,
   uint          data_offset=0,             // An offset in the array in elements, 0 by
   uint          data_count=WHOLE_ARRAY     // The number of values from the array for
   );
```

There are also versions for handling matrices and vectors.

Writes the values from the matrix to the buffer and returns true if successful.

```
uint  CLBufferWrite(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   matrix<T>     &mat                       // the values matrix for writing to the bu
   );
```

Writes the values from the vector to the buffer and returns true if successful.

```
uint  CLBufferWrite(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   vector<T>     &vec                       // the values vector for writing to the bu
   );
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array of values that should be written in the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which writing begins. By default, writing start with the very beginning of the buffer.

data_offset

[in] The index of the first array element, starting from which values from the array are written in the OpenCL buffer. By default, values from the very beginning of the array are taken.

data_count

[in] The number of values that should be written. All the values of the array, by default.

mat

[out] The matrix for reading data from the buffer can be any of the three types — matrix, matrixf or matrixc.

vec

[out] The vector for reading data from the buffer can be of any of the three types — vector, vectorf or vectorc.

Return Value

The number of written elements. 0 is returned in case of an error. For information about the error, use the GetLastError() function.

true if a matrix or a vector is handled successfully, otherwise false.

Note

For one-dimensional arrays, the number of the element, with which reading of data for writing into an OpenCL buffer begins, is calculated taking into account the AS_SERIES flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

Example of matrix multiplication using the MatMul method and parallel computing in OpenCL

```
#define M       3000      // the number of rows in the first matrix
#define K       2000      // the number of columns in the first matrix is equal to the
#define N       3000      // the number of columns in the second matrix

//+------------------------------------------------------------------+
const string clSrc=
  "#define N     "+IntegerToString(N)+"                                \r\n"
  "#define K     "+IntegerToString(K)+"                                \r\n"
  "                                                                   \r\n"
  "__kernel void matricesMul( __global float *in1,                    \r\n"
  "                           __global float *in2,                    \r\n"
  "                           __global float *out  )                  \r\n"
  "{                                                                  \r\n"
  "  int m = get_global_id( 0 );                                      \r\n"
  "  int n = get_global_id( 1 );                                      \r\n"
  "  float sum = 0.0;                                                 \r\n"
  "  for( int k = 0; k < K; k ++ )                                    \r\n"
  "     sum += in1[ m * K + k ] * in2[ k * N + n ];                   \r\n"
  "  out[ m * N + n ] = sum;                                          \r\n"
  "}                                                                  \r\n";
//+------------------------------------------------------------------+
//| Script program start function                                    |

  CLContextFree(cl_ctx);
 }
```

CLBufferRead

Reads an OpenCL buffer into an array and returns the number of read elements.

```
uint  CLBufferRead(
   int           buffer,                    // A handle to the OpenCL buffer
   const void&   data[],                    // An array of values
   uint          buffer_offset=0,           // An offset in the OpenCL buffer in bytes,
   uint          data_offset=0,             // An offset in the array in elements, 0 by
   uint          data_count=WHOLE_ARRAY     // The number of values from the buffer for
   );
```

There are also versions for handling matrices and vectors.

Reads the OpenCL buffer to the matrix and returns true if successful.

```
uint  CLBufferRead(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   const matrix& mat,                       // the matrix for receiving the values fro
   ulong         rows=-1,                   // the number of rows in the matrix
   ulong         cols=-1                    // the number of columns in the matrix
   );
```

Reads the OpenCL buffer to the vector and returns true if successful.

```
uint  CLBufferRead(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   const vector& vec,                       // the vector for receiving the values fro
   ulong         size-1,                    // vector length
   );
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array for receiving values from the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which reading begins. By default, reading start with the very beginning of the buffer.

data_offset

[in] The index of the first array element for writing the values of the OpenCL buffer. By default, writing of the read values into an array starts from the zero index.

data_count

[in] The number of values that should be read. The whole OpenCL buffer is read by default.

mat

[out] The matrix for reading data from the buffer can be any of the three types — matrix, matrixf or matrixc.

vec

[out] The vector for reading data from the buffer can be of any of the three types — vector, vectorf or vectorc.

rows=-1

[in] If the parameter is specified, the *cols* parameter should be specified as well. If the new matrix dimensions are not specified, the current ones are used. If the value is -1, then the number of rows does not change.

cols=-1

[in] If the parameter is not specified, the *rows* parameter should be skipped as well. The matrix adheres to the rule: either both parameters are specified, or none, otherwise an error will occur. If both parameters (*rows and cols*) are specified, the matrix size is changed. In case of -1, the number of columns does not change.

size=-1

[in] If the parameter is not specified or its value is -1, the vector length does not change.

Return Value

The number of read elements. 0 is returned in case of an error. For information about the error, use the GetLastError() function.

true if a matrix or a vector is handled successfully, otherwise false.

Note

For one-dimensional arrays, the number of the element, into which writing of data into an OpenCL buffer begins, is calculated taking into account the AS_SERIES flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

Example of calculating Pi using the equation:

$$\pi = \lim_{N\to\infty}\frac{1}{N}\sum_{k=0}^{N-1}\frac{4}{1+\left(\frac{2k+1}{2N}\right)^2} = 16\lim_{N\to\infty}N\sum_{k=0}^{N-1}\frac{1}{4N^2+(2k+1)^2}$$

```
#define  _num_steps        1000000000
#define  _divisor          40000
#define  _step             1.0 / _num_steps
#define  _intrnCnt         _num_steps / _divisor
```

```
//+------------------------------------------------------------------+
//|                                                                  |

```

CLExecute

The function runs an OpenCL program. There are 3 versions of the function:

1. Launching kernel functions using one kernel

```
bool  CLExecute(
   int           kernel                    // Handle to the kernel of an OpenCL prograr
   );
```

2. Launching several kernel copies (OpenCL function) with task space description

```
bool  CLExecute(
   int           kernel,                   // Handle to the kernel of an OpenCL prograr
   uint          work_dim,                 // Dimension of the tasks space
   const uint&   global_work_offset[],     // Initial offset in the tasks space
   const uint&   global_work_size[]        // Total number of tasks
   );
```

3. Launching several kernel copies (OpenCL function) with task space description and specification of the size of the group's local task subset

```
bool  CLExecute(
   int           kernel,                   // Handle to the kernel of an OpenCL prograr
   uint          work_dim,                 // Dimension of the tasks space
   const uint&   global_work_offset[],     // Initial offset in the tasks space
   const uint&   global_work_size[],       // Total number of tasks
   const uint&   local_work_size[]         // Number of tasks in the local group
   );
```

Parameters

kernel

[in] Handle to the OpenCL kernel.

work_dim

[in] Dimension of the tasks space.

global_work_offset[]

[in] Initial offset in the tasks space.

global_work_size[]

[in] The size of a subset of tasks.

local_work_size[]

[in] The size of the group's local task subset.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

Note

Consider the use of the parameters in the following example:

- *work_dim* specifies the size of *work_items[]* array that describes the tasks. If *work_dim*=3, three-dimensional array *work_items[N1, N2, N3]* is used.
- *global_work_size[]* contains the values that set the *work_items[]* array size. If work_dim=3, *global_work_size[3]* array can be {40, 100, 320}. Then we have *work_items[40, 100, 320]*. So, the total number of tasks is 40 x 100 x 320 = 1 280 000.
- *local_work_size[]* sets the subset of the tasks that will be executed by the specified kernel of OpenCL program. Its size is equal to *work_items[]* size and allows to split the common task subset into smaller subsets without loss of remainder in division. In fact, the size of *local_work_size[]* array should be selected so that the *work_items[]* global task set will be split into smaller subsets. In this example *local_work_size[3]={10, 10, 10}* will be OK, as *work_items[40, 100, 320]* can be gathered from *local_items[10, 10, 10]* array without division remainder.

CLExecutionStatus

Returns the OpenCL program execution status.

```
int  CLExecutionStatus(
   int   kernel            // handle to a kernel of an OpenCL program
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

Return Value

Returns the OpenCL program status. The value can be one of the following:

- CL_COMPLETE=0 - program complete,
- CL_RUNNING=1 - running,
- CL_SUBMITTED=2 - submitted for execution,
- CL_QUEUED=3 - queued,
- -1 (minus one) - error occurred when executing CLExecutionStatus().

Working with databases

The functions for working with databases apply the popular and easy-to-use SQLite engine. The convenient feature of this engine is that the entire database is located in a single file on a user PC's hard disk.

The functions allow for convenient creation of tables, adding data to them, performing modifications and sampling using simple SQL requests:

- receiving trading history and quotes from any formats,
- saving optimization and test results,
- preparing and exchanging data with other analysis packages,
- storing MQL5 application settings and status.

Queries allow using statistical and mathematical functions.

The functions for working with databases allow you to replace the most repetitive large data array handling operations with SQL requests, so that it is often possible to use the DatabaseExecute/DatabasePrepare calls instead of programming complex loops and comparisons. Use the DatabaseReadBind function to conveniently obtain query results in a ready-made structure. The function allows reading all record fields at once within a single call.

To accelerate reading, writing and modification, a database can be opened/created in RAM with the DATABASE_OPEN_MEMORY flag, although such a database is available only to a specific application and is not shared. When working with databases located on the hard disk, bulk data inserts/changes should be wrapped in transactions using DatabaseTransactionBegin/DatabaseTransactionCommit/DatabaseTransactionRollback. This accelerates the process hundreds of times.

To start working with the functions, read the article SQLite: Native handling of SQL databases in MQL5.

Function	Action
DatabaseOpen	Opens or creates a database in a specified file
DatabaseClose	Closes a database
DatabaseImport	Imports data from a file into a table
DatabaseExport	Exports a table or an SQL request execution result to a CSV file
DatabasePrint	Prints a table or an SQL request execution result in the Experts journal
DatabaseTableExists	Checks the presence of the table in a database
DatabaseExecute	Executes a request to a specified database
DatabasePrepare	Creates a handle of a request, which can then be executed using DatabaseRead()
DatabaseReset	Resets a request, like after calling DatabasePrepare()
DatabaseBind	Sets a parameter value in a request

Function	Action
DatabaseBindArray	Sets an array as a parameter value
DatabaseRead	Moves to the next entry as a result of a request
DatabaseReadBind	Moves to the next record and reads data into the structure from it
DatabaseFinalize	Removes a request created in DatabasePrepare()
DatabaseTransactionBegin	Starts transaction execution
DatabaseTransactionCommit	Completes transaction execution
DatabaseTransactionRollback	Rolls back transactions
DatabaseColumnsCount	Gets the number of fields in a request
DatabaseColumnName	Gets a field name by index
DatabaseColumnType	Gets a field type by index
DatabaseColumnSize	Gets a field size in bytes
DatabaseColumnText	Gets a field value as a string from the current record
DatabaseColumnInteger	Gets the int type value from the current record
DatabaseColumnLong	Gets the long type value from the current record
DatabaseColumnDouble	Gets the double type value from the current record
DatabaseColumnBlob	Gets a field value as an array from the current record

Statistical functions:

- mode - mode
- median - median (50th percentile)
- percentile_25 - 25th percentile
- percentile_75
- percentile_90
- percentile_95
- percentile_99
- stddev or stddev_samp — sample standard deviation
- stddev_pop — population standard deviation
- variance or var_samp — sample variance
- var_pop — population variance

Mathematical functions

- acos(X) - arccosine in radians
- acosh(X) - hyperbolic arccosine
- asin(X) - arcsine in radians

- asinh(X) - hyperbolic arcsine
- atan(X) - arctangent in radians
- atan2(X,Y) - arctangent in radians of the X/Y ratio
- atanh(X) - hyperbolic arctangent
- ceil(X) - rounding up to an integer
- ceiling(X) - rounding up to an integer
- cos(X) - angle cosine in radians
- cosh(X) - hyperbolic cosine
- degrees(X) - convert radians into the angle
- exp(X) - exponent
- floor(X) - rounding down to an integer
- ln(X) - natural logarithm
- log(B,X) - logarithm to the indicated base
- log(X) - decimal logarithm
- log10(X) - decimal logarithm
- log2(X) - logarithm to base 2
- mod(X,Y) - remainder of division
- pi() - approximate Pi
- pow(X,Y) - power by the indicated base
- power(X,Y) - power by the indicated base
- radians(X) - convert the angle into radians
- sin(X) - angle sine in radians
- sinh(X) - hyperbolic sine
- sqrt(X) - square root
- tan(X) - angle tangent in radians
- tanh(X) - hyperbolic tangent
- trunc(X) - truncate to an integer closest to 0

Example:

```
select
  count(*) as book_count,
  cast(avg(parent) as integer) as mean,
  cast(median(parent) as integer) as median,
  mode(parent) as mode,
  percentile_90(parent) as p90,
  percentile_95(parent) as p95,
  percentile_99(parent) as p99
from moz_bookmarks;
```

DatabaseOpen

Opens or creates a database in a specified file.

```
int  DatabaseOpen(
   string  filename,       // file name
   uint    flags           // combination of flags
   );
```

Parameters

filename

[in] File name relative to the "MQL5\Files" folder.

flags

[in] Combination of flags from the ENUM_DATABASE_OPEN_FLAGS enumeration.

Return Value

If executed successfully, the function returns the database handle, which is then used to access the database. Otherwise, it returns INVALID_HANDLE. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_WRONG_INTERNAL_PARAMETER (4002) - internal error, while accessing the "MQL5\Files" folder;
- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_FILENAME (5002) - wrong database file name;
- ERR_TOO_LONG_FILENAME (5003) - absolute path to the database file exceeds the maximum length;
- ERR_DATABASE_TOO_MANY_OBJECTS (5122) - exceeded the maximum acceptable number of Database objects;
- ERR_DATABASE_CONNECT (5123) - database connection error;
- ERR_DATABASE_MISUSE (5621) - incorrect use of the SQLite library.

Note

If the *filename* parameter features NULL or the empty string "", a temporary file is created on the disk. It is automatically deleted after closing the database connection.

If the *filename* parameter features ":memory:", the database is created in the memory and is automatically deleted after the connection to it is closed.

If the *flags* parameter features none of the DATABASE_OPEN_READONLY or DATABASE_OPEN_READWRITE flags, the DATABASE_OPEN_READWRITE flag is used.

If the file extension is not specified, ".sqlite" is used.

ENUM_DATABASE_OPEN_FLAGS

ID	Description
DATABASE_OPEN_READONLY	Read only
DATABASE_OPEN_READWRITE	Open for reading and writing
DATABASE_OPEN_CREATE	Create the file on a disk if necessary
DATABASE_OPEN_MEMORY	Create a database in RAM
DATABASE_OPEN_COMMON	The file is in the common folder of all terminals

See also

DatabaseClose

DatabaseClose

Closes a database.

```
void  DatabaseClose(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return Value

None.

Note

After calling DatabaseClose, all handles of requests to the database are automatically removed and become invalid.

If the handle is invalid, the function sets the ERR_DATABASE_INVALID_HANDLE error. You can check the error using GetLastError().

DatabaseOpen, DatabasePrepare

DatabaseImport

Imports data from a file into a table.

```
long  DatabaseImport(
   int           database,          // database handle received in DatabaseOpen
   const string  table,             // name of a table to insert data
   const string  filename,          // name of a file to import data
   uint          flags,             // combination of flags
   const string  separator,         // data separator
   ulong         skip_rows,         // how many initial strings to skip
   const string  skip_comments      // string of characters defining comments
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table

[in] Name of a table the data from a file is to be added to.

filename

[in] CSV file or ZIP archive for reading data. The name may contain subdirectories and is set relative to the MQL5\Files folder.

flags

[in] Combination of flags from the ENUM_DATABASE_IMPORT_FLAGS enumeration.

separator

[in] Data separator in CSV file.

skip_rows

[in] Number of initial strings to be skipped when reading data from the file.

skip_comments

[in] String of characters for designating strings as comments. If any character from *skip_comments* is detected at the beginning of a string, such a string is considered a comment and is not imported.

Return Value

Return the number of imported strings or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle.

Note

If there is no table named *table*, it is generated automatically. Names and field types in the created table are defined automatically based on the file data.

If there is no table named *table*, it is generated automatically. Names and field types in the created table are defined automatically based on the file data.

ENUM_DATABASE_IMPORT_FLAGS

ID	Description
DATABASE_IMPORT_HEADER	The first line contains the names of the table fields
DATABASE_IMPORT_CRLF	CRLF (the default is LF) is considered a string break
DATABASE_IMPORT_APPEND	Add data to the end of an existing table
DATABASE_IMPORT_QUOTED_STRINGS	String values enclosed in double quotes
DATABASE_IMPORT_COMMON_FOLDER	The file is stored in the common folder of all client terminals \Terminal\Common\File.

Example of reading the table from the file created by the code from the DatabaseExport example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
  string csv_filename;
//--- get the names of text files for downloading from the common folder of the client
  string filenames[];
  if(FileSelectDialog("Select a CSV file to download a table", NULL,
                      "Text files (*.csv)|*.csv",
                      FSD_WRITE_FILE|FSD_COMMON_FOLDER, filenames, "data.csv")>0)
   {
    //--- display the name of each selected file
    if(ArraySize(filenames)==1)
      csv_filename=filenames[0];
    else
     {
      Print("Unknown error while selecting file. Error code ", GetLastError());
      return;
     }
   }
  else
   {
    Print("CSV file not selected");
    return;
   }
//--- create or open a database
  string db_filename="test.sqlite";
  int db=DatabaseOpen(db_filename, DATABASE_OPEN_READWRITE|DATABASE_OPEN_CREATE);
//--- check if the TEST table exists
```

```
  if(DatabaseTableExists(db, "TEST"))
   {
    //--- remove the TEST table
    if(!DatabaseExecute(db, "DROP TABLE IF EXISTS TEST"))
     {
      Print("Failed to drop the TEST table with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
   }
  //--- import entries from the file to the TEST table
  long imported=DatabaseImport(db, "TEST", csv_filename, DATABASE_IMPORT_HEADER|DATABA
  if(imported>0)
   {
    Print(imported," lines imported in table TEST");
    DatabasePrint(db,"SELECT * FROM TEST",DATABASE_PRINT_NO_INDEX);
   }
  else
    {
     Print("DatabaseImport() failed. Error ",GetLastError());
    }
//--- close the database file and inform of that
  DatabaseClose(db);
  PrintFormat("Database: %s closed", db_filename);
 }
```

See also

DatabaseOpen, DatabasePrint

DatabaseExport

Exports a table or an SQL request execution result to a CSV file. The file is created in the UTF-8 encoding.

```
long  DatabaseExport(
   int           database,          // database handle received in DatabaseOpen
   const string  table_or_sql,      // a table name or an SQL request
   const string  filename,          // a name of a CSV file for data export
   uint          flags,             // combination of flags
   const string  separator          // data separator in the CSV file
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table_or_sql

[in] A name of a table or a text of an SQL request whose results are to be exported to a specified file.

filename

[in] A file name for data export. The path is set relative to the MQL5\Files folder.

flags

[in] Combination of flags from the ENUM_DATABASE_EXPORT_FLAGS enumeration.

separator

[in] Data separator. If NULL is specified, the '\t' tabulation character is used as a separator. An empty string "" is considered a valid separator but the obtained CSV file cannot be read as a table - it is considered as a set of strings.

Return Value

Return the number of exported entries or a negative value in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_FUNCTION_NOT_ALLOWED(4014) - specified pipe is not allowed;
- ERR_PROGRAM_STOPPED(4022) - operation canceled (MQL program stopped);
- ERR_WRONG_FILENAME (5002) - invalid file name;
- ERR_TOO_LONG_FILENAME (5003) - absolute path to the file exceeds the maximum length;
- ERR_CANNOT_OPEN_FILE(5004) - unable to open the file for writing;
- ERR_FILE_WRITEERROR(5026) - unable to write to the file;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;

- ERR_DATABASE_QUERY_PREPARE(5125) - request generation error;
- ERR_DATABASE_QUERY_NOT_READONLY - read-only request is allowed.

Note

If request results are exported, the SQL request should begin with "SELECT" or "select". In other words, the SQL request cannot alter the database status, otherwise DatabaseExport() fails with an error.

Database string values may contain the conversion character ('\r' or '\r\n'), as well as the value separator character set in the *separator* parameter. In this case, be sure to use the DATABASE_EXPORT_QUOTED_STRINGS flag in the 'flags' parameter. If this flag is present, all displayed strings are enclosed in double quotes. If a string contains a double quote, it is replaced by two double quotes.

ENUM_DATABASE_EXPORT_FLAGS

ID	Description
DATABASE_EXPORT_HEADER	Display field names in the first string
DATABASE_EXPORT_INDEX	Display string indices
DATABASE_EXPORT_NO_BOM	Do not insert BOM mark at the beginning of the file (BOM is inserted by default)
DATABASE_EXPORT_CRLF	Use CRLF for string break (the default is LF)
DATABASE_EXPORT_APPEND	Add data to the end of an existing file (by default, the file is overwritten). If the file does not exist, it will be created.
DATABASE_EXPORT_QUOTED_STRINGS	Display string values in double quotes.
DATABASE_EXPORT_COMMON_FOLDER	A CSV file is created in the common folder of all client terminals \Terminal\Common\File.

Example:

```
input int InpRates=100;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
  MqlRates rates[];
//--- remember the start time before receiving bars
  ulong start=GetMicrosecondCount();
//--- request the last 100 bars on H1
  if(CopyRates(Symbol(), PERIOD_H1, 1, InpRates, rates)<InpRates)
   {
    Print("CopyRates() failed,, Error ", GetLastError());
```

```
    return;
   }
  else
   {
    //--- how many bars were received and how much time it took to receive them
    PrintFormat("%s: CopyRates received %d bars in %d ms ",
                _Symbol, ArraySize(rates), (GetMicrosecondCount()-start)/1000);
   }
//--- set the file name for storing the database
  string filename=_Symbol+"_"+EnumToString(PERIOD_H1)+"_"+TimeToString(TimeCurrent())+
  StringReplace(filename, ":", "-"); // ":" character is not allowed in file names
//--- open/create the database in the common terminal folder
  int db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE|DATABASE_OPEN_CREATE|DATABASE_
  if(db==INVALID_HANDLE)
   {
    Print("Database: ", filename, " open failed with code ", GetLastError());
    return;
   }
  else
    Print("Database: ", filename, " opened successfully");

//--- check if the RATES table exists
  if(DatabaseTableExists(db, "RATES"))
   {
    //--- remove the RATES table
    if(!DatabaseExecute(db, "DROP TABLE IF EXISTS RATES"))
     {
      Print("Failed to drop the RATES table with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
   }
//--- create the RATES table
  if(!DatabaseExecute(db, "CREATE TABLE RATES("
                      "SYMBOL             CHAR(10),"
                      "TIME               INT NOT NULL,"
                      "OPEN               REAL,"
                      "HIGH               REAL,"
                      "LOW                REAL,"
                      "CLOSE              REAL,"
                      "TICK_VOLUME        INT,"
                      "SPREAD             INT,"
                      "REAL_VOLUME        INT);"))
   {

See also

DatabasePrint, DatabaseImport

DatabasePrint

Prints a table or an SQL request execution result in the Experts journal.

```
long  DatabasePrint(
   int           database,          // database handle received in DatabaseOpen
   const string  table_or_sql,      // a table or an SQL request
   uint          flags              // combination of flags
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table_or_sql

[in] A name of a table or a text of an SQL request whose results are displayed in the Experts journal.

flags

[in] Combination of flags defining the output formatting. The flags are defined as follows:

DATABASE_PRINT_NO_HEADER - do not display table column names (field names)
DATABASE_PRINT_NO_INDEX - do not display string indices
DATABASE_PRINT_NO_FRAME - do not display a frame separating a header and data
DATABASE_PRINT_STRINGS_RIGHT - align strings to the right.

If flags=0, the columns and the strings are displayed, the header and the data are separated by the frame, while the strings are aligned to the left.

Return Value

Return the number of exported strings or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;

Note

If the journal displays request results, the SQL request should begin with "SELECT" or "select". In other words, the SQL request cannot alter the database status, otherwise DatabasePrint() fails with an error.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string filename="departments.sqlite";
```

```
//--- create or open the database in the common terminal folder
   int db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE | DATABASE_OPEN_CREATE |DATAB
   if(db==INVALID_HANDLE)
     {
      Print("DB: ", filename, " open failed with code ", GetLastError());
      return;
     }

//--- create the COMPANY table
   if(!CreataTableCompany(db))
     {
      DatabaseClose(db);
      return;
     }
//--- create the DEPARTMENT table
   if(!CreataTableDepartment(db))
     {
      DatabaseClose(db);
      return;
     }

//--- display the list of all fields in the COMPANY and DEPARTMENT tables
   PrintFormat("Try to print request \"PRAGMA TABLE_INFO(COMPANY);PRAGMA TABLE_INFO(DE
   if(DatabasePrint(db, "PRAGMA TABLE_INFO(COMPANY);PRAGMA TABLE_INFO(DEPARTMENT)", 0)
     {
      PrintFormat("DatabasePrint(\"PRAGMA TABLE_INFO()\") failed, error code=%d", GetL
      DatabaseClose(db);
      return;
     }
//--- display the COMPANY table in the log
   PrintFormat("Try to print request \"SELECT * from COMPANY\"");
   if(DatabasePrint(db, "SELECT * from COMPANY", 0)<0)
     {
      Print("DatabasePrint failed with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
//--- request text for combining the COMPANY and DEPARTMENT tables
   string request="SELECT EMP_ID, NAME, DEPT FROM COMPANY LEFT OUTER JOIN DEPARTMENT "
                  "ON COMPANY.ID = DEPARTMENT.EMP_ID";
//--- display the table combining result
   PrintFormat("Try to print request \"SELECT EMP_ID, NAME, DEPT FROM COMPANY LEFT OUT
   if(DatabasePrint(db, request, 0)<0)
     {
      Print("DatabasePrint failed with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
//--- close the database
```

```
   DatabaseClose(db);
  }
/*
Conclusion:
Try to print request "PRAGMA TABLE_INFO(COMPANY);PRAGMA TABLE_INFO(DEPARTMENT)"

DatabaseExport, DatabaseImport

DatabaseTableExists

Checks the presence of the table in a database.

```
bool  DatabaseTableExists(
   int     database,      // database handle received in DatabaseOpen
   string  table          // table name
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table

[in] Table name.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

See also

DatabasePrepare, DatabaseFinalize

DatabaseExecute

Executes a request to a specified database.

```
bool  DatabaseExecute(
   int     database,      // database handle received in DatabaseOpen
   string  sql            // SQL request
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

sql

[in] SQL request.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

DatabasePrepare, DatabaseFinalize

DatabasePrepare

Creates a handle of a request, which can then be executed using DatabaseRead().

```
int  DatabasePrepare(
   int     database,      // database handle received in DatabaseOpen
   string  sql,           // SQL request
           ...            // request parameters
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

sql

[in] SQL request that may contain automatically substituted parameters named ?1,?2,...

...

[in] Automatically substituted request parameters.

Return Value

If successful, the function returns a handle for the SQL request. Otherwise, it returns INVALID_HANDLE. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_TOO_MANY_OBJECTS (5122) - exceeded the maximum acceptable number of Database objects;
- ERR_DATABASE_PREPARE (5125) - request generation error.

Note

The DatabasePrepare() function does not perform a request to a database. Its purpose is to verify the request parameters and return the handle for executing the SQL request based on the verification results. The request itself is set during the DatabaseRead() first call.

Example:

```
//--- Structure to store the deal
struct Deal
  {
   ulong             ticket;           // DEAL_TICKET

See also

DatabaseExecute, DatabaseFinalize

DatabaseReset

Resets a request, like after calling DatabasePrepare().

```
int  DatabaseReset(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] The handle of the request obtained in DatabasePrepare().

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- SQLite error codes starting with ERR_DATABASE_ERROR(5601).

Note

The DatabaseReset() function is intended for multiple execution of a request with different parameter values. For example, when adding data to the table in bulk using the INSERT command, a custom set of field values should be formed for each entry.

Unlike DatabasePrepare(), the DatabaseReset() call does not compile the string with SQL commands into a new request, therefore DatabaseReset() is executed much faster than DatabasePrepare().

DatabaseReset() is used together with the DatabaseBind() functions and/or DatabaseBindArray() if the request parameter values should be changed after executing DatabaseRead(). This means that before setting new values of the request parameters (before the block of DatabaseBind/DatabaseBindArray calls), DatabaseReset() should be called to reset it. The parametrized request itself should be created using DatabasePrepare().

Just like DatabasePrepare(), DatabaseReset() does not make a database request. A direct request execution is performed when calling DatabaseRead() or DatabaseReadBind().

DatabaseReset() call does not lead to resetting parameter values in the request if they were set by calling DatabaseBind()/DatabaseBindArray(), i.e. the parameters retain their values. Thus, the value of only a single parameter can be changed. There is no need to set all request parameters anew after calling DatabaseReset().

A handle of a request removed using DatabaseFinalize() cannot be passed to DatabaseReset(). This will result in an error.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

DatabaseBind

Sets a parameter value in a request.

```
bool  DatabaseBind(
   int   request,      // the handle of a request created in DatabasePrepare
   int   index,        // the parameter index in the request
   T     value         // the value of a simple type parameter
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

index

[in] The parameter index in the request a value should be set for. The numbering starts with zero.

value

[in] The value to be set. Extended types: bool, char, uchar, short, ushart, int, uint, color, datetime, long, ulong, float, double, string.

Return Value

Returns true if successful, otherwise - false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - unsupported type;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_NOT_READY (5128) - cannot use the function to make a request at the moment. The request is being executed or already complete. DatabaseReset() should be called.

Note

The function is used in case an SQL request contains "?" or "?N" parameterizable values where N means the parameter index (starting from one). At the same time, parameters indexing in DatabaseBind() starts from zero.

For example:

```
INSERT INTO table VALUES (?,?,?)
SELECT * FROM table WHERE id=?
```

The function may be called immediately after a parametrized request is created in DatabasePrepare() or after the request is reset using DatabaseReset().

Use this function together with DatabaseReset() to execute the request as many times as needed with different parameter values.

The function is designed to work with simple type parameters. If a parameter should be checked against an array, use the DatabaseBindArray() function.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

DatabasePrepare, DatabaseReset, DatabaseRead, DatabaseBindArray

DatabaseBindArray

Sets an array as a parameter value.

```
bool  DatabaseBind(
   int   request,       // the handle of a request created in DatabasePrepare
   int   index,         // the parameter index in the request
   T&    array[]        // parameter value as an array
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

index

[in] The parameter index in the request a value should be set for. The numbering starts with zero.

array[]

[in] The array to be set as a request parameter value.

Return Value

Returns true if successful, otherwise - false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - unsupported type;
- ERR_ARRAY_BAD_SIZE (4011) - array size in bytes exceeds INT_MAX;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_NOT_READY (5128) - cannot use the function to make a request at the moment (the request is being executed or already complete, DatabaseReset should be called).

Note

The function is used in case an SQL request contains "?" or "?N" parameterizable values where N means the parameter index (starting from one). At the same time, parameters indexing in DatabaseBindArray() starts from zero.

For example:

```
INSERT INTO table VALUES (?,?,?)
```

The function may be called immediately after a parametrized request is created in DatabasePrepare() or after the request is reset using DatabaseReset().

Use this function together with DatabaseReset() to execute the request as many times as needed with different parameter values.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

```
  {
//--- open the dialog for selecting files with the DAT extension
   string selected_files[];
   if(!FileSelectDialog("Select files to download", NULL,
                        "Data files (*.dat)|*.dat|All files (*.*)|*.*",
                        FSD_ALLOW_MULTISELECT, selected_files, "tester.dat")>0)
     {
      Print("Files not selected. Exit");
      return;
     }
//--- get the size of files
   ulong filesize[];
   int filehandle[];
   int files=ArraySize(selected_files);
   ArrayResize(filesize, files);
   ZeroMemory(filesize);
   ArrayResize(filehandle, files);
   double total_size=0;
   for(int i=0; i<files; i++)
     {

DatabasePrepare, DatabaseReset, DatabaseRead, DatabaseBind

DatabaseRead

Moves to the next entry as a result of a request.

```
bool  DatabaseRead(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

See also

DatabasePrepare, DatabaseReadBind

DatabaseReadBind

Moves to the next record and reads data into the structure from it.

```
bool  DatabaseReadBind(
   int    request,           // the handle of a request created in DatabasePrepare
   void&  struct_object      // the reference to the structure for reading the record
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

struct_object

[out] The reference to the structure the data from the current record is to be read to. The structure should only have numerical types and/or strings (arrays are not allowed) as members and cannot be a descendant.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

Note

A number of fields in the *struct_object* structure should not exceed DatabaseColumnsCount(). If the number of fields in the *struct_object* structure is less than the number of fields in the record, the partial reading is performed. The remaining data can be explicitly obtained using the corresponding DatabaseColumnText(), DatabaseColumnInteger() and other functions.

Example:

```
struct Person
  {
   int               id;
   string            name;
   int               age;
   string            address;
   double            salary;
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

```
  {
   int db;
   string filename="company.sqlite";
//--- open
   db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE | DATABASE_OPEN_CREATE |DATABASE_
   if(db==INVALID_HANDLE)
     {
      Print("DB: ", filename, " open failed with code ", GetLastError());
      return;
     }
//--- if the table COMPANY exists then drop the table
   if(DatabaseTableExists(db, "COMPANY"))
     {
      //--- delete the table
      if(!DatabaseExecute(db, "DROP TABLE COMPANY"))
        {
         Print("Failed to drop table COMPANY with code ", GetLastError());
         DatabaseClose(db);
         return;
        }
     }
//--- create table
   if(!DatabaseExecute(db, "CREATE TABLE COMPANY("
                       "ID INT PRIMARY KEY     NOT NULL,"
                       "NAME           TEXT    NOT NULL,"
                       "AGE            INT     NOT NULL,"
                       "ADDRESS        CHAR(50),"
                       "SALARY         REAL );"))
     {
      Print("DB: ", filename, " create table failed with code ", GetLastError());
      DatabaseClose(db);
      return;
     }

//--- insert data
   if(!DatabaseExecute(db, "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (1
                       "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (2, 'A
                       "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (3, 'T

Average salary=31250.0
*/
```

See also

DatabasePrepare, DatabaseRead

DatabaseFinalize

Removes a request created in DatabasePrepare().

```
void  DatabaseFinalize(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

None.

Note

If the handle is invalid, the function sets the ERR_DATABASE_INVALID_HANDLE error. You can check the error using GetLastError().

See also

DatabasePrepare, DatabaseExecute

DatabaseTransactionBegin

Starts transaction execution.

```
bool  DatabaseTransactionBegin(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

The DatabaseTransactionBegin() function should be called before a transaction execution. Any transaction should start with calling DatabaseTransactionBegin() and end with calling DatabaseTransactionCommit().

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create the file name
   string filename=AccountInfoString(ACCOUNT_SERVER) +"_"+IntegerToString(AccountInfol
//--- open/create the database in the common terminal folder
   int db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE | DATABASE_OPEN_CREATE | DATA
   if(db==INVALID_HANDLE)
     {
      Print("DB: ", filename, " open failed with code ", GetLastError());
      return;
     }
//--- if the DEALS table already exists, delete it
   if(!DeleteTable(db, "DEALS"))
     {
      DatabaseClose(db);
      return;
     }
```

```
//--- create the DEALS table
   if(!CreateTableDeals(db))
     {
      DatabaseClose(db);
      return;
     }
//---  request the entire trading history
   datetime from_date=0;
   datetime to_date=TimeCurrent();

DatabaseTransactionCommit

Completes transaction execution.

```
bool  DatabaseTransactionCommit(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

The DatabaseTransactionCommit() function completes all transactions executed after calling the DatabaseBeginTransaction() function. Any transaction should start with calling DatabaseTransactionBegin() and end with calling DatabaseTransactionCommit() for successful completion.

See also

DatabaseExecute, DatabasePrepare, DatabaseTransactionBegin, DatabaseTransactionRollback

DatabaseTransactionRollback

Rolls back transactions.

```
bool  DatabaseTransactionRollback(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

DatabaseTransactionRollback() call cancels all transactions executed after calling the DatabaseTransactionBegin() function. The DatabaseTransactionRollback() function is necessary for rolling back changes in a database in case errors occur when executing a transaction.

DatabaseColumnsCount

Gets the number of fields in a request.

```
int  DatabaseColumnsCount(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

Number of fields or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle.

Note

There is no need to call the DatabaseRead() function to get the number of fields of a request created in DatabasePrepare(). For the remaining DatabaseColumnXXX() functions, DatabaseRead() should be preliminarily called.

See also

DatabasePrepare, DatabaseFinalize, DatabaseClose

DatabaseColumnName

Gets a field name by index.

```
bool  DatabaseColumnName(
   int       request,      // request handle received in DatabasePrepare
   int       column,       // field index in the request
   string&   name          // the reference to the variable for receiving the field name
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

name

[out] Variable for writing the field name.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType

DatabaseColumnType

Gets a field type by index.

```
ENUM_DATABASE_FIELD_TYPE  DatabaseColumnType(
   int  request,     // request handle received in DatabasePrepare
   int  column       // field index in the request
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

Return Value

Return the field type from the ENUM_DATABASE_FIELD_TYPE enumeration. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

ENUM_DATABASE_FIELD_TYPE

ID	Description
DATABASE_FIELD_TYPE_INVALID	Error getting type, the error code can be obtained using int GetLastError()
DATABASE_FIELD_TYPE_INTEGER	Integer type
DATABASE_FIELD_TYPE_FLOAT	Real type
DATABASE_FIELD_TYPE_TEXT	String type
DATABASE_FIELD_TYPE_BLOB	Binary type
DATABASE_FIELD_TYPE_NULL	Special NULL type

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnName

DatabaseColumnSize

Gets a field size in bytes.

```
int  DatabaseColumnSize(
   int  request,     // request handle received in DatabasePrepare
   int  column       // field index in the request
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

Return Value

If successful, the field size in bytes is returned, otherwise -1. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

See also

DatabasePrepare, DatabaseColumnBlob, DatabaseColumnsCount, DatabaseColumnName, DatabaseColumnType

DatabaseColumnText

Gets a field value as a string from the current record.

```
bool  DatabaseColumnText(
   int      request,     // request handle received in DatabasePrepare
   int      column,      // field index in the request
   string&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType, DatabaseColumnName

DatabaseColumnInteger

Gets the int type value from the current record.

```
bool  DatabaseColumnInteger(
   int   request,     // request handle received in DatabasePrepare
   int   column,      // field index in the request
   int&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType, DatabaseColumnName

DatabaseColumnLong

Gets the long type value from the current record.

```
bool  DatabaseColumnLong(
   int     request,      // request handle received in DatabasePrepare
   int     column,       // field index in the request
   long&   value         // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType, DatabaseColumnName

DatabaseColumnDouble

Gets the double type value from the current record.

```
bool  DatabaseColumnDouble(
   int      request,     // request handle received in DatabasePrepare
   int      column,      // field index in the request
   double&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType, DatabaseColumnName

DatabaseColumnBlob

Gets a field value as an array from the current record.

```
bool  DatabaseColumnBlob(
   int     request,      // request handle received in DatabasePrepare
   int     column,       // field index in the request
   void&   data[]        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

data[]

[out] Reference to the array for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

Working with DirectX

DirectX 11 functions and shaders are designed for 3D visualization directly on a price chart.

Creating 3D graphics requires a graphic context (DXContextCreate) with the necessary image size. Besides, it is necessary to prepare vertex and index buffers (DXBufferCreate), as well as create vertex and pixel shaders (DXShaderCreate). This is enough to display graphics in color.

The next level of graphics requires the inputs (DXInputSet) for passing additional rendering parameters to shaders. This allows setting the camera and 3D object positions, describe light sources and implement mouse and keyboard control.

Thus, the built-in MQL5 functions enable you to create animated 3D charts directly in MetaTrader 5 with no need for third-party tools. A video card should support DX 11 and Shader Model 5.0 for the functions to work.

To start working with the library, simply read the article How to create 3D graphics using DirectX in MetaTrader 5.

Function	Action
DXContextCreate	Creates a graphic context for rendering frames of a specified size
DXContextSetSize	Changes a frame size of a graphic context created in DXContextCreate()
DXContextSetSize	Gets a frame size of a graphic context created in DXContextCreate()
DXContextClearColors	Sets a specified color to all pixels for the rendering buffer
DXContextClearDepth	Clears the depth buffer
DXContextGetColors	Gets an image of a specified size and offset from a graphic context
DXContextGetDepth	Gets the depth buffer of a rendered frame
DXBufferCreate	Creates a buffer of a specified type based on a data array
DXTextureCreate	Creates a 2D texture out of a rectangle of a specified size cut from a passed image
DXInputCreate	Creates shader inputs
DXInputSet	Sets shader inputs
DXShaderCreate	Creates a shader of a specified type
DXShaderSetLayout	Sets vertex layout for the vertex shader
DXShaderInputsSet	Sets shader inputs
DXShaderTexturesSet	Sets shader textures
DXDraw	Renders the vertices of the vertex buffer set in DXBufferSet()

Function	Action
DXDrawIndexed	Renders graphic primitives described by the index buffer from DXBufferSet()
DXPrimiveTopologySet	Sets the type of primitives for rendering using DXDrawIndexed()
DXBufferSet	Sets a buffer for the current rendering
DXShaderSet	Sets a shader for rendering
DXHandleType	Returns a handle type
DXRelease	Releases a handle

DXContextCreate

Creates a graphic context for rendering frames of a specified size.

```
int  DXContextCreate(
   uint  width,      // width in pixels
   uint  height      // height in pixels
   );
```

Parameters

width

[in] Frame width in pixels.

height

[in] Frame height in pixels.

Return Value

A handle for a created context or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

All graphical objects created using the DXBufferCreate, DXInputCreate, DXShaderCreate and DXTextureCreate functions can be used only in a graphic context they were created in.

A frame size can subsequently be changed to DXContextSetSize().

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

DXContextSetSize

Changes a frame size of a graphic context created in DXContextCreate().

```
bool  DXContextSetSize(
   int    context,      // graphic context handle
   uint&  width,        // width in pixels
   uint&  height        // height in pixels
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

width

[in] Frame width in pixels.

height

[in] Frame height in pixels.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

A frame size of a graphic context should be changed only between frame renderings.

DXContextGetSize

Gets a frame size of a graphic context created in DXContextCreate().

```
bool  DXContextGetSize(
   int    context,      // graphic context handle
   uint&  width,        // width in pixels
   uint&  height        // height in pixels
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

width

[out] Frame width in pixels.

height

[out] Frame height in pixels.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

DXContextClearColors

Sets a specified color to all pixels for the rendering buffer.

```
bool  DXContextClearColors(
   int              context,       // graphic context handle
   const DXVector&  color          // color
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

color

[in] Rendering color.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXContextClearColors() function can be used for clearing the color buffer before rendering the next frame.

DXContextClearDepth

Clears the depth buffer.

```
bool  DXContextClearDepth(
   int  context      // graphic context handle
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXContextClearDepth() function can be used for clearing the depth buffer before rendering the next frame.

DXContextGetColors

Gets an image of a specified size and offset from a graphic context.

```
bool  DXContextGetColors(
   int    context,                      // graphic context handle
   uint&  image[],                      // image pixels array
   int    image_width=WHOLE_ARRAY,      // image width in pixels
   int    image_height=WHOLE_ARRAY,     // image height in pixels
   int    image_offset_x=0,             // X offset
   int    image_offset_y=0              // Y offset
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

image

[out] The array of *image_width*image_height* pixels in ARGB format.

image_width=WHOLE_ARRAY

[in] Image width in pixels.

image_height=WHOLE_ARRAY

[in] Image height in pixels.

image_offset_x=0

[in] X offset.

image_offset_y=0

[in] Y offset.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

DXContextGetDepth

Gets the depth buffer of a rendered frame.

```
bool  DXContextGetDepth(
   int     context,      // graphic context handle
   float&  image[]       // depth value array
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

image

[out] Array of the rendered frame depth buffer values.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The returned buffer contains the depth of each pixel of a rendered frame that can be obtained in DXContextGetColors() in relative units (from 0.0 to 1.0).

DXBufferCreate

Creates a buffer of a specified type based on a data array.

```
int  DXBufferCreate(
   int                  context,              // graphic context handle
   ENUM_DX_BUFFER_TYPE  buffer_type,          // type of a created buffer
   const void&          data[],               // buffer data
   uint                 start=0,              // initial index
   uint                 count=WHOLE_ARRAY     // number of elements
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

buffer_type

[in] Buffer type from the ENUM_DX_BUFFER_TYPE enumeration.

data[]

[in] Data for creating a buffer.

start=0

[in] Index of the first element of the array, starting from which the array values are used to create a buffer. By default, the data is taken from the beginning of the array.

count=WHOLE_ARRAY

[in] Number of values. By default, the entire array is used (count=WHOLE_ARRAY).

Return Value

The handle for a created buffer or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

For the index buffer, the *data[]* array should be of 'uint' type, while the vertex buffer receives the array of structures describing vertices.

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

ENUM_DX_BUFFER_TYPE

ID	Value	Description
DX_BUFFER_VERTEX	1	Vertex buffer
DX_BUFFER_INDEX	2	Index buffer

DXTextureCreate

Creates a 2D texture out of a rectangle of a specified size cut from a passed image.

```
int  DXTextureCreate(
   int              context,          // graphic context handle
   ENUM_DX_FORMAT   format,           // pixel color format
   uint             width,            // source image width
   uint             height,           // source image height
   const void&      data[],           // array of source image pixels
   uint             data_x,           // X coordinate of a rectangle used to create a te
   uint             data_y,           // Y coordinate of a rectangle used to create a te
   uint             data_width,       // rectangle width for creating a texture
   uint             data_height       // rectangle height for creating a texture
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

format

[in] Pixel color format set from the ENUM_DX_FORMAT enumeration.

width

[in] Width of an image a texture is based on.

height

[in] Height of an image a texture is based on.

data

[in] Pixel array of an image a texture is based on.

data_x

[in] X coordinate of a rectangle (X offset) used to create a texture.

data_y

[in] Y coordinate of a rectangle (Y offset) used to create a texture.

data_width

[in] Width of a rectangle used to create a texture.

data_height

[in] Height of a rectangle used to create a texture.

Return Value

Texture handle or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

DXInputCreate

Creates shader inputs.

```
int  DXInputCreate(
   int   context,        // graphic context handle
   uint  input_size      // size of inputs in bytes
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

input_size

[in] Size of the parameter structure in bytes.

Return Value

The handle for shader inputs or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

DXInputSet

Sets shader inputs.

```
bool  DXInputSet(
   int           input,       // graphic context handle
   const void&   data         // data for setting
   );
```

Parameters

input

[in] Handle of inputs for a shader obtained in DXInputCreate().

data

[in] Data for setting shader inputs.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

DXShaderCreate

Creates a shader of a specified type.

```
int  DXShaderCreate(
   int                  context,           // graphic context handle
   ENUM_DX_SHADER_TYPE  shader_type,       // shader type
   const string         source,            // shader source code
   const string         entry_point,       // entry point
   string&              compile_error      // string for receiving compiler messages
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

shader_type

[out] The value from the ENUM_DX_SHADER_TYPE enumeration.

source

[in] Shader source code in HLSL 5.

entry_point

[in] Entry point - function name in a source code.

compile_error

[in] String for receiving compilation errors.

Return Value

Handle for shader or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

ENUM_DX_SHADER_TYPE

ID	Value	Description
DX_SHADER_VERTEX	0	Vertex shader
DX_SHADER_GEOMETRY	1	Geometry shader
DX_SHADER_PIXEL	2	Pixel shader

DXShaderSetLayout

Sets vertex layout for the vertex shader.

```
bool  DXShaderSetLayout(
   int                     shader,        // shader handle
   const DXVertexLayout&   layout[]       //
   );
```

Parameters

shader

[in] Handle of a vertex shader created in DXShaderCreate().

layout[]

[in] Array of vertex fields description. The description is set by the DXVertexLayout structure:

```
struct DXVertexLayout
  {
   string          semantic_name;        // The HLSL semantic associated with this e
   uint            semantic_index;       // The semantic index for the element. A se
   ENUM_DX_FORMAT  format;               // The data type of the element data.
  };
```

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The layout should match the type of vertices in a specified vertex buffer. It should also match the input type of vertices used at the entry point in the vertex shader code.

The vertex buffer for a shader is set in DXBufferSet().

The DXVertexLayout structure is a version of the D3D11_INPUT_ELEMENT_DESC MSDN structure.

DXShaderInputsSet

Sets shader inputs.

```
bool  DXShaderInputsSet(
   int          shader,        // shader handle
   const int&   inputs[]       // array of input handles
   );
```

Parameters

shader

[in] Handle of a shader created in DXShaderCreate().

inputs[]

[in] Array of input handles created using DXInputCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The size of the input parameter should be equal to the number of cbuffer objects declared in the shader code.

DXShaderTexturesSet

Sets shader textures.

```
bool  DXShaderTexturesSet(
   int          shader,          // shader handle
   const  int&  textures[]       // array of structure handles
   );
```

Parameters

shader

[in] Handle of a shader created in DXShaderCreate().

textures[]

[in] Array of texture handles created using DXTextureCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The size of the texture array should be equal to the number of Texture2D objects declared in the shader code.

DXDraw

Renders the vertices of the vertex buffer set in DXBufferSet().

```
bool  DXDraw(
   int   context,               // graphic context handle
   uint  start=0,               // first vertex index
   uint  count=WHOLE_ARRAY      // number of vertices
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

start=0

[in] Index of the first vertex for rendering.

count=WHOLE_ARRAY

[in] Number of vertices to render.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Shaders should be preliminarily set using DXShaderSet() for rendering vertices.

DXDrawIndexed

Renders graphic primitives described by the index buffer from DXBufferSet().

```
bool  DXDrawIndexed(
   int   context,               // graphic context handle
   uint  start=0,               // first primitive index
   uint  count=WHOLE_ARRAY      // number of primitives
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

start=0

[in] Index of the first primitive for rendering.

count=WHOLE_ARRAY

[in] Number of primitives for rendering.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The type of primitives described by the index buffer is set using DXPrimiveTopologySet().

The vertex buffer in DXBufferSet() should be preliminarily set to render primitives.

Also, shaders should be preliminarily set using DXShaderSet().

DXPrimiveTopologySet

Sets the type of primitives for rendering using DXDrawIndexed().

```
bool  DXPrimiveTopologySet(
   int                          context,               // graphic context handle
   ENUM_DX_PRIMITIVE_TOPOLOGY   primitive_topology     // primitive type
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

primitive_topology

[in] The value from the ENUM_DX_PRIMITIVE_TOPOLOGY enumeration.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

ENUM_DX_PRIMITIVE_TOPOLOGY

ID	Value	Match in D3D11_PRIMITIVE_TOPOLOGY
DX_PRIMITIVE_TOPOLOGY_POINTLIST	1	D3D11_PRIMITIVE_TOPOLOGY_POINTLIST
DX_PRIMITIVE_TOPOLOGY_LINELIST	2	D3D11_PRIMITIVE_TOPOLOGY_LINELIST
DX_PRIMITIVE_TOPOLOGY_LINESTRIP	3	D3D11_PRIMITIVE_TOPOLOGY_LINESTRIP
DX_PRIMITIVE_TOPOLOGY_TRIANGLELIST	4	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLELIST
DX_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP	5	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP
DX_PRIMITIVE_TOPOLOGY_LINELIST_ADJ	6	D3D11_PRIMITIVE_TOPOLOGY_LINELIST_ADJ
DX_PRIMITIVE_TOPOLOGY_LINESTRIP_ADJ	7	D3D11_PRIMITIVE_TOPOLOGY_LINESTRIP_ADJ
DX_PRIMITIVE_TOPOLOGY_TRIANGLELIST_ADJ	8	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLELIST_ADJ
DX_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP_ADJ	9	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP_ADJ

DXBufferSet

Sets a buffer for the current rendering.

```
bool  DXBufferSet(
   int   context,               // graphic context handle
   int   buffer,                // vertex or index buffer handle
   uint  start=0,               // initial index
   uint  count=WHOLE_ARRAY      // number of elements
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

buffer

[in] Handle of the vertex or index buffer created in DXBufferCreate().

start=0

[in] Index of the buffer first element. The data from the beginning of the buffer is used by default.

count=WHOLE_ARRAY

[in] Number of values to be used. The default is all buffer values.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXBufferSet() function should be called to set vertex and index buffers for rendering using DXDraw().

DXShaderSet

Sets a shader for rendering.

```
bool  DXShaderSet(
   int  context,      // graphic context handle
   int  shader        // shader handle
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

shader

[in] Handle of a shader created in DXShaderCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Several types of shaders can simultaneously be used for rendering (vertex, geometry and pixel ones).

DXHandleType

Returns a handle type.

```
ENUM_DX_HANDLE_TYPE  DXHandleType(
   int  handle      // handle
   );
```

Parameters

handle

[in] Handle.

Return Value

The value from the ENUM_DX_HANDLE_TYPE enumeration

ENUM_DX_HANDLE_TYPE

ID	Value	Description
DX_HANDLE_INVALID	0	Invalid handle
DX_HANDLE_CONTEXT	1	Graphic context handle
DX_HANDLE_SHADER	2	Shader handle
DX_HANDLE_BUFFER	3	Vertex or index buffer handle
DX_HANDLE_INPUT	4	Handle for shader inputs
DX_HANDLE_TEXTURE	5	Texture handle

DXRelease

Releases a handle.

```
bool  DXRelease(
   int  handle      // handle
   );
```

Parameters

context

[in] Released handle.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

All created handles that are no longer in use should be explicitly released by the DXRelease() function.

MetaTrader module for integration with Python

MQL5 is designed for the development of high-performance trading applications in the financial markets and is unparalleled among other specialized languages used in the algorithmic trading. The syntax and speed of MQL5 programs are very close to C++, there is support for OpenCL and integration with MS Visual Studio. Statistics, fuzzy logic and ALGLIB libraries are available as well. MetaEditor development environment features native support for .NET libraries with "smart" functions import eliminating the need to develop special wrappers. Third-party C++ DLLs can also be used. C++ source code files (CPP and H) can be edited and compiled into DLL directly from the editor. Microsoft Visual Studio installed on user's PC can be used for that.

Python is a modern high-level programming language for developing scripts and applications. It contains multiple libraries for machine learning, process automation, as well as data analysis and visualization.

MetaTrader package for Python is designed for convenient and fast obtaining of exchange data via interprocessor communication directly from the MetaTrader 5 terminal. The data received this way can be further used for statistical calculations and machine learning.

Installing the package from the command line:

```
pip install MetaTrader5
```

Updating the package from the command line:

```
pip install --upgrade MetaTrader5
```

Functions for integrating MetaTrader 5 and Python

Function	Action
initialize	Establish a connection with the MetaTrader 5 terminal
login	Connect to a trading account using specified parameters
shutdown	Close the previously established connection to the MetaTrader 5 terminal
version	Return the MetaTrader 5 terminal version
last_error	Return data on the last error
account_info	Get info on the current trading account
terminal_Info	Get status and parameters of the connected MetaTrader 5 terminal
symbols_total	Get the number of all financial instruments in the MetaTrader 5 terminal
symbols_get	Get all financial instruments from the MetaTrader 5 terminal
symbol_info	Get data on the specified financial instrument
symbol_info_tick	Get the last tick for the specified financial instrument
symbol_select	Select a symbol in the MarketWatch window or remove a symbol from the window

Function	Action
market_book_add	Subscribes the MetaTrader 5 terminal to the Market Depth change events for a specified symbol
market_book_get	Returns a tuple from BookInfo featuring Market Depth entries for the specified symbol
market_book_release	Cancels subscription of the MetaTrader 5 terminal to the Market Depth change events for a specified symbol
copy_rates_from	Get bars from the MetaTrader 5 terminal starting from the specified date
copy_rates_from_pos	Get bars from the MetaTrader 5 terminal starting from the specified index
copyrates_range	Get bars in the specified date range from the MetaTrader 5 terminal
copy_ticks_from	Get ticks from the MetaTrader 5 terminal starting from the specified date
copy_ticks_range	Get ticks for the specified date range from the MetaTrader 5 terminal
orders_total	Get the number of active orders.
orders_get	Get active orders with the ability to filter by symbol or ticket
order_calc_margin	Return margin in the account currency to perform a specified trading operation
order_calc_profit	Return profit in the account currency for a specified trading operation
order_check	Check funds sufficiency for performing a required trading operation
order_send	Send a request to perform a trading operation.
positions_total	Get the number of open positions
positions_get	Get open positions with the ability to filter by symbol or ticket
history_orders_total	Get the number of orders in trading history within the specified interval
history_orders_get	Get orders from trading history with the ability to filter by ticket or position
history_deals_total	Get the number of deals in trading history within the specified interval
history_deals_get	Get deals from trading history with the ability to filter by ticket or position

Example of connecting Python to MetaTrader 5

1. Download the latest version of Python 3.8 from https://www.python.org/downloads/windows
2. When installing Python, check "Add Python 3.8 to PATH%" to be able to run Python scripts from the command line.

3. Install the MetaTrader 5 module from the command line

```
pip install MetaTrader5
```

4. Add matplotlib and pandas packages

```
pip install matplotlib
pip install pandas
```

5. Launch the test script

```
from datetime import datetime
import matplotlib.pyplot as plt
import pandas as pd
from pandas.plotting import register_matplotlib_converters
register_matplotlib_converters()
import MetaTrader5 as mt5

# connect to MetaTrader 5
if not mt5.initialize():
    print("initialize() failed")
    mt5.shutdown()

# request connection status and parameters
print(mt5.terminal_info())
# get data on MetaTrader 5 version
print(mt5.version())

# request 1000 ticks from EURAUD
euraud_ticks = mt5.copy_ticks_from("EURAUD", datetime(2020,1,28,13), 1000, mt5.COPY_TI
# request ticks from AUDUSD within 2019.04.01 13:00 - 2019.04.02 13:00
audusd_ticks = mt5.copy_ticks_range("AUDUSD", datetime(2020,1,27,13), datetime(2020,1,

# get bars from different symbols in a number of ways
eurusd_rates = mt5.copy_rates_from("EURUSD", mt5.TIMEFRAME_M1, datetime(2020,1,28,13),
eurgbp_rates = mt5.copy_rates_from_pos("EURGBP", mt5.TIMEFRAME_M1, 0, 1000)
eurcad_rates = mt5.copy_rates_range("EURCAD", mt5.TIMEFRAME_M1, datetime(2020,1,27,13)

# shut down connection to MetaTrader 5
mt5.shutdown()

#DATA
print('euraud_ticks(', len(euraud_ticks), ')')
for val in euraud_ticks[:10]: print(val)

print('audusd_ticks(', len(audusd_ticks), ')')
for val in audusd_ticks[:10]: print(val)

print('eurusd_rates(', len(eurusd_rates), ')')

```

initialize

Establish a connection with the MetaTrader 5 terminal. There are three call options.

Call without parameters. The terminal for connection is found automatically.

```
initialize()
```

Call specifying the path to the MetaTrader 5 terminal we want to connect to.

```
initialize(
   path                       // path to the MetaTrader 5 terminal EXE file
   )
```

Call specifying the trading account path and parameters.

```
initialize(
   path,                      // path to the MetaTrader 5 terminal EXE file
   login=LOGIN,               // account number
   password="PASSWORD",       // password
   server="SERVER",           // server name as it is specified in the terminal
   timeout=TIMEOUT,           // timeout
   portable=False             // portable mode
   )
```

Parameters

path

[in] Path to the metatrader.exe or metatrader64.exe file. Optional unnamed parameter. It is indicated first without a parameter name. If the path is not specified, the module attempts to find the executable file on its own.

login=LOGIN

[in] Trading account number. Optional named parameter. If not specified, the last trading account is used.

password="PASSWORD"

[in] Trading account password. Optional named parameter. If the password is not set, the password for a specified trading account saved in the terminal database is applied automatically.

server="SERVER"

[in] Trade server name. Optional named parameter. If the server is not set, the server for a specified trading account saved in the terminal database is applied automatically.

timeout=TIMEOUT

[in] Connection timeout in milliseconds. Optional named parameter. If not specified, the value of 60 000 (60 seconds) is applied.

portable=False

[in] Flag of the terminal launch in portable mode. Optional named parameter. If not specified, the value of False is used.

Return Value

Returns True in case of successful connection to the MetaTrader 5 terminal, otherwise - False.

Note

If required, the MetaTrader 5 terminal is launched to establish connection when executing the initialize() call.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish MetaTrader 5 connection to a specified trading account
if not mt5.initialize(login=25115284, server="MetaQuotes-Demo",password="4zatlbqx"):
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on connection status, server name and trading account
print(mt5.terminal_info())
# display data on MetaTrader 5 version
print(mt5.version())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

shutdown, terminal_info, version

login

Connect to a trading account using specified parameters.

```
login(
   login,                    // account number
   password="PASSWORD",      // password
   server="SERVER",          // server name as it is specified in the terminal
   timeout=TIMEOUT           // timeout
   )
```

Parameters

login

[in] Trading account number. Required unnamed parameter.

password

[in] Trading account password. Optional named parameter. If the password is not set, the password saved in the terminal database is applied automatically.

server

[in] Trade server name. Optional named parameter. If no server is set, the last used server is applied automatically.

timeout=TIMEOUT

[in] Connection timeout in milliseconds. Optional named parameter. If not specified, the value of 60 000 (60 seconds) is applied. If the connection is not established within the specified time, the call is forcibly terminated and the exception is generated.

Return Value

True in case of a successful connection to the trade account, otherwise - False.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on MetaTrader 5 version
print(mt5.version())
# connect to the trade account without specifying a password and a server
account=17221085
authorized=mt5.login(account)  # the terminal database password is applied if connecti
if authorized:
    print("connected to account #{}".format(account))
else:
```

```
    print("failed to connect at account #{}, error code: {}".format(account, mt5.last_

# now connect to another trading account specifying the password
account=25115284
authorized=mt5.login(account, password="gqrtz0lbdm")
if authorized:
    # display trading account data 'as is'
    print(mt5.account_info())
    # display trading account data in the form of a list
    print("Show account_info()._asdict():")
    account_info_dict = mt5.account_info()._asdict()
    for prop in account_info_dict:
        print("  {}={}".format(prop, account_info_dict[prop]))
else:
    print("failed to connect at account #{}, error code: {}".format(account, mt5.last_

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

initialize, shutdown

shutdown

Close the previously established connection to the MetaTrader 5 terminal.

```
shutdown()
```

Return Value

None.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed")
    quit()

# display data on connection status, server name and trading account
print(mt5.terminal_info())
# display data on MetaTrader 5 version
print(mt5.version())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

initialize, login_py, terminal_info, version

version

Return the MetaTrader 5 terminal version.

```
version()
```

Return Value

Return the MetaTrader 5 terminal version, build and release date. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The version() function returns the terminal version, build and release date as a tuple of three values:

Type	Description	Sample value
integer	MetaTrader 5 terminal version	500
integer	Build	2007
string	Build release date	'25 Feb 2019'

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on MetaTrader 5 version
print(mt5.version())

# display data on connection status, server name and trading account 'as is'
print(mt5.terminal_info())
print()

# get properties in the form of a dictionary
terminal_info_dict=mt5.terminal_info()._asdict()
# convert the dictionary into DataFrame and print
df=pd.DataFrame(list(terminal_info_dict.items()),columns=['property','value'])
print("terminal_info() as dataframe:")
print(df[:-1])
```

```
# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

Result:
MetaTrader5 package author:  MetaQuotes Software Corp.

initialize, shutdown, terminal_info

last_error

Return data on the last error.

```
last_error()
```

Return Value

Return the last error code and description as a tuple.

Note

last_error() allows obtaining an error code in case of a failed execution of a MetaTrader 5 library function. It is similar to GetLastError(). However, it applies its own error codes. Possible values:

Constant	Value	Description
RES_S_OK	1	generic success
RES_E_FAIL	-1	generic fail
RES_E_INVALID_PARAMS	-2	invalid arguments/parameters
RES_E_NO_MEMORY	-3	no memory condition
RES_E_NOT_FOUND	-4	no history
RES_E_INVALID_VERSION	-5	invalid version
RES_E_AUTH_FAILED	-6	authorization failed
RES_E_UNSUPPORTED	-7	unsupported method
RES_E_AUTO_TRADING_DISABLED	-8	auto-trading disabled
RES_E_INTERNAL_FAIL	-10000	internal IPC general error
RES_E_INTERNAL_FAIL_SEND	-10001	internal IPC send failed
RES_E_INTERNAL_FAIL_RECEIVE	-10002	internal IPC recv failed
RES_E_INTERNAL_FAIL_INIT	-10003	internal IPC initialization fail
RES_E_INTERNAL_FAIL_CONNECT	-10003	internal IPC no ipc
RES_E_INTERNAL_FAIL_TIMEOUT	-10005	internal timeout

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()
```

```
# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

version, GetLastError

account_info

Get info on the current trading account.

```
account_info()
```

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function returns all data that can be obtained using AccountInfoInteger, AccountInfoDouble and AccountInfoString in one call.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# connect to the trade account specifying a password and a server
authorized=mt5.login(25115284, password="gqz0343lbdm")
if authorized:
    account_info=mt5.account_info()
    if account_info!=None:
        # display trading account data 'as is'
        print(account_info)
        # display trading account data in the form of a dictionary
        print("Show account_info()._asdict():")
        account_info_dict = mt5.account_info()._asdict()
        for prop in account_info_dict:
            print("  {}={}".format(prop, account_info_dict[prop]))
        print()

        # convert the dictionary into DataFrame and print
        df=pd.DataFrame(list(account_info_dict.items()),columns=['property','value'])
        print("account_info() as dataframe:")
        print(df)
else:

terminal_info

Get the connected MetaTrader 5 client terminal status and settings.

```
terminal_info()
```

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function returns all data that can be obtained using TerminalInfoInteger, TerminalInfoDouble and TerminalInfoDouble in one call.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

initialize, shutdown, version

symbols_total

Get the number of all financial instruments in the MetaTrader 5 terminal.

```
symbols_total()
```

Return Value

Integer value.

Note

The function is similar to SymbolsTotal(). However, it returns the number of all symbols including custom ones and the ones disabled in MarketWatch.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get the number of financial instruments
symbols=mt5.symbols_total()
if symbols>0:
    print("Total symbols =",symbols)
else:
    print("symbols not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

symbols_get, symbol_select, symbol_info

symbols_get

Get all financial instruments from the MetaTrader 5 terminal.

```
symbols_get(
   group="GROUP"      // symbol selection filter
)
```

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional parameter. If the group is specified, the function returns only symbols meeting a specified criteria.

Return Value

Return symbols in the form of a tuple. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The *group* parameter allows sorting out symbols by name. '*' can be used at the beginning and the end of a string.

The *group* parameter can be used as a named or an unnamed one. Both options work the same way. The named option (group="GROUP") makes the code easier to read.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that all symbols should be selected first and the ones containing "EUR" in their names should be excluded afterwards.

Unlike symbol_info(), the symbols_get() function returns data on all requested symbols within a single call.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get all symbols
symbols=mt5.symbols_get()
print('Symbols: ', len(symbols))
count=0
# display the first five ones
for s in symbols:
    count+=1
```

```
    print("{}. {}".format(count,s.name))
    if count==5: break
print()

# get symbols containing RU in their names
ru_symbols=mt5.symbols_get("*RU*")
print('len(*RU*): ', len(ru_symbols))
for s in ru_symbols:
    print(s.name)
print()

# get symbols whose names do not contain USD, EUR, JPY and GBP
group_symbols=mt5.symbols_get(group="*,!*USD*,!*EUR*,!*JPY*,!*GBP*")
print('len(*,!*USD*,!*EUR*,!*JPY*,!*GBP*):', len(group_symbols))
for s in group_symbols:
    print(s.name,":",s)

account_info, terminal_info

symbol_info_tick

Get the last tick for the specified financial instrument.

```
symbol_info_tick(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

Return info in the form of a tuple. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function is similar to SymbolInfoTick.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# attempt to enable the display of the GBPUSD in MarketWatch
selected=mt5.symbol_select("GBPUSD",True)
if not selected:
    print("Failed to select GBPUSD")
    mt5.shutdown()
    quit()

# display the last GBPUSD tick
lasttick=mt5.symbol_info_tick("GBPUSD")
print(lasttick)
# display tick field values in the form of a list
print("Show symbol_info_tick(\"GBPUSD\")._asdict():")
symbol_info_tick_dict = mt5.symbol_info_tick("GBPUSD")._asdict()
for prop in symbol_info_tick_dict:
    print("  {}={}".format(prop, symbol_info_tick_dict[prop]))

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

```
Result:
MetaTrader5 package author:  MetaQuotes Software Corp.
MetaTrader5 package version:  5.0.29

symbol_info, symbol_info

symbol_select

Select a symbol in the MarketWatch window or remove a symbol from the window.

```
symbol_select(
   symbol,      // financial instrument name
   enable=None  // enable or disable
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

enable

[in] Switch. Optional unnamed parameter. If 'false', a symbol should be removed from the MarketWatch window. Otherwise, it should be selected in the MarketWatch window. A symbol cannot be removed if open charts with this symbol are currently present or positions are opened on it.

Return Value

True if successful, otherwise - False.

Note

The function is similar to SymbolSelect.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

symbol_info

market_book_add

Subscribes the MetaTrader 5 terminal to the Market Depth change events for a specified symbol.

```
market_book_add(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

True if successful, otherwise - False.

Note

The function is similar to MarketBookAdd.

See also

market_book_get, market_book_release, Market Depth structure

market_book_get

Returns a tuple from BookInfo featuring Market Depth entries for the specified symbol.

```
market_book_get(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

Returns the Market Depth content as a tuple from BookInfo entries featuring order type, price and volume in lots. BookInfo is similar to the MqlBookInfo structure.

Return None in case of an error. The info on the error can be obtained using last_error().

Note

The subscription to the Market Depth change events should be preliminarily performed using the market_book_add() function.

The function is similar to MarketBookGet.

Example:

```
import MetaTrader5 as mt5
import time
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print("")

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
   # shut down connection to the MetaTrader 5 terminal
    mt5.shutdown()
    quit()

# subscribe to market depth updates for EURUSD (Depth of Market)
if mt5.market_book_add('EURUSD'):
  # get the market depth data 10 times in a loop
   for i in range(10):
        # get the market depth content (Depth of Market)
        items = mt5.market_book_get('EURUSD')
        # display the entire market depth 'as is' in a single string
        print(items)
        # now display each order separately for more clarity
        if items:
```

```
            for it in items:
                # order content
                print(it._asdict())
        # pause for 5 seconds before the next request of the market depth data
        time.sleep(5)
  # cancel the subscription to the market depth updates (Depth of Market)
   mt5.market_book_release('EURUSD')
else:
    print("mt5.market_book_add('EURUSD') failed, error code =",mt5.last_error())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

```

See also

market_book_add, market_book_release, Market Depth structure

market_book_release

Cancels subscription of the MetaTrader 5 terminal to the Market Depth change events for a specified symbol.

```
market_book_release(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

True if successful, otherwise - False.

Note

The function is similar to MarketBookRelease.

See also

market_book_add, market_book_get, Market Depth structure

copy_rates_from

Get bars from the MetaTrader 5 terminal starting from the specified date.

```
copy_rates_from(
   symbol,       // symbol name
   timeframe,    // timeframe
   date_from,    // initial bar open date
   count         // number of bars
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

date_from

[in] Date of opening of the first bar from the requested sample. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

count

[in] Number of bars to receive. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

Only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar is always less or equal to the specified one.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

TIMEFRAME is an enumeration with possible chart period values

ID	Description
TIMEFRAME_M1	1 minute

ID	Description
TIMEFRAME_M2	2 minutes
TIMEFRAME_M3	3 minutes
TIMEFRAME_M4	4 minutes
TIMEFRAME_M5	5 minutes
TIMEFRAME_M6	6 minutes
TIMEFRAME_M10	10 minutes
TIMEFRAME_M12	12 minutes
TIMEFRAME_M12	15 minutes
TIMEFRAME_M20	20 minutes
TIMEFRAME_M30	30 minutes
TIMEFRAME_H1	1 hour
TIMEFRAME_H2	2 hours
TIMEFRAME_H3	3 hours
TIMEFRAME_H4	4 hours
TIMEFRAME_H6	6 hours
TIMEFRAME_H8	8 hours
TIMEFRAME_H12	12 hours
TIMEFRAME_D1	1 day
TIMEFRAME_W1	1 week
TIMEFRAME_MN1	1 month

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz
```

```
# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' object in UTC time zone to avoid the implementation of a local tir
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
# get 10 EURUSD H4 bars starting from 01.10.2020 in UTC time zone
rates = mt5.copy_rates_from("EURUSD", mt5.TIMEFRAME_H4, utc_from, 10)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
# display each element of obtained data in a new line
print("Display obtained data 'as is'")
for rate in rates:
    print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the datetime format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame)

CopyRates, copy_rates_from_pos, copy_rates_range, copy_ticks_from, copy_ticks_range

copy_rates_from_pos

Get bars from the MetaTrader 5 terminal starting from the specified index.

```
copy_rates_from_pos(
   symbol,       // symbol name
   timeframe,    // timeframe
   start_pos,    // initial bar index
   count         // number of bars
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

start_pos

[in] Initial index of the bar the data are requested from. The numbering of bars goes from present to past. Thus, the zero bar means the current one. Required unnamed parameter.

count

[in] Number of bars to receive. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Returns None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
```

```
# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get 10 GBPUSD D1 bars from the current day
rates = mt5.copy_rates_from_pos("GBPUSD", mt5.TIMEFRAME_D1, 0, 10)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
# display each element of obtained data in a new line
print("Display obtained data 'as is'")
for rate in rates:
    print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the datetime format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame)

CopyRates, copy_rates_from, copy_rates_range, copy_ticks_from, copy_ticks_range

copy_rates_range

Get bars in the specified date range from the MetaTrader 5 terminal.

```
copy_rates_range(
   symbol,       // symbol name
   timeframe,    // timeframe
   date_from,    // date the bars are requested from
   date_to       // date, up to which the bars are requested
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

date_from

[in] Date the bars are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Bars with the open time >= date_from are returned. Required unnamed parameter.

date_to

[in] Date, up to which the bars are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Bars with the open time <= date_to are returned. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Returns None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
```

```
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' objects in UTC time zone to avoid the implementation of a local ti
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
utc_to = datetime(2020, 1, 11, hour = 13, tzinfo=timezone)
# get bars from USDJPY M5 within the interval of 2020.01.10 00:00 - 2020.01.11 13:00 i
rates = mt5.copy_rates_range("USDJPY", mt5.TIMEFRAME_M5, utc_from, utc_to)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

# display each element of obtained data in a new line
print("Display obtained data 'as is'")
counter=0
for rate in rates:
    counter+=1
    if counter<=10:
        print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the 'datetime' format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame.head(10))

Result:

See also

CopyRates, copy_rates_from, copy_rates_range, copy_ticks_from, copy_ticks_range

copy_ticks_from

Get ticks from the MetaTrader 5 terminal starting from the specified date.

```
copy_ticks_from(
   symbol,       // symbol name
   date_from,    // date the ticks are requested from
   count,        // number of requested ticks
   flags         // combination of flags defining the type of requested ticks
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

from

[in] Date the ticks are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

count

[in] Number of ticks to receive. Required unnamed parameter.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. Flag values are described in the COPY_TICKS enumeration. Required unnamed parameter.

Return Value

Returns ticks as the numpy array with the named time, bid, ask, last and flags columns. The 'flags' value can be a combination of flags from the TICK_FLAG enumeration. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyTicks function for more information.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

COPY_TICKS defines the types of ticks that can be requested using the copy_ticks_from() and copy_ticks_range() functions.

ID	Description
COPY_TICKS_ALL	all ticks
COPY_TICKS_INFO	ticks containing Bid and/or Ask price changes
COPY_TICKS_TRADE	ticks containing Last and/or Volume price changes

TICK_FLAG defines possible flags for ticks. These flags are used to describe ticks obtained by the copy_ticks_from() and copy_ticks_range() functions.

ID	Description
TICK_FLAG_BID	Bid price changed
TICK_FLAG_ASK	Ask price changed
TICK_FLAG_LAST	Last price changed
TICK_FLAG_VOLUME	Volume changed
TICK_FLAG_BUY	last Buy price changed
TICK_FLAG_SELL	last Sell price changed

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' object in UTC time zone to avoid the implementation of a local tir
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
# request 100 000 EURUSD ticks starting from 10.01.2019 in UTC time zone
ticks = mt5.copy_ticks_from("EURUSD", utc_from, 100000, mt5.COPY_TICKS_ALL)
print("Ticks received:",len(ticks))

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

# display data on each tick on a new line
print("Display obtained ticks 'as is'")
count = 0
for tick in ticks:
```

```
    count+=1
    print(tick)
    if count >= 10:
        break

# create DataFrame out of the obtained data
ticks_frame = pd.DataFrame(ticks)
# convert time in seconds into the datetime format
ticks_frame['time']=pd.to_datetime(ticks_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with ticks")
print(ticks_frame.head(10))

```

See also

CopyRates, copy_rates_from_pos, copy_rates_range, copy_ticks_from, copy_ticks_range

copy_ticks_range

Get ticks for the specified date range from the MetaTrader 5 terminal.

```
copy_ticks_range(
   symbol,       // symbol name
   date_from,    // date the ticks are requested from
   date_to,      // date, up to which the ticks are requested
   flags         // combination of flags defining the type of requested ticks
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

date_from

[in] Date the ticks are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the ticks are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. Flag values are described in the COPY_TICKS enumeration. Required unnamed parameter.

Return Value

Returns ticks as the numpy array with the named time, bid, ask, last and flags columns. The 'flags' value can be a combination of flags from the TICK_FLAG enumeration. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyTicks function for more information.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. The data obtained from MetaTrader 5 have UTC time, but Python applies the local time shift again when trying to print them. Thus, the obtained data should also be corrected for visual presentation.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
```

```
# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' objects in UTC time zone to avoid the implementation of a local ti
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
utc_to = datetime(2020, 1, 11, tzinfo=timezone)
# request AUDUSD ticks within 11.01.2020 - 11.01.2020
ticks = mt5.copy_ticks_range("AUDUSD", utc_from, utc_to, mt5.COPY_TICKS_ALL)
print("Ticks received:",len(ticks))

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

# display data on each tick on a new line
print("Display obtained ticks 'as is'")
count = 0
for tick in ticks:
    count+=1
    print(tick)
    if count >= 10:
        break

# create DataFrame out of the obtained data
ticks_frame = pd.DataFrame(ticks)
# convert time in seconds into the datetime format
ticks_frame['time']=pd.to_datetime(ticks_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with ticks")
print(ticks_frame.head(10))
```

```

CopyRates, copy_rates_from_pos, copy_rates_range, copy_ticks_from, copy_ticks_range

orders_total

Get the number of active orders.

```
orders_total()
```

Return Value

Integer value.

Note

The function is similar to OrdersTotal.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# check the presence of active orders
orders=mt5.orders_total()
if orders>0:
    print("Total orders=",orders)
else:
    print("Orders not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

orders_get, positions_total

orders_get

Get active orders with the ability to filter by symbol or ticket. There are three call options.

Call without parameters. Return active orders on all symbols.

```
orders_get()
```

Call specifying a symbol active orders should be received for.

```
orders_get(
   symbol="SYMBOL"      // symbol name
)
```

Call specifying a group of symbols active orders should be received for.

```
orders_get(
   group="GROUP"        // filter for selecting orders for symbols
)
```

Call specifying the order ticket.

```
orders_get(
   ticket=TICKET        // ticket
)
```

symbol="SYMBOL"

[in] Symbol name. Optional named parameter. If a symbol is specified, the *ticket* parameter is ignored.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only active orders meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Order ticket (ORDER_TICKET). Optional named parameter.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all active orders within one call similar to the OrdersTotal and OrderSelect tandem.

The *group* parameter allows sorting out orders by symbols. '*' can be used at the beginning and the end of a string.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that orders for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print()
# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on active orders on GBPUSD
orders=mt5.orders_get(symbol="GBPUSD")
if orders is None:
    print("No orders on GBPUSD, error code={}".format(mt5.last_error()))
else:
    print("Total orders on GBPUSD:",len(orders))
    # display all active orders
    for order in orders:
        print(order)
print()

# get the list of orders on symbols whose names contain "*GBP*"
gbp_orders=mt5.orders_get(group="*GBP*")
if gbp_orders is None:
    print("No orders with group=\"*GBP*\", error code={}".format(mt5.last_error()))
else:
    print("orders_get(group=\"*GBP*\")={}".format(len(gbp_orders)))
    # display these orders as a table using pandas.DataFrame
    df=pd.DataFrame(list(gbp_orders),columns=gbp_orders[0]._asdict().keys())
    df.drop(['time_done', 'time_done_msc', 'position_id', 'position_by_id', 'reason',
    df['time_setup'] = pd.to_datetime(df['time_setup'], unit='s')
    print(df)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

Result:
MetaTrader5 package author:  MetaQuotes Software Corp.
MetaTrader5 package version:  5.0.29

orders_total, positions_get

order_calc_margin

Return margin in the account currency to perform a specified trading operation.

```
order_calc_margin(
   action,      // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
   symbol,      // symbol name
   volume,      // volume
   price        // open price
   )
```

Parameters

action

[in] Order type taking values from the ORDER_TYPE enumeration. Required unnamed parameter.

symbol

[in] Financial instrument name. Required unnamed parameter.

volume

[in] Trading operation volume. Required unnamed parameter.

price

[in] Open price. Required unnamed parameter.

Return Value

Real value if successful, otherwise None. The error info can be obtained using last_error().

Note

The function allows estimating the margin necessary for a specified order type on the current account and in the current market environment without considering the current pending orders and open positions. The function is similar to OrderCalcMargin.

ORDER_TYPE

ID	Description
ORDER_TYPE_BUY	Market buy order
ORDER_TYPE_SELL	Market sell order
ORDER_TYPE_BUY_LIMIT	Buy Limit pending order
ORDER_TYPE_SELL_LIMIT	Sell Limit pending order
ORDER_TYPE_BUY_STOP	Buy Stop pending order
ORDER_TYPE_SELL_STOP	Sell Stop pending order
ORDER_TYPE_BUY_STOP_LIMIT	Upon reaching the order price, Buy Limit pending order is placed at StopLimit price
ORDER_TYPE_SELL_STOP_LIMIT	Upon reaching the order price, Sell Limit pending order is placed at StopLimit price

ID	Description
ORDER_TYPE_CLOSE_BY	Order for closing a position by an opposite one

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get account currency
account_currency=mt5.account_info().currency
print("Account currency:",account_currency)

# arrange the symbol list
symbols=("EURUSD","GBPUSD","USDJPY", "USDCHF","EURJPY","GBPJPY")
print("Symbols to check margin:", symbols)
action=mt5.ORDER_TYPE_BUY
lot=0.1
for symbol in symbols:
    symbol_info=mt5.symbol_info(symbol)
    if symbol_info is None:
        print(symbol,"not found, skipped")
        continue
    if not symbol_info.visible:
        print(symbol, "is not visible, trying to switch on")
        if not mt5.symbol_select(symbol,True):
            print("symbol_select({}}) failed, skipped",symbol)
            continue
    ask=mt5.symbol_info_tick(symbol).ask
    margin=mt5.order_calc_margin(action,symbol,lot,ask)
    if margin != None:
        print("   {} buy {} lot margin: {} {}".format(symbol,lot,margin,account_currer
    else:
        print("order_calc_margin failed: , error code =", mt5.last_error())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

Result:
MetaTrader5 package author:  MetaQuotes Software Corp.
MetaTrader5 package version:  5.0.29

Account currency: USD

Symbols to check margin: ('EURUSD', 'GBPUSD', 'USDJPY', 'USDCHF', 'EURJPY', 'GBPJPY')
   EURUSD buy 0.1 lot margin: 109.91 USD
   GBPUSD buy 0.1 lot margin: 122.73 USD
```

```
   USDJPY buy 0.1 lot margin: 100.0 USD
   USDCHF buy 0.1 lot margin: 100.0 USD
   EURJPY buy 0.1 lot margin: 109.91 USD
   GBPJPY buy 0.1 lot margin: 122.73 USD
```

See also

order_calc_profit, order_check

order_calc_profit

Return profit in the account currency for a specified trading operation.

```
order_calc_profit(
   action,          // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
   symbol,          // symbol name
   volume,          // volume
   price_open,      // open price
   price_close      // close price
   );
```

Parameters

action

[in] Order type may take one of the two ORDER_TYPE enumeration values: ORDER_TYPE_BUY or ORDER_TYPE_SELL. Required unnamed parameter.

symbol

[in] Financial instrument name. Required unnamed parameter.

volume

[in] Trading operation volume. Required unnamed parameter.

price_open

[in] Open price. Required unnamed parameter.

price_close

[in] Close price. Required unnamed parameter.

Return Value

Real value if successful, otherwise None. The error info can be obtained using last_error().

Note

The function allows estimating a trading operation result on the current account and in the current trading environment. The function is similar to OrderCalcProfit.

Example:

See also

order_calc_margin, order_check

order_check

Check funds sufficiency for performing a required trading operation. Check result are returned as the MqlTradeCheckResult structure.

```
order_check(
   request      // request structure
   );
```

Parameters

request

[in] MqlTradeRequest type structure describing a required trading action. Required unnamed parameter. Example of filling in a request and the enumeration content are described below.

Return Value

Check result as the MqlTradeCheckResult structure. The *request* field in the answer contains the structure of a trading request passed to order_check().

Note

Successful sending of a request **does not entail that the requested trading operation will be executed successfully**. The order_check function is similar to OrderCheck.

TRADE_REQUEST_ACTIONS

ID	Description
TRADE_ACTION_DEAL	Place an order for an instant deal with the specified parameters (set a market order)
TRADE_ACTION_PENDING	Place an order for performing a deal at specified conditions (pending order)
TRADE_ACTION_SLTP	Change open position Stop Loss and Take Profit
TRADE_ACTION_MODIFY	Change parameters of the previously placed trading order
TRADE_ACTION_REMOVE	Remove previously placed pending order
TRADE_ACTION_CLOSE_BY	Close a position by an opposite one

ORDER_TYPE_FILLING

ID	Description
ORDER_FILLING_FOK	This execution policy means that an order can be executed only in the specified volume. If the necessary amount of a financial instrument is currently unavailable in the market, the order will not be executed. The desired volume can be made up of several available offers.
ORDER_FILLING_IOC	An agreement to execute a deal at the maximum volume available in the market within the volume specified in the order. If the request cannot be filled completely, an order

ID	Description
	with the available volume will be executed, and the remaining volume will be canceled.
ORDER_FILLING_RETURN	This policy is used only for market (ORDER_TYPE_BUY and ORDER_TYPE_SELL), limit and stop limit orders (ORDER_TYPE_BUY_LIMIT, ORDER_TYPE_SELL_LIMIT, ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT) and only for the symbols with Market or Exchange execution modes. If filled partially, a market or limit order with the remaining volume is not canceled, and is processed further. During activation of the ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT orders, an appropriate limit order ORDER_TYPE_BUY_LIMIT/ORDER_TYPE_SELL_LIMIT with the ORDER_FILLING_RETURN type is created.

ORDER_TYPE_TIME

ID	Description
ORDER_TIME_GTC	The order stays in the queue until it is manually canceled
ORDER_TIME_DAY	The order is active only during the current trading day
ORDER_TIME_SPECIFIED	The order is active until the specified date
ORDER_TIME_SPECIFIED_DAY	The order is active until 23:59:59 of the specified day. If this time appears to be out of a trading session, the expiration is processed at the nearest trading time.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get account currency
account_currency=mt5.account_info().currency
print("Account currency:",account_currency)

# prepare the request structure
symbol="USDJPY"
symbol_info = mt5.symbol_info(symbol)
if symbol_info is None:
    print(symbol, "not found, can not call order_check()")
    mt5.shutdown()
    quit()
```

```
# if the symbol is unavailable in MarketWatch, add it
if not symbol_info.visible:
    print(symbol, "is not visible, trying to switch on")
    if not mt5.symbol_select(symbol,True):
        print("symbol_select({}}) failed, exit",symbol)
        mt5.shutdown()
        quit()

order_send

Send a request to perform a trading operation from the terminal to the trade server. The function is similar to OrderSend.

```
order_send(
   request      // request structure
   );
```

Parameters

request

[in] MqlTradeRequest type structure describing a required trading action. Required unnamed parameter. Example of filling in a request and the enumeration content are described below.

Return Value

Execution result as the MqlTradeResult structure. The *request* field in the answer contains the structure of a trading request passed to order_send().

The MqlTradeRequest trading request structure

Field	Description
action	Trading operation type. The value can be one of the values of the TRADE_REQUEST_ACTIONS enumeration
magic	EA ID. Allows arranging the analytical handling of trading orders. Each EA can set a unique ID when sending a trading request
order	Order ticket. Required for modifying pending orders
symbol	The name of the trading instrument, for which the order is placed. Not required when modifying orders and closing positions
volume	Requested volume of a deal in lots. A real volume when making a deal depends on an order execution type.
price	Price at which an order should be executed. The price is not set in case of market orders for instruments of the "Market Execution" (SYMBOL_TRADE_EXECUTION_MARKET) type having the TRADE_ACTION_DEAL type
stoplimit	A price a pending Limit order is set at when the price reaches the 'price' value (this condition is mandatory). The pending order is not passed to the trading system until that moment
sl	A price a Stop Loss order is activated at when the price moves in an unfavorable direction
tp	A price a Take Profit order is activated at when the price moves in a favorable direction
deviation	Maximum acceptable deviation from the requested price, specified in points
type	Order type. The value can be one of the values of the ORDER_TYPE enumeration

Field	Description
type_filling	Order filling type. The value can be one of the ORDER_TYPE_FILLING values
type_time	Order type by expiration. The value can be one of the ORDER_TYPE_TIME values
expiration	Pending order expiration time (for TIME_SPECIFIED type orders)
comment	Comment to an order
position	Position ticket. Fill it when changing and closing a position for its clear identification. Usually, it is the same as the ticket of the order that opened the position.
position_by	Opposite position ticket. It is used when closing a position by an opposite one (opened at the same symbol but in the opposite direction).

Note

A trading request passes several verification stages on the trade server. First, the validity of all the necessary *request* fields is checked. If there are no errors, the server accepts the order for further handling. See the OrderSend function description for the details about executing trading operations.

Example:

```
import time
import MetaTrader5 as mt5

# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ", mt5.__author__)
print("MetaTrader5 package version: ", mt5.__version__)

positions_total

Get the number of open positions.

```
positions_total()
```

Return Value

Integer value.

Note

The function is similar to PositionsTotal.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# check the presence of open positions
positions_total=mt5.positions_total()
if positions_total>0:
    print("Total positions=",positions_total)
else:
    print("Positions not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

positions_get, orders_total

positions_get

Get open positions with the ability to filter by symbol or ticket. There are three call options.

Call without parameters. Return open positions for all symbols.

```
positions_get()
```

Call specifying a symbol open positions should be received for.

```
positions_get(
   symbol="SYMBOL"      // symbol name
)
```

Call specifying a group of symbols open positions should be received for.

```
positions_get(
   group="GROUP"        // filter for selecting positions by symbols
)
```

Call specifying a position ticket.

```
positions_get(
   ticket=TICKET        // ticket
)
```

Parameters

symbol="SYMBOL"

[in] Symbol name. Optional named parameter. If a symbol is specified, the *ticket* parameter is ignored.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only positions meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Position ticket (POSITION_TICKET). Optional named parameter.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all open positions within one call similar to the PositionsTotal and PositionSelect tandem.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that positions for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print()
# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get open positions on USDCHF
positions=mt5.positions_get(symbol="USDCHF")
if positions==None:
    print("No positions on USDCHF, error code={}".format(mt5.last_error()))
elif len(positions)>0:
    print("Total positions on USDCHF =",len(positions))
    # display all open positions
    for position in positions:
        print(position)

# get the list of positions on symbols whose names contain "*USD*"
usd_positions=mt5.positions_get(group="*USD*")
if usd_positions==None:
    print("No positions with group=\"*USD*\", error code={}".format(mt5.last_error()))
elif len(usd_positions)>0:
    print("positions_get(group=\"*USD*\")={}".format(len(usd_positions)))
    # display these positions as a table using pandas.DataFrame
    df=pd.DataFrame(list(usd_positions),columns=usd_positions[0]._asdict().keys())
    df['time'] = pd.to_datetime(df['time'], unit='s')
    df.drop(['time_update', 'time_msc', 'time_update_msc', 'external_id'], axis=1, inp
    print(df)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

Result:

positions_total, orders_get

history_orders_total

Get the number of orders in trading history within the specified interval.

```
history_orders_total(
   date_from,     // date the orders are requested from
   date_to        // date, up to which the orders are requested
   )
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

Return Value

Integer value.

Note

The function is similar to HistoryOrdersTotal.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get the number of orders in history
from_date=datetime(2020,1,1)
to_date=datetime.now()
history_orders=mt5.history_orders_total(from_date, datetime.now())
if history_orders>0:
    print("Total history orders=",history_orders)
else:
    print("Orders not found in history")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

history_orders_get, history_deals_total

history_orders_get

Get orders from trading history with the ability to filter by ticket or position. There are three call options.

Call specifying a time interval. Return all orders falling within the specified interval.

```
history_orders_get(
   date_from,                 // date the orders are requested from
   date_to,                   // date, up to which the orders are requested
   group="GROUP"         // filter for selecting orders by symbols
   )
```

Call specifying the order ticket. Return an order with the specified ticket.

```
history_orders_get(
   ticket=TICKET         // order ticket
)
```

Call specifying the position ticket. Return all orders with a position ticket specified in the ORDER_POSITION_ID property.

```
history_orders_get(
   position=POSITION     // position ticket
)
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified first.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified second.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only orders meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Order ticket that should be received. Optional parameter. If not specified, the filter is not applied.

position=POSITION

[in] Ticket of a position (stored in ORDER_POSITION_ID) all orders should be received for. Optional parameter. If not specified, the filter is not applied.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all history orders within a specified period in a single call similar to the HistoryOrdersTotal and HistoryOrderSelect tandem.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that deals for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

history_deals_total, history_deals_get

history_deals_total

Get the number of deals in trading history within the specified interval.

```
history_deals_total(
   date_from,     // date the deals are requested from
   date_to        // date, up to which the deals are requested
   )
```

Parameters

date_from

[in] Date the deals are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the deals are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

Return Value

Integer value.

Note

The function is similar to HistoryDealsTotal.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get the number of deals in history
from_date=datetime(2020,1,1)
to_date=datetime.now()
deals=mt5.history_deals_total(from_date, to_date)
if deals>0:
    print("Total deals=",deals)
else:
    print("Deals not found in history")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

history_deals_get, history_orders_total

history_deals_get

Get deals from trading history within the specified interval with the ability to filter by ticket or position.

Call specifying a time interval. Return all deals falling within the specified interval.

```
history_deals_get(
   date_from,                 // date the deals are requested from
   date_to,                   // date, up to which the deals are requested
   group="GROUP"          // filter for selecting deals for symbols
   )
```

Call specifying the order ticket. Return all deals having the specified order ticket in the DEAL_ORDER property.

```
history_deals_get(
   ticket=TICKET          // order ticket
)
```

Call specifying the position ticket. Return all deals having the specified position ticket in the DEAL_POSITION_ID property.

```
history_deals_get(
   position=POSITION      // position ticket
)
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified first.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified second.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only deals meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Ticket of an order (stored in DEAL_ORDER) all deals should be received for. Optional parameter. If not specified, the filter is not applied.

position=POSITION

[in] Ticket of a position (stored in DEAL_POSITION_ID) all deals should be received for. Optional parameter. If not specified, the filter is not applied.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all history deals within a specified period in a single call similar to the HistoryDealsTotal and HistoryDealSelect tandem.

The *group* parameter allows sorting out deals by symbols. '*' can be used at the beginning and the end of a string.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that deals for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

```
import MetaTrader5 as mt5
from datetime import datetime
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print()
# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get the number of deals in history
from_date=datetime(2020,1,1)
to_date=datetime.now()
# get deals for symbols whose names contain "GBP" within a specified interval
deals=mt5.history_deals_get(from_date, to_date, group="*GBP*")
if deals==None:
    print("No deals with group=\"*USD*\", error code={}".format(mt5.last_error()))
elif len(deals)> 0:
    print("history_deals_get({}, {}, group=\"*GBP*\")={}".format(from_date,to_date,len

# get deals for symbols whose names contain neither "EUR" nor "GBP"
deals = mt5.history_deals_get(from_date, to_date, group="*,!*EUR*,!*GBP*")
if deals == None:
    print("No deals, error code={}".format(mt5.last_error()))
elif len(deals) > 0:
    print("history_deals_get(from_date, to_date, group=\"*,!*EUR*,!*GBP*\") =", len(de
    # display all obtained deals 'as is'
    for deal in deals:
        print("  ",deal)
    print()
    # display these deals as a table using pandas.DataFrame
```

```
    df=pd.DataFrame(list(deals),columns=deals[0]._asdict().keys())
    df['time'] = pd.to_datetime(df['time'], unit='s')
    print(df)
print("")

# get all deals related to the position #530218319
position_id=530218319
position_deals = mt5.history_deals_get(position=position_id)
if position_deals == None:
    print("No deals with position #{}".format(position_id))
    print("error code =", mt5.last_error())
elif len(position_deals) > 0:
    print("Deals with position id #{}: {}".format(position_id, len(position_deals)))
    # display these deals as a table using pandas.DataFrame
    df=pd.DataFrame(list(position_deals),columns=position_deals[0]._asdict().keys())
    df['time'] = pd.to_datetime(df['time'], unit='s')

ONNX Models in Machine Learning

ONNX (Open Neural Network Exchange) is an open-source format for machine learning models. This project has several major advantages:

- ONNX is supported by large companies such as Microsoft, Facebook, Amazon and other partners.
- Its open format enables format conversions between different machine learning toolkits, while Microsoft's ONNXMLTools allows converting models to the ONNX format.
- MQL5 provides automatic data type conversion for model inputs and outputs if the passed parameter type does not match the model.
- ONNX models can be created using various machine learning tools. They are currently supported in Caffe2, Microsoft Cognitive Toolkit, MXNet, PyTorch and OpenCV. Interfaces for other popular frameworks and libraries are also available.
- With the MQL5 language, you can implement an ONNX model in a trading strategy and use it along with all the advantages of the MetaTrader 5 platform for efficient operations in the financial markets.
- Before tunning a model for live trading, you can test the model behavior on historical data in the Strategy Tester, without using third-party tools.

MQL5 provides the following functions for working with ONNX:

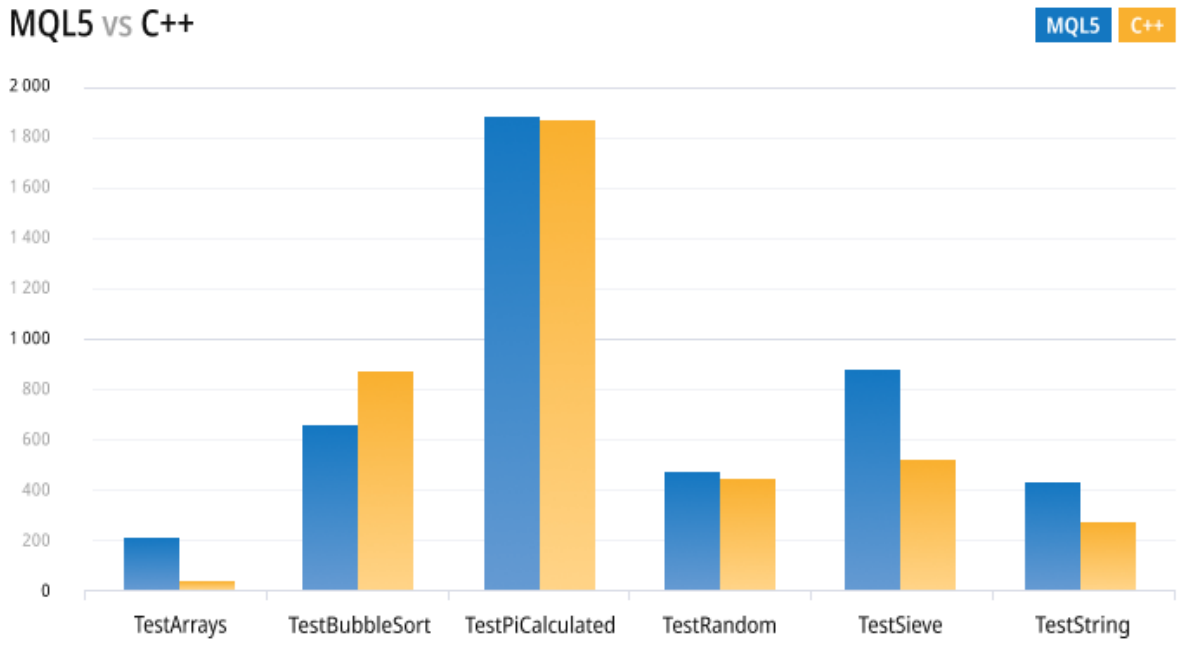
Function	Action
OnnxCreate	Create an ONNX session, loading a model from an *.onnx file
OnnxCreateFromBuffer	Create an ONNX session, loading a model from a data array
OnnxRelease	Close an ONNX session
OnnxRun	Run an ONNX model
OnnxGetInputCount	Get the number of inputs in an ONNX model
OnnxGetOutputCount	Get the number of outputs in an ONNX model
OnnxGetInputName	Get the name of a model's input by index
OnnxGetOutputName	Get the name of a model's output by index
OnnxGetInputTypeInfo	Get the description of the input type from the model
OnnxGetOutputTypeInfo	Get the description of the output type from the model
OnnxSetInputShape	Set the shape of a model's input data by index
OnnxSetOutputShape	Set the shape of a model's output data by index

ONNX Support in MQL5

ONNX is an open format build to represent machine learning models. This standard defines a common set of operators and a common file format to enable developers to use models with different frameworks, tools, runtimes and compilers.

Thus, the open ONNX format allows you to receive and transfer machine learning models between different platforms and machine learning toolkits. The ONNX is implemented in the MQL5 language to enable AI developers to run created models in the high-performance execution environment provided by the MetaTrader 5 platform.

The MQL5 execution speed is comparable to that of C++ applications. This is proved by the execution results of standard tests on MQL5 and C++. The lower the bar, the less time (in milliseconds) spent on execution and the better the result. The tests have been conducted on Windows 10 (build 17763) x64, Xeon E5-2630 v4 @ 2.20GHz, Memory: 65457 Mb.



The new asynchronous trading operations and the native ONNX support provide you with new opportunities which were previously available only to a handful of professional AI developers and institutional traders. ONNX support in MQL5 enables traders to train models for financial market trading in their preferred development environment and then to trade with low network costs, high order book update speeds and asynchronous order submission.

Currently, ONNX is being developed and maintained by partner companies such as Microsoft, Facebook, Amazon and others, which guarantees the further development of this open project.

Format Conversion

ONNX is an open format, which allows using models from different machine learning toolkits. This format is supported by many frameworks, including Chainer, Caffee2 and PyTorch.

One of the most popular tools for converting models to the ONNX format is Microsoft's ONNXMLTools.

ONNXMLTools installation and use instructions are available at the GitHub repo. The following toolkits are currently supported:

- Keras (a wrapper of keras2onnx converter)
- Tensorflow (a wrapper of tf2onnx converter)
- scikit-learn (a wrapper of skl2onnx converter)
- Apple Core ML
- Spark ML (experimental)
- LightGBM
- libscm;
- XGBoost;
- H2O
- CatBoost

ONNXMLTools can be easily installed. For installation details and model conversion examples, please see the project page at https://github.com/onnx/onnxmltools#install.

Autoconvert input and output values when running ONNX models

The current ONNX version in MQL5 supports only tensors for input/output values. Tensors are data arrays with the elements of the following data types:

ONNX type	Corresponds to MQL5 type
ONNX_DATA_TYPE_BOOL	bool
ONNX_DATA_TYPE_FLOAT	float
ONNX_DATA_TYPE_UINT8	uchar
ONNX_DATA_TYPE_INT8	char
ONNX_DATA_TYPE_UINT16	ushort
ONNX_DATA_TYPE_INT16	short
ONNX_DATA_TYPE_INT32	int
ONNX_DATA_TYPE_INT64	long
ONNX_DATA_TYPE_FLOAT16	—
ONNX_DATA_TYPE_DOUBLE	double
ONNX_DATA_TYPE_UINT32	uint
ONNX_DATA_TYPE_UINT64	ulong
ONNX_DATA_TYPE_COMPLEX64	—
ONNX_DATA_TYPE_COMPLEX128	complex
ONNX_DATA_TYPE_BFLOAT16	—
ONNX_DATA_TYPE_STRING	—

Only arrays, vectors and matrices (we will refer to them as the **Data**) can be fed into ONNX models as input/output values.

If the parameter types does not match the ONNX model's parameter type, and the OnnxRun is called without the ONNX_NO_CONVERSION flag specified, automatic data conversion will be applied. Autoconversion implies that before running an ONNX model, user **Data** will be copied into ONNX tensors with the relevant conversion.

When an ONNX model is run without the autoconversion, the model will be calculated using the **Data** without any additional copying.

> **IMPORTANT!** Autoconversion does not control overflow (truncate), therefore you should carefully monitor the data and the data types input into the ONNX model.

Autoconversion supports the following ONNX types:

- ONNX_DATA_TYPE_BOOL
- ONNX_DATA_TYPE_FLOAT
- ONNX_DATA_TYPE_UINT8
- ONNX_DATA_TYPE_INT8
- ONNX_DATA_TYPE_UINT16
- ONNX_DATA_TYPE_INT16
- ONNX_DATA_TYPE_INT32
- ONNX_DATA_TYPE_INT64
- ONNX_DATA_TYPE_FLOAT16
- ONNX_DATA_TYPE_DOUBLE
- ONNX_DATA_TYPE_UINT32
- ONNX_DATA_TYPE_UINT64
- ONNX_DATA_TYPE_COMPLEX64
- ONNX_DATA_TYPE_COMPLEX128

Unsupported types:

- ONNX_DATA_TYPE_BFLOAT16
- ONNX_DATA_TYPE_STRING

Autoconversion Rules by Tensor Types

If the MQL5 type is not included into the list of types supported by the model, running the ONNX model will return the ERR_ONNX_NOT_SUPPORTED error (error code 5802).

Note: During autoconversion, the color type is processed as uint, while datetime is processed as long.

Autoconversion of input values

ONNX type (tensor item type)	MQL5 type supported by autoconversion
ONNX_DATA_TYPE_BOOL	bool, char, uchar, short, ushort, int, color, uint, datetime, long, folat, double, complex During conversion, **Data** elements are checked by a simple comparison against 0
ONNX_DATA_TYPE_FLOAT16	float, double
ONNX_DATA_TYPE_FLOAT	char, uchar, short, ushort, int, color, uint, datetime, long, ulong, float, double
ONNX_DATA_TYPE_UINT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT16	See ONNX_DATA_TYPE_FLOAT

ONNX type (tensor item type)	MQL5 type supported by autoconversion
ONNX_DATA_TYPE_INT16	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT32	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT64	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_DOUBLE	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT32	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT64	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_COMPLEX64	complex
ONNX_DATA_TYPE_COMPLEX128	complex

Autoconversion of output values

ONNX type (tensor item type)	MQL5 type supported by autoconversion
ONNX_DATA_TYPE_BOOL	bool, char, uchar, short, ushort, int, color, uint, datetime, long, folat, double, complex If the tensor element is zero, then the Data element is set to 0; otherwise, the value is 1
ONNX_DATA_TYPE_FLOAT16	float, double
ONNX_DATA_TYPE_FLOAT	char, uchar, short, ushort, int, color, uint, datetime, long, ulong, float, double
ONNX_DATA_TYPE_UINT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT16	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT16	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT32	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT64	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_DOUBLE	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT32	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT64	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_COMPLEX64	complex
ONNX_DATA_TYPE_COMPLEX128	complex

Type Casting

Creating a Model

Multiple methods are available to obtain a ready model in the ONNX format. The popular ONNX Model Zoo library contains several pre-trained ONNX models for different types of tasks. The advantage of this collection is that each model's notebook contains links to the training dataset and references to the original paper that describes the model architecture.

Most machine learning frameworks use Python. To install the ONNX runtime for Python, use one of the following commands:

```
pip install onnxruntime        # CPU build
pip install onnxruntime-gpu    # GPU build
```

To invoke the ONNX runtime in Python, use the following command

```
import onnxruntime
session = onnxruntime.InferenceSession("path to model")
```

For model inputs and outputs, check out the relevant model's documentation. You can also use visualization tools to view the model, such as Netron or WinML Dashboard. In the ONNX runtime, you can also query a model's metadata and its inputs and outputs:

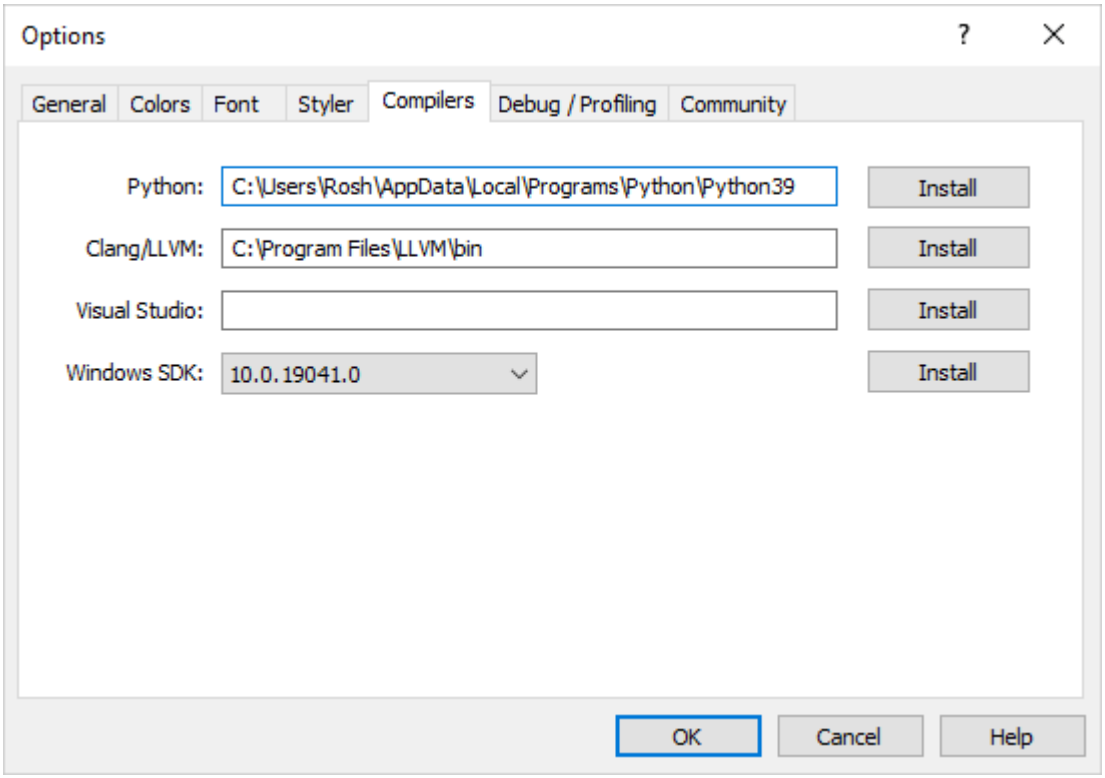
```
results = session.run(["output1", "output2"], {
                      "input1": indata1, "input2": indata2})
results = session.run([], {"input1": indata1, "input2": indata2})
```

You can create ONNX models directly in the MetaTrader 5 terminal or in MetaEditor using Python.

Python in MetaTrader 5

The MetaTrader 5 provides out-of-the-box support for Python scripts. To enable these operations, the terminal developers provide MetaTrader5 module for Python: https://pypi.org/project/MetaTrader5.

In the MetaEditor integrated development environment, in addition to creating applications in MQL5, you can also run Python scripts directly from the editor. To do this, specify the path to the executable in MetaEditor settings:



If Python is not installed on your computer, click Install to download the installation file.

You can create a Python script in MetaEdtior or upload it to the terminal's data folder and immediately run it using the F7 (Compile) key. This will open the MetaTrader 5 terminal with the script running on the current chart. Messages from the Python console (stdout, stderr) will be displayed under the Errors section.

Operations with models in MetaTrader 5

The MQL5 language allows you to run ONNX models directly in the MetaTrader 5 terminal. This is done in three steps:

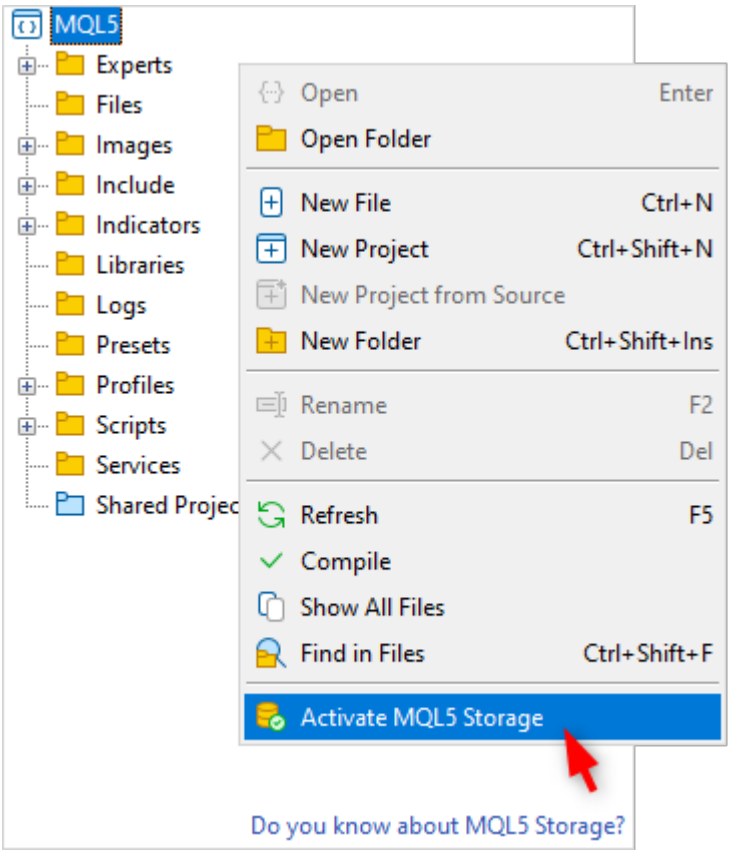
1. Train the model in a third-party platform, such as Python.
2. Convert the model to ONNX.
3. Include the ONNX model into an Expert Advisor using ONNX function and run in the MetaTrader 5 terminal.

Python integration in MQL5 allows running a python script and saving an ONNX model in the MetaEditor or run it directly on a chart in MetaTrader 5. You can train the model using a pre-written Python script as often as you need right in the terminal. The library includes ready-made functions for obtaining price data, which can be input into an ONNX model:

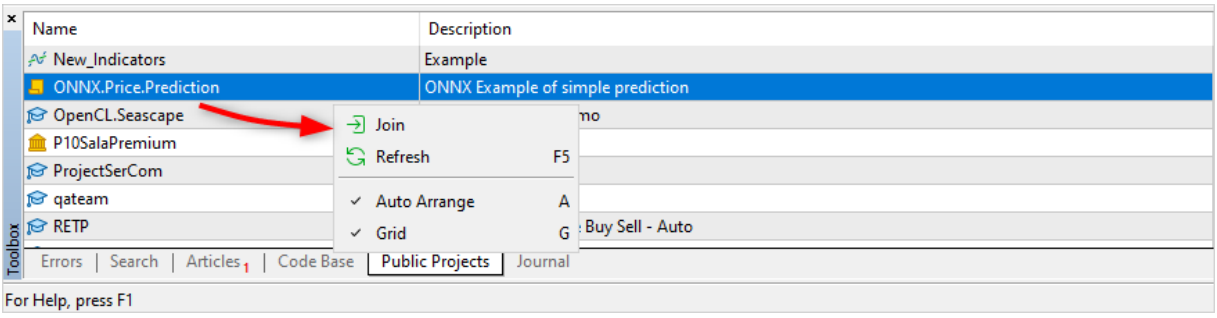
- copy_rates_from - get bars starting from the specified date
- copy_rates_from_pos - get bars starting from the specified index
- copy_rates_range - get bars for the specified date range
- copy_ticks_from - get ticks starting from the specified date
- copy_ticks_range - get ticks for the specified date range

Model example

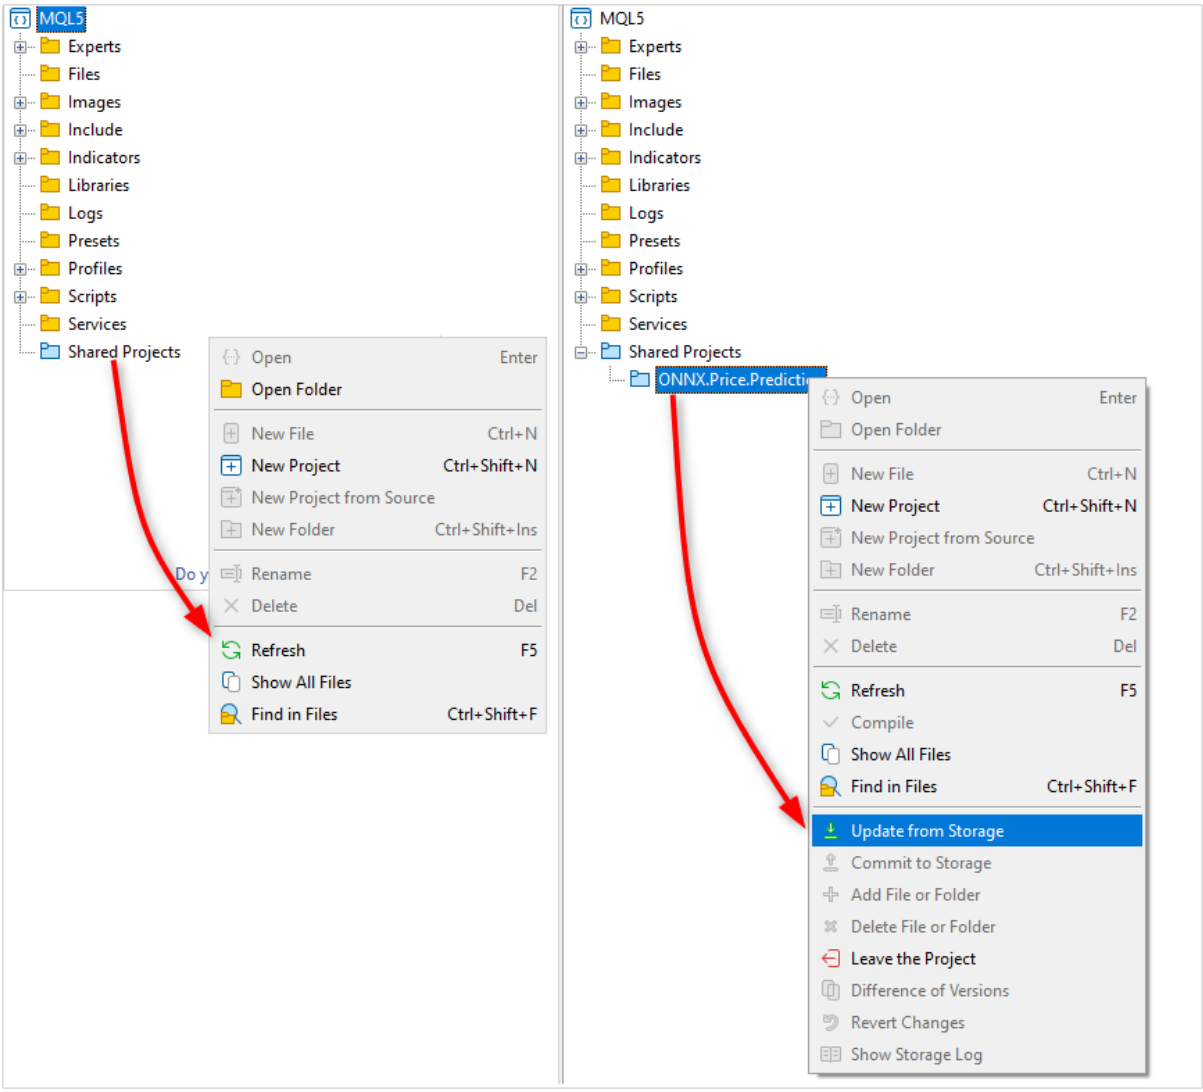
En example of a finished ONNX model is available in public projects. You should first activate MQL5 Storage in the Navigator by specifying you MQL5 login in MetaEditor settings (case sensitive).



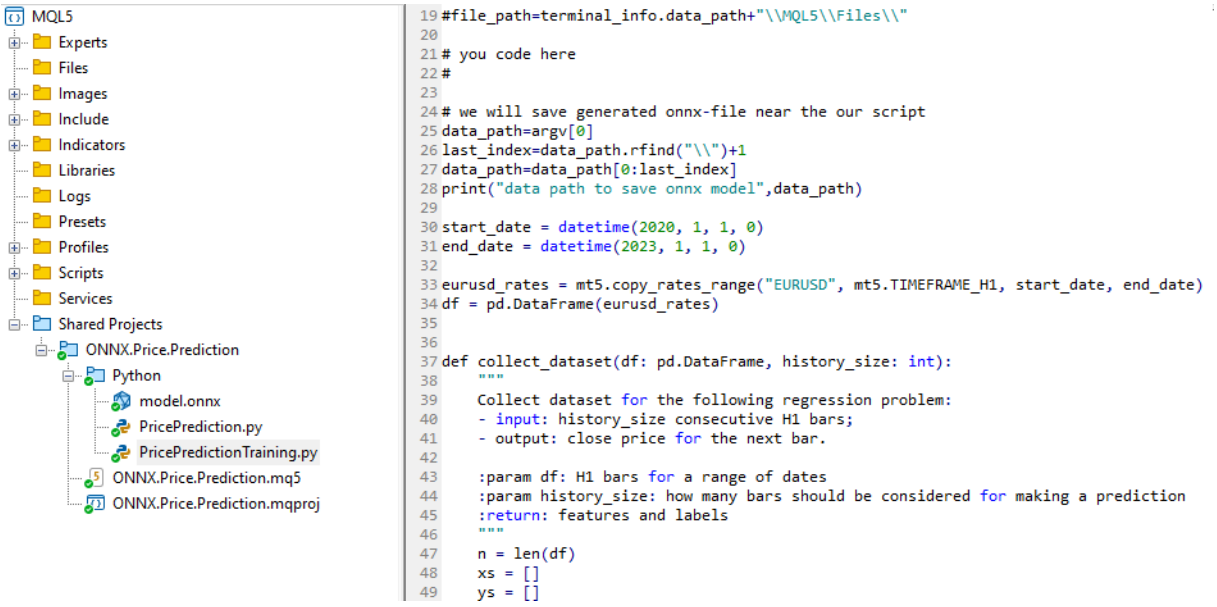
After activation, find the ONNX.Price.Prediction project and join it via the context menu command.



Next, update the project from MQL5 Storage.



The project contains an ONNX model, two python scripts, an MQL5 script for project operation, and an MQL5 project file (ONNX.Price.Prediction.mqproj).



```
#file_path=terminal_info.data_path+"\\MQL5\\Files\\"

# you code here
#

# we will save generated onnx-file near the our script
data_path=argv[0]
last_index=data_path.rfind("\\")+1
data_path=data_path[0:last_index]
print("data path to save onnx model",data_path)

start_date = datetime(2020, 1, 1, 0)
end_date = datetime(2023, 1, 1, 0)

eurusd_rates = mt5.copy_rates_range("EURUSD", mt5.TIMEFRAME_H1, start_date, end_date)
df = pd.DataFrame(eurusd_rates)

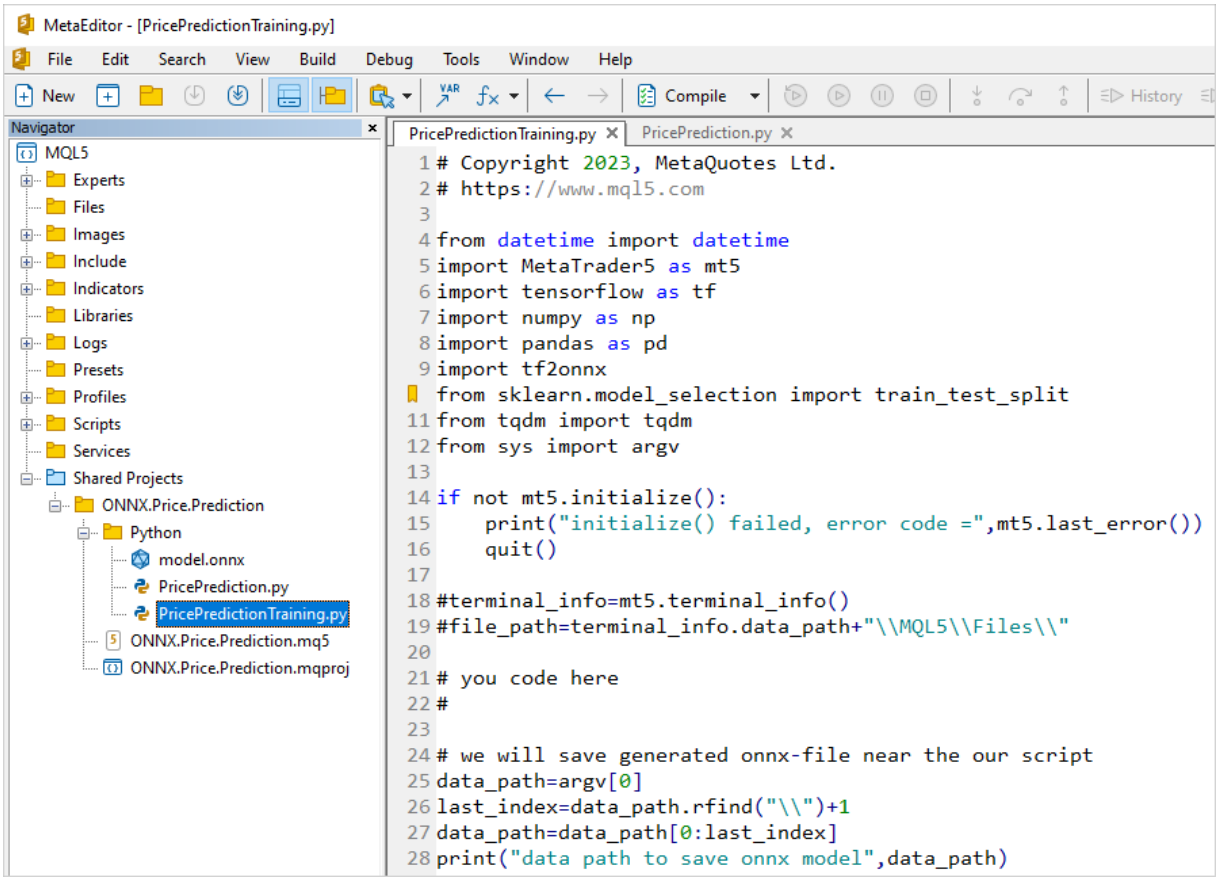
def collect_dataset(df: pd.DataFrame, history_size: int):
    """
    Collect dataset for the following regression problem:
    - input: history_size consecutive H1 bars;
    - output: close price for the next bar.

    :param df: H1 bars for a range of dates
    :param history_size: how many bars should be considered for making a prediction
    :return: features and labels
    """
    n = len(df)
    xs = []
    ys = []
```

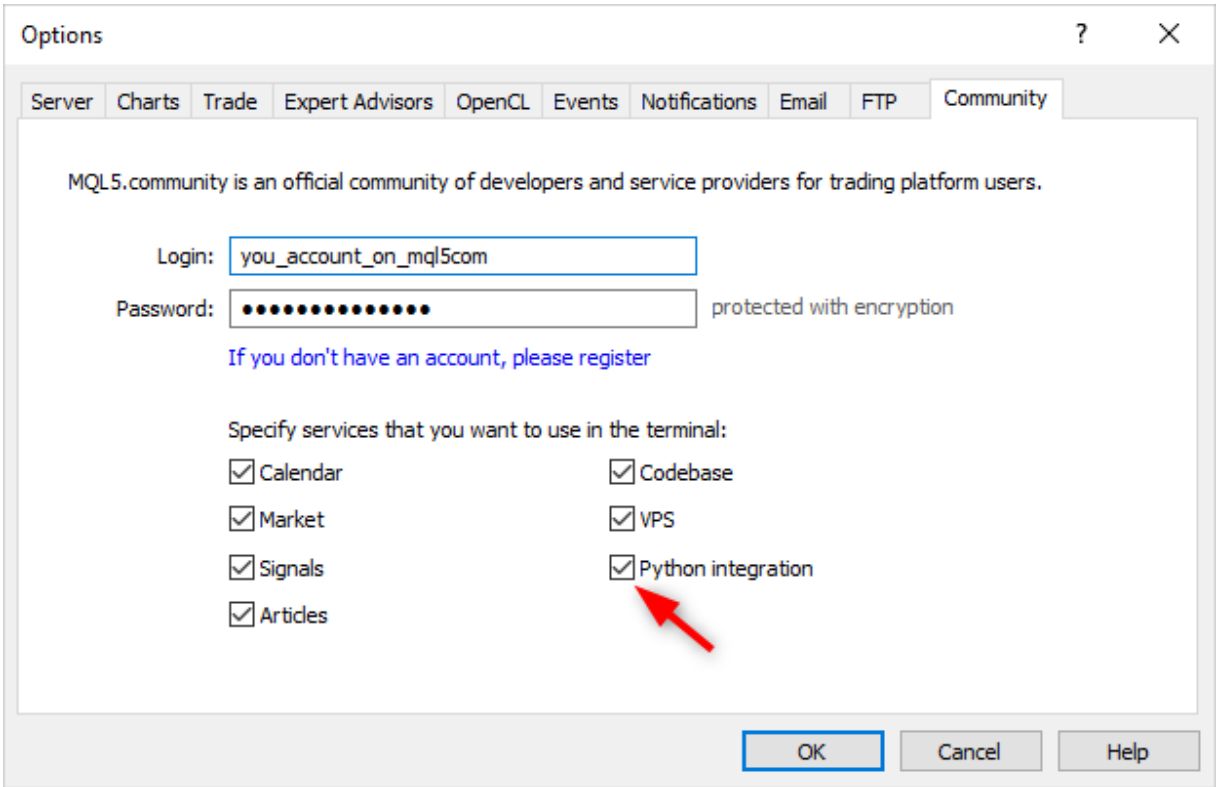
You can create the ONNX model yourself using the PricePredictionTraining.py script included in the project. To do this, you should first install the required modules from the command line.

```
python.exe -m pip install --upgrade pip
python -m pip install --upgrade tensorflow
python -m pip install --upgrade pandas
python -m pip install --upgrade scikit-learn
python -m pip install --upgrade matplotlib
python -m pip install --upgrade tqdm
python -m pip install --upgrade metatrader5
python -m pip install --upgrade onnx==1.12
python -m pip install --upgrade tf2onnx
python -m pip install --upgrade numpy
python -m pip install onnxruntime
```

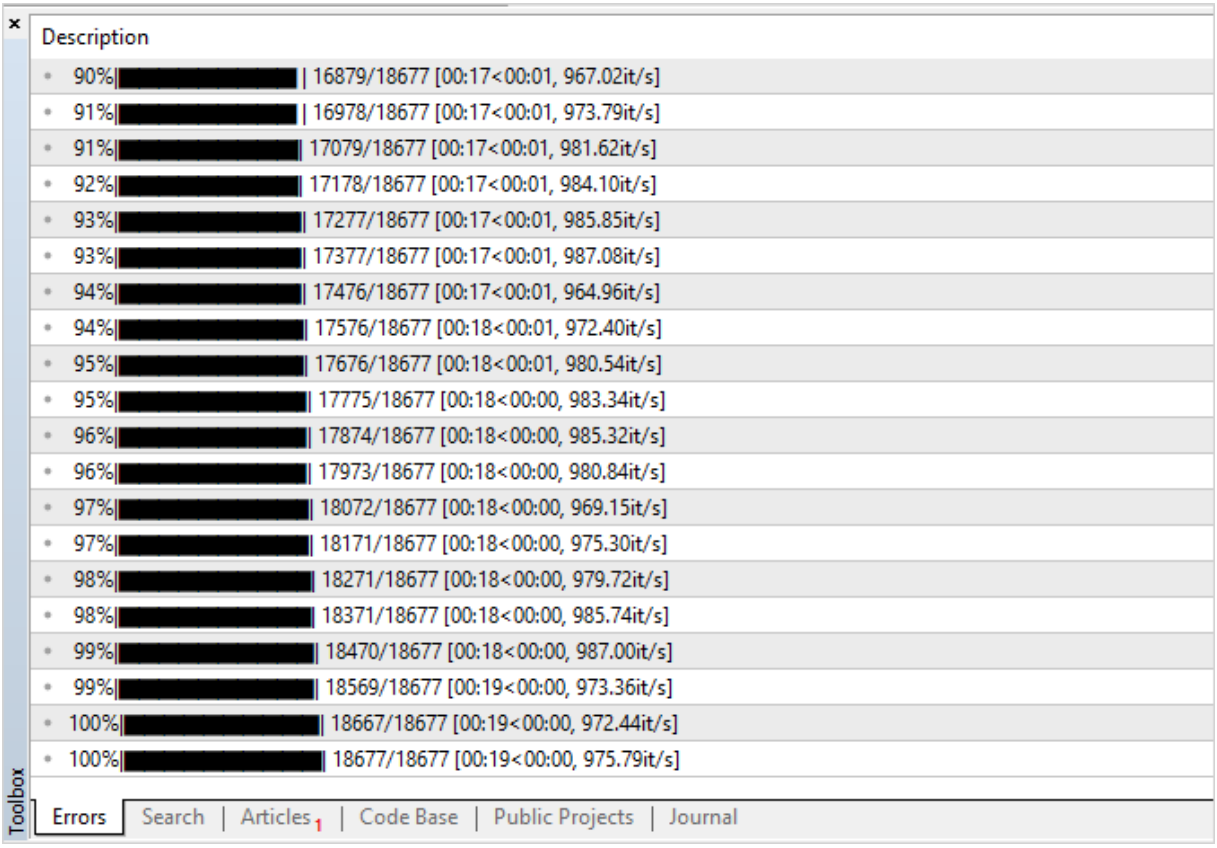
After installing the modules, open the PricePredictionTraining.py script in MetaEditor and run it with the Compile button or with the F7 key.



Before running the Python script, make sure that the MetaTrader 5 terminal is connected to a server with the EURUSD symbol available. For example, connect to the MetaQuotes-Demo server and check "Integration with Python" in terminal settings.

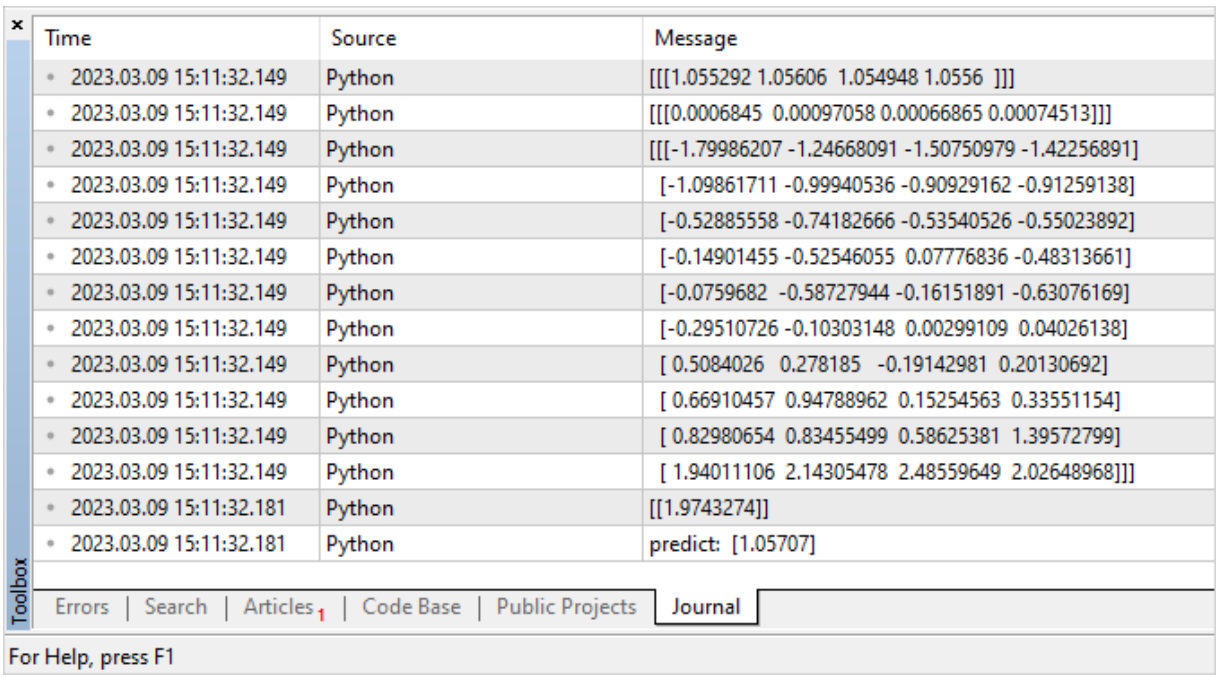


While training the network, MetaEditor will print messages from the Python script until the training is complete.



When the result is 100%, the ONNX model is ready and it is saved to the project folder at <terminal data directory>\MQL5\Shared Projects\ONNX.Price.Prediction\Python.

You can check the resulting model by running the second script PricePrediction.py, pressing **F7**.



Running a model

To run an ONNX model in MQL5, complete 3 steps:

1. Load the model from an *.onnx file using the OnnxCreate function or from an array using OnnxCreateFromBuffer.
2. Specify input and output data shapes using OnnxSetInputShape and OnnxSetOutputShape functions.
3. Run the model using the OnnxRun function, passing to it the relevant input and output parameters.
4. When needed, you can terminate the model operation using the OnnxRelease function.

When creating an ONNX model, you should consider the existing limits and restrictions, which are described at https://github.com/microsoft/onnxruntime/blob/rel-1.14.0/docs/OperatorKernels.md

Some of the examples of such restrictions are shown below:

Operation	Supported data types
ReduceSum	tensor(double), tensor(float), tensor(int32), tensor(int64)
Mul	tensor(bfloat16), tensor(double), tensor(float), tensor(float16), tensor(int32), tensor(int64), tensor(uint32), tensor(uint64)

Below is an MQL5 code example from the public project ONNX.Price.Prediction.

```
const long   ExtOutputShape[] = {1,1};     // model's output shape
const long   ExtInputShape [] = {1,10,4}; // model's input shape
#resource "Python/model.onnx" as uchar ExtModel[]// model as a resource
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart(void)
  {
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,2,10))
      return(-1);
//--- input a set of OHLC vectors
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
```

```
   x_norm-=mm;
   x_norm/=ms;
//--- create the model
   long handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- print the output value of the model to the log
   Print(y_norm);
//--- do the reverse transformation to get the predicted price
   double y_pred=y_norm[0]*s[3]+m[3];
   Print("price predicted:",y_pred);
//--- complete operation
   OnnxRelease(handle);
   return(0);
  }
```

Script run example:

```
ONNX: Creating and using per session threadpools since use_per_session_threads_ is tru
ONNX: Dynamic block base set to 0
ONNX: Initializing session.
ONNX: Adding default CPU execution provider.
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Total shared scalar initializer count: 0
```

```
ONNX: Total fused reshape node count: 0
ONNX: Use DeviceBasedPartition as default
ONNX: Saving initialized tensors.
ONNX: Done saving initialized tensors
ONNX: Session successfully initialized.
[0.28188983]
predicted 1.0559258806393044
```

The MetaTrader 5 terminal has selected the optimal executor for calculations — ONNX Runtime Execution Provider. In this example, the model was executed on the CPU.

Let's modify the script to calculate the percentage of successful Close price predictions made based on the values of the preceding 10 bars.

```
#resource "Python/model.onnx" as uchar ExtModel[]// model as a resource

#define TESTS 10000  // number of test datasets
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart()
  {
//--- create the model
   long session_handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
   if(session_handle==INVALID_HANDLE)
     {
      Print("Cannot create model. Error ",GetLastError());
      return(-1);
     }

//--- since the input tensor size is not defined for the model, specify it explicitly
//--- first index is batch size, second index is series size, third index is number of
   const long input_shape[]={1,10,4};
   if(!OnnxSetInputShape(session_handle,0,input_shape))
     {
      Print("OnnxSetInputShape error ",GetLastError());
      return(-2);
     }

//--- since the output tensor size is not defined for the model, specify it explicitly
//--- first index is batch size, must match the batch size in the input tensor
//--- second index is number of predicted prices (only Close is predicted here)
   const long output_shape[]={1,1};
   if(!OnnxSetOutputShape(session_handle,0,output_shape))
     {
      Print("OnnxSetOutputShape error ",GetLastError());
      return(-3);
     }
//--- run tests
   vector closes(TESTS);      // vector to store validation prices
```

```
   vector predicts(TESTS);     // vector to store obtained predictions
   vector prev_closes(TESTS); // vector to store preceding prices

   matrix rates;              // matrix to get the OHLC series
   matrix splitted[2];        // two submatrices to divide the series into test and va
   ulong  parts[]={10,1};     // sizes of divided submatrices

//--- start from the previous bar
   for(int i=1; i<=TESTS; i++)
     {
      //--- get 11 bars
      rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,i,11);
      //--- divide the matrix into test and validation
      rates.Vsplit(parts,splitted);
      //--- take the Close price from the validation matrix
      closes[i-1]=splitted[1][3][0];
      //--- last Close in the tested series
      prev_closes[i-1]=splitted[0][3][9];

      //--- submit the test matrix of 10 bars to testing
      predicts[i-1]=PricePredictionTest(session_handle,splitted[0]);
      //--- runtime error
      if(predicts[i-1]<=0)
        {
         OnnxRelease(session_handle);
         return(-4);
        }
     }
//--- complete operation
   OnnxRelease(session_handle);
//--- evaluate if price movement was predicted correctly
   int    right_directions=0;
   vector delta_predicts=prev_closes-predicts;
   vector delta_actuals=prev_closes-closes;

   for(int i=0; i<TESTS; i++)
      if((delta_predicts[i]>0 && delta_actuals[i]>0) || (delta_predicts[i]<0 && delta_
         right_directions++;
   PrintFormat("right direction predictions = %.2f%%",(right_directions*100.0)/double
//---
   return(0);
  }
//+------------------------------------------------------------------+
//|  Prepare the data and run the model                              |
//+------------------------------------------------------------------+
double PricePredictionTest(const long session_handle,matrix& rates)
  {
   static matrixf input_data(10,4); // matrix for the transformed input
   static vectorf output_data(1);   // vector to receive the result
```

```
   static matrix mm(10,4);          // matrix of horizontal vectors Mean
   static matrix ms(10,4);          // matrix of horizontal vectors Std

//--- a set of OHLC vertical vectors must be input into the model
   matrix x_norm=rates.Transpose();
//--- normalize prices
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
   x_norm-=mm;
   x_norm/=ms;

//--- run the model
   input_data.Assign(x_norm);
   if(!OnnxRun(session_handle,ONNX_DEBUG_LOGS,input_data,output_data))
     {
      Print("OnnxRun error ",GetLastError());
      return(0);
     }
//--- unnormalize the price from the output value
   double y_pred=output_data[0]*s[3]+m[3];

   return(y_pred);
  }
```

Run the script: the prediction accuracy is about 51%

```
ONNX: Creating and using per session threadpools since use_per_session_threads_ is tru
ONNX: Dynamic block base set to 0
ONNX: Initializing session.
ONNX: Adding default CPU execution provider.
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Use DeviceBasedPartition as default
ONNX: Saving initialized tensors.
ONNX: Done saving initialized tensors
ONNX: Session successfully initialized.
right direction predictions = 51.34 %
```

Model validation in the Strategy Tester

Models created for operations in the financial markets can be validated in the MetaTrader 5 terminal Strategy Tester. This is the fastest and most convenient option, which eliminates the need to additionally emulate the market environment and trading conditions.

To test the model, let us create an Expert Advisor based on the code from the public project ONNX.Price.Prediction. This will require some edits.

Move the model creation to the OnInit function. The onnx session will be closed in OnDeinit. Locate the main model operations block to the OnTick handler.

Also, add obtaining of the Close price of the previous two bars, which is needed to compare the actual Close price and the prediction.

The Expert Advisor code is small and easy to read.

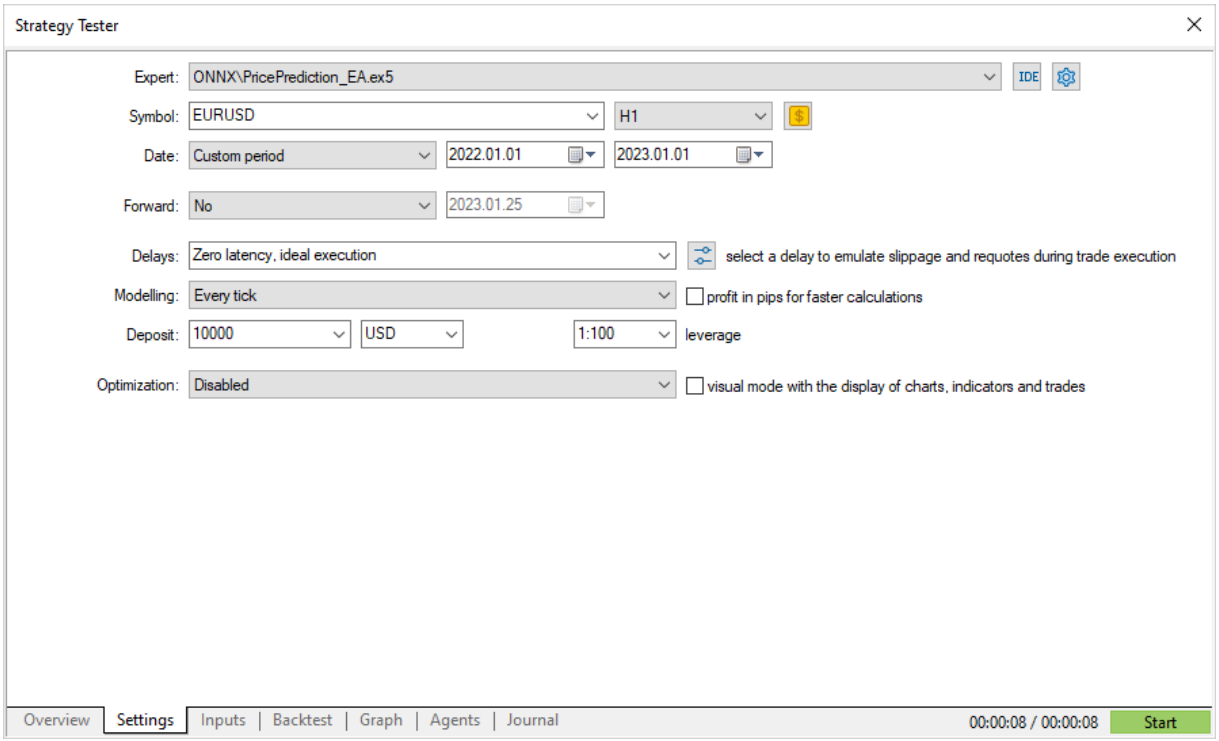
```
const long   ExtInputShape [] = {1,10,4}; // model's input shape
const long   ExtOutputShape[] = {1,1};    // model's output shape
#resource "Python/model.onnx" as uchar ExtModel[];// model as a resource

long handle;          // model handle
ulong predictions=0; // predictions counter
ulong confirmed=0;   // successful predictions counter
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- basic checks
   if(_Symbol!="EURUSD")
     {
      Print("Symbol must be EURUSD, testing aborted");
      return(-1);
     }
   if(_Period!=PERIOD_H1)
     {
      Print("Timeframe must be H1, testing aborted");
      return(-1);
     }
//--- create the model
   handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

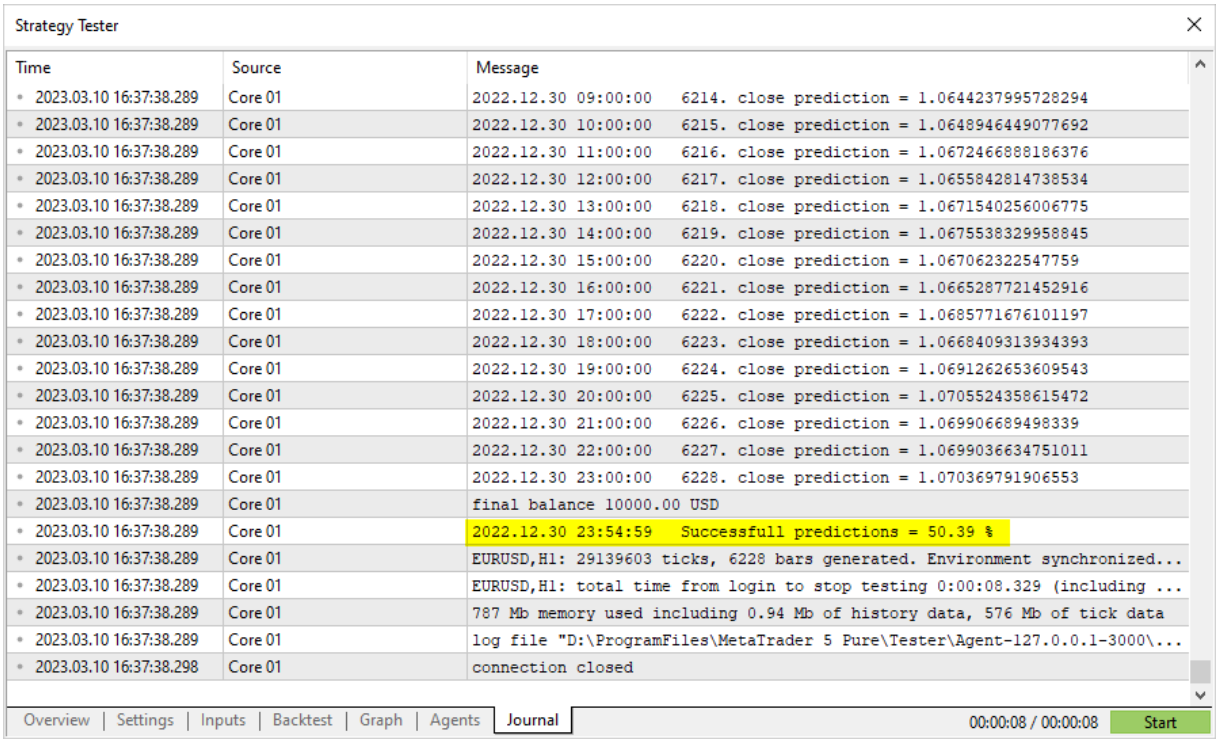
```
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- complete model operation
   OnnxRelease(handle);
//--- calculate and output prediction statistics
   PrintFormat("Successfull predictions = %.2f %%",confirmed*100./double(predictions));
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
   static datetime open_time=0;
   static double predict;
//--- check the current bar opening time
   datetime time=iTime(_Symbol,_Period,0);
   if(time==0)
     {
      PrintFormat("Failed to get Time(0), error %d", GetLastError());
      return;
     }
//--- if the opening time has not changed, exit until the next OnTick call
   if(time==open_time)
      return;
//--- get the Close prices of the last two completed bars
   double close[];
   int recieved=CopyClose(_Symbol,_Period,1,2,close);
   if(recieved!=2)
     {
      PrintFormat("CopyClose(2 bars) failed, error %d",GetLastError());
      return;
     }
   double delta_predict=predict-close[0]; // predicted price change
   double delta_actual=close[1]-close[0]; // actual price change
   if((delta_predict>0 && delta_actual>0) || (delta_predict<0 && delta_actual<0))
      confirmed++;
```

```
//--- calculate the Close price on the new bar to validate the price on the next bar
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,1,10))
      return;
//--- input a set of OHLC vectors
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
   x_norm-=mm;
   x_norm/=ms;
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
     }
//--- do reverse transformation to get the predicted price and to validate it on a new
   predict=y_norm[0]*s[3]+m[3];
   predictions++;  // increase predictions counter
   Print(predictions,". close prediction = ",predict);
//--- save the bar opening time to check on the next tick
   open_time=time;
  }
```

Compile the Expert Advisor and run testing in the period of year 2022. Specify EURUSD with the H1 timeframe, which is the data on which the model was trained. The tick modeling mode can be ignores, since the code checks the emergence of a new bar.



Run and check the result in the testing journal. It shows that a little more than 50% of ppredictions were correct in 2022.



If the preliminary model testing has generated satisfactory results, you can start writing a full-fledged trading strategy based on this model.

OnnxCreate

Create an ONNX session, loading a model from an *.onnx file.

```
long  OnnxCreate(
   string  filename,  // file path
   uint    flags      // flags to create the model
   );
```

Parameters

filename

[in] Path to the *.onnx file of the model relative to the \MQL5\Files\ folder.

flags

[in] Flags from ENUM_ONNX_FLAGS, describing the model creation mode: ONNX_COMMON_FOLDER and ONNX_DEBUG_LOGS.

Return Value

The handle of the created session or INVALID_HANDLE if error occurs. To obtain the error code, call the GetLastError function.

Note

If the specified file is not found on disk, the system retries to open the file, appending the '.onnx' extension to the name.

OnnxCreateFromBuffer

Create an ONNX session, loading a model from a data array.

```
long  OnnxCreateFromBuffer(
   const uchar&  buffer[],   // array reference
   ulong         flags       // model creation flags
   );
```

Parameters

buffer

[in] Array with ONNX model data.

flags

[in] Flags from ENUM_ONNX_FLAGS, describing the model creation mode: ONNX_COMMON_FOLDER and ONNX_DEBUG_LOGS.

Return Value

The handle of the created session or INVALID_HANDLE if error occurs. To obtain the error code, call the GetLastError function.

OnnxRelease

Close an ONNX session.

```
bool  OnnxRelease(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

OnnxRun

Run an ONNX model.

```
bool  OnnxRun(
   long    onnx_handle,  // ONNX session handle
   ulong   flags,        // flags describing the run mode
   ...                   // model's inputs and outputs
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

flags

[in] Flags from ENUM_ONNX_FLAGS describing the run mode: ONNX_DEBUG_LOGS and ONNX_NO_CONVERSION.

...

[in] [out] Model inputs and outputs.

Returns true on success or false otherwise. To obtain the error code, call the GetLastError function.

ENUM_ONNX_FLAGS

ID	Description
ONNX_DEBUG_LOGS	Output debug logs
ONNX_NO_CONVERSION	Disable auto conversion, use user data as is
ONNX_COMMON_FOLDER	Load a model file from the Common\Files folder; the value is equal to the FILE_COMMON flag

Example:

```
const long                              ExtOutputShape[] = {1,1};     // model output sh
const long                              ExtInputShape [] = {1,10,4}; // model input for
#resource "Python/model.onnx" as uchar ExtModel[]                    // model as resour
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart(void)
  {
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,2,10))
      return(-1);
//--- input a set of OHLC vectors
```

```
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
   x_norm-=mm;
   x_norm/=ms;
//--- create the model
   long handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- print the output value of the model to the log
   Print(y_norm);
//--- do the reverse transformation to get the predicted price
   double y_pred=y_norm[0]*s[3]+m[3];
   Print("price predicted:",y_pred);
//--- completed operation
   OnnxRelease(handle);
```

```
   return(0);
  };
```

OnnxSetInputShape, OnnxSetOutputShape

OnnxGetInputCount

Get the number of inputs in an ONNX model.

```
long  OnnxGetInputCount(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns the number of input parameters on success; otherwise returns -1. To get the error code, call the GetLastError function.

OnnxGetOutputCount

Get the number of outputs in an ONNX model.

```
long  OnnxGetOutputCount(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns the number of output parameters on success; otherwise returns -1. To get the error code, call the GetLastError function.

OnnxGetInputName

Get the name of a model's input by index.

```
string  OnnxGetInputName(
   long   onnx_handle,  // ONNX session handle
   long   index         // parameter index
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the input parameter, starting with 0.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

OnnxGetOutputName

Get the name of a model's output by index.

```
string  OnnxGetOutputName(
   long   onnx_handle,  // ONNX session handle
   long   index         // parameter index
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the output parameter, starting with 0.

Return Value

Returns the name of the output parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

OnnxGetInputTypeInfo

Get the description of the input type from the model.

```
bool  OnnxGetInputTypeInfo(
   long           onnx_handle,  // ONNX session handle
   long           index,        // parameter index
   OnnxTypeInfo&  typeinfo      // parameter type description
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the input parameter, starting with 0.

typeinfo

[out] The OnnxTypeInfo structure that describes the type of the input parameter.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

OnnxGetOutputTypeInfo

Get the description of the output type from the model.

```
bool  OnnxGetOutputTypeInfo(
   long           onnx_handle,  // ONNX session handle
   long           index,        // parameter index
   OnnxTypeInfo&  typeinfo      // parameter type description
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the output parameter, starting with 0.

typeinfo

[out] The OnnxTypeInfo structure that describes the type of the output parameter.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

OnnxSetInputShape

Set the shape of a model's input data by index.

```
bool  OnnxSetInputShape(
   long           onnx_handle,   // ONNX session handle
   long           input_index,   // input parameter index
   const ulong&   shape[]        // array describing input data shape
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

input_index

[in] Index of the input parameter, starting from 0.

shape

[in] Array describing model's input data shape.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

Example:

```
//---- describe the shapes of the model's input and output data
   const long  ExtOutputShape[] = {1,1};
   const long  ExtInputShape [] = {1,10,4};
//--- create the model
   long handle=OnnxCreateFromBuffer(model,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("failed, OnnxSetInputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("failed, OnnxSetOutputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

See also

OnnxSetOutputShape

OnnxSetOutputShape

Set the shape of a model's output data by index.

```
bool  OnnxSetOutputShape(
   long           onnx_handle,    // ONNX session handle
   long           output_index,   // output parameter index
   const ulong&   shape[]         // array describing output data shape
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

output_index

[in] Index of the output parameter, starting from 0.

shape

[in] Array describing model's output data shape.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

Example:

```
//---- describe the shapes of the model's input and output data
   const long  ExtOutputShape[] = {1,1};
   const long  ExtInputShape [] = {1,10,4};
//--- create the model
   long handle=OnnxCreateFromBuffer(model,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("failed, OnnxSetInputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("failed, OnnxSetOutputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

OnnxSetInputShape

Data structures

The following data structures are used for operations with ONNX models:

OnnxTypeInfo

The structure describes the type of an input or output parameter of an ONNX model

```
struct OnnxTypeInfo
 {
  ENUM_ONNX_TYPE         type;          // parameter type
  OnnxTensorTypeInfo     tensor;        // tensor description
  OnnxMapTypeInfo        map;           // map description
  OnnxSequenceTypeInfo   sequence;      // sequence description
 };
```

Only tensor (ONNX_TYPE_TENSOR) can be used as an input. In this case, only the OnnxTypeInfo::tensor field is filled with values, while other fields (map and sequence) are not defined.

Only one of the three OnnxTypeInfo types (ONNX_TYPE_TENSOR, ONNX_TYPE_MAP or ONNX_TYPE_SEQUENCE) can be used as an input. The corresponding substructure (OnnxTypeInfo::tensor, OnnxTypeInfo::map or OnnxTypeInfo::sequence) is filled depending on the type.

OnnxTensorTypeInfo

The structure describes the tensor in the input or output parameter of an ONNX model

```
struct OnnxTensorTypeInfo
 {
  const ENUM_ONNX_DATA_TYPE   data_type;      // data type in the tensor
  const long                  dimensions[];   // number of elements in the tensor
 };
```

OnnxMapTypeInfo

The structure describes the map obtained in the output parameter of an ONNX model

```
struct OnnxMapTypeInfo
 {
  const ENUM_ONNX_DATA_TYPE   key_type;       // key type
  const OnnxTypeInfo &        value_type;     // value type
 };
```

OnnxSequenceTypeInfo

The structure describes the sequence obtained in the output parameter of an ONNX model

```
struct OnnxSequenceTypeInfo
```

```
{
 const OnnxTypeInfo&        value_type;      // data type in the sequence
};
```

ENUM_ONNX_TYPE

The **ENUM_ONNX_TYPE** enumeration describes the type of a model parameter

ID	Description
ONNX_TYPE_UNKNOWN	Unknown
ONNX_TYPE_TENSOR	Tensor
ONNX_TYPE_SEQUENCE	Sequence
ONNX_TYPE_MAP	Map
ONNX_TYPE_OPAQUE	Abstract (opaque)
ONNX_TYPE_SPARSETENSOR	Sparse tensor

ENUM_ONNX_DATA_TYPE

The **ENUM_ONNX_DATA_TYPE** enumeration describes the type of data used

ID	Description
ONNX_DATA_TYPE_UNDEFINED	Undefined
ONNX_DATA_TYPE_FLOAT	float
ONNX_DATA_TYPE_INT8	8-bit int
ONNX_DATA_TYPE_UINT16	16-bit uint
ONNX_DATA_TYPE_INT16	16-bit int
ONNX_DATA_TYPE_INT32	32-bit int
ONNX_DATA_TYPE_INT64	64-bit int
ONNX_DATA_TYPE_STRING	string
ONNX_DATA_TYPE_BOOL	bool
ONNX_DATA_TYPE_FLOAT16	16-bit float
ONNX_DATA_TYPE_DOUBLE	double
ONNX_DATA_TYPE_UINT32	32-bit uint
ONNX_DATA_TYPE_UINT64	64-bit uint

ID	Description
ONNX_DATA_TYPE_COMPLEX64	64-bit complex number
ONNX_DATA_TYPE_COMPLEX128	128-bit complex number
ONNX_DATA_TYPE_BFLOAT16	16-bit bfloat (Brain Floating Point)

ENUM_ONNX_FLAGS

The **ENUM_ONNX_FLAGS** enumeration describes the model run mode

ID	Description
ONNX_DEBUG_LOGS	Output debug logs
ONNX_NO_CONVERSION	Disable auto conversion, use user data as is
ONNX_COMMON_FOLDER	Load a model file from the Common\Files folder; the value is equal to the FILE_COMMON flag

Standard Library

This group of chapters contains the technical details of the MQL5 Standard Library and descriptions of all its key components.

MQL5 Standard Library is written in MQL5 and is designed to facilitate writing programs (indicators, scripts, experts) for end users. Library provides convenient access to the most of the internal MQL5 functions.

MQL5 Standard Library is placed in the working directory of the terminal in the 'Include' folder.

Mathematics

Multiple libraries are provided to perform calculations in various areas of mathematics:

- Statistics – functions for working with various distributions of the Probability theory
- Fuzzy logic – library that implements Mamdani and Sugeno fuzzy inference systems
- ALGLIB – data analysis (clustering, decision trees, linear regression, neural networks), solving differential equations, Fourier transform, numerical integration, optimization problems, statistical analysis, and more.

Statistics

The Statistical Library provides a convenient way of working with the basic statistical distributions.

The library provides 5 functions for each distribution:

1. Calculation of probability density - functions of the form MathProbabilityDensityX()
2. Calculation of probabilities - functions of the form MathCumulativeDistributionX()
3. Calculation of distribution quantiles - functions of the form MathQuantileX()
4. Generation of random numbers with the specified distribution - functions of the form MathRandomX()
5. Calculation of the theoretical moments of the distributions - functions of the form MathMomentsX()

In addition to calculation of values for the individual random variables, the library also provides overloads for the functions, which perform the same calculations for arrays.

- Statistical Characteristics
- Normal Distribution
- Log-normal distribution
- Beta distribution
- Noncentral beta distribution
- Gamma distribution
- Chi-squared distribution
- Noncentral chi-squared distribution
- Exponential distribution
- F-distribution
- Noncentral F-distribution
- t-distribution
- Noncentral t-distribution
- Logistic distribution
- Cauchy distribution
- Uniform distribution
- Weibull distribution
- Binomial distribution
- Negative binomial distribution
- Geometric distribution
- Hypergeometric distribution
- Poisson distribution
- Subfunctions

Statistical Characteristics

This group of functions calculates the Statistical Characteristics of the array elements:

- mean,
- variance,
- skewness,
- kurtosis,
- median,
- root-mean-square and
- standard deviation.

Function	Description
MathMean	Calculates the mean (first moment) of array elements
MathVariance	Calculates the variance (second moment) of array elements
MathSkewness	Calculates the skewness (third moment) of array elements
MathKurtosis	Calculates the kurtosis (fourth moment) of array elements
MathMoments	Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements
MathMedian	Calculates the median value of array elements
MathStandardDeviation	Calculates the standard deviation of array elements
MathAverageDeviation	Calculates the average absolute deviation of array elements

MathMean

Calculates the mean (first moment) of array elements. Analog of the mean() in R.

```
double  MathMean(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation of the mean.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The mean of array elements. In case of error it returns NaN (not a number).

MathVariance

Calculates the variance (second moment) of array elements. Analog of the var() in R.

```
double  MathVariance(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Variance of array elements. In case of error it returns NaN (not a number).

MathSkewness

Calculates the skewness (third moment) of array elements. Analog of the skewness() in R (e1071 library).

```
double  MathSkewness(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Skewness of array elements. In case of error it returns NaN (not a number).

MathKurtosis

Calculates the kurtosis (fourth moment) of array elements. Analog of the kurtosis() in R (e1071 library).

```
double  MathKurtosis(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Kurtosis of array elements. In case of error it returns NaN (not a number).

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

MathMoments

Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements.

```
double  MathMoments(
   const double&  array[],              // array with data
   double&        mean,                 // mean (1st moment)
   double&        variance,             // variance (2nd moment)
   double&        skewness,             // skewness (3rd moment)
   double&        kurtosis,             // kurtosis (4th moment)
   const int      start=0,              // initial index
   const int      count=WHOLE_ARRAY     // the number of elements
   );
```

Parameters

array

[in] Array with data for calculation.

mean

[out] Variable for the mean (1st moment)

variance

[out] Variable for the variance (2nd moment)

skewness

[out] Variable for the skewness (3rd moment)

kurtosis

[out] Variable for the kurtosis (4th moment)

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

MathMedian

Calculates the median value of array elements. Analog of the median() in R.

```
double  MathMedian(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The median value of array elements. In case of error it returns NaN (not a number).

MathStandardDeviation

Calculates the standard deviation of array elements. Analog of the sd() in R.

```
double  MathStandardDeviation(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The standard deviation of array elements. In case of error it returns NaN (not a number).

MathAverageDeviation

Calculates the average absolute deviation of array elements. Analog of the aad() in R.

```
double  MathAverageDeviation(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The average absolute deviation of array elements. In case of error it returns NaN (not a number).

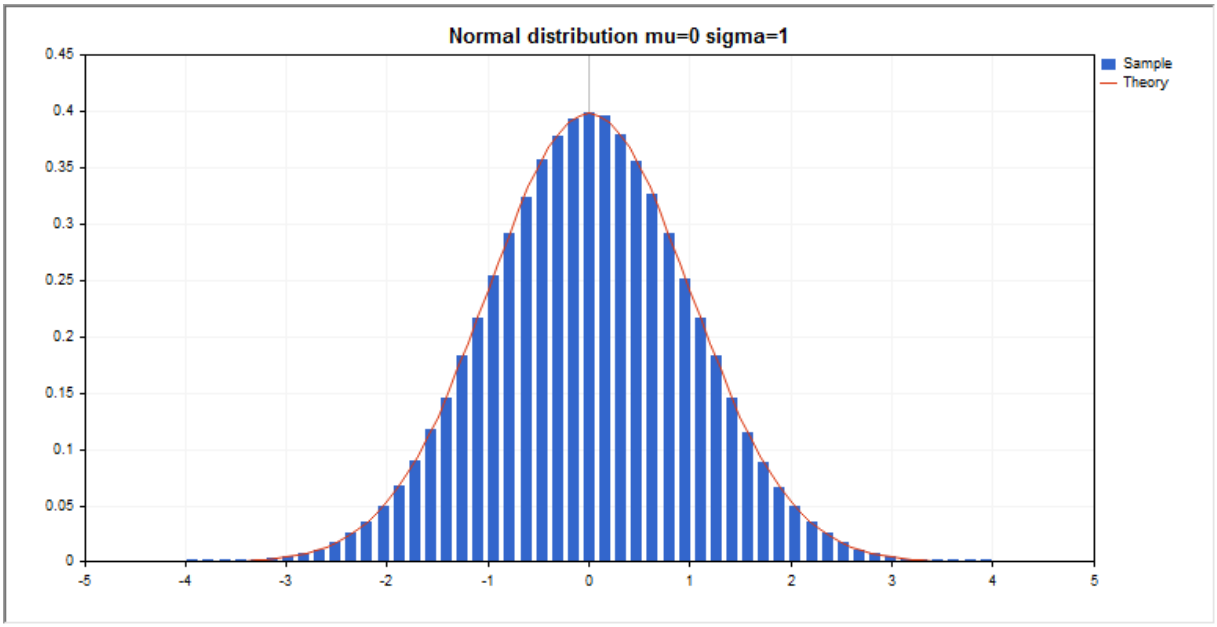
Normal Distribution

This section contains functions for working with normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the normal law. The distribution is defined by the following formula:

$$f_{Normal}(x|\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where:

- x — value of the random variable
- μ — expected value
- σ — root-mean-square deviation



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNormal	Calculates the probability density function of the normal distribution
MathCumulativeDistributionNormal	Calculates the value of the normal probability distribution function
MathQuantileNormal	Calculates the value of the inverse normal distribution function for the specified probability
MathRandomNormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the normal law

Function	Description
MathMomentsNormal	Calculates the theoretical numerical values of the first 4 moments of the normal distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Normal.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mean_value=0;  // expected value (mean)
input double std_dev=1;     // root-mean-square deviation (standard deviation)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=51;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals
   double y[];          // the number of values from the sample falling within the int
   double data[];       // sample of random values
   double max,min;      // the maximum and minimum values in the sample
//--- obtain a sample from the normal distribution
   MathRandomNormal(mean_value,std_dev,n,data);
//--- calculate the data to plot the histogram

//--- sequence generation step is also set based on the specified precision
   stepv=NormalizeDouble(MathPow(10,-degree),degree);
   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityNormal

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNormal(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution (expected value
   const double  sigma,          // sigma parameter of the distribution (root-mean-squ
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNormal(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution (expected value
   const double  sigma,          // sigma parameter of the distribution (root-mean-squ
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dnorm() in R.

```
bool  MathProbabilityDensityNormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // mean parameter of the distribution (expected valu
   const double   sigma,         // sigma parameter of the distribution (root-mean-sq
   const bool     log_mode,      // calculate the logarithm of the value
   double&        result[]       // array for values of the probability density funct
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // mean parameter of the distribution (expected valu
   const double   sigma,         // sigma parameter of the distribution (root-mean-sq
   double&        result[]       // array for values of the probability density funct
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability density function.

MathCumulativeDistributionNormal

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNormal(
   const double  x,              // value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNormal(
   const double  x,              // value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dnorm() in R.

```
bool  MathCumulativeDistributionNormal(
   const double& x[],            // array with the values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNormal(
   const double& x[],            // array with the values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If tail=true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability function.

MathQuantileNormal

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNormal(
   const double  probability,    // probability value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNormal(
   const double  probability,    // probability value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the qnorm() in R.

```
bool  MathQuantileNormal(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool  MathQuantileNormal(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If false, then calculation is performed for 1.0 - probability.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the quantiles.

MathRandomNormal

Generates a pseudorandom variable distributed according to the normal law with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathRandomNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the normal law with the mu and sigma parameters. In case of error it returns false. Analog of the rnorm() in R.

```
bool  MathRandomNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   const int     data_count,      // amount of required data
   double&       result[]         // array to obtain the pseudorandom variables
   );
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNormal

Calculates the theoretical numerical values of the first 4 moments of the normal distribution.

```
double  MathMomentsNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable to store the error code
   );
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

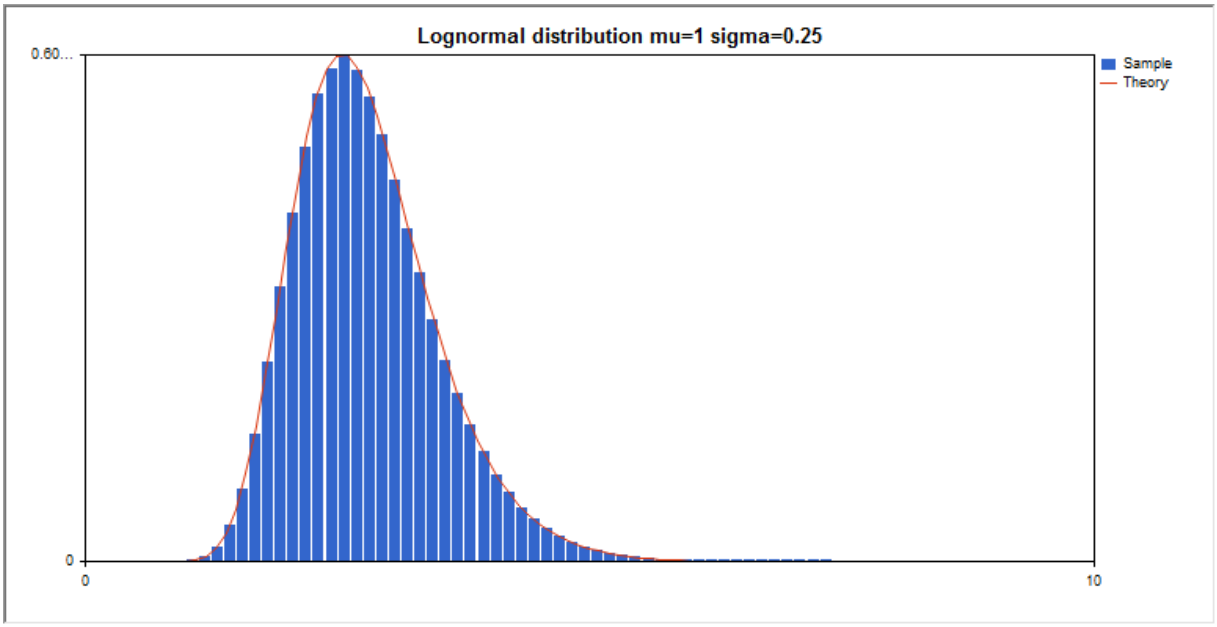
Log-normal distribution

This section contains functions for working with log-normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the log-normal law. The log-normal distribution is defined by the following formula:

$$f_{Lognormal}(x|\mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}$$

where:

- x — value of the random variable
- μ — logarithm of the expected value
- σ — logarithm of the root-mean-square deviation



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityLognormal	Calculates the probability density function of the log-normal distribution
MathCumulativeDistributionLognormal	Calculates the value of the log-normal probability distribution function
MathQuantileLognormal	Calculates the value of the inverse log-normal distribution function for the specified probability
MathRandomLognormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the log-normal law
MathMomentsLognormal	Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Lognormal.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mean_value=1.0;  // logarithm of the expected value (log mean)
input double std_dev=0.25;    // logarithm of the root-mean-square deviation (log star
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=51;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals
   double y[];          // the number of values from the sample falling within the int
   double data[];       // sample of random values
   double max,min;      // the maximum and minimum values in the sample
//--- obtain a sample from the log-normal distribution
   MathRandomLognormal(mean_value,std_dev,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityLognormal(x2,mean_value,std_dev,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
   for(int i=0; i<ncells; i++)
      y[i]/=k;
//--- output charts
   CGraphic graphic;
   if(ObjectFind(chart,name)<0)
```

```

   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityLognormal

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns NaN. Analog of the dlnorm() in R.

```
bool  MathProbabilityDensityLognormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // logarithm of the expected value (log mean)
   const double   sigma,         // logarithm of the root-mean-square deviation (log
   const bool     log_mode,      // calculate the logarithm of the value, if log_mode
   double&        result[]       // array for values of the probability density funct
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityLognormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // logarithm of the expected value (log mean)
   const double   sigma,         // logarithm of the root-mean-square deviation (log
   double&        result[]       // array for values of the probability density funct
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability density function.

MathCumulativeDistributionLognormal

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=
   int&          error_code      // variable to store the error code
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the plnorm() in R.

```
bool  MathCumulativeDistributionLognormal(
   const double&  x[],            // array with the values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   const bool     tail,           // flag of calculation, if true, then the probabilit
   const bool     log_mode,       // flag to calculate the logarithm of the value, if
   double&        result[]        // array for values of the probability function
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionLognormal(
   const double&  x[],            // array with the values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   double&        result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability function.

MathQuantileLognormal

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLognormal(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatior
   int&          error_code      // variable to store the error code
   );
```

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLognormal(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the qlnorm() in R.

```
bool  MathQuantileLognormal(
   const double&  probability[],  // array with probability values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   const bool     tail,           // flag of calculation, if false, then calculation i
   const bool     log_mode,       // flag of calculation, if log_mode=true, calculatio
   double&        result[]        // array with values of quantiles
   );
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool  MathQuantileLognormal(
   const double&  probability[],  // array with probability values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   double&        result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable occurrence.

probability[]

[in] Array with probability values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of quantiles.

MathRandomLognormal

Generates a pseudorandom variable distributed according to the log-normal law with the mu sigma parameters. In case of error it returns NaN.

```
double  MathRandomLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the log-normal law with the mu sigma parameters. In case of error it returns false. Analog of the rlnorm() in R.

```
double  MathRandomLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

data_count

[in] Amount of required data.

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of pseudorandom variables.

MathMomentsLognormal

Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution. Returns true if calculation of the moments has been successful, otherwise false.

```
double  MathMomentsLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable to store the error code
   );
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

mean

[in] Variable for the mean.

variance

[out] Variable for the variance.

skewness

[out] Variable for the skewness.

kurtosis

[out] Variable for the kurtosis.

error code

[out] Variable to store the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

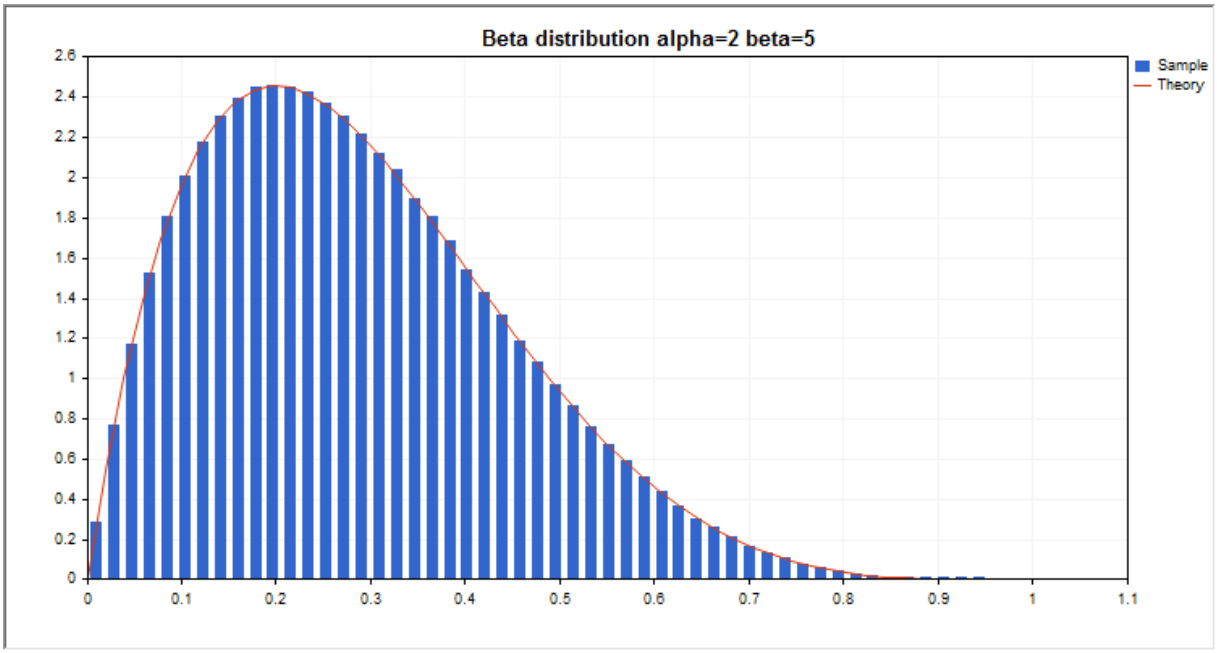
Beta distribution

This section contains functions for working with beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The beta distribution is defined by the following formula:

$$f_{Beta}(x \mid a,b) = \frac{1}{B(a,b)} x^{a-1}(1-x)^{b-1}$$

where:

- x — value of the random variable
- a — the first parameter of beta distribution
- b — the second parameter of beta distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityBeta	Calculates the probability density function of the beta distribution
MathCumulativeDistributionBeta	Calculates the value of the beta probability distribution function
MathQuantileBeta	Calculates the value of the inverse beta distribution function for the specified probability
MathRandomBeta	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the beta distribution law
MathMomentsBeta	Calculates the theoretical numerical values of the first 4 moments of the beta distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Beta.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double alpha=2;   // the first parameter of beta distribution (shape1)
input double beta=5;    // the second parameter of beta distribution (shape2)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=51;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals
   double y[];          // the number of values from the sample falling within the int
   double data[];       // sample of random values
   double max,min;      // the maximum and minimum values in the sample
//--- obtain a sample from the beta distribution
   MathRandomBeta(alpha,beta,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityBeta(x2,alpha,beta,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
   for(int i=0; i<ncells; i++)
      y[i]/=k;
//--- output charts
   CGraphic graphic;
   if(ObjectFind(chart,name)<0)
```

```
      graphic.Create(chart,name,0,0,0,780,380);
   else
      graphic.Attach(chart,name);

      frequency[i]=0;
     }
//--- fill the frequencies of falling within the interval
   for(int i=0; i<size; i++)
     {
      int ind=int((data[i]-minv)/width);
      if(ind>=cells) ind=cells-1;
      frequency[ind]++;
     }
   return (true);
  }
//+------------------------------------------------------------------+
//|  Calculates values for sequence generation                       |
//+------------------------------------------------------------------+
void GetMaxMinStepValues(double &maxv,double &minv,double &stepv)
  {
```

```
//--- calculate the absolute range of the sequence to obtain the precision of normali
   double range=MathAbs(maxv-minv);
   int degree=(int)MathRound(MathLog10(range));
//--- normalize the maximum and minimum values to the specified precision
   maxv=NormalizeDouble(maxv,degree);
   minv=NormalizeDouble(minv,degree);
//--- sequence generation step is also set based on the specified precision
   stepv=NormalizeDouble(MathPow(10,-degree),degree);
   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityBeta

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dbeta() in R.

```
bool  MathProbabilityDensityBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if 1
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionBeta

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the pbeta() in R.

```
bool  MathCumulativeDistributionBeta(
   const double& x[],             // array with the values of random variable
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   const bool    tail,            // flag of calculation, if true, then the probability
   const bool    log_mode,        // flag to calculate the logarithm of the value, if
   double&       result[]         // array for values of the probability function
   );
```

<t0>Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionBeta(
   const double& x[],             // array with the values of random variable
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   double&       result[]         // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileBeta

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false. Analog of the qbeta() in R.

```
double  MathQuantileBeta(
   const double&  probability[], // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileBeta(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

tail

[in] Flag of calculation, if lower_tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomBeta

Generates a pseudorandom variable distributed according to the law of beta distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of beta distribution with the a and b parameters. In case of error it returns false. Analog of the rbeta() in R.

```
bool  MathRandomBeta(
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   const int     data_count,      // amount of required data
   double&       result[]         // array to obtain the pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsBeta

Calculates the theoretical numerical values of the first 4 moments of the beta distribution.

```
double  MathMomentsBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

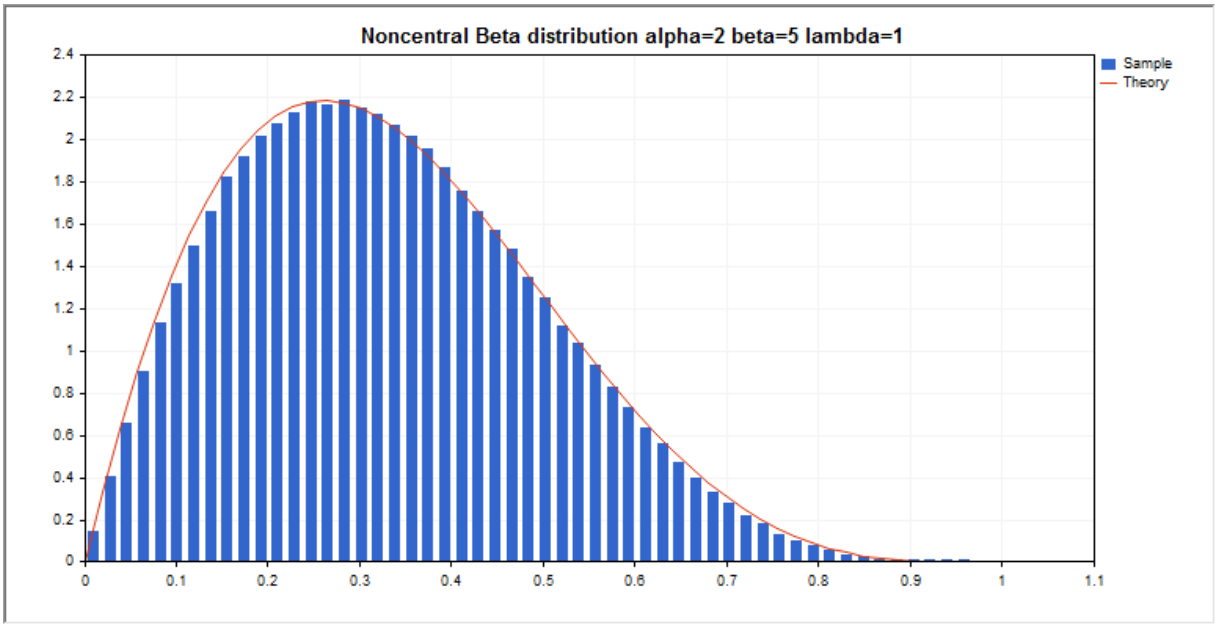
Noncentral beta distribution

This section contains functions for working with noncentral beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral beta distribution is defined by the following formula:

$$f_{NoncentralBeta}(x|a,b,\lambda)=\sum_{r=0}^{\infty}e^{-\frac{\lambda}{2}}\frac{\left(\frac{\lambda}{2}\right)^{r}}{r!}\frac{x^{a+r-1}(1-x)^{b-1}}{B(a+r,b)}$$

where:

- x — value of the random variable
- a — the first parameter of beta distribution
- b — the second parameter of beta distribution
- λ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralBeta	Calculates the probability density function of the noncentral beta distribution
MathCumulativeDistributionNoncentralBeta	Calculates the value of the noncentral beta probability distribution function
MathQuantileNoncentralBeta	Calculates the value of the inverse noncentral beta distribution function for the specified probability
MathRandomNoncentralBeta	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral beta distribution law

Function	Description
MathMomentsNoncentralBeta	Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralBeta.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double a_par=2;     // the first parameter of beta distribution (shape1)
input double b_par=5;     // the second parameter of beta distribution (shape2)
input double l_par=1;     // noncentrality parameter (lambda)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

   stepv=NormalizeDouble(MathPow(10,-degree),degree);
   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityNoncentralBeta

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the dbeta() in R.

```
bool  MathProbabilityDensityNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralBeta

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the pbeta() in R.

```
bool  MathCumulativeDistributionNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if t
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralBeta

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters for the occurrence probability of a random variable *probability*. In case of error it returns NaN.

```
double  MathQuantileNoncentralBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters for the occurrence probability of a random variable *probability*. In case of error it returns NaN.

```
double  MathQuantileNoncentralBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified probability[] array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters. In case of error it returns false. Analog of the qbeta() in R.

```
double  MathQuantileNoncentralBeta(
   const double&  probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified probability[] array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters. In case of error it returns false.

```
bool  MathQuantileNoncentralBeta(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
```

```
   const double  lambda,          // noncentrality parameter
   double&       result[]         // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralBeta

Generates a pseudorandom variable distributed according to the law of noncentral beta distribution the a, b and lambda parameters. In case of error it returns NaN.

```
double  MathRandomNoncentralBeta(
   const double  a,             // the first parameter of beta distribution (shape1)
   const double  b,             // the second parameter of beta distribution (shape2)
   const double  lambda,        // noncentrality parameter
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of noncentral beta distribution the a, b and lambda parameters. In case of error it returns false. Analog of the rbeta() in R.

```
bool  MathRandomNoncentralBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const int     data_count,     // amount of required data
   double&       result[]        // array to obtain the pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNoncentralBeta

Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution with the a, b and lambda parameters.

```
double  MathMomentsNoncentralBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

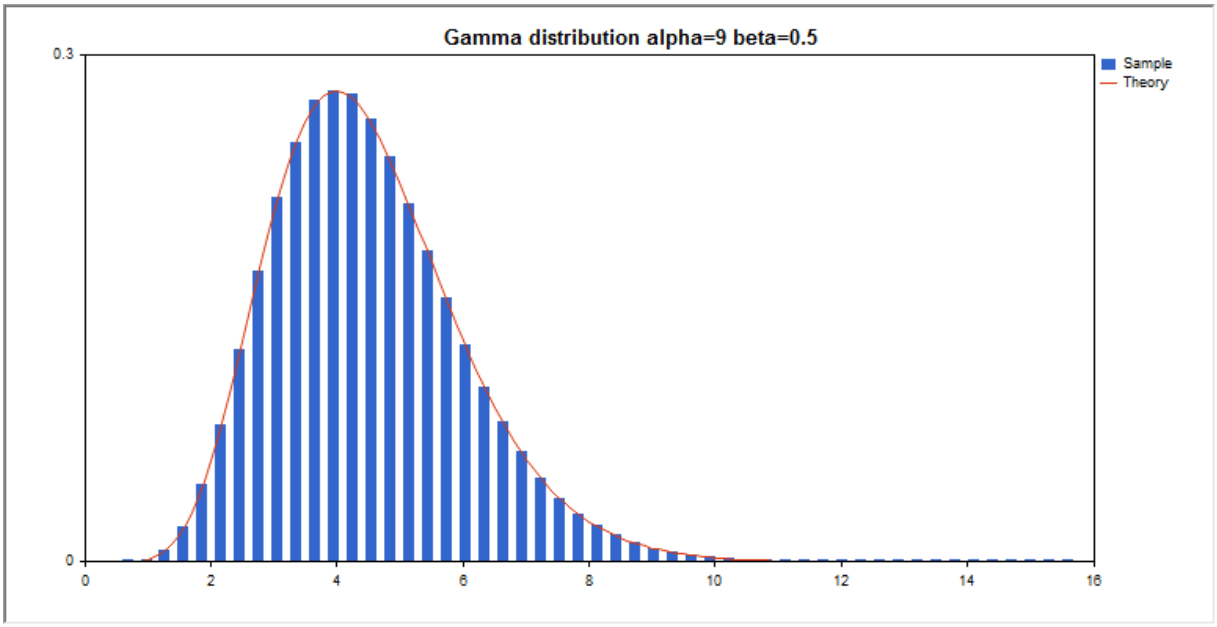
Gamma distribution

This section contains functions for working with gamma distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The gamma distribution is defined by the following formula:

$$f_{Gamma}(x|a,b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where:

- x — value of the random variable
- a — the first parameter of distribution
- b — the second parameter of distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityGamma	Calculates the probability density function of the gamma distribution
MathCumulativeDistributionGamma	Calculates the value of the gamma probability distribution function
MathQuantileGamma	Calculates the value of the inverse gamma distribution function for the specified probability
MathRandomGamma	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the gamma distribution law
MathMomentsGamma	Calculates the theoretical numerical values of the first 4 moments of the gamma distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Gamma.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double alpha=9;   // the first parameter of distribution (shape)
input double beta=0.5;  // the second parameter of distribution (scale)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=51;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals
   double y[];          // the number of values from the sample falling within the int
   double data[];       // sample of random values
   double max,min;      // the maximum and minimum values in the sample
//--- obtain a sample from the gamma distribution
   MathRandomGamma(alpha,beta,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityGamma(x2,alpha,beta,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
   for(int i=0; i<ncells; i++)
      y[i]/=k;
//--- output charts
   CGraphic graphic;
   if(ObjectFind(chart,name)<0)
```

```
      graphic.Create(chart,name,0,0,0,780,380);
   else
      graphic.Attach(chart,name);
   graphic.BackgroundMain(StringFormat("Gamma distribution alpha=%G beta=%G",alpha,bet
   graphic.BackgroundMainSize(16);
//--- disable automatic scaling of the Y axis
   graphic.YAxis().AutoScale(false);
   graphic.YAxis().Max(NormalizeDouble(theor_max,1));
   graphic.YAxis().Min(0);
//--- plot all curves
   graphic.CurveAdd(x,y,CURVE_HISTOGRAM,"Sample").HistogramWidth(6);
//--- and now plot the theoretical curve of the distribution density
   graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory");
   graphic.CurvePlotAll();
//--- plot all curves
   graphic.Update();
  }
//+------------------------------------------------------------------+
//|  Calculate frequencies for data set                              |
//+------------------------------------------------------------------+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequenc
                             double &maxv,double &minv,const int cells=10)
  {
   if(cells<=1) return (false);

   stepv=NormalizeDouble(MathPow(10,-degree),degree);
   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityGamma

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dgamma() in R.

```
bool  MathProbabilityDensityGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if 1
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionGamma

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the pgamma() in R.

```
bool  MathCumulativeDistributionGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale)

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileGamma

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileGamma(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileGamma(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false. Analog of the qgamma() in R.

```
double  MathQuantileGamma(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileGamma(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomGamma

Generates a pseudorandom variable distributed according to the law of gamma distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomGamma(
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of gamma distribution with the a and b parameters. In case of error it returns false. Analog of the rgamma() in R.

```
bool  MathRandomGamma(
   const double  a,               // the first parameter of the distribution (shape)
   const double  b,               // the second parameter of the distribution (scale)
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsGamma

Calculates the theoretical numerical values of the first 4 moments of the gamma distribution with the a and b parameters.

```
double  MathMomentsGamma(
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

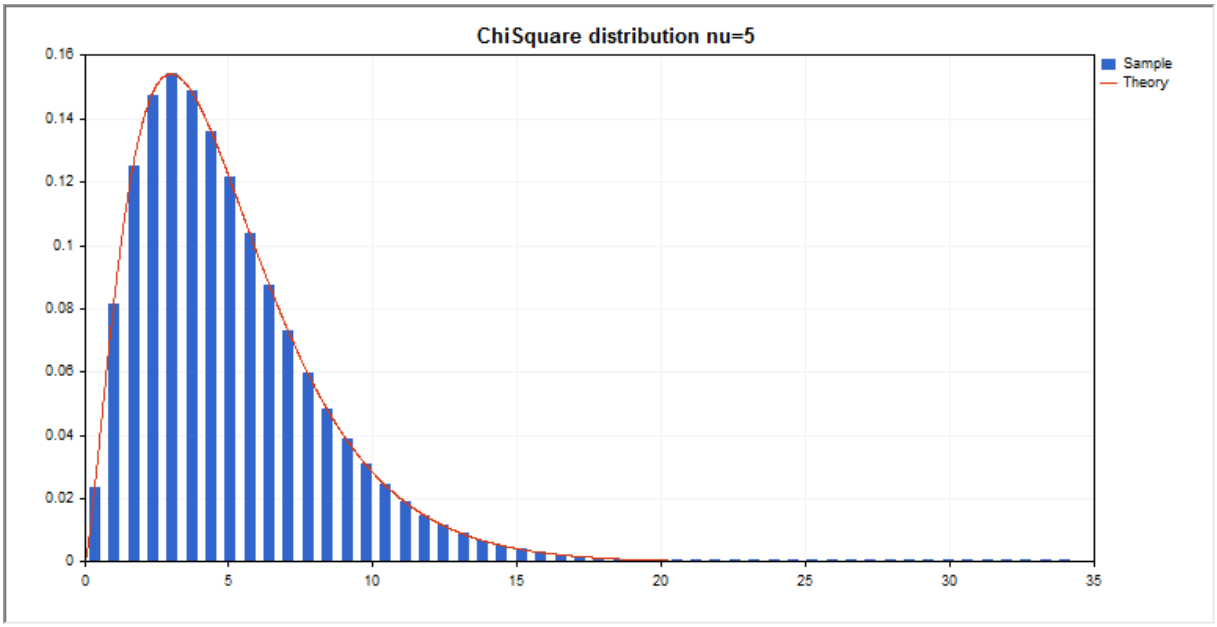
Chi-squared distribution

This section contains functions for working with chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The chi-squared distribution is defined by the following formula:

$$f_{Chi-Square}(x|\nu) = \frac{x^{\frac{(\nu-2)}{2}} e^{-\frac{x}{2}}}{2^{\frac{\nu}{2}}\Gamma\left(\frac{\nu}{2}\right)}$$

where:

- x — value of the random variable
- ν — number of degrees of freedom



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityChiSquare	Calculates the probability density function of the chi-squared distribution
MathCumulativeDistributionChiSquare	Calculates the value of the chi-squared probability distribution function
MathQuantileChiSquare	Calculates the value of the inverse chi-squared distribution function for the specified probability
MathRandomChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the chi-squared distribution law

Function	Description
MathMomentsChiSquare	Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\ChiSquare.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=5;     // the number of degrees of freedom
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;        // the number of values in the sample
   int ncells=51;        // the number of intervals in the histogram
   double x[];           // centers of the histogram intervals
   double y[];           // the number of values from the sample falling within the int
   double data[];        // sample of random values
   double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the chi-squared distribution
   MathRandomChiSquare(nu_par,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityChiSquare(x2,nu_par,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
   for(int i=0; i<ncells; i++)
```

```
      y[i]/=k;
//--- output charts

   if((maxv-minv)/stepv<10)
      stepv/=10.;
  }
```

MathProbabilityDensityChiSquare

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the dchisq() in R.

```
bool  MathProbabilityDensityChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom)

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionChiSquare

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN

```
double  MathCumulativeDistributionChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the pchisq() in R.

```
bool  MathCumulativeDistributionChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileChiSquare

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns NaN.

```
double  MathQuantileChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns NaN.

```
double  MathQuantileChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false. Analog of the qchisq() in R.

```
double  MathQuantileChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false.

```
bool  MathQuantileChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomChiSquare

Generates a pseudorandom variable distributed according to the law of chi-squared distribution with the nu parameter. In case of error it returns NaN.

```
double  MathRandomChiSquare(
   const double  nu,            // parameter of distribution (number of degrees of fre
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of chi-squared distribution with the nu parameter. In case of error it returns false. Analog of the rchisq() in R.

```
bool  MathRandomChiSquare(
   const double  nu,             // parameter of distribution (number of degrees of fr
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsChiSquare

Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution with the nu parameter.

```
double  MathMomentsChiSquare(
   const double  nu,              // parameter of distribution (number of degrees of fi
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

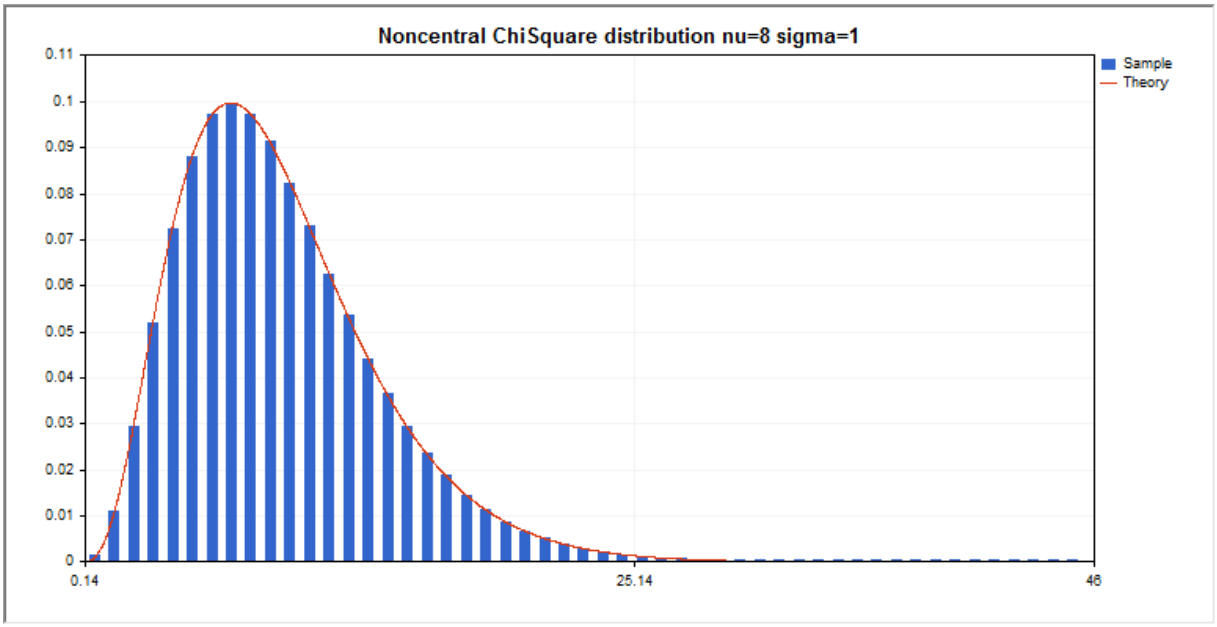
Noncentral chi-squared distribution

This section contains functions for working with noncentral chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral chi-squared distribution is defined by the following formula:

$$f_{NoncentralChiSquare}(x|\nu,\sigma)=\frac{1}{2^{\frac{\nu}{2}}\Gamma\left(\frac{1}{2}\right)}x^{\frac{\nu}{2}-1}e^{-\frac{(x+\sigma)}{2}}\sum_{r=0}^{\infty}\frac{(\lambda x)^r}{(2r)!}\frac{\Gamma\left(\frac{1}{2}+r\right)}{\Gamma\left(\frac{\nu}{2}+r\right)}$$

where:

- x — value of the random variable
- ν — number of degrees of freedom
- σ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralChiSquare	Calculates the probability density function of the noncentral chi-squared distribution
MathCumulativeDistributionNoncentralChiSquare	Calculates the value of the noncentral chi-squared probability distribution function
MathQuantileNoncentralChiSquare	Calculates the value of the inverse noncentral chi-squared distribution function for the specified probability
MathRandomNoncentralChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral chi-squared distribution law

Function	Description
MathMomentsNoncentralChiSquare	Calculates the theoretical numerical values of the first 4 moments of the noncentral chi-squared distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralChiSquare.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=8;     // the number of degrees of freedom
input double si_par=1;     // noncentrality parameter
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;        // the number of values in the sample
   int ncells=51;        // the number of intervals in the histogram
   double x[];           // centers of the histogram intervals
   double y[];           // the number of values from the sample falling within the int
   double data[];        // sample of random values
   double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the noncentral chi-squared distribution
   MathRandomNoncentralChiSquare(nu_par,si_par,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityNoncentralChiSquare(x2,nu_par,si_par,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
```

```
   for(int i=0; i<ncells; i++)
      y[i]/=k;
//--- output charts
   CGraphic graphic;
   if(ObjectFind(chart,name)<0)
      graphic.Create(chart,name,0,0,0,780,380);
   else

  }
```

MathProbabilityDensityNoncentralChiSquare

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dchisq() in R.

```
bool  MathProbabilityDensityNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralChiSquare

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=true, then the p
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the pchisq() in R.

```
bool  MathCumulativeDistributionNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=true, then the
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralChiSquare

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns false. Analog of the qchisq() in R.

```
double  MathQuantileNoncentralChiSquare(
   const double&  probability[],  // array with probability values of random variable
   const double  nu,              // parameter of distribution (number of degrees of f
   const double  sigma,           // noncentrality parameter
   const bool    tail,            // flag of calculation, if false, then calculation i
   const bool    log_mode,        // flag of calculation, if log_mode=true, calculatio
   double&       result[]         // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function. In case of error it returns false.

```
bool  MathQuantileNoncentralChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralChiSquare
