   double get(const ENUM_OBJECT_PROPERTY_DOUBLE property, const int modifier = 0)
   {
      return ObjectGetDouble(chart(), name(), property, modifier);
   }
   string get(const ENUM_OBJECT_PROPERTY_STRING property, const int modifier = 0)
   {
      return ObjectGetString(chart(), name(), property, modifier);
   }
   bool set(const ENUM_OBJECT_PROPERTY_INTEGER property, const long value,
      const int modifier = 0)
   {
      return ObjectSetInteger(chart(), name(), property, modifier, value);
   }
   bool set(const ENUM_OBJECT_PROPERTY_DOUBLE property, const double value,
      const int modifier = 0)
   {
      return ObjectSetDouble(chart(), name(), property, modifier, value);
   }
   bool set(const ENUM_OBJECT_PROPERTY_STRING property, const string value,
      const int modifier = 0)
   {
      return ObjectSetString(chart(), name(), property, modifier, value);
   }

   virtual string name() = 0;
   virtual void name(const string) { }
   virtual long chart() { return 0; }
   virtual void chart(const long) { }
};
```

Let's implement these methods in the descendant class (later we will supplement the class hierarchy with the object property monitor, similar to the chart property monitor).

```
class ObjectSelector: public ObjectProxy
{
protected:
   long host; // chart ID
   string id; // chart ID
public:
   ObjectSelector(const string _id, const long _chart = 0): id(_id), host(_chart) { }

   virtual string name()
   {
      return id;
   }
   virtual void name(const string _id)
   {
      id = _id;
   }
   virtual void chart(const long _chart) override
   {
      host = _chart;
   }
};
```

We have separated the abstract interface *ObjectProxy* and its minimal implementation in *ObjectSelector* because later we may need to implement an array of proxies for multiple objects of the same type, for example. Then it is enough to store an array of names or their common prefix in the new "multiselector" class and ensure that one of them is returned from the *name* method by calling the overloaded operator []:*multiSelector[i].get(OBJPROP_XYZ)*.

Now let's go back to the *ObjectCleanup2.mq5* script and describe two input variables for specifying a color and an anchor point as additional conditions for selecting objects to be deleted.

```
// ObjectCleanup2.mq5
...
input color CustomColor = clrRed;
input ENUM_ARROW_ANCHOR CustomAnchor = ANCHOR_TOP;
```

Let's pass these values to the *CustomDeleteAllObjects* function, and the new condition checks in the loop over objects can be formulated more compactly thanks to the mediator class.

```
#include <MQL5Book/ObjectMonitor.mqh>

void OnStart()
{
   const int n = UseCustomDeleteAll ?
      CustomDeleteAllObjects(0, ObjNamePrefix, CustomColor, CustomAnchor) :
      ObjectsDeleteAll(0, ObjNamePrefix);
   PrintFormat("%d objects deleted", n);
}

int CustomDeleteAllObjects(const long chart, const string prefix,
   color clr, ENUM_ARROW_ANCHOR anchor,
   const int window = -1, const int type = -1)
{
   int count = 0;
   for(int i = ObjectsTotal(chart, window, type) - 1; i >= 0; --i)
   {
      const string name = ObjectName(chart, i, window, type);

      ObjectSelector s(name);
      ResetLastError();
      if((StringLen(prefix) == 0 || StringFind(s.get(OBJPROP_NAME), prefix) == 0)
      && s.get(OBJPROP_COLOR) == CustomColor
      && s.get(OBJPROP_ANCHOR) == CustomAnchor
      && _LastError != 4203) // OBJECT_WRONG_PROPERTY
      {
         count += ObjectDelete(chart, name);
      }
   }
   return count;
}
```

It is important to note that we specify the name of the object (and the implicit identifier of the current chart 0) only once when creating the *ObjectSelector* object. Further, all properties are requested by the *get* method with a single parameter describing the desired property, and the appropriate *ObjectGet* function will be chosen by the compiler automatically.

The additional check for error code 4203 (OBJECT_WRONG_PROPERTY) allows filtering out objects that do not have the requested property, such as OBJPROP_ANCHOR. In this way, in particular, it is possible to make a selection in which all types of arrows will fall (without the need to separately request different types of OBJ_ARROW_XYZ), but lines and "events" will be excluded from processing.

This is easy to check by first running the *ObjectSimpleShowcase.mq5* script on the chart (it will create 14 objects of different types) and then *ObjectCleanup2.mq5*. If you turn on the *UseCustomDeleteAll* mode, there will be 5 non-deleted objects on the chart: OBJ_VLINE, OBJ_HLINE, OBJ_ARROW_BUY, OBJ_ARROW_SELL, and OBJ_EVENT. The first two and the last do not have the OBJPROP_ANCHOR property, and the buy and sell arrows do not pass by color (it is assumed that the color of all other created objects is red by default).

However, *ObjectSelector* is provided not only for the sake of the above simple application. It is the basis for creating a property monitor for a single object, similar to what was implemented for charts. So the *ObjectMonitor.mqh* header file contains something more interesting.

```
class ObjectMonitorInterface: public ObjectSelector
{
public:
   ObjectMonitorInterface(const string _id, const long _chart = 0):
      ObjectSelector(_id, _chart) { }
   virtual int snapshot() = 0;
   virtual void print() { };
   virtual int backup() { return 0; }
   virtual void restore() { }
   virtual void applyChanges(ObjectMonitorInterface *reference) { }
};
```

This set of methods should remind you *ChartModeMonitorInterface* from *ChartModeMonitor.mqh*. The only innovation is the *applyChanges* method, which copies the properties of one object to another.

Based on *ObjectMonitorInterface*, here is the description of the basic implementation of a property monitor for a pair of template types: a property value type (one of *long*, *double*, or *string*) and the enumeration type (one of ENUM_OBJECT_PROPERTY_-ish).

```
template<typename T,typename E>
class ObjectMonitorBase: public ObjectMonitorInterface
{
protected:
   MapArray<E,T> data;  // array of pairs [property, value], current state
   MapArray<E,T> store; // backup (filled on demand)
   MapArray<E,T> change;// committed changes between two states
   ...
```

The *ObjectMonitorBase* constructor has two parameters: the name of the object and an array of flags with identifiers of the properties to be observed in the specified object. A significant portion of this code is almost identical to *ChartModeMonitor*. In particular, as before, an array of flags is passed to the helper method *detect*, the main purpose of which is to identify those integer constants that are elements of the *E* enumeration, and weed out all the rest. The only addition that needs to be clarified is getting a property with the number of levels in an object via *ObjectGetInteger(0, id, OBJPROP_LEVELS)*. This is necessary to support iteration of properties with multiple values due to the presence of levels (for example, Fibonacci). For objects without levels, we will get the quantity 0, and such a property will be the usual, scalar one.

```
public:
   ObjectMonitorBase(const string _id, const int &flags[]): ObjectMonitorInterface(_i
   {
      const int levels = (int)ObjectGetInteger(0, id, OBJPROP_LEVELS);
      for(int i = 0; i < ArraySize(flags); ++i)
      {
         detect(flags[i], levels);
      }
   }
   ...
```

Of course, the *detect* method is somewhat different from what we saw in *ChartModeMonitor*. Recall that to begin with, it contains a fragment with a check if the *v* constant belongs to the *E* enumeration, using a call to the *EnumToString* function: if there is no such element in the enumeration, an error code will be raised. If the element exists, we add the value of the corresponding property to the *data* array.

```
// ChartModeMonitor.mqh
bool detect(const int v)
{
   ResetLastError();
   conststrings = EnumToString((E)v); // resulting string is not important
   if(_LastError == 0)                // analyze the error code
   {
      data.put((E)v, get((E)v));
      return true;
   }
   return false;
}
```

In the object monitor, we are forced to complicate this scheme, since some properties are multi-valued due to the *modifier* parameter in the *ObjectGet* and *ObjectSet* functions.

So we introduce a static array *modifiables* with a list of those properties that modifiers support (each property will be discussed in detail later). The bottom line is that for such multi-valued properties, you need to read them and store them in the *data* array not once, but several times.

```
// ObjectMonitor.mqh
   bool detect(const int v, const int levels)
   {
      // the following properties support multiple values
      static const int modifiables[] =
      {
         OBJPROP_TIME,        // anchor point by time
         OBJPROP_PRICE,       // anchor point by price
         OBJPROP_LEVELVALUE,  // level value
         OBJPROP_LEVELTEXT,   // inscription on the level line
         // NB: the following properties do not generate errors when exceeded
         // actual number of levels or files
         OBJPROP_LEVELCOLOR,  // level line color
         OBJPROP_LEVELSTYLE,  // level line style
         OBJPROP_LEVELWIDTH,  // width of the level line
         OBJPROP_BMPFILE,     // image files
      };
      ...
```

Here, we also use the trick with *EnumToString* to check the existence of a property with the *v* identifier. If successful, we check if it is in the list of *modifiables* and set the corresponding flag *modifiable* to *true* or *false*.

```
      bool result = false;
      ResetLastError();
   conststrings =EnumToString((E)v); // resulting string is not important
   if(_LastError ==0)// analyze the error code
      {
         bool modifiable = false;
         for(int i = 0; i < ArraySize(modifiables); ++i)
         {
            if(v == modifiables[i])
            {
               modifiable = true;
               break;
            }
         }
         ...
```

By default, any property is considered unambiguous and therefore the required number of readings through the *ObjectGet* function or entries via the *ObjectSet* function is equal to 1 (the *k* variable below).

```
         int k = 1;
         // for properties with modifiers, set the correct amount
         if(modifiable)
         {
            if(levels > 0) k = levels;
            else if(v == OBJPROP_TIME || v == OBJPROP_PRICE) k = MOD_MAX;
            else if(v == OBJPROP_BMPFILE) k = 2;
         }
```

If an object supports levels, we limit the potential number of reads/writes with the *levels* parameter (as we recall, it is obtained in the calling code from the OBJPROP_LEVELS property).

For the OBJPROP_BMPFILE property, as we will soon learn, only two states are allowed: on (button pressed, flag set) or off (button released, flag cleared), so *k = 2*.

Finally, object coordinates - OBJPROP_TIME and OBJPROP_PRICE - are convenient because they generate an error when trying to read/write a non-existent anchor point. Therefore we assign to *k* some obviously large value of MOD_MAX, and then we can interrupt the cycle of reading points at a non-zero value *_LastError*.

```
            // read property value - one or many
            for(int i = 0; i < k; ++i)
            {
               ResetLastError();
               T temp = get((E)v, i);
               // if there is no i-th modifier, we will get an error and break the loop
               if(_LastError != 0) break;
               data.put((E)MOD_COMBINE(v, i), temp);
               result = true;
            }
         }
         return result;
      }
```

Since one property can have several values, which are read in a loop up to *k*, we can no longer simply write *data.put((E)v, get((E)v))*. We need to somehow combine the property identifier *v* and its modification number *i*. Fortunately, the number of properties is also limited in an integer constant (type*int*) no more than two lower bytes are occupied. So we can use bitwise operators to put *i* to the top byte. The MOD_COMBINE macro has been developed for this purpose.

```
#define MOD_COMBINE(V,I) (V | (I << 24))
```

Of course, reverse macros are provided to retrieve the property ID and revision number.

```
#define MOD_GET_NAME(V)  (V & 0xFFFFFF)
#define MOD_GET_INDEX(V) (V >> 24)
```

For example, here we can see how they are used in the *snapshot* method.

```
virtual int snapshot() override
{
   MapArray<E,T> temp;
   change.reset();

   // collect all required properties in temp
   for(int i = 0; i < data.getSize(); ++i)
   {
      const E e = (E)MOD_GET_NAME(data.getKey(i));
      const int m = MOD_GET_INDEX(data.getKey(i));
      temp.put((E)data.getKey(i), get(e, m));
   }

   int changes = 0;
   // compare previous and new state
   for(int i = 0; i < data.getSize(); ++i)
   {
      if(data[i] != temp[i])
      {
         // save the differences in the change array
         if(changes == 0) Print(id);
         const E e = (E)MOD_GET_NAME(data.getKey(i));
         const int m = MOD_GET_INDEX(data.getKey(i));
         Print(EnumToString(e), (m > 0 ? (string)m : ""), " ", data[i], " -> ", te
         change.put(data.getKey(i), temp[i]);
         changes++;
      }
   }

   // save the new state as current
   data = temp;
   return changes;
}
```

This method repeats all the logic of the method of the same name in *ChartModeMonitor.mqh*, however, to read properties everywhere, you must first extract the property name from the stored key using MOD_GET_NAME and the number using MOD_GET_INDEX.

A similar complication has to be done in the *restore* method.

```
virtual void restore() override
{
   data = store;
   for(int i = 0; i < data.getSize(); ++i)
   {
      const E e = (E)MOD_GET_NAME(data.getKey(i));
      const int m = MOD_GET_INDEX(data.getKey(i));
      set(e, data[i], m);
   }
}
```

The most interesting innovation of *ObjectMonitorBase* is how it works with changes.

```
   MapArray<E,T> * const getChanges()
   {
      return &change;
   }

   virtual void applyChanges(ObjectMonitorInterface *intf) override
   {
      ObjectMonitorBase *reference = dynamic_cast<ObjectMonitorBase<T,E> *>(intf);
      if(reference)
      {
         MapArray<E,T> *event = reference.getChanges();
         if(event.getSize() > 0)
         {
            Print("Modifing ", id, " by ", event.getSize(), " changes");
            for(int i = 0; i < event.getSize(); ++i)
            {
               data.put(event.getKey(i), event[i]);
               const E e = (E)MOD_GET_NAME(event.getKey(i));
               const int m = MOD_GET_INDEX(event.getKey(i));
               Print(EnumToString(e), " ", m, " ", event[i]);
               set(e, event[i], m);
            }
         }
      }
   }
```

Passing to the *applyChanges* method states of the monitor of another object, we can adopt all the latest changes from it.

To support properties of all three basic types (*long*,*double*,*string*), we need to implement the *ObjectMonitor* class (analog of *ChartModeMonitor* from *ChartModeMonitor.mqh*).

```
class ObjectMonitor: public ObjectMonitorInterface
{
protected:
   AutoPtr<ObjectMonitorInterface> m[3];

   ObjectMonitorInterface *getBase(const int i)
   {
      return m[i][];
   }

public:
   ObjectMonitor(const string objid, const int &flags[]): ObjectMonitorInterface(obji
   {
      m[0] = new ObjectMonitorBase<long,ENUM_OBJECT_PROPERTY_INTEGER>(objid, flags);
      m[1] = new ObjectMonitorBase<double,ENUM_OBJECT_PROPERTY_DOUBLE>(objid, flags);
      m[2] = new ObjectMonitorBase<string,ENUM_OBJECT_PROPERTY_STRING>(objid, flags);
   }
   ...
```

The previous code structure is also preserved here, and only methods have been added to support changes and names (charts, as we remember, do not have names).

```
   ...
   virtual string name() override
   {
      return m[0][].name();
   }

   virtual void name(const string objid) override
   {
      m[0][].name(objid);
      m[1][].name(objid);
      m[2][].name(objid);
   }

   virtual void applyChanges(ObjectMonitorInterface *intf) override
   {
      ObjectMonitor *monitor = dynamic_cast<ObjectMonitor *>(intf);
      if(monitor)
      {
         m[0][].applyChanges(monitor.getBase(0));
         m[1][].applyChanges(monitor.getBase(1));
         m[2][].applyChanges(monitor.getBase(2));
      }
   }
```

Based on the created object monitor, it is easy to implement several tricks that are not supported in the terminal. In particular, this is the creation of copies of objects and group editing of objects.

Script ObjectCopy

The *ObjectCopy.mq5* script demonstrates how to copy selected objects. At the beginning of its *OnStart* function, we fill the *flags* array with consecutive integers that are candidates for elements of ENUM_OBJECT_PROPERTY_ enumerations of different types. The numbering of the enumeration elements has a pronounced grouping by purpose, and there are large gaps between the groups (apparently, a margin for future elements), so the formed array is quite large: 2048 elements.

```
#include <MQL5Book/ObjectMonitor.mqh>

#define PUSH(A,V) (A[ArrayResize(A, ArraySize(A) + 1) - 1] = V)

void OnStart()
{
   int flags[2048];
   // filling the array with consecutive integers, which will be
   // checked against the elements of enumerations of object properties,
   // invalid values will be discarded in the monitor's detect method
   for(int i = 0; i < ArraySize(flags); ++i)
   {
      flags[i] = i;
   }
   ...
```

Next, we collect into an array the names of objects that are currently selected on the chart. For this, we use the OBJPROP_SELECTED property.

```
   string selected[];
   const int n = ObjectsTotal(0);
   for(int i = 0; i < n; ++i)
   {
      const string name = ObjectName(0, i);
      if(ObjectGetInteger(0, name, OBJPROP_SELECTED))
      {
         PUSH(selected, name);
      }
   }
   ...
```

Finally, in the main loop over the selected elements, we read the properties of each object, form the name of its copy, and create an object under it with the same set of attributes.

```
   for(int i = 0; i < ArraySize(selected); ++i)
   {
      const string name = selected[i];

     // make a backup of the properties of the current object using the monitor
      ObjectMonitor object(name, flags);
      object.print();
      object.backup();
      // form a correct, appropriate name for the copy
      const string copy = GetFreeName(name);

      if(StringLen(copy) > 0)
      {
         Print("Copy name: ", copy);
         // create an object of the same type OBJPROP_TYPE
         ObjectCreate(0, copy,
            (ENUM_OBJECT)ObjectGetInteger(0, name, OBJPROP_TYPE),
            ObjectFind(0, name), 0, 0);
         // change the name of the object in the monitor to a new one
         object.name(copy);
         // restore all properties from the backup to a new object
         object.restore();
      }
      else
      {
         Print("Can't create copy name for: ", name);
      }
   }
}
```

It is important to note here that the OBJPROP_TYPE property is one of the few read-only properties, and therefore it is vital to create an object of the required type to begin with.

The helper function *GetFreeName* tries to append the string "/Copy #x" to the object name, where x is the copy number. Thus, by running the script several times, you can create the 2nd, 3rd, and so on copies.

```
string GetFreeName(const string name)
{
   const string suffix = "/Copy №";
   // check if there is a copy in the suffix name
   const int pos = StringFind(name, suffix);
   string prefix;
   int n;

   if(pos <= 0)
   {
      // if suffix is not found, assume copy number 1
      const string candidate = name + suffix + "1";
      // checking if the copy name is free, and if so, return it
      if(ObjectFind(0, candidate) < 0)
      {
         return candidate;
      }
      // otherwise, prepare for a loop with iteration of copy numbers
      prefix = name;
      n = 0;
   }
   else
   {
      // if the suffix is found, select the name without it
      prefix = StringSubstr(name, 0, pos);
      // and find the copy number in the string
      n = (int)StringToInteger(StringSubstr(name, pos + StringLen(suffix)));
   }

   Print("Found: ", prefix, " ", n);
   // loop trying to find a free copy number above n, but no more than 1000
   for(int i = n + 1; i < 1000; ++i)
   {
      const string candidate = prefix + suffix + (string)i;
      // check for the existence of an object with a name ending "Copy #i"
      if(ObjectFind(0, candidate) < 0)
      {
         return candidate; // return vacant copy name
      }
   }
   return NULL; // too many copies
}
```

The terminal remembers the last settings of a particular type of object, and if they are created one after the other, this is equivalent to copying. However, the settings usually change in the process of working with different charts, and if after a while there is a need to duplicate some "old" object, then the settings for it, as a rule, have to be done completely. This is especially expensive for object types with a large number of properties, for example, Fibonacci tools. In such cases, this script will come in handy.

Some of the pictures from this chapter, which contain objects of the same type, were created using this script.

ObjectGroupEdit indicator

The second example of using *ObjectMonitor* is the *ObjectGroupEdit.mq5* indicator, which allows you to edit the properties of a group of selected objects at once.

Imagine that we have selected several objects on the chart (not necessarily of the same type), for which it is necessary to uniformly change one or another property. Next, we open the properties dialog of any of these objects, configure it, and by clicking *OK* these changes are applied to all selected objects. This is how our next MQL program works.

We needed an indicator as a type of program because it involves chart events. For this aspect of MQL5 programming, there will be a whole dedicated chapter, but we will get to know some of the basics right now.

Since the indicator does not have charts, the *#property* directives contain zeros and the *OnCalculate* function is virtually empty.

```
#property indicator_chart_window
#property indicator_buffers 0
#property indicator_plots   0

int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   return rates_total;
}
```

To automatically generate a complete set of all properties for an object, we will again use an array of 2048 elements with consecutive integer values. We will also provide an array for the names of the selected elements and an array of monitor objects of the *ObjectMonitor* class.

```
int consts[2048];
string selected[];
ObjectMonitor *objects[];
```

In the *OnInit* handler, we initialize the array of numbers and start the timer.

```
void OnInit()
{
   for(int i = 0; i < ArraySize(consts); ++i)
   {
      consts[i] = i;
   }

   EventSetTimer(1);
}
```

In the timer handler, we save the names of the selected objects in an array. If the selection list has changed, you need to reconfigure the monitor objects, for which the auxiliary *TrackSelectedObjects* function is called.

```
void OnTimer()
{
   string updates[];
   const int n = ObjectsTotal(0);
   for(int i = 0; i < n; ++i)
   {
      const string name = ObjectName(0, i);
      if(ObjectGetInteger(0, name, OBJPROP_SELECTED))
      {
         PUSH(updates, name);
      }
   }

   if(ArraySize(selected) != ArraySize(updates))
   {
      ArraySwap(selected, updates);
      Comment("Selected objects: ", ArraySize(selected));
      TrackSelectedObjects();
   }
}
```

The *TrackSelectedObjects* function itself is quite simple: delete the old monitors and create new ones. If you wish, you can make it more intelligent by maintaining the unchanged part of the selection.

```
void TrackSelectedObjects()
{
   for(int j = 0; j < ArraySize(objects); ++j)
   {
      delete objects[j];
   }

   ArrayResize(objects, 0);

   for(int i = 0; i < ArraySize(selected); ++i)
   {
      const string name = selected[i];
      PUSH(objects, new ObjectMonitor(name, consts));
   }
}
```

Recall that when creating a monitor object, it immediately takes a "cast" of all the properties of the corresponding graphical object.

Now we finally get to the part where events come into play. As was already mentioned in the overview of event functions, the handler is responsible for the *OnChartEvent* events on the chart. In this example, we are interested in a specific CHARTEVENT_OBJECT_CHANGE event: it occurs when the user changes any attributes in the object's properties dialog. The name of the modified object is passed in the *sparam* parameter.

If this name matches one of the monitored objects, we ask the monitor to make a new snapshot of its properties, that is, we call *objects[i].snapshot()*.

```
void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   if(id == CHARTEVENT_OBJECT_CHANGE)
   {
      Print("Object changed: ", sparam);
      for(int i = 0; i < ArraySize(selected); ++i)
      {
         if(sparam == selected[i])
         {
            const int changes = objects[i].snapshot();
            if(changes > 0)
            {
               for(int j = 0; j < ArraySize(objects); ++j)
               {
                  if(j != i)
                  {
                     objects[j].applyChanges(objects[i]);
                  }
               }
            }
            ChartRedraw();
            break;
         }
      }
   }
}
```

If the changes are confirmed (and it is unlikely otherwise), their number in the *changes* variable will be greater than 0. Then a loop is started over all the selected objects, and the detected changes are applied to each of them, except for the original one.

Since we can potentially change many objects, we call the chart redraw request with *ChartRedraw*.

In the *OnDeinit* handler, we remove all monitors.

```
void OnDeinit(const int)
{
   for(int j = 0; j < ArraySize(objects); ++j)
   {
      delete objects[j];
   }
   Comment("");
}
```

That's all: the new tool is ready.

This indicator allowed you to customize the general appearance of several groups of label objects in the section on Defining the object anchor point.

By the way, according to a similar principle with the help of *ObjectMonitor* you can make another popular tool that is not available in the terminal: to undo edits to object properties, as the *restore* method is ready now.

5.8.8 Main object properties

All objects have some universal attributes. The main ones are listed in the following table. We will see other general special-purpose properties later (see the Object state management, Z-order, and Visibility of objects in timeframe context sections).

Identifier	Description	Type
OBJPROP_NAME	Object name	string
OBJPROP_TYPE	Object type (r/o)	ENUM_OBJECT
OBJPROP_CREATETIME	Object creation time (r/o)	datetime
OBJPROP_TEXT	Description of the object (text contained in the object)	string
OBJPROP_TOOLTIP	Mouseover tooltip text	string

The OBJPROP_NAME property is an object identifier. Editing it is equivalent to deleting the old object and creating a new one.

For some types of objects capable of displaying text (such as labels or buttons), the OBJPROP_TEXT property is always displayed directly on the chart, inside the object. For other objects (for example, lines), this property contains a description that is displayed on the chart next to the object and only if the "Show object descriptions option" is enabled in the chart settings. In either case, OBJPROP_TEXT is displayed in the tooltip.

The OBJPROP_CREATETIME property exists only until the end of the current session and is not written to chr files.

You can change the name of an object programmatically or manually (in the object's properties dialog), while its creation time will remain the same. Looking ahead, we note that programmatic renaming does not cause any events about objects on the chart. As we are about to learn in the next chapter, manual renaming triggers three events:

- deleting an object under the old name (CHARTEVENT_OBJECT_DELETE),
- creating an object under a new name (CHARTEVENT_OBJECT_CREATE) and
- modification of a new object (CHARTEVENT_OBJECT_CHANGE).

If the OBJPROP_TOOLTIP property is not set, a tooltip is displayed for the object, automatically generated by the terminal. To disable the tooltip, set its value to "\n" (line feed).

Let's adapt the *ObjectFinder.mq5* script from the Finding objects section to log all the above properties of objects on the current chart. Let's name the new script as *ObjectListing.mq5*.

At the very beginning of *OnStart*, we will create or modify a vertical straight line located on the last bar (at the moment the script is launched). If there is an option to show object descriptions in the chart settings, then we will see the "Latest Bar At The Moment" text along the right vertical line.

```
void OnStart()
{
   const string vline = ObjNamePrefix + "current";
   ObjectCreate(0, vline, OBJ_VLINE, 0, iTime(NULL, 0, 0), 0);
   ObjectSetString(0, vline, OBJPROP_TEXT, "Latest Bar At The Moment");
   ...
```

Next, in a loop through the subwindows, we will query all objects up to *ObjectsTotal* and their main properties.

```
   int count = 0;
   const long id = ChartID();
   const int win = (int)ChartGetInteger(id, CHART_WINDOWS_TOTAL);
   // loop through subwindows
   for(int k = 0; k < win; ++k)
   {
      PrintFormat("  Window %d", k);
      const int n = ObjectsTotal(id, k);
      //loop through objects
      for(int i = 0; i < n; ++i)
      {
         const string name = ObjectName(id, i, k);
         const ENUM_OBJECT type =
            (ENUM_OBJECT)ObjectGetInteger(id, name, OBJPROP_TYPE);
         const datetime created =
            (datetime)ObjectGetInteger(id, name, OBJPROP_CREATETIME);
         const string description = ObjectGetString(id, name, OBJPROP_TEXT);
         const string hint = ObjectGetString(id, name, OBJPROP_TOOLTIP);
         PrintFormat("    %s %s %s %s %s", EnumToString(type), name,
            TimeToString(created), description, hint);
         ++count;
      }
   }

   PrintFormat("%d objects found", count);
}
```

We get the following entries in the log.

```
  Window 0
    OBJ_VLINE ObjShow-current 2021.12.21 20:20 Latest Bar At The Moment
    OBJ_VLINE abc 2021.12.21 19:25
    OBJ_VLINE xyz 1970.01.01 00:00
3 objects found
```

A zero OBJPROP_CREATETIME value (1970.01.01 00:00) means that the object was not created during the current session, but earlier.

5.8.9 Price and time coordinates

For objects of the types that exist in the quotes coordinate system, the MQL5 API supports a couple of properties for specifying time and price bindings. In the event that an object has several anchor points,

properties require the specification of a modifier parameter containing the index of the anchor point when calling the *ObjectSet* and *ObjectGet* functions.

Identifier	Description	Value type
OBJPROP_TIME	Time coordinate	datetime
OBJPROP_PRICE	Price coordinate	double

These properties are available for absolutely all objects, but it makes no sense to set or read them for objects with screen coordinates.

To demonstrate how to work with coordinates, let's analyze the bufferless indicator *ObjectHighLowChannel.mq5*. For a given segment of bars, it draws two trend lines. Their start and end points on the time axis coincide with the first and last bar of the segment, and along the price axis, the values are calculated differently for each of the lines: the highest and lowest *High* prices are used for the upper line and the highest and lowest *Low* prices are used for the lower line. As the chart updates, our impromptu channel should move with prices.

The range of bars is set using two input variables: the number of the initial bar *BarOffset* and the number of bars *BarCount*. By default, the lines are drawn at the most recent prices, because *bar offset = 0*.

```
input int BarOffset = 0;
input int BarCount = 10;

const string Prefix = "HighLowChannel-";
```

Objects have a common name prefix "HighLowChannel-".

In the *OnCalculate* handler, we monitor the emergence of new bars over the *iTime* time of the 0-th bar. As soon as the bar is formed, the prices are analyzed on the specified segment, the maximum and minimum values of the prices of each of the two types (MODE_HIGH, MODE_LOW) are taken and the auxiliary function *DrawFigure* is called for them, and this is where the work with objects takes place: the creation and modification of coordinates.

```
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   static datetime now = 0;
   if(now != iTime(NULL, 0, 0))
   {
      const int hh = iHighest(NULL, 0, MODE_HIGH, BarCount, BarOffset);
      const int lh = iLowest(NULL, 0, MODE_HIGH, BarCount, BarOffset);
      const int ll = iLowest(NULL, 0, MODE_LOW, BarCount, BarOffset);
      const int hl = iHighest(NULL, 0, MODE_LOW, BarCount, BarOffset);

      datetime t[2] = {iTime(NULL, 0, BarOffset + BarCount), iTime(NULL, 0, BarOffset
      double ph[2] = {iHigh(NULL, 0, fmax(hh, lh)), iHigh(NULL, 0, fmin(hh, lh))};
      double pl[2] = {iLow(NULL, 0, fmax(ll, hl)), iLow(NULL, 0, fmin(ll, hl))};

      DrawFigure(Prefix + "Highs", t, ph, clrBlue);
      DrawFigure(Prefix + "Lows", t, pl, clrRed);

      now = iTime(NULL, 0, 0);
   }
   return rates_total;
}
```

And here is the *DrawFigure* function itself.

```
bool DrawFigure(const string name, const datetime &t[], const double &p[],
   const color clr)
{
   if(ArraySize(t) != ArraySize(p)) return false;

   ObjectCreate(0, name, OBJ_TREND, 0, 0, 0);

   for(int i = 0; i < ArraySize(t); ++i)
   {
      ObjectSetInteger(0, name, OBJPROP_TIME, i, t[i]);
      ObjectSetDouble(0, name, OBJPROP_PRICE, i, p[i]);
   }

   ObjectSetInteger(0, name, OBJPROP_COLOR, clr);
   return true;
}
```

After the *ObjectCreate* call that guarantees the existence of an object, the appropriate ObjectSet functions for OBJPROP_TIME and OBJPROP_PRICE are called at all anchor points (two in this case).

The image below shows the result of the indicator.

Channel on two trend lines at High and Low prices

You can run the indicator in the visual tester to see how the line coordinates change on the go.

5.8.10 Anchor window corner and screen coordinates

For objects that use a coordinate system in the form of points (pixels) on the chart, you must select one of the four corners of the window, relative to which the values along the horizontal X-axis and vertical Y-axis will be counted to the anchor point on the object. These aspects are controlled by the properties in the following table.

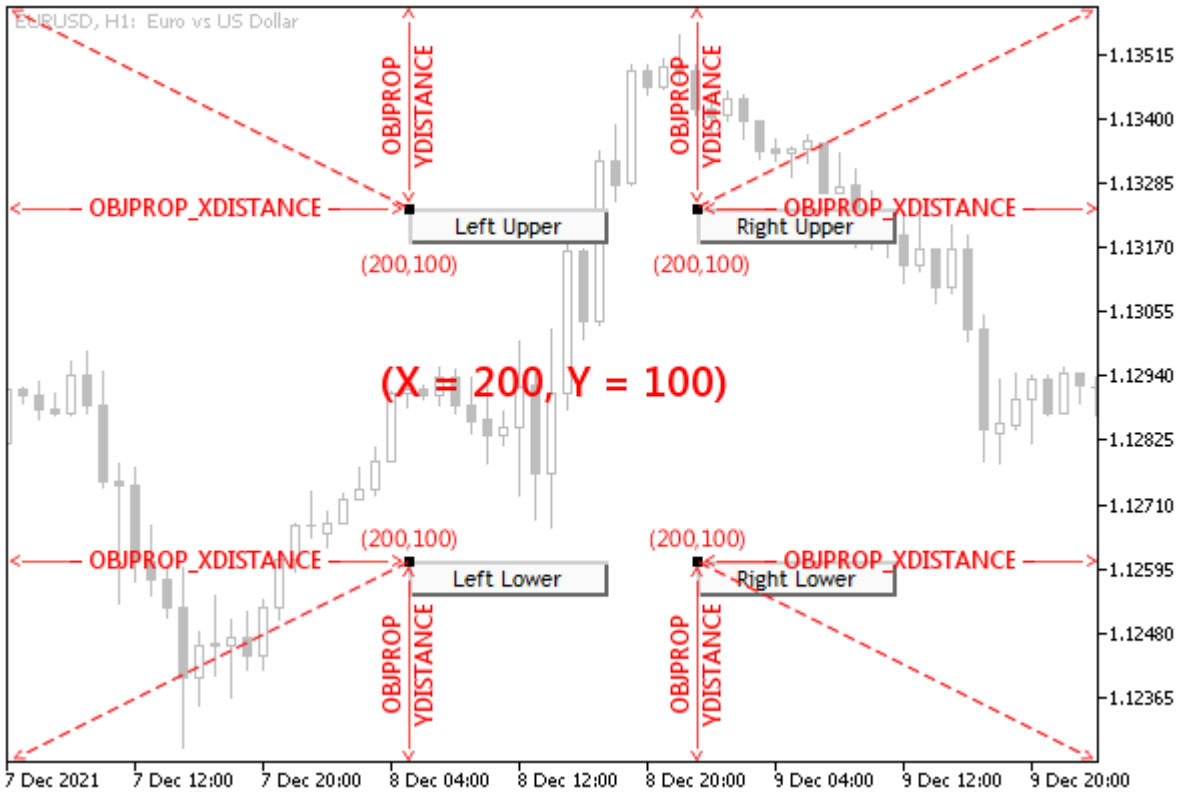
Identifier	Description	Type
OBJPROP_CORNER	Chart corner for anchoring the graphic object	ENUM_BASE_CORNER
OBJPROP_XDISTANCE	Distance in pixels along the X-axis from the anchor corner	int
OBJPROP_YDISTANCE	Distance in pixels along the Y-axis from the anchor corner	int

Valid options for OBJPROP_CORNER are summarized in the ENUM_BASE_CORNER enumeration.

Identifier	Coordinate center location
CORNER_LEFT_UPPER	Upper left corner of the window
CORNER_LEFT_LOWER	Lower left corner of the window
CORNER_RIGHT_LOWER	Lower right corner of the window
CORNER_RIGHT_UPPER	Upper right corner of the window

The default is the top left corner.

The following figure shows four Button objects with the same size and distance from the anchor corner in the window. Each of these objects differs only in the binding angle itself. Recall that buttons have one anchor point which is always located in the upper left corner of the button.

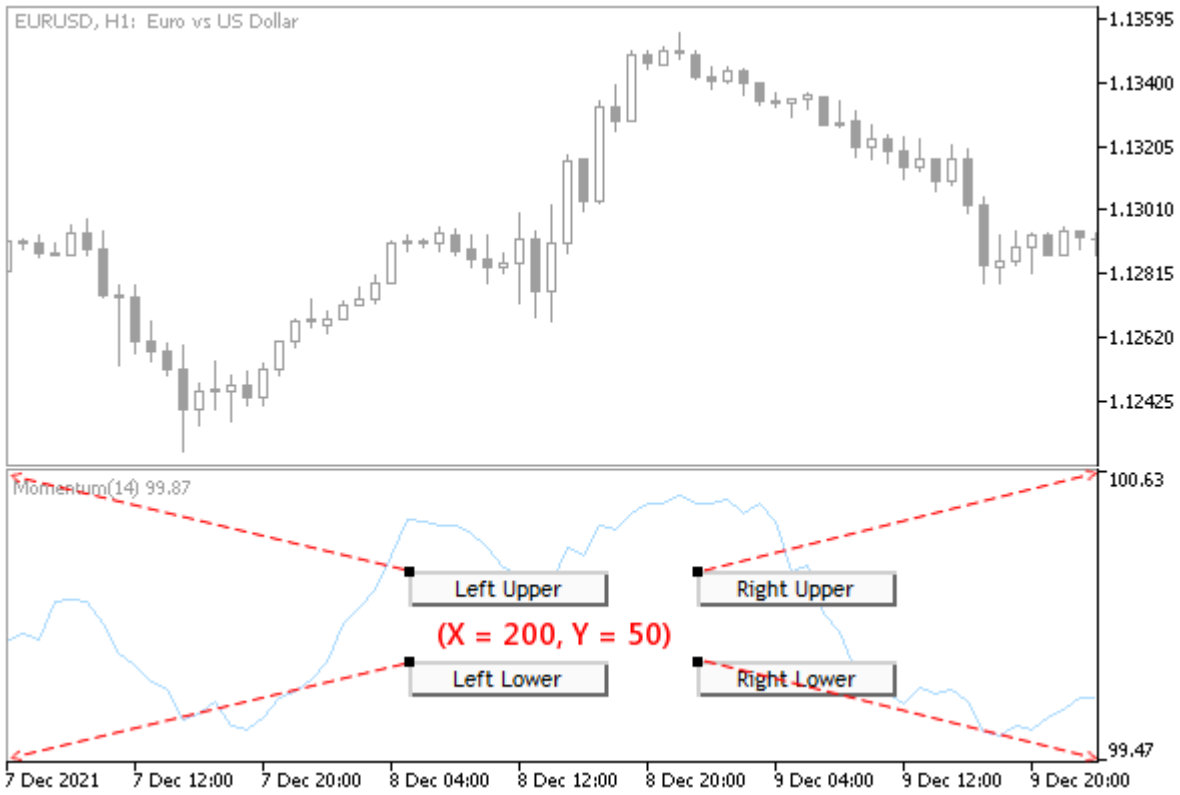


Arrangement of objects bound to different corners of the main window

All four objects are currently selected on the chart, so their anchor points are highlighted in a contrasting color.

When we talk about window corners, we mean the specific window or subwindow in which the object is located and not the entire chart. In other words, in objects in subwindows, the Y coordinate is measured from the top or bottom border of this subwindow.

The following illustration shows similar objects in a subwindow, snapped to the corners of the subwindow.



Location of objects with binding to different corners of the subwindow

Using the *ObjectCornerLabel.mq5* script the user can test the movement of a text inscription, for which the anchor angle in the window is specified in the input parameter *Corner*.

```
#property script_show_inputs

input ENUM_BASE_CORNER Corner = CORNER_LEFT_UPPER;
```

The coordinates change periodically and are displayed in the text of the inscription itself. Thus, the inscription moves in the window and, when it reaches the border, bounces off it. The object is created in the window or subwindow where the script was dropped by the mouse.

```
void OnStart()
{
   const int t = ChartWindowOnDropped();
   const string legend = EnumToString(Corner);

   const string name = "ObjCornerLabel-" + legend;
   int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS, t);
   int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
   int x = w / 2;
   int y = h / 2;
   ...
```

For correct positioning, we find the dimensions of the window (and then check if they have changed) and find the middle for the initial placement of the object: the variables with the coordinates *x* and *y*.

Next, we create and set up an inscription, without coordinates yet. It is important to note that we enable the ability to select an object (OBJPROP_SELECTABLE) and select it (OBJPROP_SELECTED), as this allows us to see the anchor point on the object itself, to which the distance from the window corner

(coordinate center) is measured. These two properties are described in more detail in the section on Object state management.

```
   ObjectCreate(0, name, OBJ_LABEL, t, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_SELECTABLE, true);
   ObjectSetInteger(0, name, OBJPROP_SELECTED, true);
   ObjectSetInteger(0, name, OBJPROP_CORNER, Corner);
   ...
```

In the variables *px* and *py*, we will record the increments of coordinates for motion emulation. The coordinate modification itself will be performed in an infinite loop until it is interrupted by the user. The iteration counter will allow periodically, at every 50 iterations, to change the direction of movement at random.

```
   int px = 0, py = 0;
   int pass = 0;

   for( ;!IsStopped(); ++pass)
   {
      if(pass % 50 == 0)
      {
         h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS, t);
         w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
         px = rand() * (w / 20) / 32768 - (w / 40);
         py = rand() * (h / 20) / 32768 - (h / 40);
      }

      // bounce off window borders so object doesn't hide
      if(x + px > w || x + px < 0) px = -px;
      if(y + py > h || y + py < 0) py = -py;
      // recalculate label positions
      x += px;
      y += py;

      // update the coordinates of the object and add them to the text
      ObjectSetString(0, name, OBJPROP_TEXT, legend
         + "[" + (string)x + "," + (string)y + "]");
      ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
      ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);

      ChartRedraw();
      Sleep(100);
   }

   ObjectDelete(0, name);
}
```

Try running the script multiple times, specifying different anchor corners.

In the next section, we'll augment this script by also controlling the anchor point on the object.

5.8.11 Defining anchor point on an object

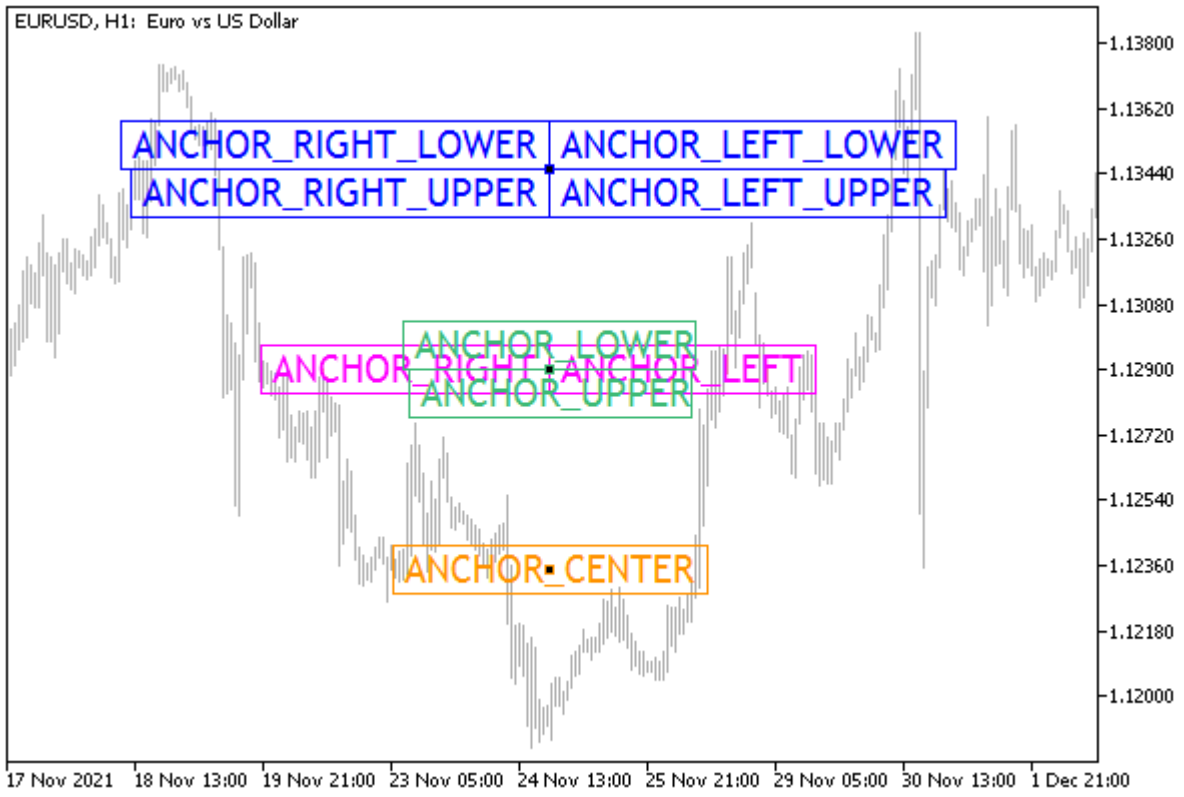
Some types of objects allow you to select an anchor point. The types that fall into this category include text label (OBJ_TEXT) and bitmap image (OBJ_BITMAP) linked to quotes, as well as caption (OBJ_LABEL) and panel with image (OBJ_BITMAP_LABEL), positioned in screen coordinates.

To read and set the anchor point, use the functions *ObjectGetInteger* and *ObjectSetInteger* with the OBJPROP_ANCHOR property.

All point selection options are collected in the ENUM_ANCHOR_POINT enumeration.

Identifier	Anchor point location
ANCHOR_LEFT_UPPER	In the upper left corner
ANCHOR_LEFT	Left center
ANCHOR_LEFT_LOWER	In the lower left corner
ANCHOR_LOWER	Bottom center
ANCHOR_RIGHT_LOWER	In the lower right corner
ANCHOR_RIGHT	Right center
ANCHOR_RIGHT_UPPER	In the upper right corner
ANCHOR_UPPER	Top center
ANCHOR_CENTER	Strictly in the center of the object

The points are clearly shown in the image below, where several label objects are applied to the chart.



OBJ_LABEL text objects with different anchor points

The upper group of four labels has the same pair of coordinates (X,Y), however, due to anchoring to different corners of the object, they are located on different sides of the point. A similar situation is in the second group of four text labels, however, there the anchoring is made to the midpoints of different sides of the objects. Finally, the caption is shown separately at the bottom, anchored in its center, so that the point is inside the object.

The button (OBJ_BUTTON), rectangular panel (OBJ_RECTANGLE_LABEL), input field (OBJ_EDIT), and chart object (OBJ_CHART) have a fixed anchor point in the upper left corner (ANCHOR_LEFT_UPPER).

Some graphical objects of the group of single price marks (OBJ_ARROW, OBJ_ARROW_THUMB_UP, OBJ_ARROW_THUMB_DOWN, OBJ_ARROW_UP, OBJ_ARROW_DOWN, OBJ_ARROW_STOP, OBJ_ARROW_CHECK) have two ways of anchoring their coordinates, specified by identifiers of another enumeration ENUM_ARROW_ANCH OR.

Identifier	Anchor point location
ANCHOR_TOP	Top center
ANCHOR_BOTTOM	Bottom center

The rest of the objects in this group have predefined anchor points: the buy (OBJ_ARROW_BUY) and sell (OBJ_ARROW_SELL) arrows are respectively in the middle of the upper and lower sides, and the price labels (OBJ_ARROW_RIGHT_PRICE, OBJ_ARROW_LEFT_PRICE) are on the left and right.

Similar to the script *ObjectCornerLabel.mq5* from the previous section, let's create the script *ObjectAnchorLabel.mq5*. In the new version, in addition to moving the inscription, we will randomly change the anchor point on it.

The corner of the window for anchoring will be selected, as before, by the user when the script is launched.

```
input ENUM_BASE_CORNER Corner = CORNER_LEFT_UPPER;
```

We will display the name of the angle on the chart as a comment.

```
void OnStart()
{
   Comment(EnumToString(Corner));
   ...
```

In an infinite loop, one of 9 possible anchor point values is generated at selected times.

```
   ENUM_ANCHOR_POINT anchor = 0;
   for( ;!IsStopped(); ++pass)
   {
      if(pass % 50 == 0)
      {
        ...
         anchor = (ENUM_ANCHOR_POINT)(rand() * 9 / 32768);
         ObjectSetInteger(0, name, OBJPROP_ANCHOR, anchor);
      }
      ...
```

The name of the anchor point becomes the text content of the label, along with the current coordinates.

```
      ObjectSetString(0, name, OBJPROP_TEXT, EnumToString(anchor)
         + "[" + (string)x + "," + (string)y + "]");
```

The rest of the code snippets remained largely unchanged.

After compiling and running the script, notice how the inscription changes its position relative to the current coordinates (x, y) depending on the selected anchor point.

For now, we control and prevent the anchor point itself from going outside the window. However, the object has some dimensions, and therefore it may turn out that most of the inscription is cut off. In the future, after studying the relevant properties, we will deal with this problem (see the *ObjectSizeLabel.mq5* example in the section on Determining object width and height).

5.8.12 Managing the object state

Among the general properties of objects, there are several ones that control the state of objects. All such properties have a Boolean type, meaning they can be turned on (*true*) or off (*false*), and therefore require the use of the functions *ObjectGetInteger* and *ObjectSetInteger*.

Identifier	Description
OBJPROP_HIDDEN	Disable displaying the name of a graphical object in the list of objects in the relevant dialog (called from the context menu of the chart or by pressing Ctrl+B).
OBJPROP_SELECTED	Object selection
OBJPROP_SELECTABLE	Availability of an object for selection

A value of *true* for OBJPROP_HIDDEN allows you to hide an unnecessary object from the user's list. By default, *true* is set for objects that display calendar events, the trading history, as well as for objects created from MQL programs. To see such graphical objects and access their properties, press the *All* button in the *Object List* dialog.

An object hidden in the list remains visible on the chart. To hide an object on the chart without deleting it, you can use the Visibility of objects in the context of timeframes setting.

The user cannot select and change the properties of objects for which OBJPROP_SELECTABLE is equal to *false*. Objects created programmatically are not allowed to be selected by default. As we saw in the *ObjectCornerLabel.mq5* and *ObjectAnchorLabel.mq5* scripts in the previous sections, it was necessary to explicitly set OBJPROP_SELECTABLE to *true* to unlock the ability to include OBJPROP_SELECTED as well. This is how we highlighted the anchor points on the object.

Usually, MQL programs allow the selection of their objects only if these objects serve as controls. For example, a trend line with a predefined name, which the user moves at will, can mean a condition for sending a trade order when the price crosses it.

5.8.13 Priority of objects (Z-Order)

Objects on the chart provide not only the presentation of information but also interaction with the user and MQL programs through events, which will be discussed in detail in the next chapter. One of the event sources is the mouse pointer. The chart is able, in particular, to track the movement of the mouse and pressing its buttons.

If an object is under the mouse, specific event handling can be performed for it. However, objects can overlap each other (when their coordinates overlap, taking into account sizes). In this case, the OBJPROP_ZORDER integer property comes into play. It sets the priority of the graphical object to receive mouse events. When objects overlap, only one object, whose priority is higher than the rest will receive the event.

By default, when an object is created, its Z-order is zero, but you can increase it if necessary.

> It's important to note that Z-order only affects the handling of mouse events, not the drawing of objects. Objects are always drawn in the order they were added to the chart. This can be a source of misunderstanding. For example, a tooltip may not be displayed for an object that is visually on top of another because the overlapped object has a higher Z-priority (see example).

In the *ObjectZorder.mq5* script we will create 12 objects of type OBJ_RECTANGLE_LABEL, placing them in a circle, like on a clock face. The order of adding objects corresponds to hours: from 1 to 12. For clarity, all rectangles will get a random color (for the OBJPROP_BGCOLOR property, see the next section), as well as random priority. By moving the mouse over objects, the user will be able to determine which object it belongs to by means of a tooltip.

For the convenience of setting the properties of objects, we define the special class *ObjectBuilder*, derived from *Object Selector*.

```
#include "ObjectPrefix.mqh"
#include <MQL5Book/ObjectMonitor.mqh>

class ObjectBuilder: public ObjectSelector
{
protected:
   const ENUM_OBJECT type;
   const int window;
public:
   ObjectBuilder(const string _id, const ENUM_OBJECT _type,
      const long _chart = 0, const int _win = 0):
      ObjectSelector(_id, _chart), type(_type), window(_win)
   {
      ObjectCreate(host, id, type, window, 0, 0);
   }

   // changing the name and chart is prohibited
   virtual void name(const string _id) override = delete;
   virtual void chart(const long _chart) override = delete;
};
```

Fields with identifiers of the object (*id*) and chart (*host*) are already in the *ObjectSelector* class. In the derivative, we add an object type (*ENUM_OBJECT type*) and a window number (*int window*). The constructor calls *ObjectCreate*.

Setting and reading properties is fully inherited as a group of *get* and *set* methods from *ObjectSelector*.

As in the previous test scripts, we determine the window where the script is dropped, the dimensions of the window, and the coordinates of the middle.

```
void OnStart()
{
   const int t = ChartWindowOnDropped();
   int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS, t);
   int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
   int x = w / 2;
   int y = h / 2;
   ...
```

Since the object type OBJ_RECTANGLE_LABEL supports explicit pixel dimensions, we calculate the width of *dx* and height of *dy* of each rectangle as a quarter window. We use them to set the OBJPROP_XSIZE and OBJPROP_YSIZE properties discussed in the section on Determining object width and height.

```
   const int dx = w / 4;
   const int dy = h / 4;
   ...
```

Next, in the loop, we create 12 objects. Variables *px* and *py* contain the offset of the next "mark" on the "dial" relative to the center (x, y). The priority of *z* is chosen randomly. The name of the object and

its tooltip (OBJPROP_TOOLTIP) include a string like "XX - YYY", XX is the number of the "hour" (the position on the dial is from 1 to 12), YYY is the priority.

```
for(int i = 0; i < 12; ++i)
{
   const int px = (int)(MathSin((i + 1) * 30 * M_PI / 180) * dx) - dx / 2;
   const int py = -(int)(MathCos((i + 1) * 30 * M_PI / 180) * dy) - dy / 2;

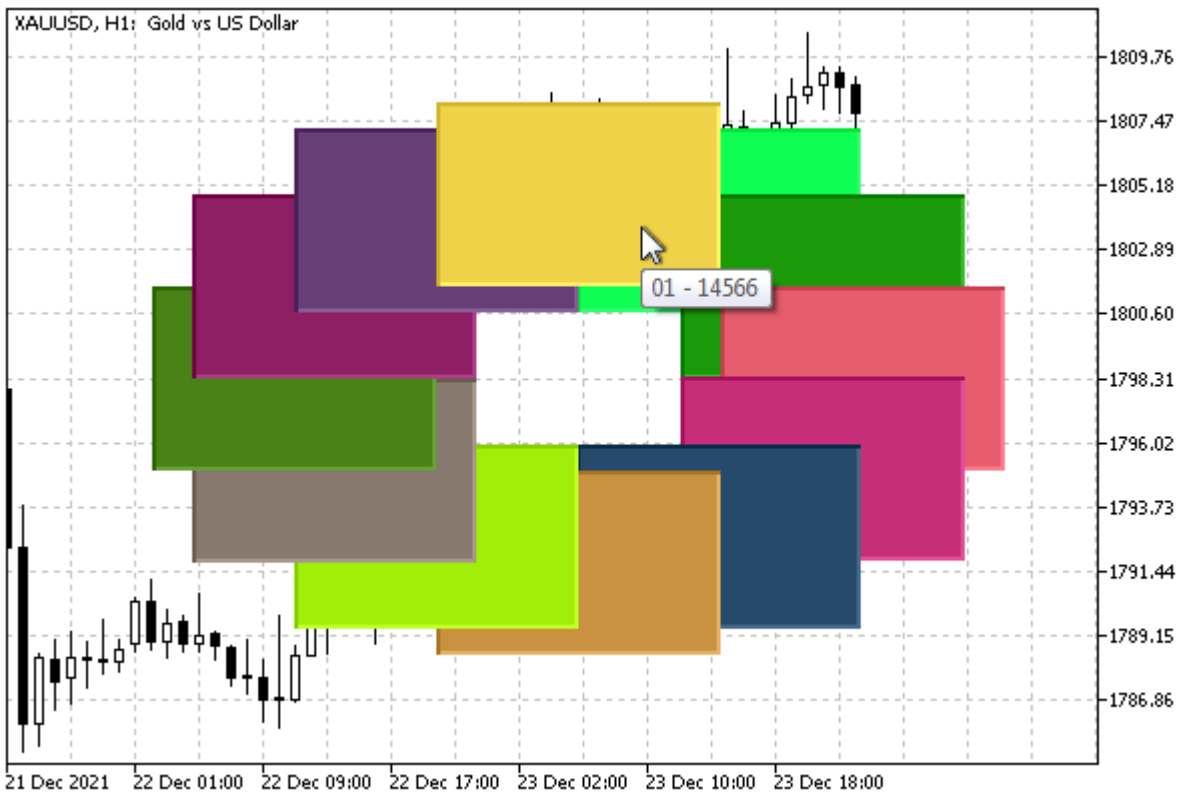
   const int z = rand();
   const string text = StringFormat("%02d - %d", i + 1, z);

   ObjectBuilder *builder =
      new ObjectBuilder(ObjNamePrefix + text, OBJ_RECTANGLE_LABEL);
   builder.set(OBJPROP_XDISTANCE, x + px).set(OBJPROP_YDISTANCE, y + py)
   .set(OBJPROP_XSIZE, dx).set(OBJPROP_YSIZE, dy)
   .set(OBJPROP_TOOLTIP, text)
   .set(OBJPROP_ZORDER, z)
   .set(OBJPROP_BGCOLOR, (rand() << 8) | rand());
   delete builder;
}
```

After the *ObjectBuilder* constructor is called, for the new *builder* object the calls to the overloaded *set* method for different properties are chained (the *set* method returns a pointer to the object itself).

Since the MQL object is no longer needed after the creation and configuration of the graphical object, we immediately delete *builder*.

As a result of the script execution, approximately the following objects will appear on the chart.



Object overlay and Z-order priority tooltips

The colors and priorities will be different each time you run it, but the visual overlay of the rectangles will always be the same, in the order of creation from 1 at the bottom to 12 at the top (here we mean the overlay of objects, not the fact that 12 is located at the top of the watch face).

In the image, the mouse cursor is positioned in a place where two objects exist, that is, 01 (fluorescent lime green) and 12 (sandy). In this case, the tooltip for object 01 is visible, although visually object 12 is displayed on top of object 01. This is because 01 was randomly generated with a higher priority than 12.

Only one tooltip is displayed at a time, so you can check the priority relationship by moving the mouse cursor to other areas where there is no object overlap and the information in the tooltip belongs to the single object under the cursor.

When we learn about mouse event handling in the next chapter, we can improve on this example and test the effect of Z-order on mouse clicks on objects.

To delete the created objects, you can use the *ObjectCleanup1.mq5* script.

5.8.14 Object display settings: color, style, and frame

The appearance of objects can be changed using a variety of properties, which we'll explore in this section, starting with color, style, line width, and borders. Other formatting aspects such as font, skew, and text alignment will be covered in the following sections.

All properties from the table below have types that are compatible with integers and therefore are managed by the functions *ObjectGetInteger* and *ObjectSetInteger*.

Identifier	Description	Property type
OBJPROP_COLOR	The color of the line and the main element of the object (for example, font or fill)	color
OBJPROP_STYLE	Line style	ENUM_LINE_STYLE
OBJPROP_WIDTH	Line thickness in pixels	int
OBJPROP_FILL	Filling an object with color (for OBJ_RECTANGLE, OBJ_TRIANGLE, OBJ_ELLIPSE, OBJ_CHANNEL, OBJ_STDDEVCHANNEL, OBJ_REGRESSION)	bool
OBJPROP_BACK	Object in the background	bool
OBJPROP_BGCOLOR	Background color for OBJ_EDIT, OBJ_BUTTON, OBJ_RECTANGLE_LABEL	color
OBJPROP_BORDER_TYPE	Frame type for rectangular panel OBJ_RECTANGLE_LABEL	ENUM_BORDER_TYPE
OBJPROP_BORDER_COLOR	Frame color for input field OBJ_EDIT and button OBJ_BUTTON	color

Unlike most objects with lines (separate vertical and horizontal, trend, cyclic, channels, etc.), where the OBJPROP_COLOR property defines the color of the line, for the OBJ_BITMAP_LABEL and OBJ_BITMAP images it defines the frame color, and OBJPROP_STYLE defines the frame drawing type.

We have already met the ENUM_LINE_STYLE enumeration, used for OBJPROP_STYLE, in the chapter on indicators, in the section on Plot settings.

It is necessary to distinguish the fill performed by the foreground color OBJPROP_COLOR from the background color OBJPROP_BGCOLOR. Both are supported by different groups of object types, which are listed in the table.

The OBJPROP_BACK property requires a separate explanation. The fact is that objects and indicators are displayed on top of the price chart by default. The user can change this behavior for the entire chart by going to the *Setting* dialog of the chart, and further to the *Shared* bookmark, the *Chart on top* option. This flag also has a software counterpart, the CHART_FOREGROUND property (see Chart display modes). However, sometimes it is desirable to remove not all objects, but only selected ones, into the background. Then for them, you can set OBJPROP_BACK to *true*. In this case, the object will be overlapped even by the grid and period separators, if they are enabled on the chart.

When the OBJPROP_FILL fill mode is enabled, the color of the bars falling inside the shape depends on the OBJPROP_BACK property. By default, with OBJPROP_BACK equal to *false*, bars overlapping the object are drawn in inverted color with respect to OBJPROP_COLOR (the inverted color is obtained by switching all bits in the color value to the opposite ones, for example, 0x00FF7F is obtained for

0xFF0080). With OBJPROP_BACK equal to *true*, bars are drawn in the usual way, since the object is displayed in the background, "under" the chart (see an example below).

The ENUM_BORDER_TYPE enumeration contains the following elements:

Identifier	Appearance
BORDER_FLAT	Flat
BORDER_RAISED	Convex
BORDER_SUNKEN	Concave

When the border is flat (BORDER_FLAT), it is drawn as a line with color, style, and width according to the properties OBJPROP_COLOR, OBJPROP_STYLE, OBJPROP_WIDTH. The convex and concave versions imitate volume chamfers around the perimeter in shades of OBJPROP_BGCOLOR.

When the border color OBJPROP_BORDER_COLOR is not set (default, which corresponds to *clrNone*), the input field is framed by a line of the main color OBJPROP_COLOR, and a three-dimensional frame with chamfers in shades of OBJPROP_BGCOLOR is drawn around the button.

To test the new properties, consider the *ObjectStyle.mq5* script. In it, we will create 5 rectangles of the OBJ_RECTANGLE type, i.e., with reference to time and prices. They will be evenly spaced across the entire width of the window, highlighting the range between the maximum price *High* and minimum price *Low* in each of the five time periods. For all objects, we will adjust and periodically change the line color, style, and thickness, as well as the filling and display option behind the chart.

Let's use again the helper class *ObjectBuilder*, derived from the *Object Selector*. In contrast to the previous section, we add to *ObjectBuilder* a destructor in which we will call *ObjectDelete*.

```
#include <MQL5Book/ObjectMonitor.mqh>
#include <MQL5Book/AutoPtr.mqh>

class ObjectBuilder: public ObjectSelector
{
...
public:
   ~ObjectBuilder()
   {
      ObjectDelete(host, id);
   }
   ...
};
```

This will make it possible to assign to this class not only the configuration of objects but also their automatic removal upon completion of the script.

In the *OnStart* function, we find out the number of visible bars and the index of the first bar, and also calculate the width of one rectangle in bars.

```
#define OBJECT_NUMBER 5

void OnStart()
{
   const string name = "ObjStyle-";
   const int bars = (int)ChartGetInteger(0, CHART_VISIBLE_BARS);
   const int first = (int)ChartGetInteger(0, CHART_FIRST_VISIBLE_BAR);
   const int rectsize = bars / OBJECT_NUMBER;
   ...
```

Let's reserve an array of smart pointers for objects to ensure the call of *ObjectBuilder* destructors.

```
   AutoPtr<ObjectBuilder> objects[OBJECT_NUMBER];
```

Define a color palette and create 5 rectangle objects.

```
   color colors[OBJECT_NUMBER] = {clrRed, clrGreen, clrBlue, clrMagenta, clrOrange};

   for(int i = 0; i < OBJECT_NUMBER; ++i)
   {
      // find the indexes of the bars that determine the range of prices in the i-th
      const int h = iHighest(NULL, 0, MODE_HIGH, rectsize, i * rectsize);
      const int l = iLowest(NULL, 0, MODE_LOW, rectsize, i * rectsize);
      // create and set up an object in the i-th subrange
      ObjectBuilder *object = new ObjectBuilder(name + (string)(i + 1), OBJ_RECTANGLE
      object.set(OBJPROP_TIME, iTime(NULL, 0, i * rectsize), 0);
      object.set(OBJPROP_TIME, iTime(NULL, 0, (i + 1) * rectsize), 1);
      object.set(OBJPROP_PRICE, iHigh(NULL, 0, h), 0);
      object.set(OBJPROP_PRICE, iLow(NULL, 0, l), 1);
      object.set(OBJPROP_COLOR, colors[i]);
      object.set(OBJPROP_WIDTH, i + 1);
      object.set(OBJPROP_STYLE, (ENUM_LINE_STYLE)i);
      // save to array
      objects[i] = object;
   }
   ...
```

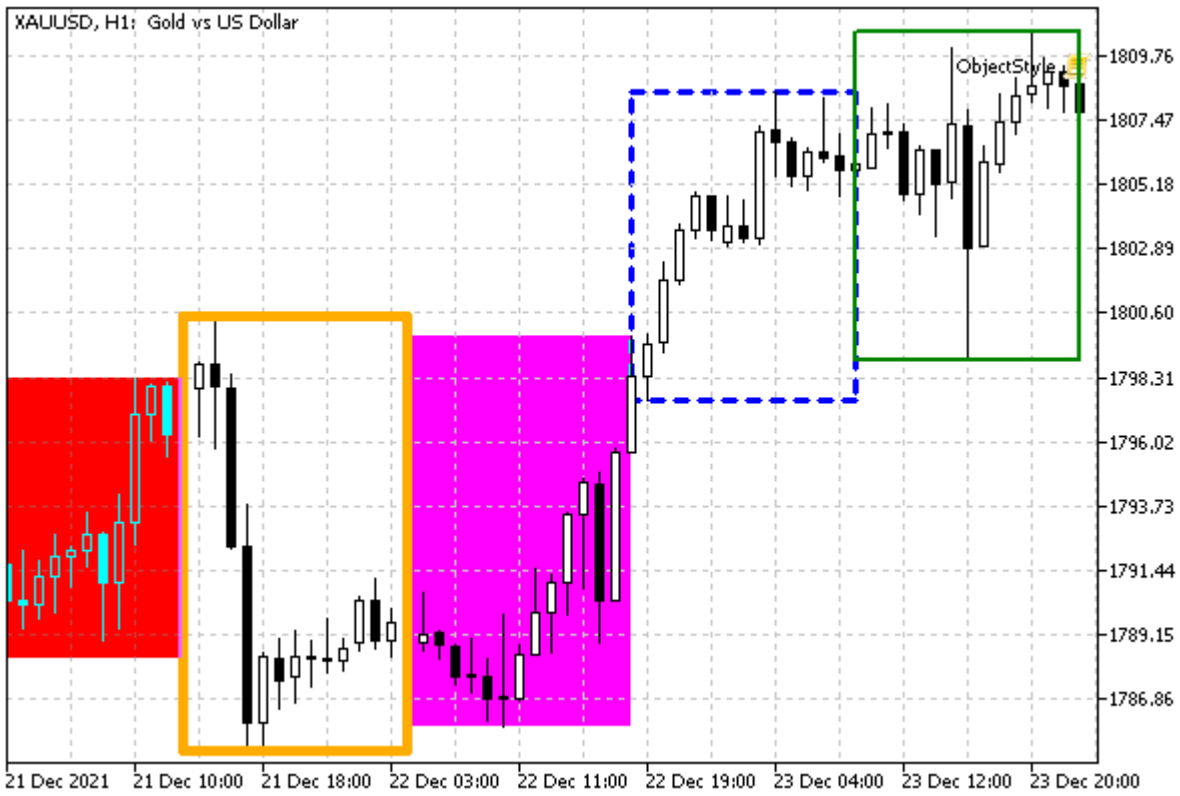
Here, for each object, the coordinates of two anchor points are calculated; the initial color, style, and line width are set.

Next, in an infinite loop, we change the properties of objects. When *ScrollLock* is on, the animation can be paused.

```
const int key = TerminalInfoInteger(TERMINAL_KEYSTATE_SCRLOCK);
int pass = 0;
int offset = 0;

for( ;!IsStopped(); ++pass)
{
   Sleep(200);
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_SCRLOCK) != key) continue;
   // change color/style/width/fill/background from time to time
   if(pass % 5 == 0)
   {
      ++offset;
      for(int i = 0; i < OBJECT_NUMBER; ++i)
      {
         objects[i][].set(OBJPROP_COLOR, colors[(i + offset) % OBJECT_NUMBER]);
         objects[i][].set(OBJPROP_WIDTH, (i + offset) % OBJECT_NUMBER + 1);
         objects[i][].set(OBJPROP_FILL, rand() > 32768 / 2);
         objects[i][].set(OBJPROP_BACK, rand() > 32768 / 2);
      }
   }
   ChartRedraw();
}
```

Here's what it looks like on a chart.



OBJ_RECTANGLE rectangles with different display settings

The left-most red rectangle has its fill mode turned on and is in the foreground. So, the bars inside it are displayed in contrasting bright blue (*clrAqua*, also commonly known as *cyan*, which is the inverted

clrRed). The purple rectangle also has a fill, but with a background option, so the bars in it are displayed in a standard way.

Please note that the orange rectangle completely covers the bars at the beginning and end of its sub-range due to the large width of the lines and display on top of the chart.

When the fill is on, the line width is not taken into account. When the border width is greater than 1, some broken line styles are not applied.

ObjectShapesDraw

For the second example of this section, remember the hypothetical shape-drawing program we sketched out in Part 3 when we learned OOP. Our progress stopped at the fact that in the virtual drawing method (and it was called draw) we could only print a message to the log that we were drawing a specific shape. Now, after getting acquainted with graphic objects, we have the opportunity to implement drawing.

Let's take the *Shapes5stats.mq5* script as a starting point. The updated version will be called *ObjectShapesDraw.mq5*.

Recall that in addition to the base class *Shape* we have described several classes of shapes: *Rectangle*, *Ellipse*, *Triangle*, *Square*, *Circle*. All of them successfully overlay graphic objects of types OBJ_RECTANGLE, OBJ_ELLIPSE, OBJ_TRIANGLE. But there are some nuances.

All specified objects are bound to time and price coordinates, while our drawing program assumes unified X and Y axes with point positioning. In this regard, we will need to set up a graph for drawing in a special way and use the *ChartXYToTimePrice* function to recalculate screen points in time and price.

In addition, OBJ_ELLIPSE and OBJ_TRIANGLE objects allow arbitrary rotation (in particular, the small and large radius of an ellipse can be rotated), while OBJ_RECTANGLE always has its sides oriented horizontally and vertically. To simplify the example, we restrict ourselves to the standard position of all shapes.

In theory, the new implementation should be viewed as a demonstration of graphical objects, and not a drawing program. A more correct approach for full-fledged drawing, devoid of the restrictions that graphic objects impose (since they are intended for other purposes in general - like chart marking), is using graphic resources. Therefore, we will return to rethinking the drawing program in the chapter on resources.

In the new *Shape* class, let's get rid of the nested structure *Pair* with object coordinates: this structure served as a means to demonstrate several principles of OOP, but now it is easier to return the original description of the fields *int x, y* directly to the class *Shape*. We will also add a field with the name of the object.

```
class Shape
{
   ...
protected:
   int x, y;
   color backgroundColor;
   const string type;
   string name;

   Shape(int px, int py, color back, string t) :
      x(px), y(py),
      backgroundColor(back),
      type(t)
   {
   }

public:
   ~Shape()
   {
      ObjectDelete(0, name);
   }
   ...
```

The *name* field will be required to set the properties of a graphical object, as well as to remove it from the chart, which is logical to do in the destructor.

Since different types of shapes require a different number of points or characteristic sizes, we will add the *setup* method, in addition to the *draw* virtual method, into the *Shape* interface:

```
virtual void setup(const int &parameters[]) = 0;
```

Recall that in the script we have implemented a nested class *Shape::Registrator*, which was engaged in counting the number of shapes by type. The time has come to entrust it with something more responsible to work as a factory of shapes. The "factory" classes or methods are good because they allow you to create objects of different classes in a unified way.

To do this, we add to *Registrator* a method for creating a shape with the parameters that include the mandatory coordinates of the first point, a color, and an array of additional parameters (each shape will be able to interpret it according to its own rules, and in the future, read from or write to a file).

```
virtual Shape *create(const int px, const int py, const color back,
         const int &parameters[]) = 0;
```

The method is abstract virtual because certain types of shapes can only be created by derived registrar classes described in descendant classes of *Shape*. To simplify the writing of derived logger classes, we introduce a template class *MyRegistrator* with an implementation of the *create* method suitable for all cases.

```
template<typename T>
class MyRegistrator : public Shape::Registrator
{
public:
   MyRegistrator() : Registrator(typename(T))
   {
   }

   virtual Shape *create(const int px, const int py, const color back,
      const int &parameters[]) override
   {
      T *temp = new T(px, py, back);
      temp.setup(parameters);
      return temp;
   }
};
```

Here we call the constructor of some previously unknown shape T, adjust it by calling *setup* and return an instance to the calling code.

Here's how it's used in the *Rectangle* class, which has two additional parameters for width and height.

```
class Rectangle : public Shape
{
   static MyRegistrator<Rectangle> r;

protected:
   int dx, dy; // dimensions (width, height)

   Rectangle(int px, int py, color back, string t) :
      Shape(px, py, back, t), dx(1), dy(1)
   {
   }

public:
   Rectangle(int px, int py, color back) :
      Shape(px, py, back, typename(this)), dx(1), dy(1)
   {
      name = typename(this) + (string)r.increment();
   }

   virtual void setup(const int &parameters[]) override
   {
      if(ArraySize(parameters) < 2)
      {
         Print("Insufficient parameters for Rectangle");
         return;
      }
      dx = parameters[0];
      dy = parameters[1];
   }
   ...
};

static MyRegistrator<Rectangle> Rectangle::r;
```

When creating a shape, its name will contain not only the class name (*typename*), but also the ordinal number of the instance, calculated in the *r.increment()* call.

Other classes of shapes are described similarly.

Now it's time to look into the *draw* method for *Rectangle*. In it, we translate a pair of points (x,y) and (x + dx, y + dy) into time/price coordinates using *ChartXYToTimePrice* and create an OBJ_RECTANGLE object.

```
void draw() override
{
   // Print("Drawing rectangle");
   int subw;
   datetime t;
   double p;
   ChartXYToTimePrice(0, x, y, subw, t, p);
   ObjectCreate(0, name, OBJ_RECTANGLE, 0, t, p);
   ChartXYToTimePrice(0, x + dx, y + dy, subw, t, p);
   ObjectSetInteger(0, name, OBJPROP_TIME, 1, t);
   ObjectSetDouble(0, name, OBJPROP_PRICE, 1, p);

   ObjectSetInteger(0, name, OBJPROP_COLOR, backgroundColor);
   ObjectSetInteger(0, name, OBJPROP_FILL, true);
}
```

Of course, don't forget to set the color to OBJPROP_COLOR and the fill to OBJPROP_FILL.

For the *Square* class, nothing needs to be changed as such: it is enough just to set *dx* and *dy* equal to each other.

For the *Ellipse* class, two additional options, *dx* and *dy*, determine the small and large radii plotted relative to the center (x,y). Accordingly, in the method *draw* we calculate 3 anchor points and create an OBJ_ELLIPSE object.

```
class Ellipse : public Shape
{
   static MyRegistrator<Ellipse> r;
protected:
   int dx, dy; // large and small radii
   ...
public:
   void draw() override
   {
      // Print("Drawing ellipse");
      int subw;
      datetime t;
      double p;

      // (x, y) center
      // p0: x + dx, y
      // p1: x - dx, y
      // p2: x, y + dy

      ChartXYToTimePrice(0, x + dx, y, subw, t, p);
      ObjectCreate(0, name, OBJ_ELLIPSE, 0, t, p);
      ChartXYToTimePrice(0, x - dx, y, subw, t, p);
      ObjectSetInteger(0, name, OBJPROP_TIME, 1, t);
      ObjectSetDouble(0, name, OBJPROP_PRICE, 1, p);
      ChartXYToTimePrice(0, x, y + dy, subw, t, p);
      ObjectSetInteger(0, name, OBJPROP_TIME, 2, t);
      ObjectSetDouble(0, name, OBJPROP_PRICE, 2, p);

      ObjectSetInteger(0, name, OBJPROP_COLOR, backgroundColor);
      ObjectSetInteger(0, name, OBJPROP_FILL, true);
   }
};

static MyRegistrator<Ellipse> Ellipse::r;
```

Circle is a special case of an ellipse with equal radii.

Finally, only equilateral triangles are supported at this stage: the size of the side is contained in an additional field *dx*. You are invited to learn their method*draw* in the source code independently.

The new script will, as before, generate a given number of random shapes. They are created by the function *addRandomShape*.

```
Shape *addRandomShape()
{
   const int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
   const int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS);

   const int n = random(Shape::Registrator::getTypeCount());

   int cx = 1 + w / 4 + random(w / 2), cy = 1 + h / 4 + random(h / 2);
   int clr = ((random(256) << 16) | (random(256) << 8) | random(256));
   int custom[] = {1 + random(w / 4), 1 + random(h / 4)};
   return Shape::Registrator::get(n).create(cx, cy, clr, custom);
}
```

This is where we see the use of the factory method *create*, called on a randomly selected registrar object with the number *n*. If we decide to add other shape classes later, we won't need to change anything in the generation logic.

All shapes are placed in the central part of the window and have dimensions no larger than a quarter of the window.

It remains to consider directly the calls to the *addRandomShape* function, and the special schedule setting we have already mentioned.

To provide a "square" representation of points on the screen, set the CHART_SCALEFIX_11 mode. In addition, we will choose the densest (compressed) scale along the time axis CHART_SCALE (0), because in it one bar occupies 1 horizontal pixel (maximum accuracy). Finally, disable the display of the chart itself by setting CHART_SHOW to *false*.

```
void OnStart()
{
   const int scale = (int)ChartGetInteger(0, CHART_SCALE);
   ChartSetInteger(0, CHART_SCALEFIX_11, true);
   ChartSetInteger(0, CHART_SCALE, 0);
   ChartSetInteger(0, CHART_SHOW, false);
   ChartRedraw();
   ...
```

To store the shapes, let's reserve an array of smart pointers and fill it with random shapes.

```
#define FIGURES 21
...
void OnStart()
{
   ...
   AutoPtr<Shape> shapes[FIGURES];

   for(int i = 0; i < FIGURES; ++i)
   {
      Shape *shape = shapes[i] = addRandomShape();
      shape.draw();
   }

   ChartRedraw();
   ...
```

Then we run an infinite loop until the user stops the script, in which we slightly move the shapes using the *move* method.

```
   while(!IsStopped())
   {
      Sleep(250);
      for(int i = 0; i < FIGURES; ++i)
      {
         shapes[i][].move(random(20) - 10, random(20) - 10);
         shapes[i][].draw();
      }
      ChartRedraw();
   }
   ...
```

In the end, we restore the chart settings.

```
   // it's not enough to disable CHART_SCALEFIX_11, you need CHART_SCALEFIX
   ChartSetInteger(0, CHART_SCALEFIX, false);
   ChartSetInteger(0, CHART_SCALE, scale);
   ChartSetInteger(0, CHART_SHOW, true);
}
```

The following screenshot shows what a graph with the shapes drawn might look like.

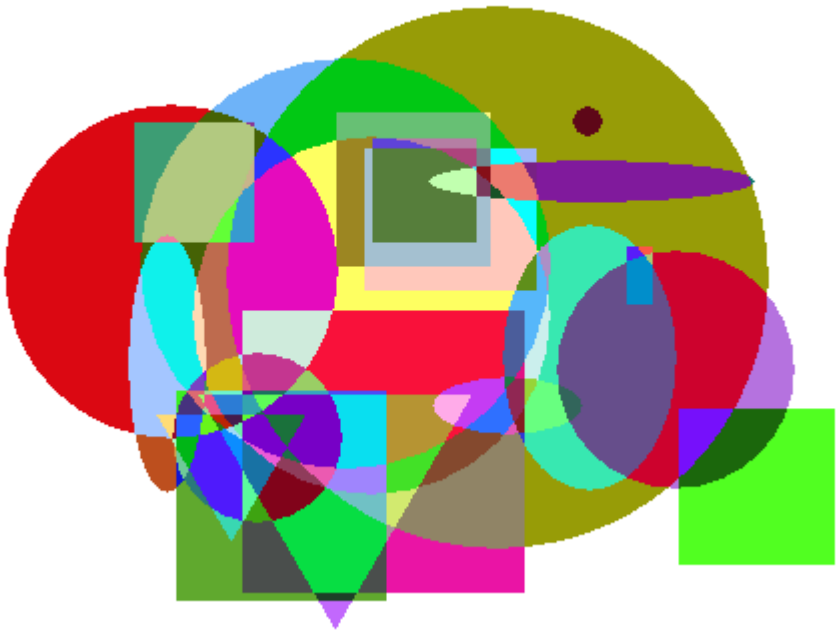


Chart shape objects

The specifics of drawing objects is the "multiplication" of colors in those places where they overlap.

Because the Y-axis goes up and down, all the triangles are upside down, but that's not critical, because we're going to redo the resource-based paint program anyway.

5.8.15 Font settings

All types of objects enable the setting of certain texts for them (OBJPROP_TEXT). Many of them display the specified text directly on the chart, for the rest it becomes an informative part of the tooltip.

When text is displayed inside an object (for types OBJ_TEXT, OBJ_LABEL, OBJ_BUTTON, and OBJ_EDIT), you can choose a font name and size. For objects of other types, the font settings are not applied: their descriptions are always displayed in the chart's standard font.

Identifier	Description	Type
OBJPROP_FONTSIZE	Font size in pixels	int
OBJPROP_FONT	Font	string

You cannot set the font size in printing points here.

The test script *ObjectFont.mq5* creates objects with text and changes the name and font size. Let's use the *ObjectBuilder* class from the previous script.

At the beginning of *OnStart*, the script calculates the middle of the window both in screen coordinates and in the time/price axes. This is required because objects of different types participating in the test use different coordinate systems.

```
void OnStart()
{
   const string name = "ObjFont-";

   const int bars = (int)ChartGetInteger(0, CHART_WIDTH_IN_BARS);
   const int first = (int)ChartGetInteger(0, CHART_FIRST_VISIBLE_BAR);

   const datetime centerTime = iTime(NULL, 0, first - bars / 2);
   const double centerPrice =
      (ChartGetDouble(0, CHART_PRICE_MIN)
      + ChartGetDouble(0, CHART_PRICE_MAX)) / 2;

   const int centerX = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS) / 2;
   const int centerY = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS) / 2;
   ...
```

The list of tested object types is specified in the *types* array. For some of them, in particular OBJ_HLINE and OBJ_VLINE, the font settings will have no effect, although the text of the descriptions will appear on the screen (to ensure this, we turn on the CHART_SHOW_OBJECT_DESCR mode).

```
   ChartSetInteger(0, CHART_SHOW_OBJECT_DESCR, true);

   ENUM_OBJECT types[] =
   {
      OBJ_HLINE,
      OBJ_VLINE,
      OBJ_TEXT,
      OBJ_LABEL,
      OBJ_BUTTON,
      OBJ_EDIT,
   };
   int t = 0; // cursor
   ...
```

The *t* variable will be used to sequentially switch from one type to another.

The *fonts* array contains the most popular standard Windows fonts.

```
string fonts[] =
{
   "Comic Sans MS",
   "Consolas",
   "Courier New",
   "Lucida Console",
   "Microsoft Sans Serif",
   "Segoe UI",
   "Tahoma",
   "Times New Roman",
   "Trebuchet MS",
   "Verdana"
};

int f = 0; // cursor
...
```

We will iterate over them using the *f* variable.

Inside the demo loop, we instruct *ObjectBuilder* to create an object of the current type *types[t]* in the middle of the window (for unification, the coordinates are specified in both coordinate systems, so as not to make differences in the code depending on the type: coordinates not supported by the object simply will not have an effect).

```
while(!IsStopped())
{

   const string str = EnumToString(types[t]);
   ObjectBuilder *object = new ObjectBuilder(name + str, types[t]);
   object.set(OBJPROP_TIME, centerTime);
   object.set(OBJPROP_PRICE, centerPrice);
   object.set(OBJPROP_XDISTANCE, centerX);
   object.set(OBJPROP_YDISTANCE, centerY);
   object.set(OBJPROP_XSIZE, centerX / 3 * 2);
   object.set(OBJPROP_YSIZE, centerY / 3 * 2);
   ...
```

Next, we set up the text and font (the size is chosen randomly).

```
   const int size = rand() * 15 / 32767 + 8;
   Comment(str + " " + fonts[f] + " " + (string)size);
   object.set(OBJPROP_TEXT, fonts[f] + " " + (string)size);
   object.set(OBJPROP_FONT, fonts[f]);
   object.set(OBJPROP_FONTSIZE, size);
   ...
```

For the next pass, we move the cursors in the arrays of object types and font names.

```
   t = ++t % ArraySize(types);
   f = ++f % ArraySize(fonts);
   ...
```

Finally, we update the chart, wait 1 second, and delete the object to create another one.

```
         ChartRedraw();
         Sleep(1000);
         delete object;
      }
   }
```

The image below shows the moment the script is running.

Button with custom font settings

5.8.16 Rotating text at an arbitrary angle

Objects of text types – label OBJ_TEXT (in quotation coordinates) and panel OBJ_LABEL (in screen coordinates) – allow you to rotate the text label at an arbitrary angle. For this purpose, there is the OBJPROP_ANGLE property of type *double*. It contains the angle in degrees relative to the object's normal position. Positive values rotate the object counterclockwise, and negative values rotate it clockwise.

However, it should be borne in mind that angles with a difference that is a multiple of 360 degrees are identical, that is, for example, +315 and -45 are the same. Rotation is performed around the anchor point on the object (by default, top left).

Rotate OBJ_LABEL and OBJ_TEXT objects by angles that are multiples of 45 degrees

You can check the effect of the OBJPROP_ANGLE property on an object using the *ObjectAngle.mq5* script. It creates a text label OBJ_LABEL in the center of the window, after which it begins to periodically rotate 45 degrees until the user stops the process.

```
void OnStart()
{
   const string name = "ObjAngle";
   ObjectCreate(0, name, OBJ_LABEL, 0, 0, 0);
   const int centerX = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS) / 2;
   const int centerY = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS) / 2;
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, centerX);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, centerY);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_CENTER);

   int angle = 0;
   while(!IsStopped())
   {
      ObjectSetString(0, name, OBJPROP_TEXT, StringFormat("Angle: %d°", angle));
      ObjectSetDouble(0, name, OBJPROP_ANGLE, angle);
      angle += 45;

      ChartRedraw();
      Sleep(1000);
   }
   ObjectDelete(0, name);
}
```

The text displays the current value of the angle.

5.8.17 Determining object width and height

Some types of objects allow you to set their dimensions in pixels. These include OBJ_BUTTON, OBJ_CHART, OBJ_BITMAP, OBJ_BITMAP_LABEL, OBJ_EDIT, and OBJ_RECTANGLE_LABEL. In addition, OBJ_LABEL objects support reading (but not setting) sizes because labels automatically expand or contract to fit the text they contain. Attempting to access properties on other types of objects will result in an OBJECT_WRONG_PROPERTY (4203) error.

Identifier	Description
OBJPROP_XSIZE	Width of the object along the X-axis in pixels
OBJPROP_YSIZE	Height of the object along the Y-axis in pixels

Both sizes are integers and are therefore handled by the *ObjectGetInteger/ObjectSetInteger* functions.

Special dimension handling is performed for OBJ_BITMAP and OBJ_BITMAP_LABEL objects.

Without assigning an image, these objects allow you to set an arbitrary size. At the same time, they are drawn transparent (only the frame is visible if it is not "hidden" also by setting the color *clrNone*), but they receive all events, in particular, about mouse movements (with a text description, if any, in a tooltip) and clicks of its buttons on the object.

When an image is assigned, it defaults to the object's height and width. However, an MQL program can set smaller sizes and select a fragment of an image to display; more on this in the section on framing. If you try to set the height or width larger than the image size, it stops being displayed, and the object's dimensions do not change.

As an example, let's develop an improved version of the script *ObjectAnchorLabel.mq5* from the section titled Defining anchor point on an object. In that section, we moved the text label around the window and reversed it when it reached any of the window borders, but we did this while only taking into account the anchor point. Because of this, depending on the location of the anchor point on the object, there could be a situation where the label is almost completely traveled beyond the window. For example, if the anchor point was on the right side of the object, moving to the left would cause almost all of the text to go beyond the left border of the window before the anchor point touched the edge.

In the new script *ObjectSizeLabel.mq5*, we will take into account the size of the object and change the direction of movement as soon as it touches the edge of the window with any of its sides.

For the correct implementation of this mode, it should be taken into account that each window corner used as the center of reference of coordinates to the anchor point on the object determines the characteristic direction of both the X and Y axes. For example, if the user selects the upper left corner in the ENUM_BASE_CORNER Corner input variable, then X increases from left to right and Y increases from top to bottom. If the center is considered to be the lower right corner, then X increases from right to left of it, and Y increases from bottom to top.

A different mutual combination of the anchor corner in the window and the anchor point on the object requires different adjustments of the distances between the object edges and the window borders. In particular, when one of the right corners and one of the anchor points on the right side of the object is selected, then the correction at the right border of the window is not required, and at the opposite side, the left, we must take into account the width of the object (so that its dimensions do not go out of the window to the left).

This rule about correcting for the size of an object can be generalized:

- On the border of the window adjacent to the anchor corner, the correction is needed when the anchor point is on the far side of the object relative to this corner;
- On the border of the window opposite the anchor corner, the correction is needed when the anchor point is on the near side of the object relative to this corner.

In other words, if the name of the corner (in the ENUM_BASE_CORNER element) and the anchor point (in the ENUM_ANCHOR_POINT element) contain a common word (for example, RIGHT), the correction is needed on the far side of the window (that is, far from the selected corner). If opposite directions are found in the combination of ENUM_BASE_CORNER and ENUM_ANCHOR_POINT sides (for example, LEFT and RIGHT), the correction is needed at the nearest side of the window. These rules work the same for the horizontal and vertical axes.

Additionally, it should be taken into account that the anchor point can be in the middle of any side of the object. Then in the perpendicular direction, an indent from the window borders is required, equal to half the size of the object.

A special case is the anchor point at the center of the object. For it, you should always have a margin of distance in any direction, equal to half the size of the object.

The logic described is implemented in a special function called *GetMargins*. It takes as inputs the selected corner and anchor point, as well as the dimensions of the object (*dx* and *dy*). The function returns a structure with 4 fields containing the sizes of additional indents that should be set aside from the anchor point in the direction of the near and far borders of the window so that the object does not go out of view. Indents reserve the distance according to the dimensions and relative position of the object itself.

```
struct Margins
{
   int nearX; // X increment between the object point and the window border adjacent
   int nearY; // Y increment between the object point and the window border adjacent
   int farX;  // X increment between the object's point and the opposite corner of th
   int farY;  // Y increment between the object's point and the opposite corner of th
};

Margins GetMargins(const ENUM_BASE_CORNER corner, const ENUM_ANCHOR_POINT anchor,
   int dx, int dy)
{
   Margins margins = {}; // zero corrections by default
   ...
   return margins;
}
```

To unify the algorithm, the following macro definitions of directions (sides) are introduced:

```
#define LEFT 0x1
#define LOWER 0x2
#define RIGHT 0x4
#define UPPER 0x8
#define CENTER 0x16
```

With their help, bit masks (combinations) are defined that describe the elements of the ENUM_BASE_CORNER and ENUM_ANCHOR_POINT enumerations.

```
const int corner_flags[] = // flags for ENUM_BASE_CORNER elements
{
   LEFT | UPPER,
   LEFT | LOWER,
   RIGHT | LOWER,
   RIGHT | UPPER
};

const int anchor_flags[] = // flags for ENUM_ANCHOR_POINT elements
{
   LEFT | UPPER,
   LEFT,
   LEFT | LOWER,
   LOWER,
   RIGHT | LOWER,
   RIGHT,
   RIGHT | UPPER,
   UPPER,
   CENTER
};
```

Each of the arrays, *corner_flags* and *anchor_flags*, contains exactly as many elements as there are in the corresponding enumeration.

Next comes the main function code. First of all, let's deal with the simplest option: the central anchor point.

```
if(anchor == ANCHOR_CENTER)
{
   margins.nearX = margins.farX = dx / 2;
   margins.nearY = margins.farY = dy / 2;
}
else
{
   ...
}
```

To analyze the rest of the situations, we will use the bit masks from the above arrays by directly addressing them by the received values *corner* and *anchor*.

```
   const int mask = corner_flags[corner] & anchor_flags[anchor];
   ...
```

If the corner and the anchor point are on the same horizontal side, the following condition will work and the object width at the far edge of the window will be adjusted.

```
   if((mask & (LEFT | RIGHT)) != 0)
   {
      margins.farX = dx;
   }
   ...
```

If they are not on the same side, then they may be on opposite sides, or it may be the case that the anchor point is in the middle of the horizontal side (top or bottom). Checking for an anchor point in the

middle is done using the expression *(anchor_flags[anchor] & (LEFT | RIGHT)) == 0* - then the correction is equal to half the width of the object.

```
else
{
   if((anchor_flags[anchor] & (LEFT | RIGHT)) == 0)
   {
      margins.nearX = dx / 2;
      margins.farX = dx / 2;
   }
   else
   {
      margins.nearX = dx;
   }
}
...
```

Otherwise, with the opposite orientation of the corner and the anchor point, we make an adjustment to the width of the object at the near border of the window.

Similar checks are made for the Y-axis.

```
if((mask & (UPPER | LOWER)) != 0)
{
   margins.farY = dy;
}
else
{
   if((anchor_flags[anchor] & (UPPER | LOWER)) == 0)
   {
      margins.farY = dy / 2;
      margins.nearY = dy / 2;
   }
   else
   {
      margins.nearY = dy;
   }
}
```

Now the *GetMargins* function is ready, and we can proceed to the main code of the script in the *OnStart* function. As before, we determine the size of the window, calculate the initial coordinates in the center, create an OBJ_LABEL object, and select it.

```
void OnStart()
{
   const int t = ChartWindowOnDropped();
   Comment(EnumToString(Corner));

   const string name = "ObjSizeLabel";
   int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS, t) - 1;
   int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS) - 1;
   int x = w / 2;
   int y = h / 2;

   ObjectCreate(0, name, OBJ_LABEL, t, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_SELECTABLE, true);
   ObjectSetInteger(0, name, OBJPROP_SELECTED, true);
   ObjectSetInteger(0, name, OBJPROP_CORNER, Corner);
   ...
```

For animation, an infinite loop provides variables *pass* (iteration counter) and *anchor* (the anchor point, which will be periodically chosen randomly).

```
   int pass = 0;
   ENUM_ANCHOR_POINT anchor = 0;
   ...
```

But there are some changes compared to *ObjectAnchorLabel.mq5*.

We will not generate random movements of the object. Instead, let's set a constant speed of 5 pixels diagonally.

```
   int px = 5, py = 5;
```

To store the size of the text label, we will reserve two new variables.

```
   int dx = 0, dy = 0;
```

The result of counting additional indents will be stored in a variable *m* of type *Margins*.

```
   Margins m = {};
```

This is followed directly by the loop of moving and modifying the object. In it, at every 75th iteration (one iteration of 100 ms, see further), we randomly select a new anchor point, form a new text (the contents of the object) from it, and wait for the changes to be applied to the object (calling *ChartRedraw*). The latter is necessary because the size of the inscription is automatically adjusted to the content, and the new size is important for us in order to correctly calculate the indents in the *GetMargins* call.

We get the dimensions using calls *ObjectGetInteger* with properties OBJPROP_XSIZE and OBJPROP_YSIZE.

```
for( ;!IsStopped(); ++pass)
{
   if(pass % 75 == 0)
   {
      // ENUM_ANCHOR_POINT consists of 9 elements: randomly choose one
      const int r = rand() * 8 / 32768 + 1;
      anchor = (ENUM_ANCHOR_POINT)((anchor + r) % 9);
      ObjectSetInteger(0, name, OBJPROP_ANCHOR, anchor);
      ObjectSetString(0, name, OBJPROP_TEXT, " " + EnumToString(anchor)
         + StringFormat("[%3d,%3d] ", x, y));
      ChartRedraw();
      Sleep(1);

      dx = (int)ObjectGetInteger(0, name, OBJPROP_XSIZE);
      dy = (int)ObjectGetInteger(0, name, OBJPROP_YSIZE);

      m = GetMargins(Corner, anchor, dx, dy);
   }
   ...
```

Once we know the anchor point and all distances, we move the object. If it "bumps" against the wall, we change the direction of movement to the opposite (*px* to *-px* or *py* to *-py*, depending on the side).

```
// bounce off window borders, object fully visible
if(x + px >= w - m.farX)
{
   x = w - m.farX + px - 1;
   px = -px;
}
else if(x + px < m.nearX)
{
   x = m.nearX + px;
   px = -px;
}

if(y + py >= h - m.farY)
{
   y = h - m.farY + py - 1;
   py = -py;
}
else if(y + py < m.nearY)
{
   y = m.nearY + py;
   py = -py;
}

// calculate the new label position
x += px;
y += py;
...
```

It remains to update the state of the object itself: display the current coordinates in the text label and assign them to the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.

```
ObjectSetString(0, name, OBJPROP_TEXT, " " + EnumToString(anchor)
   + StringFormat("[%3d,%3d] ", x, y));
ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);
...
```

After changing the object, we call *ChartRedraw* and wait 100ms to ensure a reasonably smooth animation.

```
ChartRedraw();
Sleep(100);
...
```

At the end of the loop, we check the window size again, since the user can change it while the script is running, and we also repeat the size request.

```
h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS, t) - 1;
w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS) - 1;

dx = (int)ObjectGetInteger(0, name, OBJPROP_XSIZE);
dy = (int)ObjectGetInteger(0, name, OBJPROP_YSIZE);
m = GetMargins(Corner, anchor, dx, dy);
```

```
}
```

We omitted some other innovations of the *ObjectSizeLabel.mq5* script in order to keep the explanation concise. Those who wish can refer to the code. In particular, distinctive colors were used for the inscription: each specific color corresponds to its own anchor point, which makes the switching points more noticeable. Also, you can click *Delete* while the script is running: this will remove the selected object from the chart and the script will automatically end.

5.8.18 Visibility of objects in the context of timeframes

MetaTrader 5 users know about the Display tab in the object properties dialog where you can use the switches to select on which timeframes the object will be displayed and on which it will be hidden. In particular, you can temporarily hide the object completely on all timeframes.

MQL5 has a similar program property, OBJPROP_TIMEFRAMES, which controls the object visibility on a timeframe. The value of this property can be any combination of special integer flags: each flag (constant) contains a bit corresponding to one timeframe (see the table). To set/get the OBJPROP_TIMEFRAMES property, use the *ObjectSetInteger/ObjectGetInteger* functions.

Constant	Value	Visibility in timeframes
OBJ_NO_PERIODS	0	The object is hidden in all timeframes
OBJ_PERIOD_M1	0x00000001	M1
OBJ_PERIOD_M2	0x00000002	M2
OBJ_PERIOD_M3	0x00000004	M3
OBJ_PERIOD_M4	0x00000008	M4
OBJ_PERIOD_M5	0x00000010	M5
OBJ_PERIOD_M6	0x00000020	M6
OBJ_PERIOD_M10	0x00000040	M10
OBJ_PERIOD_M12	0x00000080	M12
OBJ_PERIOD_M15	0x00000100	M15
OBJ_PERIOD_M20	0x00000200	M20
OBJ_PERIOD_M30	0x00000400	M30
OBJ_PERIOD_H1	0x00000800	H1
OBJ_PERIOD_H2	0x00001000	H2
OBJ_PERIOD_H3	0x00002000	H3
OBJ_PERIOD_H4	0x00004000	H4
OBJ_PERIOD_H6	0x00008000	H6
OBJ_PERIOD_H8	0x00010000	H8

Constant	Value	Visibility in timeframes
OBJ_PERIOD_H12	0x00020000	H12
OBJ_PERIOD_D1	0x00040000	D1
OBJ_PERIOD_W1	0x00080000	W1
OBJ_PERIOD_MN1	0x00100000	MN1
OBJ_ALL_PERIODS	0x001fffff	All timeframes

The flags can be combined using the bitwise OR operator ("|"), for example, the superposition of flags OBJ_PERIOD_M15 | OBJ_PERIOD_H4 means that the object will be visible on the 15-minute and 4-hour timeframes.

Note that each flag can be obtained by shifting by 1 to the left by the number of bits equal to the number of the constant in the table. This makes it easier to generate flags dynamically when the algorithm operates in multiple timeframes rather than one particular one.

We will use this feature in the test script *ObjectTimeframes.mq5*. Its task is to create a lot of large text labels on the chart with the names of the timeframes, and each title should be displayed only in the corresponding timeframe. For example, a large label "D1" will be visible only on the daily chart, and when switching to H4, we will see "H4".

To get the short name of the timeframe, without the "PERIOD_" prefix, a simple auxiliary function is implemented.

```
string GetPeriodName(const int tf)
{
   const static int PERIOD_ = StringLen("PERIOD_");
   return StringSubstr(EnumToString((ENUM_TIMEFRAMES)tf), PERIOD_);
}
```

To get the list of all timeframes from the ENUM_TIMEFRAMES enumeration, we will use the EnumToArray function which was presented in the section on conversion of Enumerations.

```
#include "ObjectPrefix.mqh"
#include <MQL5Book/EnumToArray.mqh>

void OnStart()
{
   ENUM_TIMEFRAMES tf = 0;
   int values[];
   const int n = EnumToArray(tf, values, 0, USHORT_MAX);
   ...
```

All labels will be displayed in the center of the window at the moment the script is launched. Resizing the window after the script ends will cause the created captions to no longer be centered. This is a consequence of the fact that MQL5 supports anchoring only to the corners of the window, but not to the center. If you want to automatically maintain the position of objects, you should implement a similar algorithm in the indicator and respond to window resize events. Alternatively, we could display labels in a corner, for example, the lower right.

```
const int centerX = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS) / 2;
const int centerY = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS) / 2;
...
```

In the cycle through timeframes, we create an OBJ_LABEL object for each of them, and place it in the middle of the window anchored in the center of the object.

```
for(int i = 1; i < n; ++i)
{
   // create and setup text label for each timeframe
   const string name = ObjNamePrefix + (string)i;
   ObjectCreate(0, name, OBJ_LABEL, 0, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, centerX);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, centerY);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_CENTER);
   ...
```

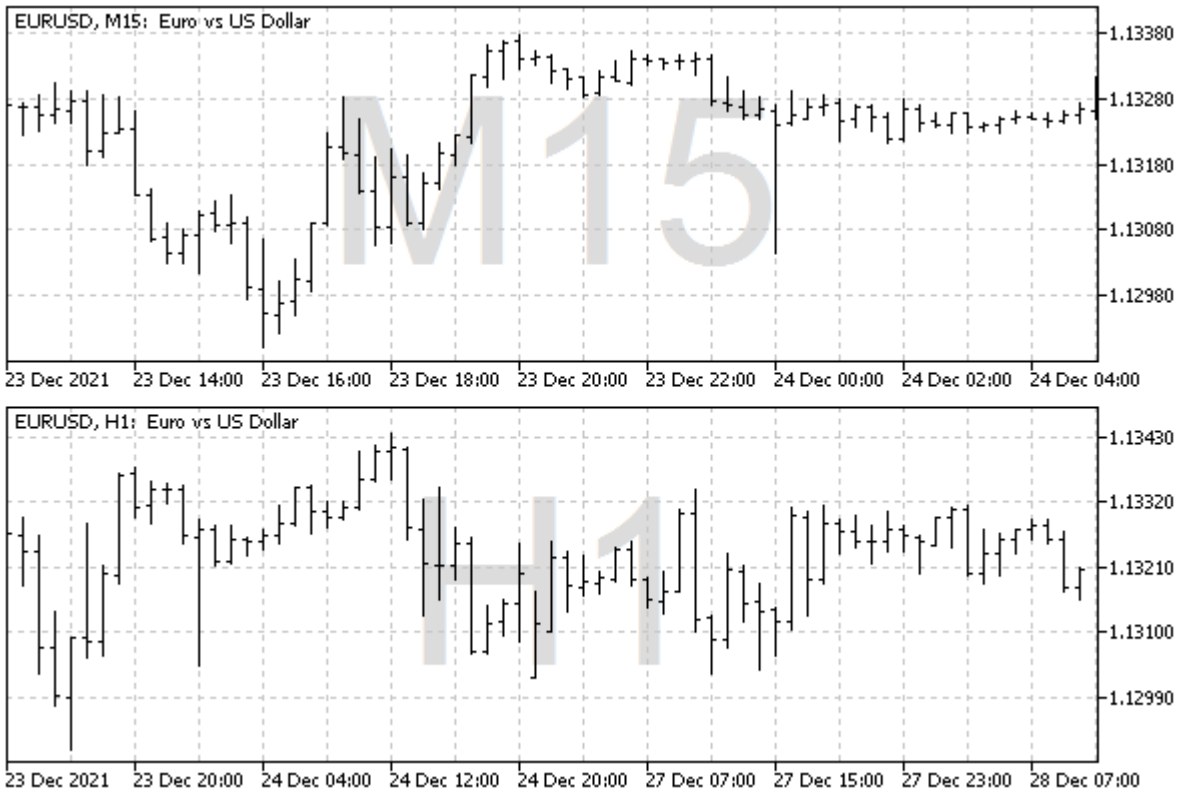
Next, we set the text (name of the timeframe), large font size, gray color and display property in the background.

```
   ObjectSetString(0, name, OBJPROP_TEXT, GetPeriodName(values[i]));
   ObjectSetInteger(0, name, OBJPROP_FONTSIZE, fmin(centerY, centerX));
   ObjectSetInteger(0, name, OBJPROP_COLOR, clrLightGray);
   ObjectSetInteger(0, name, OBJPROP_BACK, true);
   ...
```

Finally, we generate the correct visibility flag for the *i*-th timeframe and write it to the OBJPROP_TIMEFRAMES property.

```
   const int flag = 1 << (i - 1);
   ObjectSetInteger(0, name, OBJPROP_TIMEFRAMES, flag);
}
```

See what happened on the chart when switching timeframes.



Labels with timeframe names

If you open the *Object List* dialog and enable *All* objects in the list, it is easy to make sure that there are generated labels for all timeframes and check their visibility flags.

To remove objects, you can run the *ObjectCleanup1.mq5* script.

5.8.19 Assigning a character code to a label

As mentioned in the review of Objects linked to time and price, the OBJ_ARROW label allows you to display an arbitrary Wingdings font symbol on the chart (the full list of available symbols is provided in the MQL5 documentation). The character code for the object itself is determined by the integer property OBJPROP_ARROWCODE.

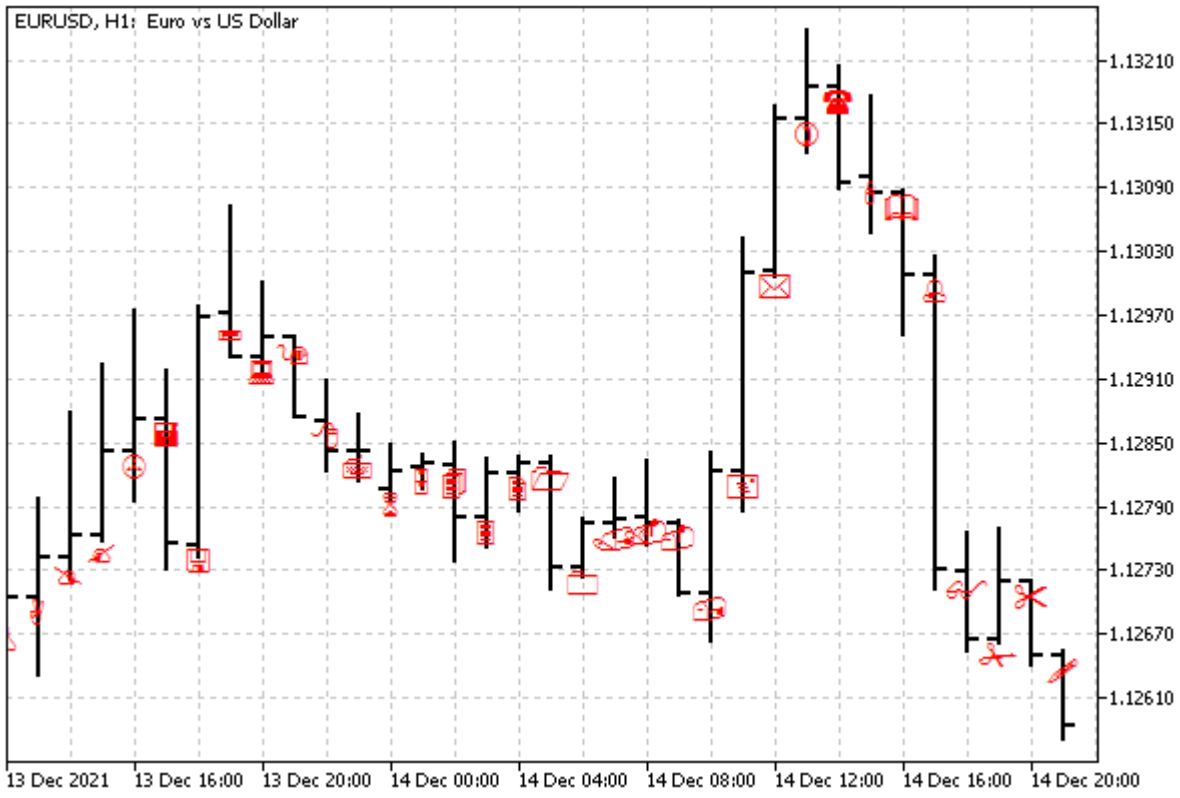
Script allows to demonstrate all characters of the *ObjectWingdings.mq5 font*. In it, we create labels with different characters in a loop, placing them one by one on the bar.

```
#include "ObjectPrefix.mqh"

void OnStart()
{
   for(int i = 33; i < 256; ++i) // character codes
   {
      const int b = i - 33; // bar number
      const string name = ObjNamePrefix + "Wingdings-"
         + (string)iTime(_Symbol, _Period, b);
      ObjectCreate(0, name, OBJ_ARROW,
         0, iTime(_Symbol, _Period, b), iOpen(_Symbol, _Period, b));
      ObjectSetInteger(0, name, OBJPROP_ARROWCODE, i);
   }

   PrintFormat("%d objects with arrows created", 256 - 33);
}
```

How it looks on the chart is shown in the following screenshot.



Wingdings characters in OBJ_ARROW labels

5.8.20 Ray properties for objects with straight lines

Among graphical objects, there are several types in which the lines between anchor points can be displayed either as segments (i.e., strictly between a pair of points) or as endless straight lines continuing in one or another direction across the entire window visibility area. Such objects are:

- Trend line
- Trendline by angle

- All types of channels (equidistant, standard deviations, regression, Andrews pitchfork)
- Gann line
- Fibonacci lines
- Fibonacci channel
- Fibonacci expansion

For them, you can separately enable line continuation to the left or right using the OBJPROP_RAY_LEFT and OBJPROP_RAY_RIGHT properties, respectively. In addition, for a vertical line, you can specify whether it should be drawn in all chart subwindows or only in the current one (where the anchor point is located): the OBJPROP_RAY property is responsible for this. All properties are boolean, meaning they can be enabled (*true*) or disabled (*false*).

Identifier	Description
OBJPROP_RAY_LEFT	Ray continues to the left
OBJPROP_RAY_RIGHT	Ray continues to the right
OBJPROP_RAY	Vertical line extends to all chart windows

You can check the operation of the rays using the *ObjectRays.mq5* script. It creates 3 standard deviation channels with different ray settings.

One specific object is created and configured by the helper function *SetupChannel*. Through its parameters, the channel length in bars and the channel width (deviation) are set, as well as options for displaying rays to the left and right, and color.

```
#include "ObjectPrefix.mqh"

void SetupChannel(const int length, const double deviation = 1.0,
   const bool right = false, const bool left = false,
   const color clr = clrRed)
{
   const string name = ObjNamePrefix + "Channel"
      + (right ? "R" : "") + (left ? "L" : "");
   // NB: Anchor point 0 must have an earlier time than anchor point 1,
   // otherwise the channel will degenerate
   ObjectCreate(0, name, OBJ_STDDEVCHANNEL, 0, iTime(NULL, 0, length), 0);
   ObjectSetInteger(0, name, OBJPROP_TIME, 1, iTime(NULL, 0, 0));
   // deviation
   ObjectSetDouble(0, name, OBJPROP_DEVIATION, deviation);
   // color and description
   ObjectSetInteger(0, name, OBJPROP_COLOR, clr);
   ObjectSetString(0, name, OBJPROP_TEXT, StringFormat("%2.1", deviation)
      + ((!right && !left) ? " NO RAYS" : "")
      + (right ? " RIGHT RAY" : "") + (left ? " LEFT RAY" : ""));
   // properties of rays
   ObjectSetInteger(0, name, OBJPROP_RAY_RIGHT, right);
   ObjectSetInteger(0, name, OBJPROP_RAY_LEFT, left);
   // lighting up objects by highlighting
   // (besides, it's easier for the user to remove them)
   ObjectSetInteger(0, name, OBJPROP_SELECTABLE, true);
   ObjectSetInteger(0, name, OBJPROP_SELECTED, true);
}
```

In the *OnStart* function, we call *SetupChannel* for 3 different channels.

```
void OnStart()
{
   SetupChannel(24, 1.0, true);
   SetupChannel(48, 2.0, false, true, clrBlue);
   SetupChannel(36, 3.0, false, false, clrGreen);
}
```

As a result, we get a chart of the following form.

Channels with different OBJPROP_RAY_LEFT and OBJPROP_RAY_RIGHT property settings

When rays are enabled, it becomes possible to request the object to extrapolate time and price values using the functions that we will describe in the Getting time or price at given points on lines section.

5.8.21 Managing object pressed state

For objects like buttons (OBJ_BUTTON) and panels with an image (OBJ_BITMAP_LABEL), the terminal supports a special property that visually switches the object from the normal (released) state to the pressed state and vice versa. The OBJPROP_STATE constant is reserved for this. The property is of a Boolean type: when the value is *true*, the object is considered to be pressed, and when it is *false*, it is considered to be released (by default).

For OBJ_BUTTON, the effect of a three-dimensional frame is drawn by the terminal itself, while for OBJ_BITMAP_LABEL the programmer must specify two images (as files or resources) that will provide a suitable external representation. Because this property is technically just a toggle, it's easy to use it for other purposes, and not just for "press" and "release" effects. For example, with the help of appropriate images, you can implement a flag (option).

The use of images in objects will be discussed in the next section.

The object state usually changes in interactive MQL programs that respond to user actions, in particular mouse clicks. We will discuss this possibility in the chapter on events.

Now let's test the property on simple buttons, in static mode. The *ObjectButtons.mq5* script creates two buttons on the chart: one in the pressed state, and the other in the released state.

The setting of a single button is given to the *SetupButton* function with parameters that specify the name and text of the button, as well as its coordinates, size, and state.

```
#include "ObjectPrefix.mqh"

void SetupButton(const string button,
   const int x, const int y,
   const int dx, const int dy,
   const bool state = false)
{
   const string name = ObjNamePrefix + button;
   ObjectCreate(0, name, OBJ_BUTTON, 0, 0, 0);
   // position and size
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);
   ObjectSetInteger(0, name, OBJPROP_XSIZE, dx);
   ObjectSetInteger(0, name, OBJPROP_YSIZE, dy);
   // label on the button
   ObjectSetString(0, name, OBJPROP_TEXT, button);

   // pressed (true) / released (false)
   ObjectSetInteger(0, name, OBJPROP_STATE, state);
}
```

Then in *OnStart* we call this function twice.

```
void OnStart()
{
   SetupButton("Pressed", 100, 100, 100, 20, true);
   SetupButton("Normal", 100, 150, 100, 20);
}
```

The resulting buttons might look like this.

Pressed and released OBJ_BUTTON buttons

Interestingly, you can click on any of the buttons with the mouse, and the button will change its state. However, we have not yet discussed how to intercept a notification about this.

It is important to note that this automatic state switching is performed only if the option *Disable selection* is checked in the object properties, but this condition is the default for all objects created programmatically. Recall that, if necessary, this selection can be enabled: for this, you must explicitly set the OBJPROP_SELECTABLE property to *true*. We used it in some previous examples.

To remove buttons that have become unnecessary, use the *ObjectCleanup1.mq5* script.

5.8.22 Adjusting images in bitmap objects

Objects of OBJ_BITMAP_LABEL type (a panel with a picture positioned in screen coordinates) allow displaying bitmap images. Bitmap images mean the BMP graphic format: although in principle there are many other raster formats (for example, PNG or GIF), they are currently not supported in MQL5, just like vector ones.

The string property OBJPROP_BMPFILE allows you to specify an image for an object. It must contain the name of the BMP file or resource.

Since this object supports the possibility of two-position state switching (see OBJPROP_STATE), a modifier parameter should be used for it: a picture for the "on"/"pressed" state is set under index 0, and the "off"/"released" state is set under index 1. If you specify only one picture (no modifier, which is equivalent to 0), it will be used for both states. The default state of an object is "off"/"released".

The size of the object becomes equal to the size of the image, but it can be changed by specifying smaller values in the OBJPROP_XSIZE and OBJPROP_YSIZE properties: in this case, only a part of the image is displayed (for details, see the next section on framing).

The length of the OBJPROP_BMPFILE string must not exceed 63 characters. It can contain not only the file name but also the path to it. If the string starts with a path separator character (forward slash '/' or double backslash '\\'), then the file is searched relative to *terminal_data_directory/MQL5/*. Otherwise, the file is searched relative to the folder where the MQL program is located.

For example, the string "\\Images\\euro.bmp" (or "/Images/euro.bmp") refers to a file in the directory *MQL5/Images/euro.bmp*. The standard terminal delivery pack includes the *Images* folder in the MQL5 directory, and there are a couple of test files *euro.bmp* and *dollar.bmp*, so the path is working. If you specify the string "Images\\euro.bmp" or ("Images/euro.bmp"), then this will imply, for example, for a script launched from *MQL5/Scripts/MQL5Book/*, that the *Images* folder with the *euro.bmp* file should be located directly there, that is, the whole path will be *MQL5/Scripts/MQL5Book/Images/euro.bmp*. There is no such file in our book, and this would lead to an error loading the image. However, this arrangement of graphic files next to the program has its advantages: it is easier to control the assembly, and there is no confusion with mixed pictures of different programs.

The *ObjectBitmap.mq5* script creates a panel with an image on the chart and assigns two images to it: "\\Images\\dollar.bmp" and "\\Images\\euro.bmp".

```
#include "ObjectPrefix.mqh"

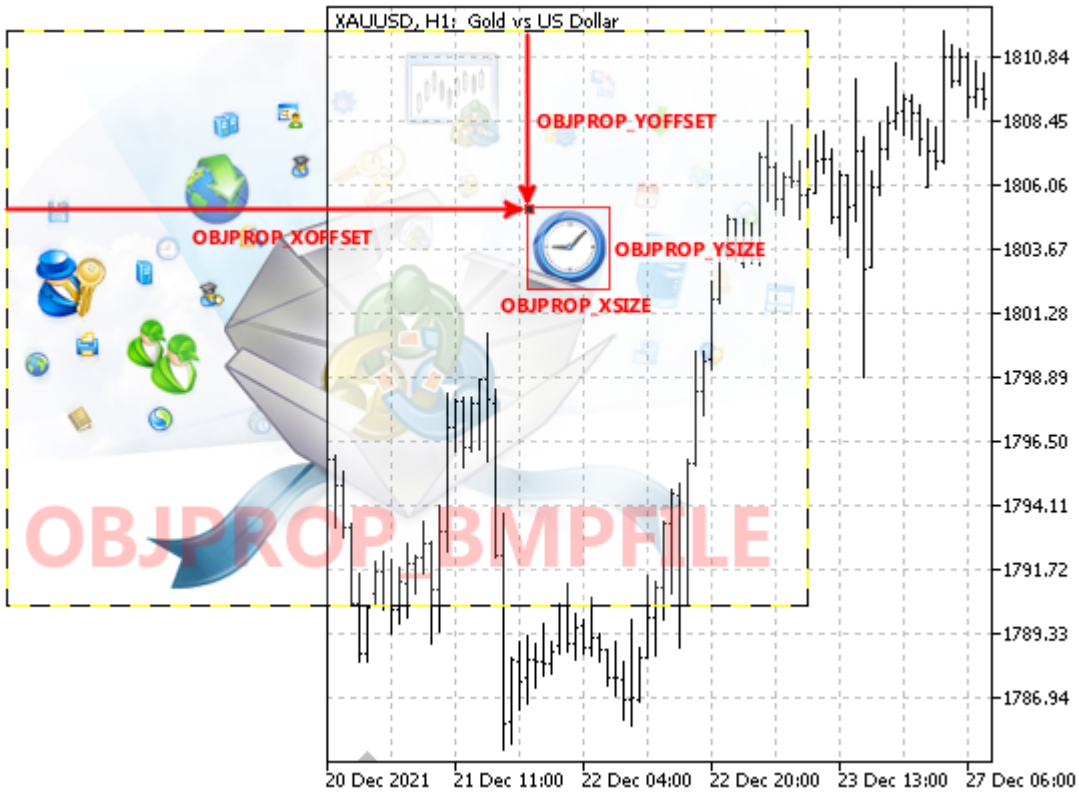
void SetupBitmap(const string button, const int x, const int y,
   const string imageOn, const string imageOff = NULL)
{
   // creating a panel
   const string name = ObjNamePrefix + "Bitmap";
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);
   // set position
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);
   // include images
   ObjectSetString(0, name, OBJPROP_BMPFILE, 0, imageOn);
   if(imageOff != NULL) ObjectSetString(0, name, OBJPROP_BMPFILE, 1, imageOff);
}

void OnStart()
{
   SetupBitmap("image", 100, 100,
      "\\Images\\dollar.bmp", "\\Images\\euro.bmp");
}
```

As with the result of the script from the previous section, here you can also click on the picture object and see that it switches from the dollar to the euro image and back.

5.8.23 Cropping (outputting part) of an image

For graphical objects with pictures (OBJ_BITMAP_LABEL and OBJ_BITMAP), MQL5 allows you to enable the display of a part of the image specified by the property OBJPROP_BMPFILE. To do this, you need to set the size of the object (OBJPROP_XSIZE and OBJPROP_YSIZE) smaller than the image size and set the coordinates of the upper left corner of the visible rectangular fragment using the integer properties OBJPROP_XOFFSET and OBJPROP_YOFFSET. These two properties set, respectively, the indent along X and Y in pixels from the left and top borders of the original image.



Outputting part of an image to an object

Typically, a similar technique using part of a large image is used for toolbar icons (sets of buttons, menus, etc.): a single file with all the icons provides more efficient resource consumption than many small files with individual icons.

The test script *ObjectBitmapOffset.mq5* creates several panels with pictures (OBJ_BITMAP_LABEL), and for all of them the same graphic file is specified in the OBJPROP_BMPFILE property. However, due to the OBJPROP_XOFFSET and OBJPROP_YOFFSET properties, all objects display different parts of the image.

```
void SetupBitmap(const int i, const int x, const int y, const int size,
   const string imageOn, const string imageOff = NULL)
{
   // create an object
   const string name = ObjNamePrefix + "Tool-" + (string)i;
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_CORNER, CORNER_RIGHT_UPPER);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_RIGHT_UPPER);
   // position and size
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);
   ObjectSetInteger(0, name, OBJPROP_XSIZE, size);
   ObjectSetInteger(0, name, OBJPROP_YSIZE, size);
   // offset in the original image, according to which the i-th fragment is read
   ObjectSetInteger(0, name, OBJPROP_XOFFSET, i * size);
   ObjectSetInteger(0, name, OBJPROP_YOFFSET, 0);
   // generic image (file)
   ObjectSetString(0, name, OBJPROP_BMPFILE, imageOn);
}

void OnStart()
{
   const int icon = 46; // size of one icon
   for(int i = 0; i < 7; ++i) // loop through the icons in the file
   {
      SetupBitmap(i, 10, 10 + i * icon, icon,
         "\\Files\\MQL5Book\\icons-322-46.bmp");
   }
}
```

The original image contains several small icons 46 x 46 pixels each. The script "cuts" them out one by one and places them vertically at the right edge of the window.

The following shows a generic file (*/Files/MQL5Book/icons-322-46.bmp*), and what happened on the chart.

BMP file with icons

Button objects with icons on the chart

5.8.24 Input field properties: text alignment and read-only

For objects of type OBJ_EDIT (input field), an MQL program can set two specific properties defined using the *ObjectSetInteger/ObjectGetInteger* functions.

Identifier	Description	Value type
OBJPROP_ALIGN	Horizontal text alignment	ENUM_ALIGN_MODE
OBJPROP_READONLY	Ability to edit text	bool

The ENUM_ALIGN_MODE enumeration contains the following members.

Identifier	Description
ALIGN_LEFT	Left alignment
ALIGN_CENTER	Center alignment
ALIGN_RIGHT	Right alignment

Note that, unlike OBJ_TEXT and OBJ_LABEL objects, the input field does not automatically resize itself to fit the text entered, so for long strings, you may need to explicitly set the OBJPROP_XSIZE property.

In the edit mode, horizontal text scrolling works inside the input field.

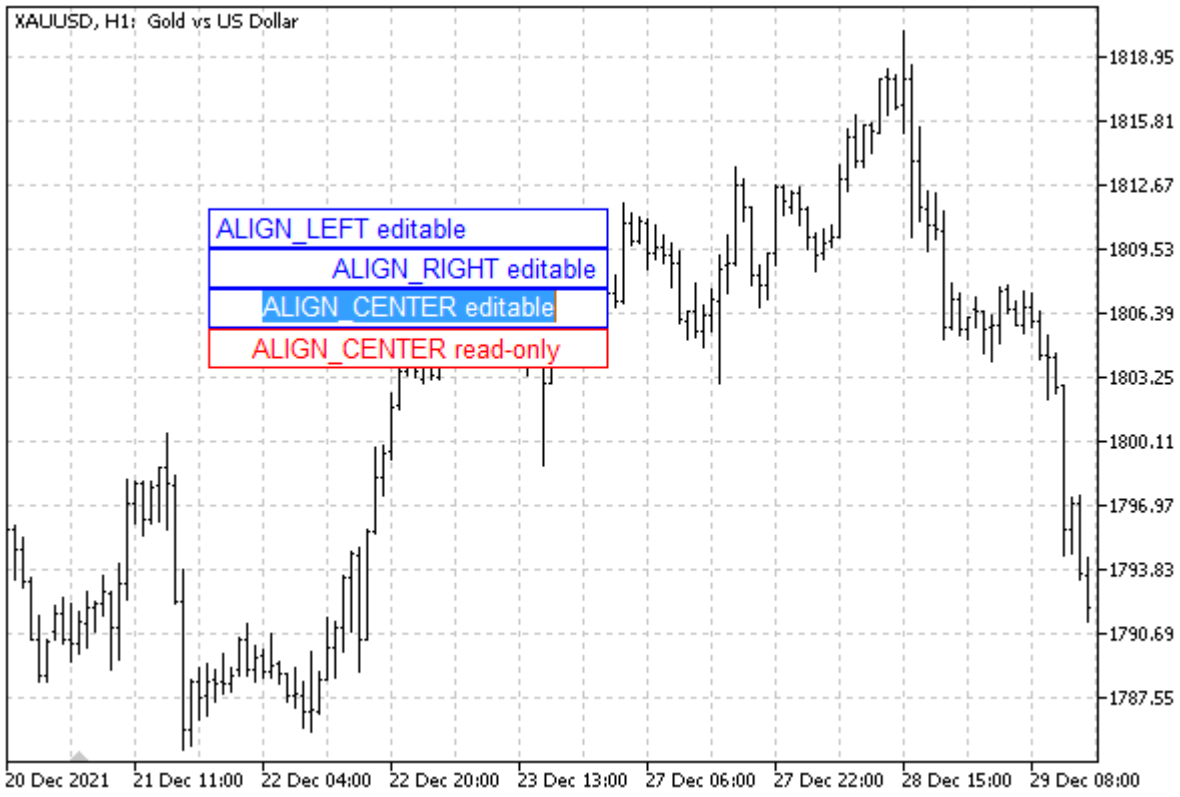
The *ObjectEdit.mq5* script creates four OBJ_EDIT objects: three of them are editable with different text alignment methods and the fourth one is in the read-only mode.

```
#include "ObjectPrefix.mqh"

void SetupEdit(const int x, const int y, const int dx, const int dy,
   const ENUM_ALIGN_MODE alignment = ALIGN_LEFT, const bool readonly = false)
{
   // create an object with a description of the properties
   const string props = EnumToString(alignment)
      + (readonly ? " read-only" : " editable");
   const string name = ObjNamePrefix + "Edit" + props;
   ObjectCreate(0, name, OBJ_EDIT, 0, 0, 0);
   // position and size
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, x);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, y);
   ObjectSetInteger(0, name, OBJPROP_XSIZE, dx);
   ObjectSetInteger(0, name, OBJPROP_YSIZE, dy);
   // specific properties of input fields
   ObjectSetInteger(0, name, OBJPROP_ALIGN, alignment);
   ObjectSetInteger(0, name, OBJPROP_READONLY, readonly);
   // colors (different depending on editability)
   ObjectSetInteger(0, name, OBJPROP_BGCOLOR, clrWhite);
   ObjectSetInteger(0, name, OBJPROP_COLOR, readonly ? clrRed : clrBlue);
   // content
   ObjectSetString(0, name, OBJPROP_TEXT, props);
   // tooltip for editable
   ObjectSetString(0, name, OBJPROP_TOOLTIP,
      (readonly ? "\n" : "Click me to edit"));
}

void OnStart()
{
   SetupEdit(100, 100, 200, 20);
   SetupEdit(100, 120, 200, 20, ALIGN_RIGHT);
   SetupEdit(100, 140, 200, 20, ALIGN_CENTER);
   SetupEdit(100, 160, 200, 20, ALIGN_CENTER, true);
}
```

The result of the script is shown in the image below.



Input fields in different modes

You can click on any editable field and change its content.

5.8.25 Standard deviation channel width

The standard deviation channel OBJ_STDDEVCHANNEL has a special property that defines the channel width as a multiplier for the standard (root mean square) deviation. The property is called OBJPROP_DEVIATION and can take positive real values (*double*). By default, it equals 1.0.

We have already seen an example of its use in the *ObjectRays.mq5* script in the section on Ray properties for objects with straight lines.

5.8.26 Setting levels in level objects

Some graphical objects are built using multiple levels (repetitive lines). These include:

- Andrews pitchfork OBJ_PITCHFORK
- Fibonacci tools:
  - OBJ_FIBO levels
  - Time zones OBJ_FIBOTIMES
  - Fan OBJ_FIBOFAN
  - Arcs OBJ_FIBOARC
  - Channel OBJ_FIBOCHANNEL
  - Extension OBJ_EXPANSION

MQL5 allows you to set level properties for such objects. The properties include their number, colors, values, and labels.

Identifier	Description	Type
OBJPROP_LEVELS	Number of levels	int
OBJPROP_LEVELCOLOR	Level line color	color
OBJPROP_LEVELSTYLE	Level line style	ENUM_LINE_STYLE
OBJPROP_LEVELWIDTH	Level line width	int
OBJPROP_LEVELTEXT	Level description	string
OBJPROP_LEVELVALUE	Level value	double

When calling the *ObjectGet* and *ObjectSet* functions for all properties except OBJPROP_LEVELS, it is required to provide an additional modifier parameter with the number of a specific level.

As an example, let's consider the indicator *ObjectHighLowFibo.mq5*. For a given range of bars, which is defined as the number of the last bar (*baroffset*) and the number of bars (*BarCount*) to the left of it, the indicator finds the *High* and *Low* prices and then creates the OBJ_FIBO object for these points. As new bars form, Fibonacci levels will shift to the right to more current prices.

```
#property indicator_chart_window
#property indicator_buffers 0
#property indicator_plots   0

#include <MQL5Book/ColorMix.mqh>

input int BarOffset = 0;
input int BarCount = 24;

const string Prefix = "HighLowFibo-";

int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   static datetime now = 0;
   if(now != iTime(NULL, 0, 0))
   {
      const int hh = iHighest(NULL, 0, MODE_HIGH, BarCount, BarOffset);
      const int ll = iLowest(NULL, 0, MODE_LOW, BarCount, BarOffset);

      datetime t[2] = {iTime(NULL, 0, hh), iTime(NULL, 0, ll)};
      double p[2] = {iHigh(NULL, 0, hh), iLow(NULL, 0, ll)};

      DrawFibo(Prefix + "Fibo", t, p, clrGray);

      now = iTime(NULL, 0, 0);
   }
   return rates_total;
}
```

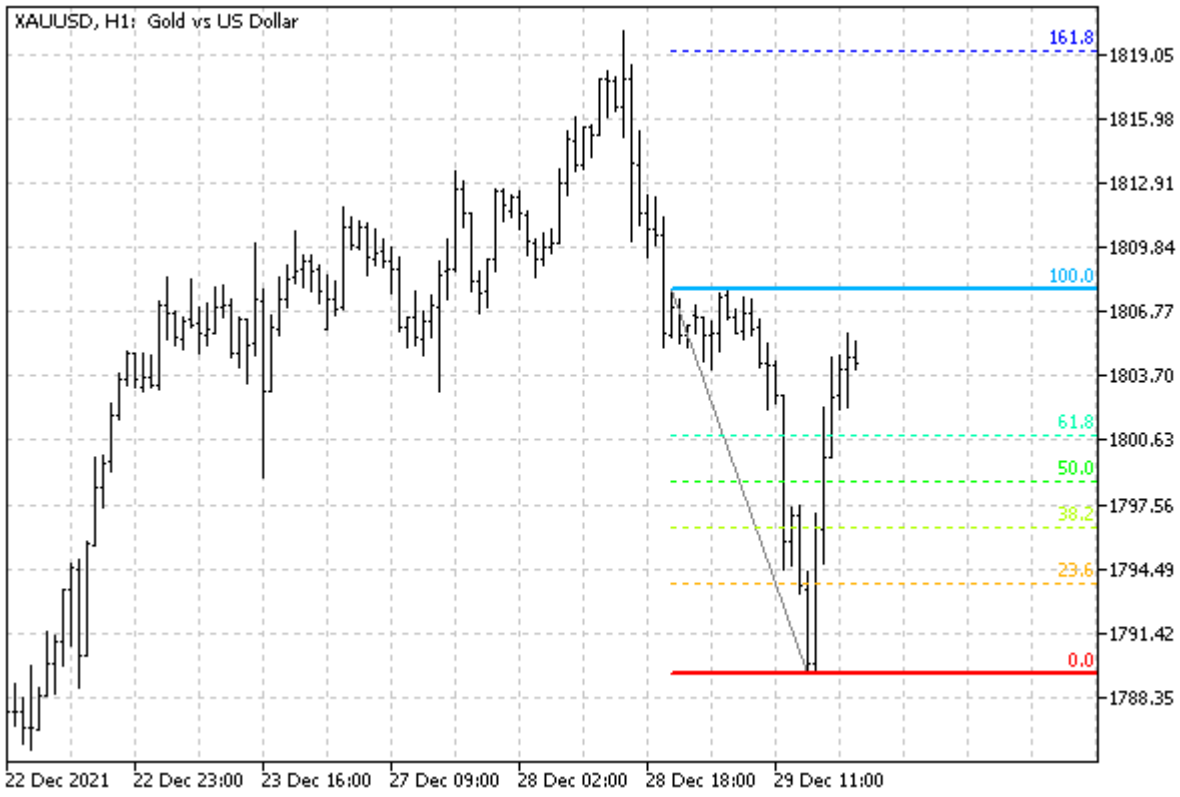
The direct setting of the object is done in the auxiliary function *DrawFibo*. In it, in particular, the levels are painted in rainbow colors, and their style and thickness are determined based on whether the corresponding values are "round" (without a fractional part).

```
bool DrawFibo(const string name, const datetime &t[], const double &p[],
   const color clr)
{
   if(ArraySize(t) != ArraySize(p)) return false;

   ObjectCreate(0, name, OBJ_FIBO, 0, 0, 0);
   // anchor points
   for(int i = 0; i < ArraySize(t); ++i)
   {
      ObjectSetInteger(0, name, OBJPROP_TIME, i, t[i]);
      ObjectSetDouble(0, name, OBJPROP_PRICE, i, p[i]);
   }
   // general settings
   ObjectSetInteger(0, name, OBJPROP_COLOR, clr);
   ObjectSetInteger(0, name, OBJPROP_RAY_RIGHT, true);
   // level settings
   const int n = (int)ObjectGetInteger(0, name, OBJPROP_LEVELS);
   for(int i = 0; i < n; ++i)
   {
      const color gradient = ColorMix::RotateColors(ColorMix::HSVtoRGB(0),
         ColorMix::HSVtoRGB(359), n, i);
      ObjectSetInteger(0, name, OBJPROP_LEVELCOLOR, i, gradient);
      const double level = ObjectGetDouble(0, name, OBJPROP_LEVELVALUE, i);
      if(level - (int)level > DBL_EPSILON * level)
      {
         ObjectSetInteger(0, name, OBJPROP_LEVELSTYLE, i, STYLE_DOT);
         ObjectSetInteger(0, name, OBJPROP_LEVELWIDTH, i, 1);
      }
      else
      {
         ObjectSetInteger(0, name, OBJPROP_LEVELSTYLE, i, STYLE_SOLID);
         ObjectSetInteger(0, name, OBJPROP_LEVELWIDTH, i, 2);
      }
   }

   return true;
}
```

Here is a variant of what an object might look like on a chart.



Fibonacci object with level settings

5.8.27 Additional properties of Gann, Fibonacci, and Elliot objects

Gann, Fibonacci, and Elliot objects have specific, unique properties. Depending on the property type, use the *ObjectGetInteger/ObjectSetInteger* or *ObjectGetDouble/ObjectSetDouble* functions.

Identifier	Description	Type
OBJPROP_DIRECTION	Gann object trend (Fan OBJ_GANNFAN and Grid OBJ_GANNGRID)	ENUM_GANN_DIRECTION
OBJPROP_DEGREE	Elliot wave degree levels	ENUM_ELLIOT_WAVE_DEGREE
OBJPROP_DRAWLINES	Displaying lines for the Elliot wave levels	bool
OBJPROP_SCALE	Scale in points per bar (property of Gann objects and the Fibonacci Arcs object)	double
OBJPROP_ELLIPSE	Full ellipse display for the Fibonacci Arcs object (OBJ_FIBOARC)	bool

The ENUM_GANN_DIRECTION enumeration has the following members:

Constant	Trend direction
GANN_UP_TREND	Ascending lines
GANN_DOWN_TREND	Descending lines

ENUM_ELLIOT_WAVE_DEGREE is used to set the size (labeling method) of Elliot waves.

Constant	Description
ELLIOTT_GRAND_SUPERCYCLE	Grand Supercycle
ELLIOTT_SUPERCYCLE	Supercycle
ELLIOTT_CYCLE	Cycle
ELLIOTT_PRIMARY	Primary cycle
ELLIOTT_INTERMEDIATE	Intermediate link
ELLIOTT_MINOR	Minor cycle
ELLIOTT_MINUTE	Minute
ELLIOTT_MINUETTE	Minuette
ELLIOTT_SUBMINUETTE	Subminuette

5.8.28 Chart object

The chart object OBJ_CHART allows you to create thumbnails of other charts inside the chart for other instruments and timeframes. Chart objects are included in the general chart list, which we obtained programmatically using the *ChartFirst* and *ChartNext* functions. As mentioned in the section on Checking the main window status, the special chart property CHART_IS_OBJECT allows you to find out by identifier whether it is a full-fledged window or a chart object. In the latter case, calling *ChartGetInteger(id, CHART_IS_OBJECT)* will return *true*.

The chart object has a set of properties specific only to it.

Identifier	Description	Type
OBJPROP_CHART_ID	Chart ID (r/o)	long
OBJPROP_PERIOD	Chart Period	ENUM_TIMEFRAMES
OBJPROP_DATE_SCALE	Show the time scale	bool
OBJPROP_PRICE_SCALE	Show the price scale	bool
OBJPROP_CHART_SCALE	Scale (value in the range 0 - 5)	int
OBJPROP_SYMBOL	Symbol	string

The identifier obtained through the OBJPROP_CHART_ID property allows you to manage the object like a regular chart using the functions from the chapter Working with charts. However, there are some limitations:

- The object cannot be closed with *ChartClose*
- It is not possible to change the symbol/period in the object using the *CartSetSymbolPeriod* function
- Properties CHART_SCALE, CHART_BRING_TO_TOP,CHART_SHOW_DATE_SCALE and CHART_SHOW_PRICE_SCALE are not modified in the object.

By default, all properties (except OBJPROP_CHART_ID) are equal to the corresponding properties of the current window.

The demonstration of chart objects is implemented as a bufferless indicator *ObjectChart.mq5*. It creates a subwindow with two chart objects for the same symbol as the current chart but with adjacent timeframes above and below the current one.

Objects snap to the upper right corner of the subwindow and have the same predefined sizes:

```
#define SUBCHART_HEIGHT 150
#define SUBCHART_WIDTH  200
```

Of course, the height of the subwindow must match the height of the objects, until we can respond adaptively to resize events.

```
#property indicator_separate_window
#property indicator_height SUBCHART_HEIGHT
#property indicator_buffers 0
#property indicator_plots   0
```

One mini-chart is configured in the *SetupSubChart* function, which takes the number of the object, its dimensions, and the required timeframe as inputs. The result of *SetupSubChart* is the identifier of the chart object, which we just output into the log for reference.

```
void OnInit()
{
   Print(SetupSubChart(0, SUBCHART_WIDTH, SUBCHART_HEIGHT, PeriodUp(_Period)));
   Print(SetupSubChart(1, SUBCHART_WIDTH, SUBCHART_HEIGHT, PeriodDown(_Period)));
}
```

Macros *PeriodUp* and *PeriodDown* use the helper function *PeriodRelative*.

```
#define PeriodUp(P) PeriodRelative(P, +1)
#define PeriodDown(P) PeriodRelative(P, -1)

ENUM_TIMEFRAMES PeriodRelative(const ENUM_TIMEFRAMES tf, const int step)
{
   static const ENUM_TIMEFRAMES stdtfs[] =
   {
      PERIOD_M1,  // =1 (1)
      PERIOD_M2,  // =2 (2)
      ...
      PERIOD_W1,  // =32769 (8001)
      PERIOD_MN1, // =49153 (C001)
   };
   const int x = ArrayBsearch(stdtfs, tf == PERIOD_CURRENT ? _Period : tf);
   const int needle = x + step;
   if(needle >= 0 && needle < ArraySize(stdtfs))
   {
      return stdtfs[needle];
   }
   return tf;
}
```

Here is the main working function *SetupSubChart*.

```
long SetupSubChart(const int n, const int dx, const int dy,
   ENUM_TIMEFRAMES tf = PERIOD_CURRENT, const string symbol = NULL)
{
   // create an object
   const string name = Prefix + "Chart-"
      + (symbol == NULL ? _Symbol : symbol) + PeriodToString(tf);
   ObjectCreate(0, name, OBJ_CHART, ChartWindowFind(), 0, 0);

   // anchor to the top right corner of the subwindow
   ObjectSetInteger(0, name, OBJPROP_CORNER, CORNER_RIGHT_UPPER);
   // position and size
   ObjectSetInteger(0, name, OBJPROP_XSIZE, dx);
   ObjectSetInteger(0, name, OBJPROP_YSIZE, dy);
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, (n + 1) * dx);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, 0);

   // specific chart settings
   if(symbol != NULL)
   {
      ObjectSetString(0, name, OBJPROP_SYMBOL, symbol);
   }

   if(tf != PERIOD_CURRENT)
   {
      ObjectSetInteger(0, name, OBJPROP_PERIOD, tf);
   }
   // disable the display of lines
   ObjectSetInteger(0, name, OBJPROP_DATE_SCALE, false);
   ObjectSetInteger(0, name, OBJPROP_PRICE_SCALE, false);
   // add the MA indicator to the object by its id just for demo
   const long id = ObjectGetInteger(0, name, OBJPROP_CHART_ID);
   ChartIndicatorAdd(id, 0, iMA(NULL, tf, 10, 0, MODE_EMA, PRICE_CLOSE));
   return id;
}
```

For a chart object, the anchor point is always fixed in the upper left corner of the object, so when anchoring to the right corner of the window, you need to add the width of the object (this is done by +1 in the expression*(n+1)*dx* for OBJPROP_XDISTANCE).

The following screenshot shows the result of the indicator on the XAUUSD,H1 chart.

Two chart objects in the indicator subwindow

As we can see, the mini-charts display the M30 and H2 timeframes.

It is important to note that you can add indicators to chart objects and apply tpl templates, including those with Expert Advisors. However, you cannot create objects inside chart objects.

> When the chart object is hidden due to disabled visualization on the current timeframe or on all timeframes, the CHART_WINDOW_IS_VISIBLE property for the internal chart still returns *true*.

5.8.29 Moving objects

To move objects in time/price coordinates, you can use not only the *ObjectSet* functions of property change but also the special function *ObjectMove*, which changes the coordinates of the specified anchor point of the object.

bool ObjectMove(long chartId, const string name, int index, datetime time, double price)

The *chartId* parameter sets the chart ID (0 is for the current chart). The name of the object is passed in the *name* parameter. The anchor point index and coordinates are specified in the *index*, *time*, and *price* parameters, respectively.

The function uses an asynchronous call, that is, it sends a command to the chart's event queue and does not wait for the movement itself.

The function returns an indication of whether the command was successfully queued (in this case, the result is *true*). The actual position of the object should be learned using calls to the *ObjectGet* functions.

In the indicator *ObjectHighLowFibo.mq5*, we modify the *DrawFibo* function in such a way as to enable *ObjectMove*. Instead of two calls to *ObjectSet* functions in the loop through the anchor points, we now have one *ObjectMove* call:

```
bool DrawFibo(const string name, const datetime &t[], const double &p[],
   const color clr)
{
   ...
   for(int i = 0; i < ArraySize(t); ++i)
   {
      // was:
      // ObjectSetInteger(0, name, OBJPROP_TIME, i, t[i]);
      // ObjectSetDouble(0, name, OBJPROP_PRICE, i, p[i]);
      // became:
      ObjectMove(0, name, i, t[i], p[i]);
   }
   ...
}
```

It makes sense to apply the *ObjectMove* function where both coordinates of the anchor point change. In some cases, only one coordinate has an effect (for example, in the channels of standard deviation and linear regression at the anchor points, only the start and end dates/times are important, and the channels calculate the price value at these points automatically). In such cases, a single call of the *ObjectSet* function is more appropriate than *ObjectMove*.

5.8.30 Getting time or price at the specified line points

Many graphical objects include one or more straight lines. MQL5 allows you to interpolate and extrapolate points on these lines and get another coordinate from one coordinate, for example, price by time or time by price.

Interpolation is always available: it works "inside" the object, i.e., between anchor points. Extrapolation outside an object is possible only if the ray property in the corresponding direction is enabled for it (see Ray properties for objects with straight lines).

The *ObjectGetValueByTime* function returns the price value for the specified time. The *ObjectGetTimeByValue* function returns the time value for the specified price

double ObjectGetValueByTime(long chartId, const string name, datetime time, int line)
datetime ObjectGetTimeByValue(long chartId, const string name, double value, int line)

Calculations are made for an object named *name* on the chart with *chartId*. The *time* and *value* parameters specify a known coordinate for which the unknown should be calculated. Since an object can have several lines, several values will correspond to one coordinate, and therefore it is necessary to specify the line number in the *line* parameter.

The function returns the price or time value for the projection of the point with the specified initial coordinate relative to the line.

In case of an error, 0 will be returned, and the error code will be written to *_LastError*. For example, attempting to extrapolate a line value with the beam property disabled generates an OBJECT_GETVALUE_FAILED (4205) error.

The functions are applicable to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLINE)
- Equidistant channel (OBJ_CHANNEL), 2 lines
- Linear regression channel (OBJ_REGRESSION); 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL); 3 lines
- Arrow line (OBJ_ARROWED_LINE)

Let's check the operation of the function using a bufferless indicator *ObjectChannels.mq5*. It creates two objects with standard deviation and linear regression channels, after which it requests and displays in the comment the price of the upper and lower lines on future bars. For the standard deviation channel, the OBJPROP_RAY_RIGHT property is enabled, but for the regression channel, it is not (intentionally). In this regard, no values will be received from the second channel, and zeros are always displayed on the screen for it.

As new bars form, the channels will automatically move to the right. The length of the channels is set in the input parameter *WorkPeriod* (10 bars by default).

```
input int WorkPeriod = 10;

const string Prefix = "ObjChnl-";
const string ObjStdDev = Prefix + "StdDev";
const string ObjRegr = Prefix + "Regr";

void OnInit()
{
   CreateObjects();
   UpdateObjects();
}
```

The *CreateObjects* function creates 2 channels and makes initial settings for them.

```
void CreateObjects()
{
   ObjectCreate(0, ObjStdDev, OBJ_STDDEVCHANNEL, 0, 0, 0);
   ObjectCreate(0, ObjRegr, OBJ_REGRESSION, 0, 0, 0);
   ObjectSetInteger(0, ObjStdDev, OBJPROP_COLOR, clrBlue);
   ObjectSetInteger(0, ObjStdDev, OBJPROP_RAY_RIGHT, true);
   ObjectSetInteger(0, ObjRegr, OBJPROP_COLOR, clrRed);
   // NB: ray is not enabled for the regression channel (intentionally)
}
```

The *UpdateObjects* function moves channels to the last *WorkPeriod* bars.

```
void UpdateObjects()
{
   const datetime t0 = iTime(NULL, 0, WorkPeriod);
   const datetime t1 = iTime(NULL, 0, 0);

   // we don't use ObjectMove because channels work
   // only with time coordinate (price is calculated automatically)
   ObjectSetInteger(0, ObjStdDev, OBJPROP_TIME, 0, t0);
   ObjectSetInteger(0, ObjStdDev, OBJPROP_TIME, 1, t1);
   ObjectSetInteger(0, ObjRegr, OBJPROP_TIME, 0, t0);
   ObjectSetInteger(0, ObjRegr, OBJPROP_TIME, 1, t1);
}
```

In the *OnCalculate* handler, we update the position of the channels on new bars, and on each tick, we call *DisplayObjectData* to get price extrapolation and display it as a comment.

```
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   static datetime now = 0;
   if(now != iTime(NULL, 0, 0))
   {
      UpdateObjects();
      now = iTime(NULL, 0, 0);
   }

   DisplayObjectData();

   return rates_total;
}
```

In the *DisplayObjectData* function, we will find prices at anchor points on the middle line (OBJPROP_PRICE). Also, using *ObjectGetValueByTime*, we will request price values for the upper and lower channel lines through *WorkPeriod* bars in the future.

```
void DisplayObjectData()
{
   const double p0 = ObjectGetDouble(0, ObjStdDev, OBJPROP_PRICE, 0);
   const double p1 = ObjectGetDouble(0, ObjStdDev, OBJPROP_PRICE, 1);

   // the following equalities are always true due to the channel calculation algorit
   // - the middle lines of both channels are the same,
   // - anchor points always lie on the middle line,
   // ObjectGetValueByTime(0, ObjStdDev, iTime(NULL, 0, 0), 0) == p1
   // ObjectGetValueByTime(0, ObjRegr, iTime(NULL, 0, 0), 0) == p1

   // trying to extrapolate future prices from the upper and lower lines
   const double d1 = ObjectGetValueByTime(0, ObjStdDev, iTime(NULL, 0, 0)
      + WorkPeriod * PeriodSeconds(), 1);
   const double d2 = ObjectGetValueByTime(0, ObjStdDev, iTime(NULL, 0, 0)
      + WorkPeriod * PeriodSeconds(), 2);

   const double r1 = ObjectGetValueByTime(0, ObjRegr, iTime(NULL, 0, 0)
      + WorkPeriod * PeriodSeconds(), 1);
   const double r2 = ObjectGetValueByTime(0, ObjRegr, iTime(NULL, 0, 0)
      + WorkPeriod * PeriodSeconds(), 2);

   // display all received prices in a comment
   Comment(StringFormat("%.*f %.*f\ndev: up=%.*f dn=%.*f\nreg: up=%.*f dn=%.*f",
      _Digits, p0, _Digits, p1,
      _Digits, d1, _Digits, d2,
      _Digits, r1, _Digits, r2));
}
```

It is important to note that due to the fact that the ray property is not enabled for the regression channel, it always gives zeros in the future (although if we asked for prices within the channel's time period, we would get the correct values).

Channels and price values at the points of their lines

Here, for channels that are 10 bars long, the extrapolation is also done on 10 bars ahead, which gives the future values shown in the line with "dev:", approximately corresponding to the right border of the window.

5.9 Interactive events on charts

MetaTrader 5 charts not only provide a visual representation of data and are the execution environment for MQL programs, but also support the mechanism of interactive events, which allows programs to respond to the actions of the user and other programs. This is done by a special event type – *OnChartEvent* – which we already discussed in the Overview of event handling functions.

Any indicator or Expert Advisor can receive such events provided that the event processing function of the same name with a predefined signature is described in the code. In some of the indicator examples that we considered earlier, we have already had to take advantage of this opportunity. In this chapter, we will look at the event system in detail.

The *OnChartEvent* event is generated by the client terminal during the following chart manipulations performed by the user:

- Changing the chart size or settings
- Keystrokes when the chart window is in focus
- Mouse cursor movement
- Mouse clicks on the chart
- Mouse clicks on graphical objects
- Creating a graphical object

- Deleting a graphical object
- Moving a graphical object with the mouse
- Finishing to edit the test in the input field of the OBJ_EDIT object

The MQL program receives the listed events only from the chart on which it is running. Like other event types, they are added to a queue. All events are then processed one by one in the order of arrival. If there is already an *OnChartEvent* event of a particular type in the MQL program queue or it is being processed, a new event of the same type is not queued (discarded).

Some event types are always active, while others are disabled by default and must be explicitly enabled by setting the appropriate chart properties using the *ChartSetInteger* call. Such disabled events include, in particular, mouse movements and mouse wheel scrolling. All of them are characterized by the fact that they can generate massive event streams, and in order to save resources, it is recommended to enable them only when necessary.

In addition to standard events, there is the concept of "custom events". The meaning and content of parameters for such events are assigned and interpreted by the MQL program itself (one or several, if we are talking about the interaction of a complex of programs). An MQL program can send "user events" to a chart (including another one) using the function *EventChartCustom*. Such events are also handled by the *OnChartEvent* function.

If there are several MQL programs on the chart with the *OnChartEvent* handler, they will all receive the same stream of events.

> All MQL programs run in threads other than the main thread of the application. The main terminal thread is responsible for processing all Windows system messages, and as a result of this processing, in turn, it generates Windows messages for its own application. For example, dragging a chart with the mouse generates several WM_MOUSE_MOVE system messages (in terms of the Windows API) for subsequent drawing of the application window, and also sends internal messages to Expert Advisors and indicators launched on this chart. In this case, a situation may arise that the main thread of the application has not yet managed to process the system message about redrawing the WM_PAINT window (and therefore has not yet changed the appearance of the chart), and the Expert Advisor or indicator has already received an event about moving the mouse cursor. Then the chart property CHART_FIRST_VISIBLE_BAR will be changed only after the chart is drawn.

Since of the two types of interactive MQL programs, we have studied only indicators so far, all the examples in this chapter will be built on the basis of indicators. The second type, Expert Advisors, will be described in the next Part of the book. However, the principles of working with events in them completely coincide with those presented here.

5.9.1 Event handling function OnChartEvent

An indicator or Expert Advisor can receive interactive events from the terminal if the code contains the *OnChartEvent* function with the following prototype.

```
void OnChartEvent(const int event, const long &lparam, const double &dparam, const string &sparam)
```

This function will be called by the terminal in response to user actions or in case of generating a "user event" using *EventChartCustom*.

In the *event* parameter, the event identifier (its type) is passed as one of the values of the ENUM_CHART_EVENT enumeration (see the table).

Identifier	Description
CHARTEVENT_KEYDOWN	Keyboard action
CHARTEVENT_MOUSE_MOVE	Moving the mouse and clicking mouse buttons (if the CHART_EVENT_MOUSE_MOVE property is set for the chart)
CHARTEVENT_MOUSE_WHEEL	Clicking or scrolling the mouse wheel (if the CHART_EVENT_MOUSE_WHEEL property is set for the chart)
CHARTEVENT_CLICK	Mouse-click on the chart
CHARTEVENT_OBJECT_CREATE	Creating a graphical object (if the CHART_EVENT_OBJECT_CREATE property is set for the chart)
CHARTEVENT_OBJECT_CHANGE	Modifying a graphical object through the properties dialog
CHARTEVENT_OBJECT_DELETE	Deleting a graphical object (if the CHART_EVENT_OBJECT_DELETE property is set for the chart)
CHARTEVENT_OBJECT_CLICK	Mouse-click on a graphical object
CHARTEVENT_OBJECT_DRAG	Dragging a graphical object
CHARTEVENT_OBJECT_ENDEDIT	Finishing text editing in the "input field" graphical object
CHARTEVENT_CHART_CHANGE	Changing the chart dimensions or properties (via the properties dialog, toolbar, or context menu)
CHARTEVENT_CUSTOM	The starting number of the event from the custom event range
CHARTEVENT_CUSTOM_LAST	The end number of the event from the custom event range

The *lparam*, *dparam*, and *sparam* parameters are used differently depending on the event type. In general, we can say that they contain additional data necessary to process a particular event. The following sections provide details for each type.

> Attention! The *OnChartEvent* function is called only for indicators and Expert Advisors that are directly plotted on the chart. If any indicator is created programmatically using *iCustom* or *IndicatorCreate*, the *OnChartEvent* events will not be translated to it.
>
> In addition, the *OnChartEvent* handler is not called in the tester, even in visual mode.

For the first demonstration of the *OnChartEvent* handler, let's consider a bufferless indicator *EventAll.mq5* which intercepts and logs all events.

```
void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   ENUM_CHART_EVENT evt = (ENUM_CHART_EVENT)id;
   PrintFormat("%s %lld %f '%s'", EnumToString(evt), lparam, dparam, sparam);
}
```

By default, all types of events can be generated on the chart, except for four mass events, which, as indicated in the table above, are enabled by the special properties of the chart. In the next section, we will supplement the indicator with settings to include certain types according to preferences.

Run the indicator on a chart with existing objects or create objects while the indicator is running.

Change the size or settings of the chart, make mouse clicks, and edit the properties of objects. The following entries will appear in the log.

```
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
CHARTEVENT_CLICK 149 144.000000 ''
CHARTEVENT_OBJECT_CLICK 112 105.000000 'Daily Rectangle 53404'
CHARTEVENT_CLICK 112 105.000000 ''
CHARTEVENT_KEYDOWN 46 1.000000 '339'
CHARTEVENT_CLICK 13 252.000000 ''
CHARTEVENT_OBJECT_DRAG 0 0.000000 'Daily Button 61349'
CHARTEVENT_OBJECT_CLICK 145 104.000000 'Daily Button 61349'
CHARTEVENT_CLICK 145 104.000000 ''
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
CHARTEVENT_OBJECT_DRAG 0 0.000000 'Daily Vertical Line 22641'
CHARTEVENT_OBJECT_DRAG 0 0.000000 'Daily Vertical Line 22641'
CHARTEVENT_OBJECT_CLICK 177 206.000000 'Daily Vertical Line 22641'
CHARTEVENT_CLICK 177 206.000000 ''
CHARTEVENT_OBJECT_CHANGE 0 0.000000 'Daily Rectangle 37930'
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
CHARTEVENT_CLICK 152 118.000000 ''
```

Here we see events of various types, the meanings of their parameters will become clear after reading the following sections.

5.9.2 Event-related chart properties

Four types of events are capable of generating a lot of messages and therefore are disabled by default. To activate or disable them later, set the appropriate chart properties using the *ChartSetInteger* function. All properties are of Boolean type: *true* means enabled, and *false* means disabled.

Identifier	Description
CHART_EVENT_MOUSE_WHEEL	Sending CHARTEVENT_MOUSE_WHEEL messages about mouse wheel events to the chart
CHART_EVENT_MOUSE_MOVE	Sending CHARTEVENT_MOUSE_MOVE messages about mouse movements to the chart
CHART_EVENT_OBJECT_CREATE	Sending CHARTEVENT_OBJECT_CREATE messages about the creation of graphical objects to the chart
CHART_EVENT_OBJECT_DELETE	Sending CHARTEVENT_OBJECT_DELETE messages about the deletion of graphical objects to the chart

If any MQL program changes one of these properties, it affects all other programs running on the same chart and remains in effect even after the original program terminates.

By default, all properties have the *false* value.

Let's complement the *EventAll.mq5* indicator from the previous section with four input variables that allow you to enable any of these types of events (in addition to the rest that cannot be disabled). In addition, we will describe four auxiliary variables in order to be able to restore the chart settings after deleting the indicator.

```
input bool ShowMouseMove = false;
input bool ShowMouseWheel = false;
input bool ShowObjectCreate = false;
input bool ShowObjectDelete = false;

bool mouseMove, mouseWheel, objectCreate, objectDelete;
```

At startup, remember the current values of the properties and then apply the settings selected by the user.

```
void OnInit()
{
   mouseMove = PRTF(ChartGetInteger(0, CHART_EVENT_MOUSE_MOVE));
   mouseWheel = PRTF(ChartGetInteger(0, CHART_EVENT_MOUSE_WHEEL));
   objectCreate = PRTF(ChartGetInteger(0, CHART_EVENT_OBJECT_CREATE));
   objectDelete = PRTF(ChartGetInteger(0, CHART_EVENT_OBJECT_DELETE));

   ChartSetInteger(0, CHART_EVENT_MOUSE_MOVE, ShowMouseMove);
   ChartSetInteger(0, CHART_EVENT_MOUSE_WHEEL, ShowMouseWheel);
   ChartSetInteger(0, CHART_EVENT_OBJECT_CREATE, ShowObjectCreate);
   ChartSetInteger(0, CHART_EVENT_OBJECT_DELETE, ShowObjectDelete);
}
```

Properties are restored in the *OnDeinit* handler.

```
void OnDeinit(const int)
{
   ChartSetInteger(0, CHART_EVENT_MOUSE_MOVE, mouseMove);
   ChartSetInteger(0, CHART_EVENT_MOUSE_WHEEL, mouseWheel);
   ChartSetInteger(0, CHART_EVENT_OBJECT_CREATE, objectCreate);
   ChartSetInteger(0, CHART_EVENT_OBJECT_DELETE, objectDelete);
}
```

Run the indicator with the new event types enabled. Be prepared for a lot of mouse movement messages. Here is a snippet of the log:

```
CHARTEVENT_MOUSE_WHEEL 5308557 -120.000000 ''
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
CHARTEVENT_MOUSE_WHEEL 5308557 -120.000000 ''
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
CHARTEVENT_MOUSE_MOVE 141 81.000000 '2'
CHARTEVENT_MOUSE_MOVE 141 81.000000 '0'
...
CHARTEVENT_OBJECT_CREATE 0 0.000000 'Daily Rectangle 37664'
CHARTEVENT_MOUSE_MOVE 323 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 322 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 321 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 320 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 318 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 316 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 314 146.000000 '0'
CHARTEVENT_MOUSE_MOVE 314 145.000000 '0'
...
CHARTEVENT_OBJECT_DELETE 0 0.000000 'Daily Rectangle 37664'
CHARTEVENT_KEYDOWN 46 1.000000 '339
```

We will disclose the specifics of information for each type of event in the relevant sections below.

5.9.3 Chart change event

When changing the chart size, price display modes, scale, or other parameters, the terminal sends the CHARTEVENT_CHART_CHANGE event, which has no parameters. The MQL program must find out the changes on its own using *ChartGet* function calls.

We have already used this event in the *ChartModeMonitor.mq5* example in the section on Chart display modes. Now let's take another example.

As you know, MetaTrader 5 allows the saving of the screenshot of the current chart to a file of a specified size (the *Save as Picture* command of the context menu). However, this method of obtaining a screenshot is not suitable for all cases. In particular, if you need an image with a tooltip or when an object of the input field type is active (when text is selected inside the field and the text cursor is visible), the standard command will not help, since it re-forms the chart image without taking into account these and some other nuances of the current state of the window.

The only alternative to get an exact copy of the window is to use means that are external to the terminal (for example, the *PrtSc* key via the Windows clipboard), but this method does not guarantee the required window size. In order not to select the size by trial and error, or some additional programs,

we will create an indicator *EventWindowSizer.mq5*, which will track the user's size setting on the go and output the current value in a comment.

All work is done in the *OnChartEvent* handler, starting with checking the event ID for CHARTEVENT_CHART_CHANGE. The dimensions of the window in pixels can be obtained using the CHART_WIDTH_IN_PIXELS and CHART_HEIGHT_IN_PIXELS properties. However, they return dimensions without taking into account borders, and the borders are usually wanted for a screenshot. Therefore, we will display in the comment not only the property values (marked with the word "Screen"), but also the corrected values (marked with the word "Picture"): 2 pixels should be added in width, and 1 pixel in vertical (these are the features of window rendering in the terminal).

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_CHART_CHANGE)
   {
      const int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
      const int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS);
      // "Raw" sizes "as is" are displayed with the "Screen" mark,
      // correction for (-2,-1) is needed to include frames - it is displayed with th
      // correction for (-54,-22) is needed to include scales - it is displayed with
      Comment(StringFormat("Screen: %d x %d\nPicture: %d x %d\nIncluding scales: %d x
         w, h, w + 2, h + 1, w + 2 + 54, h + 1 + 22));
   }
}
```

Moreover, the obtained values do not take into account time and price scales. If they should also be taken into account in the size of the screenshot, then an adjustment should be made for their size as well. Unfortunately, the MQL5 API does not provide a way to find out these sizes, so we can only determine them empirically: for standard Windows font settings, the price scale width is 54 pixels, and the time scale height is 22 pixels. These constants may differ for your version of Windows, so you should edit them, or set them using input parameters.

After running the indicator on a chart, try resizing the window and see how the numbers in the comment will change.

Window s

Window screenshot with a tooltip and current sizes in the comment

5.9.4 Keyboard events

MQL programs can receive messages about keystrokes from the terminal by processing in the *OnChartEvent* function the CHARTEVENT_KEYDOWN events.

It is important to note that events are generated only in the active chart, and only when it has the input focus.

In Windows, focus is the logical and visual selection of one particular window that the user is currently interacting with. As a rule, the focus is moved by a mouse click or special keyboard shortcuts (*Tab*, *Ctrl+Tab*), causing the selected window to be highlighted. For example, a text cursor will appear in the input field, the current line will be colored in the list with an alternative color, and so on.

Similar visual effects are noticeable in the terminal, in particular, when one of the *Market Watch*, *Data Window* windows, or the Expert log receives focus. However, the situation is somewhat different with chart windows. It is not always possible to distinguish by external signs whether the chart visible in the foreground has the input focus or not. It is guaranteed that you can switch the focus, as already mentioned, by clicking on the required chart (on the chart, and not on the window title or its frame) or using hot keys:

- Alt+W brings up a window with a list of charts, where you can select one.
- Ctrl+F6 switches to the next chart (in the list of windows, where the order corresponds, as a rule, to the order of tabs).
- Crtl+Shift+F6 switches to the previous chart.

The full list of MetaTrader 5 hotkeys can be found in the documentation. Please pay attention that some combinations do not comply with the general recommendations of Microsoft (for example, F10 opens the quotes window, but does not activate the main menu).

The CHARTEVENT_KEYDOWN event parameters contain the following information:

- *lparam* – code of the pressed key
- *dparam* – the number of keystrokes generated during the time it was held down
- *sparam* – a bitmask describing the status of the keyboard keys, converted to a string

Bits	Description
0–7	Key scan code (depends on hardware, OEM)
8	Extended keyboard key attribute
9–12	For Windows service purposes (do not use)
13	Key state *Alt* (1 - pressed, 0 - released), not available (see below)
14	Previous key state (1 - pressed, 0 - released)
15	Changed key state (1 if released, 0 if pressed)

The state of the *Alt* key is actually not available, because it is intercepted by the terminal and this bit is always 0. Bit 15 is also always equal to 0 due to the triggering context of this event: only key presses are passed to the MQL program, not key releases.

The attribute of the extended keyboard (bit 8) is set, for example, for the keys of the numeric block (on laptops it is usually activated by *Fn*), keys such as *NumLock*, *ScrollLock*, right *Ctrl* (as opposed to the left, main *Ctrl*), and so on. Read more about this in the Windows documentation.

The first time any non-system key is pressed, bit 14 will be 0. If you keep the key pressed, subsequent automatically generated repetitions of the event will have 1 in this bit.

The following structure will help ensure that the description of the bits is correct.

```
struct KeyState
{
   uchar scancode;
   bool extended;
   bool altPressed;
   bool previousState;
   bool transitionState;

   KeyState() { }
   KeyState(const ushort keymask)
   {
      this = keymask; // use operator overload=
   }
   void operator=(const ushort keymask)
   {
      scancode = (uchar)(0xFF & keymask);
      extended = 0x100 & keymask;
      altPressed = 0x2000 & keymask;
      previousState = 0x4000 & keymask;
      transitionState = 0x8000 & keymask;
   }
};
```

In an MQL program, it can be used like this.

```
void OnChartEvent(const int id,
                  const long &lparam,
                  const double &dparam,
                  const string &sparam)
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      PrintFormat("%lld %lld %4llX", lparam, (ulong)dparam, (ushort)sparam);
      KeyState state[1];
      state[0] =(ushort)sparam;
      ArrayPrint(state);
   }
}
```

For practical purposes, it is more convenient to extract bit attributes from the key mask using macros.

```
#define KEY_SCANCODE(SPARAM) ((uchar)(((ushort)SPARAM) & 0xFF))
#define KEY_EXTENDED(SPARAM) ((bool)(((ushort)SPARAM) & 0x100))
#define KEY_PREVIOUS(SPARAM) ((bool)(((ushort)SPARAM) & 0x4000))
```

You can run the *EventAll.mq5* indicator from the Event-related chart properties section on the chart and see what parameter values will be displayed in the log when certain keys are pressed.

It is important to note that the code in *lparam* is one of the virtual keyboard key codes. Their list can be seen in the file *MQL5/Include/VirtualKeys.mqh*, which comes with MetaTrader 5. For example, here are some of them:

```
#define VK_SPACE          0x20
#define VK_PRIOR          0x21
#define VK_NEXT           0x22
#define VK_END            0x23
#define VK_HOME           0x24
#define VK_LEFT           0x25
#define VK_UP             0x26
#define VK_RIGHT          0x27
#define VK_DOWN           0x28
...
#define VK_INSERT         0x2D
#define VK_DELETE         0x2E
...
// VK_0 - VK_9 ASCII codes of characters '0' - '9' (0x30 - 0x39)
// VK_A - VK_Z ASCII codes of characters 'A' - 'Z' (0x41 - 0x5A)
```

The codes are called virtual because the corresponding keys may be located differently on different keyboards, or even implemented through the joint pressing of auxiliary keys (such as *Fn* on laptops). In addition, virtuality has another side: the same key can generate different symbols or control actions. For example, the same key can denote different letters in different language layouts. Also, each of the letter keys can generate an uppercase or lowercase letter, depending on the mode of *CapsLock* and the state of the *Shift* keys.

In this regard, to get a character from a virtual key code, the MQL5 API has the special function *TranslateKey*.

short TranslateKey(int key)

The function returns a Unicode character based on the passed virtual key code, given the current input language and the state of the control keys.

In case of an error, the value -1 will be returned. An error can occur if the code does not match the correct character, for example, when trying to get a character for the *Shift* key.

Recall that in addition to the received code of the pressed key, an MQL program can additionally Check keyboard status in terms of control keys and modes. By the way, constants of the form TERMINAL_KEYSTATE_XXX, passed as a parameter to the *TerminalInfoInteger* function, are based on the principle of 1000 + virtual key code. For example, TERMINAL_KEYSTATE_UP is 1038 because VK_UP is 38 (0x26).

When planning algorithms that react to keystrokes, keep in mind that the terminal can intercept many key combinations, since they are reserved for performing certain actions (the link to the documentation was given above). In particular, pressing the spacebar opens a field for quick navigation along the time axis. The MQL5 API allows you to partly control such built-in keyboard processing and disable it if necessary. See the section on Mouse and keyboard control.

The simple bufferless indicator *EventTranslateKey.mq5* serves as a demonstration of this function. In its *OnChartEvent* handler for the CHARTEVENT_KEYDOWN events, *TranslateKey*is is called to get a valid *Unicode* character. If it succeeds, the symbol is added to the message string that is displayed in the plot comment. On pressing *Enter*, a newline is inserted into the text, and on pressing *Backspace,* the last character is erased from the end.

```
#include <VirtualKeys.mqh>

string message = "";

void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      if(lparam == VK_RETURN)
      {
         message += "\n";
      }
      else if(lparam == VK_BACK)
      {
         StringSetLength(message, StringLen(message) - 1);
      }
      else
      {
         ResetLastError();
         const ushort c = TranslateKey((int)lparam);
         if(_LastError == 0)
         {
            message += ShortToString(c);
         }
      }
      Comment(message);
   }
}
```

You can try entering characters in different cases and different languages.

Be careful. The function returns the signed *short* value, mainly to be able to return an error code of -1. However, the type of a "wide" two-byte character is considered to be an unsigned integer, *ushort*. If the receiving variable is declared as *ushort*, a check using -1 (for example,*c!=-1*) will issue a "sign mismatch" compiler warning (explicit type casting required), while the other (*c >= 0*) is generally erroneous, since it is always equal to *true*.

In order to be able to insert spaces between words in the message, quick navigation activated by the spacebar is pre-disabled in the *OnInit* handler.

```
void OnInit()
{
   ChartSetInteger(0, CHART_QUICK_NAVIGATION, false);
}
```

As a full-fledged example of using keyboard events, consider the following application task. Terminal users know that the scale of the main chart window can be changed interactively without opening the settings dialog using the mouse: just press the mouse button in the price scale and, without releasing it, move up/down. Unfortunately, this method does not work in subwindows.

Subwindows always scale automatically to fit all the content, and to change the scale you have to open a dialog and enter values manually. Sometimes the need for this arises if the indicators in the

subwindow show "outliers" – too large single readings that interfere with the analysis of the rest of the normal (medium) size data. In addition, sometimes it is desirable to simply enlarge the picture in order to deal with finer details.

To solve this problem and allow the user to adjust the scale of the subwindow using keystrokes, we have implemented the *SubScalermq5* indicator. It has no buffers and does not display anything.

SubScaler must be the first indicator in the subwindow, or, to put it more strictly, it must be added to the subwindow before the working indicator of interest to you is added there, the scale of which you want to control. To make *SubScaler* the first indicator, it should be placed on the chart (in the main window) and thereby create a new subwindow, where you can then add a subordinate indicator.

In the working indicator settings dialog, it is important to enable the option *Inherit scale* (on the tab *Scale*).

When both indicators are running in a subwindow, you can use the arrow keys *Up/Down* to zoom in/out. If the *Shift* key is pressed, the current visible range of values on the vertical axis is shifted up or down.

Zooming in means zooming in on details ("camera zoom"), so that some of the data may go outside the window. Zooming out means that the overall picture becomes smaller ("camera zoom out").

The input parameters set are:

- Initial maximum – the upper limit of the data during the initial placement on the chart, +1000 by default.
- Initial minimum – the lower data limit during the initial placement on the chart, by default -1000.
- Scaling factor – step with which the scale will change by pressing the keys, value in the range [0.01 ... 0.5], by default 0.1.

We are forced to ask the user for the minimum and maximum because *SubScaler* cannot know in advance the working range of values of an arbitrary third-party indicator, which will be added to the subwindow next.

When the chart is restored after starting a new terminal session or when a tpl template is loaded, *SubScaler* picks up the scale of the previous (saved) state.

Now let's look at the implementation of *SubScaler*.

The above settings are set in the corresponding input variables:

```
input double FixedMaximum = 1000;  // Initial Maximum
input double FixedMinimum = -1000; // Initial Minimum
input double _ScaleFactor = 0.1;   // Scale Factor [0.01 ... 0.5]
input bool Disabled = false;
```

In addition, the *Disabled* variable allows you to temporarily disable the keyboard response for a specific instance of the indicator in order to set up several different scales in different subwindows (one by one).

Since the input variables are read-only in MQL5, we are forced to declare one more variable *ScaleFactor* to correct the entered value within the allowed range [0.01 ... 0.5].

```
double ScaleFactor;
```

The number of the current subwindow (*w*) and the number of indicators in it (*n*) are stored in global variables: they are all filled in the *OnInit* handler.

```
int w = -1, n = -1;

void OnInit()
{
  ScaleFactor = _ScaleFactor;
  if(ScaleFactor < 0.01 || ScaleFactor > 0.5)
  {
    PrintFormat("ScaleFactor %f is adjusted to default value 0.1,"
       " valid range is [0.01, 0.5]", ScaleFactor);
    ScaleFactor = 0.1;
  }
  w = ChartWindowFind();
  n = ChartIndicatorsTotal(0, w);
}
```

In the *OnChartEvent* function, we process two types of events: chart changes and keyboard events. The CHARTEVENT_CHART_CHANGE event is necessary to keep track of the addition of the next indicator to the subwindow (working indicator to be scaled). At the same time, we request the current range of subwindow values (CHART_PRICE_MIN, CHART_PRICE_MAX) and determine whether it is degenerate, that is, when both the maximum and minimum are equal to zero. In this case, it is necessary to apply the initial limits specified in the input parameters (*FixedMinimum*,*FixedMaximum*).

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   switch(id)
   {
   case CHARTEVENT_CHART_CHANGE:
      if(ChartIndicatorsTotal(0, w) > n)
      {
         n = ChartIndicatorsTotal(0, w);
         const double min = ChartGetDouble(0, CHART_PRICE_MIN, w);
         const double max = ChartGetDouble(0, CHART_PRICE_MAX, w);
         PrintFormat("Change: %f %f %d", min, max, n);
         if(min == 0 && max == 0)
         {
            IndicatorSetDouble(INDICATOR_MINIMUM, FixedMinimum);
            IndicatorSetDouble(INDICATOR_MAXIMUM, FixedMaximum);
         }
      }
      break;
   ...
   }
}
```

When a keyboard press event is received, the main *Scale* function is called, which receives not only *lparam* but also the state of the *Shift* key obtained by referring to *TerminalInfoInteger(TERMINAL_KEYSTATE_SHIFT)*.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
  switch(id)
  {
    case CHARTEVENT_KEYDOWN:
      if(!Disabled)
         Scale(lparam, TerminalInfoInteger(TERMINAL_KEYSTATE_SHIFT));
      break;
    ...
  }
}
```

Inside the *Scale* function, the first thing we do is get the current range of values into the *min* and *max* variables.

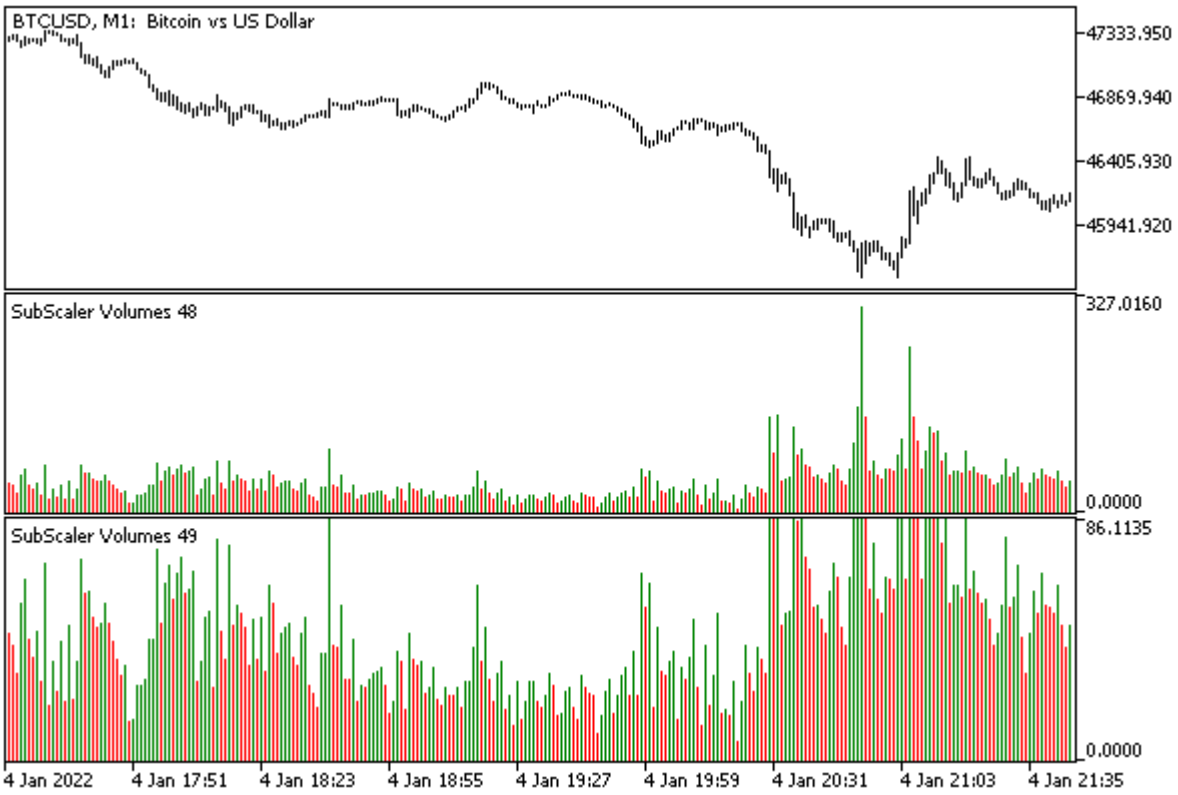
```
void Scale(const long cmd, const int shift)
{
   const double min = ChartGetDouble(0, CHART_PRICE_MIN, w);
   const double max = ChartGetDouble(0, CHART_PRICE_MAX, w);
   ...
```

Then, depending on whether the *Shift* key is currently pressed, either zooming or panning is performed, i.e. shifting the visible range of values up or down. In both cases, the modification is performed with a given step (multiplier) *ScaleFactor*, relative to the limits *min* and *max*, and they are assigned to the indicator properties INDICATOR_MINIMUM and INDICATOR_MAXIMUM, respectively. Due to the fact that the subordinate indicator has the Inherit scale setting, it becomes a working setting for it as well.

```
   if((shift &0x10000000) ==0)// Shift is not pressed - scalechange
     {
        if(cmd == VK_UP) // enlarge (zoom in)
        {
           IndicatorSetDouble(INDICATOR_MINIMUM, min / (1.0 + ScaleFactor));
           IndicatorSetDouble(INDICATOR_MAXIMUM, max / (1.0 + ScaleFactor));
           ChartRedraw();
        }
        else if(cmd == VK_DOWN) // shrink (zoom out)
        {
           IndicatorSetDouble(INDICATOR_MINIMUM, min * (1.0 + ScaleFactor));
           IndicatorSetDouble(INDICATOR_MAXIMUM, max * (1.0 + ScaleFactor));
           ChartRedraw();
        }
     }
     else // Shift pressed - pan/shift range
     {
        if(cmd == VK_UP) // shifting charts up
        {
           const double d = (max - min) * ScaleFactor;
           IndicatorSetDouble(INDICATOR_MINIMUM, min - d);
           IndicatorSetDouble(INDICATOR_MAXIMUM, max - d);
           ChartRedraw();
        }
        else if(cmd == VK_DOWN) // shifting charts down
        {
           const double d = (max - min) * ScaleFactor;
           IndicatorSetDouble(INDICATOR_MINIMUM, min + d);
           IndicatorSetDouble(INDICATOR_MAXIMUM, max + d);
           ChartRedraw();
        }
     }
  }
```

For any change, *ChartRedraw* is called to update the chart.

Let's see how *SubScaler* works with the standard indicator of volumes (any other indicators, including custom ones, are controlled in the same way).



A different scale set by SubScaler indicators in two subwindows

Here in two subwindows, two instances of *SubScaler* apply different vertical scales to volumes.

5.9.5 Mouse events

We already had the opportunity to make sure that we receive mouse events using the indicator *EventAll.mq5* from the section Event-related chart properties. The CHARTEVENT_CLICK event is sent to the MQL program on each click of the mouse button in the window, and the CHARTEVENT_MOUSE_MOVE cursor movement and CHARTEVENT_MOUSE_WHEEL wheel scroll events require prior activation in the chart settings, for which the CHART_EVENT_MOUSE_MOVE and CHART_EVENT_MOUSE_WHEEL properties serve, respectively (both are disabled by default).

If there is a graphic object under the mouse, when the button is pressed, not only the CHARTEVENT_CLICK event is generated but also CHARTEVENT_OBJECT_CLICK.

For the CHARTEVENT_CLICK and CHARTEVENT_MOUSE_MOVE events, the parameters of the *OnChartEvent* handler contain the following information:

- lparam - X coordinate
- dparam - Y coordinate

In addition, for the CHARTEVENT_MOUSE_MOVE event, the *sparam* parameter contains a string representation of a bitmask describing the status of mouse buttons and control keys (*Ctrl*, *Shift*). Setting a particular bit to 1 means pressing the corresponding button or key.

Bits	Description
0	Left mouse button state

Bits	Description
1	Right mouse button state
2	SHIFT key state
3	CTRL key state
4	Middle mouse button state
5	State of the first additional mouse button
6	State of the second additional mouse button

For example, if the 0th bit is set, it will give the number 1 (1 << 0), and if the 4th bit is set, it will give the number 16 (1 << 4). Simultaneous pressing of buttons or keys is indicated by a superposition of bits.

For the CHARTEVENT_MOUSE_WHEEL event, the X and Y coordinates, as well as the status flags of the mouse buttons and control keys, are encoded in a special way inside the *lparam* parameter, and the *dparam* parameter reports the direction (plus/minus) and amount of wheel scrolling (multiples of ±120).

8-byte integer *lparam* combines several of the mentioned information fields.

Bytes	Description
0	Value of *short* type with the X coordinate
1	
2	Value of *short* type with the Y coordinate
3	
4	Bitmask of button and key states
5	Not used
6	
7	

Regardless of the type of event, mouse coordinates are transmitted relative to the entire window, including subwindows, so they should be recalculated for a specific subwindow if necessary.

For a better understanding of CHARTEVENT_MOUSE_WHEEL, use the indicator *EventMouseWheel.mq5*. It receives and decodes the messages, and then outputs their description to the log.

```
#define KEY_FLAG_NUMBER 7

const string keyNameByBit[KEY_FLAG_NUMBER] =
{
   "[Left Mouse] ",
   "[Right Mouse] ",
   "(Shift) ",
   "(Ctrl) ",
   "[Middle Mouse] ",
   "[Ext1 Mouse] ",
   "[Ext2 Mouse] ",
};

void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   if(id == CHARTEVENT_MOUSE_WHEEL)
   {
      const int keymask = (int)(lparam >> 32);
      const short x = (short)lparam;
      const short y = (short)(lparam >> 16);
      const short delta = (short)dparam;
      string message = "";

      for(int i = 0; i < KEY_FLAG_NUMBER; ++i)
      {
         if(((1 << i) & keymask) != 0)
         {
            message += keyNameByBit[i];
         }
      }

      PrintFormat("X=%d Y=%d D=%d %s", x, y, delta, message);
   }
}
```

Run the indicator on the chart and scroll the mouse wheel by pressing various buttons and keys in turn. Here is an example result:

```
X=186 Y=303 D=-120
X=186 Y=312 D=120
X=230 Y=135 D=-120
X=230 Y=135 D=-120 (Ctrl)
X=230 Y=135 D=-120 (Shift) (Ctrl)
X=230 Y=135 D=-120 (Shift)
X=230 Y=135 D=120
X=230 Y=135 D=-120 [Middle Mouse]
X=230 Y=135 D=120 [Middle Mouse]
X=236 Y=210 D=-240
X=236 Y=210 D=-360
```

5.9.6 Graphical object events

For the graphical objects located on the chart, the terminal generates several specialized events. Most of them apply to objects of any type. The text editing end event in the input field – CHARTEVENT_OBJECT_ENDEDIT – is generated only for objects of the OBJ_EDIT type.

Object click (CHARTEVENT_OBJECT_CLICK), mouse drag (CHARTEVENT_OBJECT_DRAG) and object property change (CHARTEVENT_OBJECT_CHANGE) events are always active, while CHARTEVENT_OBJECT_CREATE object creation and CHARTEVENT_OBJECT_DELETE object creation events require explicit enabling by setting chart the relevant properties: CHART_EVENT_OBJECT_CREATE and CH ART_EVENT_OBJECT_DELETE.

When renaming an object manually (from the properties dialog), the terminal generates a sequence of events CHARTEVENT_OBJECT_DELETE, CHARTEVENT_OBJECT_CREATE, CHARTEVENT_OBJECT_CHANGE. When you programmatically rename an object, these events are not generated.

All events in objects carry the name of the associated object in the *sparam* parameter of the *OnChartEvent* function.

In addition, click coordinates are passed for CHARTEVENT_OBJECT_CLICK: X in the *lparam* parameter and Y in the *dparam* parameter. Coordinates are common to the entire chart, including subwindows.

Clicking on objects works differently depending on the object type. For some, such as the ellipse, the cursor must be over any anchor point. For others (triangle, rectangle, lines), the cursor may be over the object's perimeter, not just over a point. In all such cases, hovering the mouse cursor over the interactive area of the object displays a tooltip with the name of the object.

Objects linked to screen coordinates, which allow to form the graphical interface of the program, in particular, a button, an input field, and a rectangular panel, generate events when the mouse is clicked anywhere inside the object.

If there are multiple objects under the cursor, an event is generated for the object with the largest Z-priority. If the priorities of the objects are equal, the event is assigned to the one that was created later (this corresponds to their visual display, that is, the later one overlaps the earlier one).

The new version of the indicator will help you check events in objects *EventAllObjects.mq5*. We will create and configure it using the already known class *Object Selector* of several objects, and then intercept in the handler *OnChartEvent* their characteristic events.

```
#include <MQL5Book/ObjectMonitor.mqh>

class ObjectBuilder: public ObjectSelector
{
protected:
   const ENUM_OBJECT type;
   const int window;
public:
   ObjectBuilder(const string _id, const ENUM_OBJECT _type,
      const long _chart = 0, const int _win = 0):
      ObjectSelector(_id, _chart), type(_type), window(_win)
   {
      ObjectCreate(host, id, type, window, 0, 0);
   }
};
```

Initially, in *OnInit* we create a button object and a vertical line. For the line, we will track the event of movement (towing), and on pressing the button, we will create an input field for which we will check the entered text.

```
const string ObjNamePrefix = "EventShow-";
const string ButtonName = ObjNamePrefix + "Button";
const string EditBoxName = ObjNamePrefix + "EditBox";
const string VLineName = ObjNamePrefix + "VLine";

bool objectCreate, objectDelete;

void OnInit()
{
   // remember the original settings to restore in OnDeinit
   objectCreate = ChartGetInteger(0, CHART_EVENT_OBJECT_CREATE);
   objectDelete = ChartGetInteger(0, CHART_EVENT_OBJECT_DELETE);

   // set new properties
   ChartSetInteger(0, CHART_EVENT_OBJECT_CREATE, true);
   ChartSetInteger(0, CHART_EVENT_OBJECT_DELETE, true);

   ObjectBuilder button(ButtonName, OBJ_BUTTON);
   button.set(OBJPROP_XDISTANCE, 100).set(OBJPROP_YDISTANCE, 100)
   .set(OBJPROP_XSIZE, 200).set(OBJPROP_TEXT, "Click Me");

   ObjectBuilder line(VLineName, OBJ_VLINE);
   line.set(OBJPROP_TIME, iTime(NULL, 0, 0))
   .set(OBJPROP_SELECTABLE, true).set(OBJPROP_SELECTED, true)
   .set(OBJPROP_TEXT, "Drag Me").set(OBJPROP_TOOLTIP, "Drag Me");

   ChartRedraw();
}
```

Along the way, do not forget to set the chart properties CHART_EVENT_OBJECT_CREATE and CHART_EVENT_OBJECT_DELETE to *true* to be notified when a set of objects changes.

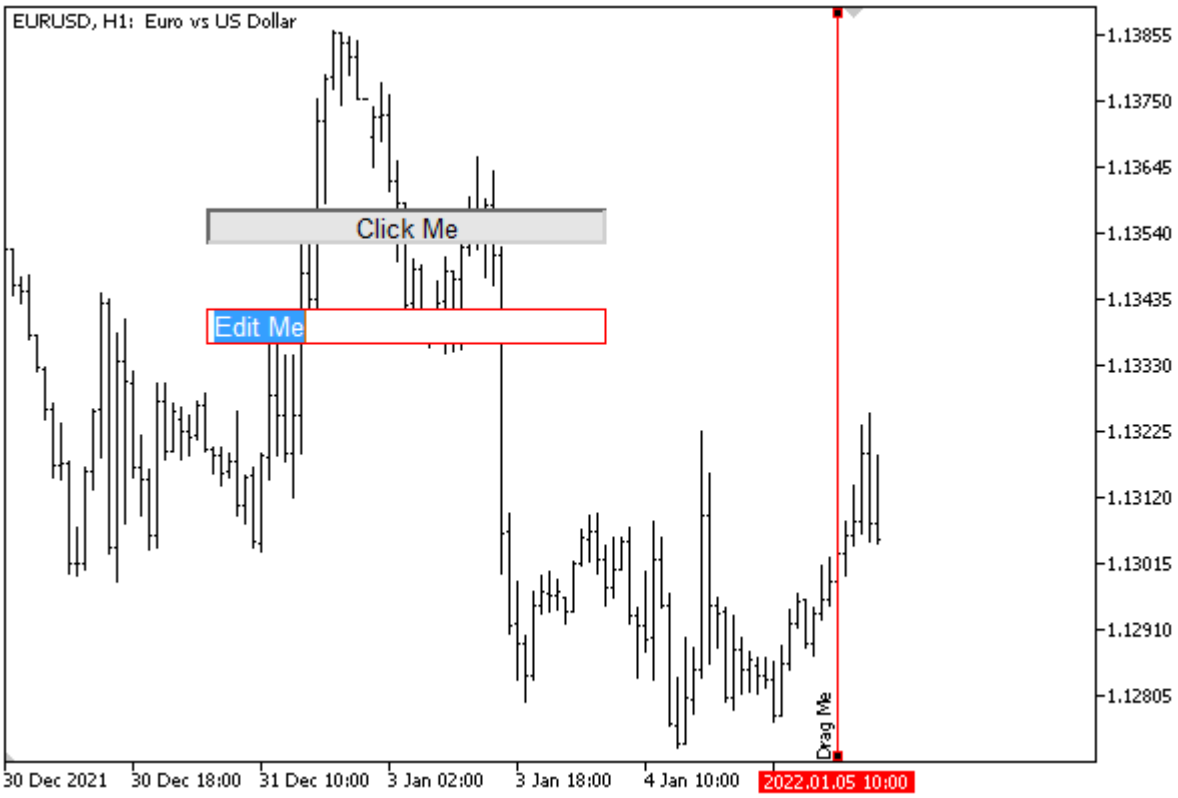
In the *OnChartEvent* function, we will provide an additional response to the required events: after the dragging is completed, we will display the new position of the line in the log and, after editing the text in the input field, its contents.

```
void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   ENUM_CHART_EVENT evt = (ENUM_CHART_EVENT)id;
   PrintFormat("%s %lld %f '%s'", EnumToString(evt), lparam, dparam, sparam);
   if(id == CHARTEVENT_OBJECT_CLICK && sparam == ButtonName)
   {
      if(ObjectGetInteger(0, ButtonName, OBJPROP_STATE))
      {
         ObjectBuilder edit(EditBoxName, OBJ_EDIT);
         edit.set(OBJPROP_XDISTANCE, 100).set(OBJPROP_YDISTANCE, 150)
         .set(OBJPROP_BGCOLOR, clrWhite)
         .set(OBJPROP_XSIZE, 200).set(OBJPROP_TEXT, "Edit Me");
      }
      else
      {
         ObjectDelete(0, EditBoxName);
      }

      ChartRedraw();
   }
   else if(id == CHARTEVENT_OBJECT_ENDEDIT && sparam == EditBoxName)
   {
      Print(ObjectGetString(0, EditBoxName, OBJPROP_TEXT));
   }
   else if(id == CHARTEVENT_OBJECT_DRAG && sparam == VLineName)
   {
      Print(TimeToString((datetime)ObjectGetInteger(0, VLineName, OBJPROP_TIME)));
   }
}
```

Note that when the button is pressed for the first time, its state changes from released to pressed, and in response to this, we create an input field. If you click the button again, it will change its state back, as a result of which the input field will be removed from the chart.

Below is an image of the chart during the operation of the indicator.



Objects controlled by the OnChartEvent event handler

Immediately after the indicator is launched, the following lines appear in the log:

```
CHARTEVENT_OBJECT_CREATE 0 0.000000 'EventShow-Button'
CHARTEVENT_OBJECT_CREATE 0 0.000000 'EventShow-VLine'
CHARTEVENT_CHART_CHANGE 0 0.000000 ''
```

If we then drag the line with the mouse, we will see something like this:

```
CHARTEVENT_OBJECT_DRAG 0 0.000000 'EventShow-VLine'
2022.01.05 10:00
```

Next, you can click the button and edit the text in the newly created input field (when editing is complete, click *Enter* or click outside the input field). This will result in the following entries in the log (the coordinates and the text of the message may differ; the text "new message" was entered here):

```
CHARTEVENT_OBJECT_CLICK 181 113.000000 'EventShow-Button'
CHARTEVENT_CLICK 181 113.000000 ''
CHARTEVENT_OBJECT_CREATE 0 0.000000 'EventShow-EditBox'
CHARTEVENT_OBJECT_CLICK 152 160.000000 'EventShow-EditBox'
CHARTEVENT_CLICK 152 160.000000 ''
CHARTEVENT_OBJECT_ENDEDIT 0 0.000000 'EventShow-EditBox'
new message
```

If you then release the button, the input field will be deleted.

```
CHARTEVENT_OBJECT_CLICK 162 109.000000 'EventShow-Button'
CHARTEVENT_CLICK 162 109.000000 ''
CHARTEVENT_OBJECT_DELETE 0 0.000000 'EventShow-EditBox'
```

It is worth noting that the button works by default as a two-position switch, that is, it sticks alternately in the pressed or released state as a result of a mouse click. For a regular button, this behavior is redundant: in order to simply track button presses, you should return it to the released state when processing the event by calling *ObjectSetInteger(0, ButtonName, OBJPROP_STATE, false)*.

5.9.7 Generation of custom events

In addition to standard events, the terminal supports the ability to programmatically generate custom events, the essence and content of which are determined by the MQL program. Such events are added to the general queue of chart events and can be processed in the function *OnChartEvent* by all interested programs.

A special range of 65536 integer identifiers is reserved for custom events: from CHARTEVENT_CUSTOM to CHARTEVENT_CUSTOM_LAST inclusive. In other words, the custom event must have the ID CHARTEVENT_CUSTOM + n, where n is between 0 and 65535. CHARTEVENT_CUSTOM_LAST is exactly equal to CHARTEVENT_CUSTOM + 65535.

Custom events are sent to the chart using the *EventChartCustom* function.

```
bool EventChartCustom(long chartId, ushort customEventId,
   long lparam, double dparam, string sparam)
```

chartId is the identifier of the event recipient chart, while 0 indicates the current chart; *customEventId* is the event ID (selected by the MQL program developer). This identifier is automatically added to the CHARTEVENT_CUSTOM value and converted to an integer type. This value will be passed to the *OnChartEvent* handler as the first argument. Other parameters of *EventChartCustom* correspond to the standard event parameters in *OnChartEvent* with types *long*, *double* and *string*, and may contain arbitrary information.

The function returns *true* in case of successful queuing of the user event or *false* in case of an error (the error code will become available in *_LastError*).

As we approach the most complex and important part of our book devoted directly to trading automation, we will begin to solve applied problems that will be useful in the development of trading robots. Now, in the context of demonstrating the capabilities of custom events, let's turn to the multicurrency (or, more generally, multisymbol) analysis of the trading environment.

A little earlier, in the chapter on indicators, we considered multicurrency indicators but did not pay attention to an important point: despite the fact that the indicators processed quotes of different symbols, the calculation itself was launched in the *OnCalculate* handler, which was triggered by the arrival of a new tick of only one the working symbol of the chart. It turns out that the ticks of other instruments are essentially skipped. For example, if the indicator works on symbol A, when its tick arrives, we simply take the last known ticks of other symbols (B, C, D), but it is likely that other ticks managed to slip through each of them.

If you place a multicurrency indicator on the most liquid instrument (where ticks are received most often), this is not so critical. However, different instruments can be faster than others at different times of the day, and if an analytical or trading algorithm requires the fastest possible response to new

quotes of all instruments in the portfolio, we are faced with the fact that the current solution does not suit us.

Unfortunately, the standard event of a new tick arrival works in MQL5 only for one symbol, which is the working symbol of the current chart. In indicators, the *OnCalculate* handler is called at such moments, and the *OnTick* handler is called in Expert Advisors.

Therefore, it is necessary to invent some mechanism so that the MQL program can receive notifications about ticks on all instruments of interest. This is where custom events will help us. Of course, this is not necessary for programs that analyze only one instrument.

We will now develop an example of the *EventTickSpy.mq5* indicator, which, being launched on a specific symbol X, will be able to send tick notifications from its *OnCalculate* function using *EventChartCustom*. As a result, in the handler *OnChartEvent*, which is specially prepared to receive such notifications, it will be possible to collect notifications from different instances of the indicator from different symbols.

This example is provided for illustration purposes. Subsequently, when studying multicurrency automated trading, we will adapt this technique for more convenient use in Expert Advisors.

First of all, let's think of a custom event number for the indicator. Since we are going to send tick notifications for many different symbols from some given list, we can choose different tactics here. For example, you can select one event identifier, and pass the number of the symbol in the list and/or the name of the symbol in the *lparam* and *sparam* parameters, respectively. Or you can take some constant (greater than and equal to CHARTEVENT_CUSTOM) and get event numbers by adding the symbol number to this constant (then we have all parameters free, in particular, *lparam* and *dparam*, and they can be used to transfer prices *Ask*, *Bid* or something else).

We will focus on the option when there is one event code. Let's declare it in the TICKSPY macro. This will be the default value, which the user can change to avoid collisions (albeit unlikely) with other programs if necessary.

```
#define TICKSPY 0xFEED // 65261
```

This value is taken on purpose as being rather far removed from the first allowed CHARTEVENT_CUSTOM.

During the initial (interactive) launch of the indicator, the user must specify the list of instruments whose ticks the indicator should track. For this purpose, we will describe the input string variable *SymbolList* with a comma-separated list of symbols.

The identifier of the user event is set in the *message* parameter.

Finally, we need the identifier of the receiving chart to pass the event. We will provide the *Chart* parameter for this purpose. The user should not edit it: in the first instance of the indicator launched manually, the chart is known implicitly by attaching it to the chart. In other copies of the indicator that our first instance will run programmatically, this parameter will fill the algorithm with a call of the function *ChartID* (see below).

```
input string SymbolList = "EURUSD,GBPUSD,XAUUSD,USDJPY"; // List of symbols separated
input ushort message = TICKSPY;                          // Custom message
input longchart = 0;                                     // Receiving chart (do not e
```

In the *SymbolList* parameter, for example, a list with four common tools is indicated. Edit it as needed to suit your *Market Watch*.

In the *OnInit* handler, we convert the list to the *Symbols* array of symbols, and then in a loop we run the same indicator for all symbols from the array, except for the current one (as a rule, there is such a match, because the current symbol is already being processed by this initial copy of the indicator).

```
string Symbols[];

void OnInit()
{
   PrintFormat("Starting for chart %lld, msg=0x%X [%s]", Chart, Message, SymbolList);
   if(Chart == 0)
   {
      if(StringLen(SymbolList) > 0)
      {
         const int n = StringSplit(SymbolList, ',', Symbols);
         for(int i = 0; i < n; ++i)
         {
            if(Symbols[i] != _Symbol)
            {
               ResetLastError();
               // run the same indicator on another symbol with different settings,
               // in particular, we pass our ChartID to receive notifications back
               iCustom(Symbols[i], PERIOD_CURRENT, MQLInfoString(MQL_PROGRAM_NAME),
                  "", Message, ChartID());
               if(_LastError != 0)
               {
                  PrintFormat("The symbol '%s' seems incorrect", Symbols[i]);
               }
            }
         }
      }
      else
      {
         Print("SymbolList is empty: tracking current symbol only!");
         Print("To monitor other symbols, fill in SymbolList, i.e."
            " 'EURUSD,GBPUSD,XAUUSD,USDJPY'");
      }
   }
}
```

At the beginning of *OnInit*, information about the launched instance of the indicator is displayed in the log so that it is clear what is happening.

If we chose the option with separate event codes for each character, we would have to call *iCustom* as follows (add*i* to *message*):

```
iCustom(Symbols[i], PERIOD_CURRENT, MQLInfoString(MQL_PROGRAM_NAME), "",
   Message + i, ChartID());
```

Note that the non-zero value of the *Chart* parameter implies that this copy is launched programmatically and that it should monitor a single symbol, that is, the working symbol of the chart. Therefore, we don't need to pass a list of symbols when running the slave copies.

In the *OnCalculate* function, which is called when a new tick is received, we send the *Message* custom event to the *Chart* chart by calling *EventChartCustom*. In this case, the *lparam* parameter is not used (equal to 0). In the *dparam* parameter, we pass the current (last) price *price[0]* (this is *Bid* or *Last*, depending on what type of price the chart is based on: it is also the price of the last tick processed by the chart), and we pass the symbol name in the *sparam* parameter.

```
int OnCalculate(const int rates_total, const int prev_calculated,
   const int, const double &price[])
{
   if(prev_calculated)
   {
      ArraySetAsSeries(price, true);
      if(Chart > 0)
      {
         // send a tick notification to the parent chart
         EventChartCustom(Chart, Message, 0, price[0], _Symbol);
      }
      else
      {
         OnSymbolTick(_Symbol, price[0]);
      }
   }

   return rates_total;
}
```

In the original instance of the indicator, where the *Chart* parameter is 0, we directly call a special function, a kind of a multiasset tick handler *OnSymbolTick*. In this case, there is no need to call *EventChartCustom*: although such a message will still arrive on the chart and this copy of the indicator, the transmission takes several milliseconds and loads the queue in vain.

The only purpose of *OnSymbolTick* in this demo is to print the name of the symbol and the new price in the log.

```
void OnSymbolTick(const string &symbol, const double price)
{
   Print(symbol, " ", DoubleToString(price,
      (int)SymbolInfoInteger(symbol, SYMBOL_DIGITS)));
}
```

Of course, the same function is called from the *OnChartEvent* handler in the receiving (source) copy of the indicator, provided that our message has been received. Recall that the terminal calls *OnChartEvent* only in the interactive copy of the indicator (applied to the chart) and does not appear in those copies that we created "invisible" using *iCustom*.

```
void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   if(id >= CHARTEVENT_CUSTOM + Message)
   {
      OnSymbolTick(sparam, dparam);
      // OR (if using custom event range):
      // OnSymbolTick(Symbols[id - CHARTEVENT_CUSTOM - Message], dparam);
   }
}
```

We could avoid sending either the price or the name of the symbol in our event since the general list of symbols is known in the initial indicator (which initiated the process), and therefore we could somehow tell it the number of the symbol from the list. This could be done in the *lparam* parameter or, as mentioned above, by adding a number to the base constant of the user event. Then the original indicator, while receiving events, could take a symbol by index from the array and get all the information about the last tick using *SymbolInfoTick*, including different types of prices.

Let's run the indicator on the EURUSD chart with default settings, including the "EURUSD,GBPUSD,XAUUSD,USDJPY" test list. Here is the log:

```
16:45:48.745 (EURUSD,H1) Starting for chart 0, msg=0xFEED [EURUSD,GBPUSD,XAUUSD,USDJP
16:45:48.761 (GBPUSD,H1) Starting for chart 132358585987782873, msg=0xFEED []
16:45:48.761 (USDJPY,H1) Starting for chart 132358585987782873, msg=0xFEED []
16:45:48.761 (XAUUSD,H1) Starting for chart 132358585987782873, msg=0xFEED []
16:45:48.777 (EURUSD,H1) XAUUSD 1791.00
16:45:49.120 (EURUSD,H1) EURUSD 1.13068 *
16:45:49.135 (EURUSD,H1) USDJPY 115.797
16:45:49.167 (EURUSD,H1) XAUUSD 1790.95
16:45:49.167 (EURUSD,H1) USDJPY 115.796
16:45:49.229 (EURUSD,H1) USDJPY 115.797
16:45:49.229 (EURUSD,H1) XAUUSD 1790.74
16:45:49.369 (EURUSD,H1) XAUUSD 1790.77
16:45:49.572 (EURUSD,H1) GBPUSD 1.35332
16:45:49.572 (EURUSD,H1) XAUUSD 1790.80
16:45:49.791 (EURUSD,H1) XAUUSD 1790.80
16:45:49.791 (EURUSD,H1) USDJPY 115.796
16:45:49.931 (EURUSD,H1) EURUSD 1.13069 *
16:45:49.931 (EURUSD,H1) XAUUSD 1790.86
16:45:49.931 (EURUSD,H1) USDJPY 115.795
16:45:50.056 (EURUSD,H1) USDJPY 115.793
16:45:50.181 (EURUSD,H1) XAUUSD 1790.88
16:45:50.321 (EURUSD,H1) XAUUSD 1790.90
16:45:50.399 (EURUSD,H1) EURUSD 1.13066 *
16:45:50.727 (EURUSD,H1) EURUSD 1.13067 *
16:45:50.773 (EURUSD,H1) GBPUSD 1.35334
```

Please note that in the column with (symbol,timeframe) which is the source of the record, we first see the starting indicator instances on four requested symbols.

After launch, the first tick was XAUUSD, not EURUSD. Further symbol ticks come with approximately equal intensity, interspersed. EURUSD ticks are marked with asterisks, so you can get an idea of how many other ticks would have been missed without notifications.

Timestamps have been saved in the left column for reference.

Places where two prices of two consecutive events from the same symbol coincide usually indicate that the *Ask* price has changed (we simply do not display it here).

A little later, after studying the trading MQL5 API, we will apply the same principle to respond to multicurrency ticks in Expert Advisors.

Part 6. Trading automation

In this part, we will study the most complex and important component of the MQL5 API which allows the automation of trading actions.

We will start by describing the entities without which it is impossible to write a proper Expert Advisor. These include financial symbols and trading account settings.

Then we will look at built-in trading functions and data structures, along with robot-specific events and operating modes. In particular, the key feature of Expert Advisors is integration with the tester, which allows users to evaluate financial performance and optimize trading strategies. We will consider the internal optimization mechanisms and optimization management through the API.

The strategy tester is an essential tool for developing MQL programs since it provides the ability to debug programs in various modes, including bars and ticks, based on modeled or real ticks, with or without visualization of the price stream.

We've already tried to test indicators in visual mode. However, the set of testing parameters is limited for indicators. When developing Expert Advisors, we will have access to the full range of tester capabilities.

In addition, we will be introduced to a new form of market information: the Depth of Market and its software interface.

 MQL5 Programming for Traders – Source Codes from the Book. Part 6

 Examples from the book are also available in the public project \MQL5\Shared Projects\MQL5Book

6.1 Financial instruments and Market Watch

MetaTrader 5 allows users to analyze and trade financial instruments (a.k.a. symbols or tickers), which form the basis of almost all terminal subsystems. Charts, indicators, and the price history of quotes exist in relation to trading symbols. The main functionality of the terminal is built on financial instruments such as trading orders, deals, control of margin requirements, and trading account history.

Via the terminal, brokers deliver to traders a specified list of symbols, from which each user chooses the preferred ones, forming the Market Watch. The Market Watch window determines the symbols for which the terminal requests online quotes and allows you to open charts and view the history.

The MQL5 API provides similar software tools that allow you to view and analyze the characteristics of all symbols, add them to the Market Watch, or exclude them from there.

In addition to standard symbols with information provided by brokers, MetaTrader 5 makes it possible to create custom symbols: their properties and price history can be loaded from arbitrary data sources and calculated using formulas or MQL programs. Custom symbols also participate in the Market Watch and can be used for testing strategies and technical analysis, however, they also have a natural limitation – they cannot be traded online using regular MQL5 API tools, since these symbols are not available on the server. Custom symbols will be reviewed in a separate chapter, in the last, seventh part of the book.

A little while ago, in the relevant chapters, we have already touched on time series with price data of individual symbols, including history paging using an example with indicators. All this functionality actually assumes that the corresponding symbols are already enabled in the Market Watch. This is especially true for multicurrency indicators and Expert Advisors that refer not only to the working symbol of the chart but also to other symbols. In this chapter, we will learn how the Market Watch list is managed from MQL programs.

The chapter on charts has already described some of the symbol properties made available through basic property-getter functions of a current chart (*Point*, *Digits*) since the chart cannot work without the symbol associated with it. Now we will study most of the properties of symbols, including their specification. Their full set can be found in the MQL5 documentation on the website.

6.1.1 Getting available symbols and Market Watch lists

The MQL5 API has several functions for operations with symbols. Using them, you can find the total number of available symbols, the number of symbols selected in *Market Watch*, as well as their names. As you know, the general list of symbols available in the terminal is indicated in the form of a hierarchical structure in the dialog *Symbols*, which the user can open with the command *View -> Symbols*, or from the *Market Watch* context menu. This list includes both the symbols provided by the broker and custom symbols created locally. You can use the *SymbolsTotal* function to find the total number of symbols.

int SymbolsTotal(bool selected)

The *selected* parameter specifies whether only symbols in *Market Watch* (*true*) or all available symbols (*false*) are requested.

The *SymbolName* function is often used along with *SymbolsTotal*. It returns the name of the symbol by its index (grouping the storage of symbols into logical folders is not taken into account here, see property SYMBOL_PATH).

string SymbolName(int index, bool selected)

The *index* parameter specifies the index of the requested symbol. *Index* value must be between 0 and the number of symbols, subject to the request context specified by the second parameter *selected*: *true* limits the enumeration to the symbols chosen in *Market Watch*, while *false* matches absolutely all symbols (by analogy with *SymbolsTotal*). Therefore, when calling *SymbolName*, set the *selected* parameter to the same value as in the previous *SymbolsTotal* call which is used to define the index range.

In case of an error, in particular, if the requested index is out of the list range, the function will return an empty string, and the error code will be written to the variable *_LastError*.

> It is important to note that when the option *selected* is enabled, the pair of functions *SymbolsTotal* and *SymbolName* returns information for the list of symbols actually updated by the terminal, that is, symbols for which constant synchronization with the server is performed and for which the history of quotes is available for MQL programs. This list may be larger than the list visible in *Market Watch*, where elements are added explicitly: by the user or by an MQL program (to learn how to do this, see the section Editing the list in *Market Watch*). Such symbols, invisible in the window, are automatically connected by the terminal when they are needed for calculating cross-rates. Among the symbol properties, there are two that allow you to distinguish between explicit selection (SYMBOL_VISIBLE) and implicit selection (SYMBOL_SELECT); they will be discussed in the section on symbol status check. Strictly speaking, for the *SymbolsTotal* and *SymbolName* functions, the

setting of *selected* to *true* matches the extended symbols set with SYMBOL_SELECT cocked, not just those with SYMBOL_VISIBLE equal to *true*.

The order in which *Market Watch* symbols are returned corresponds to the terminal window (taking into account the possible rearrangement made by the user, and not taking into account sorting by any column, if it is enabled). Changing the order of symbols in *Market Watch* programmatically is not possible.

The order in the general list of *Symbols* is set by the terminal itself (content and sorting of *Market Watch* does not affect it).

As an example, let's look at the simple script *SymbolList.mq5*, which prints the available symbols to the log. The input parameter *MarketWatchOnly* allows the user to limit the list to the *Market Watch* symbols only (if the parameter is *true*) or to get the full list (*false*).

```
#property script_show_inputs

#include <MQL5Book/PRTF.mqh>

input bool MarketWatchOnly = true;

void OnStart()
{
   const int n = SymbolsTotal(MarketWatchOnly);
   Print("Total symbol count: ", n);
   // write a list of symbols in the Market Watch or all available
   for(int i = 0; i < n; ++i)
   {
      PrintFormat("%4d %s", i, SymbolName(i, MarketWatchOnly));
   }
   // intentionally asking for out-of-range to show an error
   PRTF(SymbolName(n, MarketWatchOnly)); // MARKET_UNKNOWN_SYMBOL(4301)
}
```

Below is an example log.

```
Total symbol count: 10
   0 EURUSD
   1 XAUUSD
   2 BTCUSD
   3 GBPUSD
   4 USDJPY
   5 USDCHF
   6 AUDUSD
   7 USDCAD
   8 NZDUSD
   9 USDRUB
SymbolName(n,MarketWatchOnly)= / MARKET_UNKNOWN_SYMBOL(4301)
```

6.1.2 Editing the Market Watch list

Using the *SymbolSelect* function, the MQL program developer can add a specific symbol to *Market Watch* or remove it from there.

bool SymbolSelect(const string name, bool select)

The *name* parameter contains the name of the symbol being affected by this operation. Depending on the value of the *select* parameter, a symbol is added to *Market Watch* (*true*) or removed from it. Symbol names are case-sensitive: for example, "EURUSD.m" is not equal to "EURUSD.M".

The function returns an indication of success (*true*) or error (*false*). The error code can be found in *_LastError*.

> A symbol cannot be removed if there are open charts or open positions for this symbol. In addition, you cannot delete a symbol that is explicitly used in the formula for calculating a synthetic (custom) instrument added to *Market Watch*.

It should be kept in mind that even if there are no open charts and positions for a symbol, it can be indirectly used by MQL programs: for example, they can read its history of quotes or ticks. Removing such a symbol may cause problems in these programs.

The following script *SymbolRemoveUnused.mq5* is able to hide all symbols that are not used explicitly, so it is recommended to check it on a demo account or save the current symbols set through the context menu first.

```
#include <MQL5Book/MqlError.mqh>

#define PUSH(A,V) (A[ArrayResize(A, ArraySize(A) + 1) - 1] = V)

void OnStart()
{
   // request user confirmation for deletion
   if(IDOK == MessageBox("This script will remove all unused symbols"
      " from the Market Watch. Proceed?", "Please, confirm", MB_OKCANCEL))
   {
      const int n = SymbolsTotal(true);
      ResetLastError();
      string removed[];
      // go through the symbols of the Market Watch in reverse order
      for(int i = n - 1; i >= 0; --i)
      {
         const string s = SymbolName(i, true);
         if(SymbolSelect(s, false))
         {
            // remember what was deleted
            PUSH(removed, s);
         }
         else
         {
            // in case of an error, display the reason
            PrintFormat("Can't remove '%s': %s (%d)", s, E2S(_LastError), _LastError)
         }
      }
      const int r = ArraySize(removed);
      PrintFormat("%d out of %d symbols removed", r, n);
      ArrayPrint(removed);
      ...
```

After the user confirms the analysis of the list of symbols, the program attempts to hide each symbol sequentially by calling *SymbolSelect(s, false)*. This only works for instruments that are not used explicitly. The enumeration of symbols is performed in the reverse order so as not to violate the indexing. All successfully removed symbols are collected in the *removed* array. The log displays statistics and the array itself.

If *Market Watch* is changed, the user is then given the opportunity to restore all deleted symbols by calling *SymbolSelect(removed[i], true)* in a loop.

```
      if(r > 0)
      {
         // it is possible to return the deleted symbols back to the Market Watch
         // (at this point, the window displays a reduced list)
         if(IDOK == MessageBox("Do you want to restore removed symbols"
            " in the Market Watch?", "Please, confirm", MB_OKCANCEL))
         {
            int restored = 0;
            for(int i = r - 1; i >= 0; --i)
            {
               restored += SymbolSelect(removed[i], true);
            }
            PrintFormat("%d symbols restored", restored);
         }
      }
   }
}
```

Here's what the log output might look like.

```
Can't remove 'EURUSD': MARKET_SELECT_ERROR (4305)
Can't remove 'XAUUSD': MARKET_SELECT_ERROR (4305)
Can't remove 'BTCUSD': MARKET_SELECT_ERROR (4305)
Can't remove 'GBPUSD': MARKET_SELECT_ERROR (4305)
...
Can't remove 'USDRUB': MARKET_SELECT_ERROR (4305)
2 out of 10 symbols removed
"NZDUSD" "USDCAD"
2 symbols restored
```

Please note that although the symbols are restored in their original order, as they were in *Market Watch* relative to each other, the addition occurs at the end of the list, after the remaining symbols. Thus, all "busy" symbols will be at the beginning of the list, and all the restored will follow them. Such is the specific operation of *SymbolSelect*: a symbol is always added to the end of the list, that is, it is impossible to insert a symbol in a specific position. So, the rearrangement of the list elements is available only for manual editing.

6.1.3 Checking if a symbol exists

Instead of looking through the entire list of symbols, an MQL program can check for the presence of a particular symbol by its name. For this purpose, there is the *SymbolExist* function.

bool SymbolExist(const string name, bool &isCustom)

In the *name* parameter, you should pass the name of the desired symbol. The *isCustom* parameter passed by reference will be set by the function according to whether the specified symbol is standard (*false*) or custom (*true*).

The function returns *false* if the symbol is not found in either the standard or custom symbols.

A partial analog of this function is the SYMBOL_EXIST property query.

Let's analyze the simple script *SymbolExists.mq5* to test this feature. In its parameter, the user can specify the name, which is then passed to *SymbolExist*, and the result is logged. If an empty string is input, the working symbol of the current chart will be checked. By default, the parameter is set to "XYZ", which presumably does not match any of the available symbols.

```
#property script_show_inputs

input string SymbolToCheck = "XYZ";

void OnStart()
{
   const string _SymbolToCheck = SymbolToCheck == "" ? _Symbol : SymbolToCheck;
   bool custom = false;
   PrintFormat("Symbol '%s' is %s", _SymbolToCheck,
      (SymbolExist(_SymbolToCheck, custom) ? (custom ? "custom" : "standard") : "miss
}
```

When the script is run two times, first with the default value and then with an empty line on the EURUSD chart, we will get the following entries in the log.

```
Symbol 'XYZ' is missing
Symbol 'EURUSD' is standard
```

If you already have custom symbols or create a new one with a simple calculation formula, you can make sure the custom variable is populated. For example, if you open the *Symbols* window in the terminal and press the *Create symbol* button, you can enter "SP500/FTSE100" (index names may differ for your broker) in the *Synthetic tool formula* field and "GBPUSD.INDEX" in the field with the *Symbol* name. A click on *OK* will create a custom instrument for which you can open a chart, and our script should display the following on it:

```
Symbol 'GBPUSD.INDEX' is custom
```

When setting up your own symbol, do not forget to set not only the formula but also sufficiently "small" values for the point size and the price change step (tick). Otherwise, the series of synthetic quotes may turn out to be "stepped", or even degenerate into a straight line.

6.1.4 Checking the symbol data relevance

Due to the distributed client-server architecture, client and server data may occasionally be different. For example, this can happen immediately after the start of the terminal session, when the connection is lost, or when the computer resources are heavily loaded. Also, the symbol will most likely remain out of sync for some time immediately after it is added to the Market Watch. The MQL5 API allows you to check the relevance of quote data for a particular symbol using the *SymbolIsSynchronized* function.

bool SymbolIsSynchronized(const string name)

The function returns *true* if the local data on the symbol named *name* is synchronized with the data on the trade server.

The section Obtaining characteristics of price arrays, among other timeseries properties, introduced the SERIES_SYNCHRONIZED property which returns an attribute of synchronization that is narrower in its meaning: it applies to a specific combination of a symbol and a timeframe. In contrast to this property, the *SymbolIsSynchronized* function returns an attribute of synchronization of the general history for a symbol.

The construction of all timeframes starts only after the completion of the history download. Due to the multi-threaded architecture and parallel computing in the terminal, it might happen that *SymbolIsSynchronized* will return *true*, and for a timeframe on the same symbol, the SERIES_SYNCHRONIZED property will be temporarily equal to *false*.

Let's see how the new function works in the *SymbolListSync.mq5* indicator. It is designed to periodically check all symbols from *Market Watch* for synchronization. The check period is set by the user in seconds in the *SyncCheckupPeriod* parameter. It causes the timer to start in *OnInit*.

```
#property indicator_chart_window
#property indicator_plots 0

input int SyncCheckupPeriod = 1; // SyncCheckupPeriod (seconds)

void OnInit()
{
   EventSetTimer(SyncCheckupPeriod);
}
```

In the *OnTimer* handler, in a loop, we call *SymbolIsSynchronized* and collect all unsynchronized symbols into a common string, after which they are displayed in the comment and the log.

```
void OnTimer()
{
   string unsynced;
   const int n = SymbolsTotal(true);
   // check all symbols in the Market Watch
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, true);
      if(!SymbolIsSynchronized(s))
      {
         unsynced += s + "\n";
      }
   }

   if(StringLen(unsynced) > 0)
   {
      Comment("Unsynced symbols:\n" + unsynced);
      Print("Unsynced symbols:\n" + unsynced);
   }
   else
   {
      Comment("All Market Watch is in sync");
   }
}
```

For example, if we add some previously missing symbol (Brent) to the *Market Watch*, we get an entry like this:

```
Unsynced symbols:
Brent
```

Under normal conditions, most of the time (while the indicator is running) there should be no such messages in the log. However, a flood of alerts may be generated during communication problems.

6.1.5 Getting the last tick of a symbol

In the chapter about timeseries, in the Working with arrays of real ticks section, we introduced the built-in structure *MqlTick* containing fields with price and volume values for a particular symbol, known at the time of each change in quotes. In online mode, an MQL program can query the last received prices and volumes using the *SymbolInfoTick* function that adopts the same structure.

bool SymbolInfoTick(const string symbol, MqlTick &tick)

For a symbol with a given name *symbol*, the function fills the *tick* structure passed by reference. If successful, it returns *true*.

As you know, indicators and Expert Advisors are automatically called by the terminal upon the arrival of a new tick, if they contain the description of the corresponding handlers *OnCalculate* and *OnTick*. However, information about the meaning of price changes, the volume of the last trade, and the tick generation time are not transferred directly to the handlers. More detailed information can be obtained with the *SymbolInfoTick* function.

Tick events are generated only for a chart symbol, and therefore we have already considered the option of obtaining our own multi-symbol event for ticks based on custom events. In this case, *SymbolInfoTick* makes it possible to read information about ticks on third-party symbols about receiving notifications.

Let's take the *EventTickSpy.mq5* indicator and convert it to *SymbolTickSpy.mq5*, which will request the *MqlTick* structure for the corresponding symbol on each "multicurrency" tick and then calculate and display all spreads on the chart.

Let's add a new input parameter *Index*. It will be required for a new way of sending notifications: we will send only the index of the changed symbol in the user event (see further along).

```
#define TICKSPY 0xFEED // 65261

input string SymbolList =
   "EURUSD,GBPUSD,XAUUSD,USDJPY,USDCHF"; // List of symbols, comma separated (example
input ushort Message = TICKSPY;          // Custom message id
input long Chart = 0;                    // Receiving chart id (do not edit)
input int Index = 0;                     // Index in symbol list (do not edit)
```

Also, we add the *Spreads* array to store spreads by symbols and the *SelfIndex* variable to remember the position of the current chart's symbol in the list (if it is included in the list, which is usually so). The latter is needed to call our new tick handling function from *OnCalculate* in the original copy of the indicator. It is easier and more correct to take a ready-made index for *_Symbol* explicitly and not send it in an event back to ourselves.

```
int Spreads[];
int SelfIndex = -1;
```

The introduced data structures are initialized in *OnInit*. Otherwise, *OnInit* remained unchanged, including the launch of subordinate instances of the indicator on third-party symbols (these lines are omitted here).

```
void OnInit()
{
   ...
         const int n = StringSplit(SymbolList, ',', Symbols);
         ArrayResize(Spreads, n);
         for(int i = 0; i < n; ++i)
         {
            if(Symbols[i] != _Symbol)
            {
               ...
            }
            else
            {
               SelfIndex = i;
            }
            Spreads[i] = 0;
         }
   ...
}
```

In the *OnCalculate* handler, we generate a custom event on each tick if the copy of the indicator works on the other symbol (at the same time, the ID of the *Chart* chart to which notifications should be sent is not equal to 0). Please note that the only parameter filled in the event is *lparam* which is equal to *Index* (*dparam* is 0, and *sparam* is NULL). If *Chart* equals 0, this means we are in the main copy of the indicator working on the chart symbol *_Symbol*, and if it is found in the input symbol list, we call directly *OnSymbolTick* with the corresponding *SelfIndex* index.

```
int OnCalculate(const int rates_total, const int prev_calculated, const int, const do
{
   if(prev_calculated)
   {
      if(Chart > 0)
      {
         EventChartCustom(Chart, Message, Index, 0, NULL);
      }
      else if(SelfIndex > -1)
      {
         OnSymbolTick(SelfIndex);
      }
   }

   return rates_total;
}
```

In the receiving part of the event algorithm in *OnChartEvent*, we also call *OnSymbolTick*, but this time we get the symbol number from the list in *lparam* (what was sent as the *Index* parameter from another copy of the indicator).

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_CUSTOM + Message)
   {
      OnSymbolTick((int)lparam);
   }
}
```

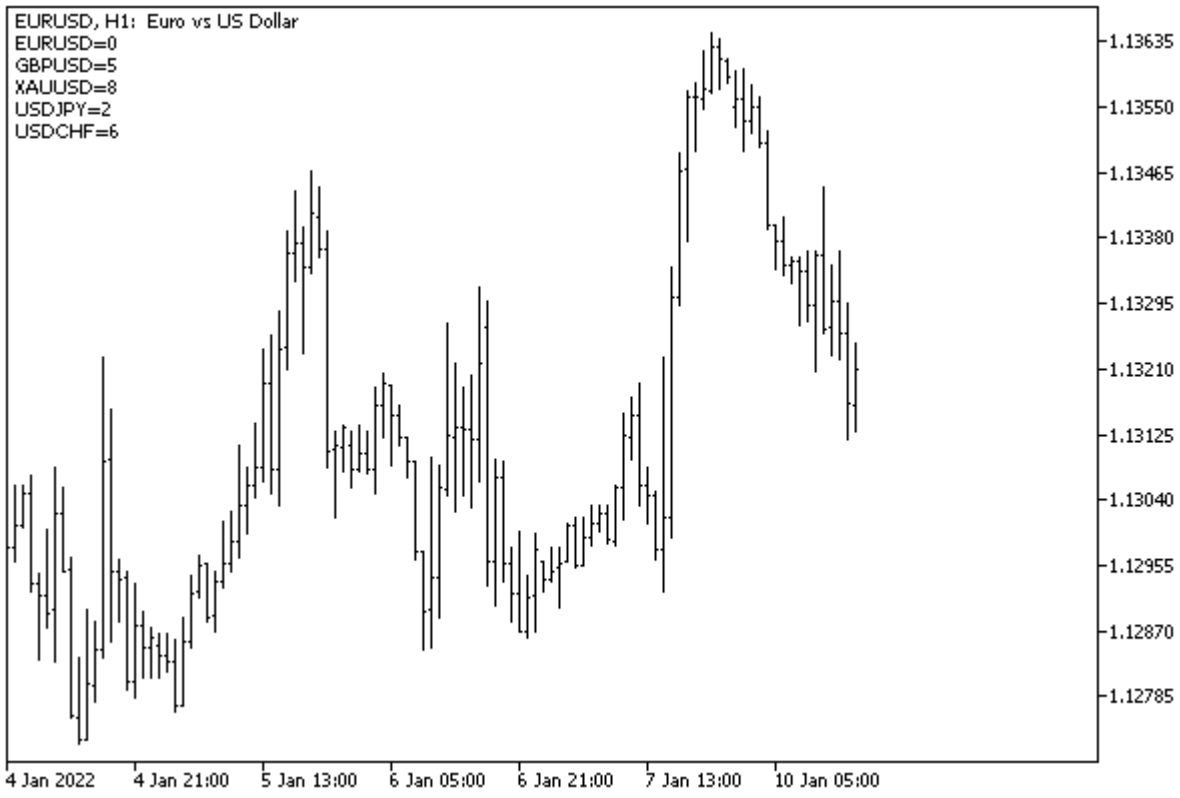
The *OnSymbolTick* function requests full tick information using *SymbolInfoTick* and calculates the spread as the difference between the *Ask* and *Bid* prices divided by the point size (the SYMBOL_POINT property will be discussed later).

```
void OnSymbolTick(const int index)
{
   const string symbol = Symbols[index];

   MqlTick tick;
   if(SymbolInfoTick(symbol, tick))
   {
      Spreads[index] = (int)MathRound((tick.ask - tick.bid)
         / SymbolInfoDouble(symbol, SYMBOL_POINT));
      string message = "";
      for(int i = 0; i < ArraySize(Spreads); ++i)
      {
         message += Symbols[i] + "=" + (string)Spreads[i] + "\n";
      }

      Comment(message);
   }
}
```

The new spread updates the corresponding cell in the *Spreads* array, after which the entire array is displayed on the chart in the comment. Here's what it looks like.



Current spreads for the requested list of symbols

You can compare in real time the correspondence of the information in the comment and in the *Market Watch* window.

6.1.6 Schedules of trading and quoting sessions

A little later, in further chapters, we will discuss the MQL5 API functions that allow us to automate trading operations. But first, we should study the technical features of the platform, which determine the success of calling these APIs. In particular, some restrictions are imposed by the specifications of financial instruments. In this chapter, we will gradually consider their programmatic analysis in full, and we will start with such an item as sessions.

When trading financial instruments, it should be taken into account that many international markets, such as stock exchanges, have predetermined opening hours, and information and trading are available only during these hours. Despite the fact that the terminal is constantly connected to the broker's server, an attempt to make a deal outside the working schedule will fail. In this regard, for each symbol, the terminal stores a schedule of sessions, that is, the time periods within a day when certain actions can be performed.

As you know, there are two main types of sessions: quoting and trading. During the quoting session, the terminal receives (may receive) current quotes. During the trading session, it is allowed to send trade orders and make deals. During the day, there may be several sessions of each type, with breaks (for example, morning and evening). It is obvious that the duration of the quoting sessions is greater than or equal to the trading ones.

In any case, session times, that is, opening and closing hours, are translated by the terminal from the local time zone of the exchange to the broker's time zone (server time).

The MQL5 API allows you to find out the quoting and trading sessions of each instrument using the *SymbolInfoSessionQuote* and *SymbolInfoSessionTrade* functions. In particular, this important information allows the program to check whether the market is currently open before sending a trade request to the server. Thus, we prevent the inevitable erroneous result and avoid unnecessary server loads. Keep in mind that in the case of massive erroneous requests to the server due to an incorrectly implemented MQL program, the server may begin to "ignore" your terminal, refusing to execute subsequent commands (even correct ones) for some time.

```
bool SymbolInfoSessionQuote(const string symbol, ENUM_DAY_OF_WEEK dayOfWeek, uint
sessionIndex, datetime &from, datetime &to)
bool SymbolInfoSessionTrade(const string symbol, ENUM_DAY_OF_WEEK dayOfWeek, uint
sessionIndex, datetime &from, datetime &to)
```

The functions work in the same way. For a given *symbol* and day of the week *dayOfWeek*, they fill in the *from* and *to* parameters passed by reference with the opening and closing times of the session with *sessionIndex*. Session indexing starts from 0. The ENUM_DAY_OF_WEEK structure was described in the section Enumerations.

There are no separate functions for querying the number of sessions: instead, we should be calling *SymbolInfoSessionQuote* and*SymbolInfoSessionTrade* with increasing index *sessionIndex*, until the function returns an error flag (*false*). When a session with the specified number exists, and the output arguments *from* and *to* received correct values, the functions return a success indicator (*true*).

According to the MQL5 documentation, in the received values of *from* and *to* of type *datetime*, the date should be ignored and only the time should be considered. This is because the information is an intraday schedule. However, there is an important exception to this rule.

Since the market is potentially open 24 hours a day, as in the case of Forex, or an exchange on the other side of the world, where daytime business hours coincide with the change of dates in your broker's "timezone", the end of sessions can have a time equal to or greater than 24 hours. For

example, if the start of Forex sessions is 00:00, then the end is 24:00. However, from the point of view of the *datetime* type, 24 hours is 00 hours 00 minutes the very next day.

The situation becomes more confusing for those exchanges, where the schedule is shifted relative to your broker's time zone by several hours in such a way that the session starts on one day and ends on another. Because of this, the *to* variable registers not only time but also an extra day that cannot be ignored, because otherwise intraday time *from* will be more than intraday time *to* (for example, a session can last from 21:00 today to 8:00 tomorrow, that is, 21 > 8). In this case, the check for the occurrence of the current time inside the session ("time x is greater than the start and less than the end") will turn out to be incorrect (for example, the condition x >= 21 && x < 8 is not fulfilled for x = 23, although the session is actually active).

Thus, we come to the conclusion that it is impossible to ignore the date in the *from/to* parameters, and this point should be taken into account in the algorithms (see example).

To demonstrate the capabilities of the functions, let's return to an example of the script *EnvPermissions.mq5* which was presented in the Permissions section. One of the types of permissions (or restrictions, if you like) refers specifically to the availability of trading. Earlier, the script took into account the terminal settings (TERMINAL_TRADE_ALLOWED) and the settings of a specific MQL program (MQL_TRADE_ALLOWED). Now we can add to it session checks to determine the trading permissions that are valid at a given moment for a particular symbol.

The new version of the script is called *SymbolPermissions.mq5*. It is also not final: in one of the following chapters, we will study the limitations imposed by the trading account settings.

Recall that the script implements the class *Permissions*, which provides a centralized description of all types of permissions/restrictions applicable to MQL programs. Among other things, the class has methods for checking the availability of trading: *isTradeEnabled* and *isTradeOnSymbolEnabled*. The first of these relates to global permissions and will remain almost unchanged:

```
class Permissions
{
public:
   static bool isTradeEnabled(const string symbol = NULL, const datetime now = 0)
   {
      return TerminalInfoInteger(TERMINAL_TRADE_ALLOWED)
          && MQLInfoInteger(MQL_TRADE_ALLOWED)
          && isTradeOnSymbolEnabled(symbol == NULL ? _Symbol : symbol, now);
   }
   ...
```

After checking the properties of the terminal and the MQL program, the script proceeds to *isTradeOnSymbolEnabled* where the symbol specification is analyzed. Previously, this method was practically empty.

In addition to the working symbol passed in the symbol parameter, the *isTradeOnSymbolEnabled* function receives the current time (*now*) and the required trading mode (*mode*). We will discuss the latter in more detail in the following sections (see Trading permissions). For now, let's just note that the default value of SYMBOL_TRADE_MODE_FULL gives maximum freedom (all trading operations are allowed).

```
static bool isTradeOnSymbolEnabled(string symbol, const datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   // checking sessions
   bool found = now == 0;
   if(!found)
   {
      const static ulong day = 60 * 60 * 24;
      const ulong time = (ulong)now % day;
      datetime from, to;
      int i = 0;

      ENUM_DAY_OF_WEEK d = TimeDayOfWeek(now);

      while(!found && SymbolInfoSessionTrade(symbol, d, i++, from, to))
      {
         found = time >= (ulong)from && time < (ulong)to;
      }
   }
   // checking the trading mode for the symbol
   return found && (SymbolInfoInteger(symbol, SYMBOL_TRADE_MODE) == mode);
}
```

If the *now* time is not specified (it is equal to 0 by default), we consider that we are not interested in sessions. This means that the *found* variable with an indication that a suitable session has been found (that is, a session containing the given time) is immediately set to *true*. But if the *now* parameter is specified, the function gets into the trading session analysis block.

To extract time without taking into account the date from the values of the *datetime* type, we describe the *day* constant equal to the number of seconds in a day. An expression like *now % day* will return the remainder of dividing the full date and time by the duration of one day, which will give only the time (the most significant digits in *datetime* will be null).

The *TimeDayOfWeek* function returns the day of the week for the given *datetime* value. It is located in the *MQL5Book/DateTime.mqh* header file which we have already used before (see Date and time).

Further in the *while* loop, we call the *SymbolInfoSessionTrade* function while constantly incrementing the session index *i* until a suitable session is found or the function returns *false* (no more sessions). Thus, the program can get a complete list of sessions by day of the week, similar to what is displayed in the terminal in the symbol *Specifications* window.

Obviously, a suitable session is the one that contains the specified *time* value between the session beginning *from* and end *to* times. It is here that we take into account the problem associated with the possible round-the-clock trading: *from* and *to* are compared against *time* "as is", without discarding the day (*from % day* or *to % day*).

Once *found* becomes equal to *true*, we exit the loop. Otherwise, the loop will end when the allowed number of sessions is exceeded (function *SymbolInfoSessionTrade* will return *false*) and a suitable session will never be found.

If, according to the session schedule, trading is now allowed, we additionally check the trading mode for the symbol (SYMBOL_TRADE_MODE). For example, symbol trading can be completely prohibited ("indicative") or be in the "only closing positions" mode.

The above code has some simplifications compared to the final version in the file *SymbolPermissions.mq5*. It additionally implements a mechanism for marking the source of the restriction that caused the trade to be disabled. All such sources are summarized in the TRADE_RESTRICTIONS enumeration.

```
enum TRADE_RESTRICTIONS
{
   TERMINAL_RESTRICTION = 1,
   PROGRAM_RESTRICTION = 2,
   SYMBOL_RESTRICTION = 4,
   SESSION_RESTRICTION = 8,
};
```

At the moment, the restriction can come from 4 instances: the terminal, the program, the symbol, and the session schedule. We will add more options later.

To register the fact that a constraint was found in the *Permissions* class, we have the *lastFailReasonBitMask* variable which allows the collection of a bit mask from the elements of the enumeration using an auxiliary method *pass* (the bit is set up when the checked condition *value* is false, and the bit equals *false*).

```
static uint lastFailReasonBitMask;
static bool pass(const bool value, const uint bitflag)
{
   if(!value) lastFailReasonBitMask |= bitflag;
   return value;
}
```

Calling the *pass* method with a specific flag is done at the appropriate validation steps. For example, the *isTradeEnabled* method in full looks like this:

```
static bool isTradeEnabled(const string symbol = NULL, const datetime now = 0)
{
   lastFailReasonBitMask = 0;
   return pass(TerminalInfoInteger(TERMINAL_TRADE_ALLOWED), TERMINAL_RESTRICTION)
       && pass(MQLInfoInteger(MQL_TRADE_ALLOWED), PROGRAM_RESTRICTION)
       && isTradeOnSymbolEnabled(symbol == NULL ? _Symbol : symbol, now);
}
```

Due to this, with a negative result of the call *TerminalInfoInteger(TERMINAL_TRADE_ALLOWED)* or *MQLInfoInteger(MQL_TRADE_ALLOWED)*, either the TERMINAL_RESTRICTION or the PROGRAM_RESTRICTION flag will be set, respectively.

The *isTradeOnSymbolEnabled* method also sets its own flags when problems are detected, including session flags.

```
static bool isTradeOnSymbolEnabled(string symbol, const datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   ...
   return pass(found, SESSION_RESTRICTION)
      && pass(SymbolInfoInteger(symbol, SYMBOL_TRADE_MODE) == mode, SYMBOL_RESTRIC
}
```

As a result, the MQL program that is using the query *Permissions::isTradeEnabled*, after receiving a restriction, may clarify its meaning using the *getFailReasonBitMask* and *explainBitMask* methods: the first one returns the mask of set prohibition flags "as is", and the second one forms a user-friendly text description of the restrictions.

```
static uint getFailReasonBitMask()
{
   return lastFailReasonBitMask;
}

static string explainBitMask()
{
   string result = "";
   for(int i = 0; i < 4; ++i)
   {
      if(((1 << i) & lastFailReasonBitMask) != 0)
      {
         result += EnumToString((TRADE_RESTRICTIONS)(1 << i));
      }
   }
   return result;
}
```

With the above *Permissions* class in the *OnStart* handler, a check is made for the availability of trading for all symbols from the *Market Watch* (currently, *TimeCurrent*).

```
void OnStart()
{
   string disabled = "";

   const int n = SymbolsTotal(true);
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, true);
      if(!Permissions::isTradeEnabled(s, TimeCurrent()))
      {
         disabled += s + "=" + Permissions::explainBitMask() +"\n";
      }
   }
   if(disabled != "")
   {
      Print("Trade is disabled for the following symbols and origins:");
      Print(disabled);
   }
}
```

If trading is prohibited for a certain symbol, we will see an explanation in the log.

```
Trade is disabled for following symbols and origins:
USDRUB=SESSION_RESTRICTION
SP500m=SYMBOL_RESTRICTION
```

In this case, the market is closed for "USDRUB" and trading is disabled for the "SP500m" symbol (more strictly, it does not correspond to the SYMBOL_TRADE_MODE_FULL mode).

It is assumed that when running the script, algorithmic trading was enabled globally in the terminal. Otherwise, we will additionally see TERMINAL_RESTRICTION and PROGRAM_RESTRICTION prohibitions in the log.

6.1.7 Symbol margin rates

Among the characteristics of the symbol specification available in the MQL5 API, which we will discuss in detail in further sections, there are several characteristics related to margin requirements, which apply when opening and maintaining trading positions. Due to the fact that the terminal provides trading on different markets and different types of instruments, these requirements may vary significantly. In a generalized form, this is expressed in the application of margin correction rates that are set individually for symbols and different types of trading operations. For the user, the rates are displayed in the terminal in the *Specifications* window.

As we will see below, the multiplier (if applied) is multiplied by the margin value from the symbol properties. The margin ratio can be obtained programmatically using the *SymbolInfoMarginRate* function.

bool SymbolInfoMarginRate(const string symbol, ENUM_ORDER_TYPE orderType, double &initial, double &maintenance)

For the specified symbol and order type (ENUM_ORDER_TYPE), the function fills in passed by reference *initial* and *maintenance* parameters with initial and maintaining margin ratios, respectively. The resulting rates should be multiplied by the margin value of the corresponding type (how to request it is

described in the section on margin requirements) to get the amount that will be reserved in the account when placing an order such as *orderType*.

The function returns *true* in case of successful execution.

Let's use as an example a simple script *SymbolMarginRate.mq5*, which outputs margin ratios for *Market Watch* or all available symbols, depending on the *MarketWatchOnly* parameter. The operation type can be specified in the *OrderType* parameter.

```
#include <MQL5Book/MqlError.mqh>

input bool MarketWatchOnly = true;
input ENUM_ORDER_TYPE OrderType = ORDER_TYPE_BUY;

void OnStart()
{
   const int n = SymbolsTotal(MarketWatchOnly);
   PrintFormat("Margin rates per symbol for %s:", EnumToString(OrderType));
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, MarketWatchOnly);
      double initial = 1.0, maintenance = 1.0;
      if(!SymbolInfoMarginRate(s, OrderType, initial, maintenance))
      {
         PrintFormat("Error: %s(%d)", E2S(_LastError), _LastError);
      }
      PrintFormat("%4d %s = %f %f", i, s, initial, maintenance);
   }
}
```

Below is the log.

```
Margin rates per symbol for ORDER_TYPE_BUY:
   0 EURUSD = 1.000000 0.000000
   1 XAUUSD = 1.000000 0.000000
   2 BTCUSD = 0.330000 0.330000
   3 USDCHF = 1.000000 0.000000
   4 USDJPY = 1.000000 0.000000
   5 AUDUSD = 1.000000 0.000000
   6 USDRUB = 1.000000 1.000000
```

You can compare the received values with the symbol specifications in the terminal.

6.1.8 Overview of functions for getting symbol properties

The complete specification of each symbol can be obtained by querying its properties: for this purpose, the MQL5 API provides three functions, namely *SymbolInfoInteger*, *SymbolInfoDouble*, and *SymbolInfoString*, each of which is responsible for the properties of a particular type. The properties are described as members of three enumerations: ENUM_SYMBOL_INFO_INTEGER, ENUM_SYMBOL_INFO_DOUBLE, and ENUM_SYMBOL_INFO_STRING, respectively. A similar technique is used in the chart and object APIs we already know.

The name of the symbol and the identifier of the requested property are passed to any of the functions.

Each of the functions is presented in two forms: abbreviated and full. The abbreviated version directly returns the requested property, while the full one writes it to the out parameter passed by reference. For example, for properties that are compatible with an integer type, the functions have prototypes like this:

```
long SymbolInfoInteger(const string symbol, ENUM_SYMBOL_INFO_INTEGER property)
bool SymbolInfoInteger(const string symbol, ENUM_SYMBOL_INFO_INTEGER property, long &value)
```

The second form returns a boolean indicator of success (*true*) or error (*false*). The most possible reasons why a function might return *false* include an invalid symbol name (MARKET_UNKNOWN_SYMBOL, 4301) or an invalid identifier for the requested property (MARKET_WRONG_PROPERTY, 4303). The details are provided in *_LastError*.

As before, the properties in the ENUM_SYMBOL_INFO_INTEGER enumeration are of various integer-compatible types: *bool*, *int*, *long*, *color*, *datetime*, and special enumerations (all of which will be discussed in separate sections).

For properties with a real number type, the following two forms of the *SymbolInfoDouble* function are defined.

```
double SymbolInfoDouble(const string symbol, ENUM_SYMBOL_INFO_DOUBLE property)
bool SymbolInfoDouble(const string symbol, ENUM_SYMBOL_INFO_DOUBLE property, double &value)
```

Finally, for string properties, similar functions look like this:

```
string SymbolInfoString(const string symbol, ENUM_SYMBOL_INFO_STRING property)
bool SymbolInfoString(const string symbol, ENUM_SYMBOL_INFO_STRING property, string &value)
```

The properties of various types which will be often used later when developing Expert Advisors are logically grouped in the descriptions of the following sections of this chapter.

Based on the above functions, we will create a universal class *SymbolMonitor* (file*SymbolMonitor.mqh*) to get any symbol properties. It will be based on a set of overloaded *get* methods for three enumerations.

```
class SymbolMonitor
{
public:
   const string name;
   SymbolMonitor(): name(_Symbol) { }
   SymbolMonitor(const string s): name(s) { }

   long get(const ENUM_SYMBOL_INFO_INTEGER property) const
   {
      return SymbolInfoInteger(name, property);
   }

   double get(const ENUM_SYMBOL_INFO_DOUBLE property) const
   {
      return SymbolInfoDouble(name, property);
   }

   string get(const ENUM_SYMBOL_INFO_STRING property) const
   {
      return SymbolInfoString(name, property);
   }
   ...
```

The other three similar methods make it possible to eliminate the enumeration type in the first parameter and select the necessary overload by the compiler due to the second dummy parameter (its type here always matches the result type). We will use this in future template classes.

```
   long get(const int property, const long) const
   {
      return SymbolInfoInteger(name, (ENUM_SYMBOL_INFO_INTEGER)property);
   }

   double get(const int property, const double) const
   {
      return SymbolInfoDouble(name, (ENUM_SYMBOL_INFO_DOUBLE)property);
   }

   string get(const int property, const string) const
   {
      return SymbolInfoString(name, (ENUM_SYMBOL_INFO_STRING)property);
   }
   ...
```

Thus, by creating an object with the desired symbol name, you can uniformly query its properties of any type. To query and log all properties of the same type, we could implement something like this.

```
// project (draft)
template<typename E,typename R>
void list2log()
{
   E e = (E)0;
   int array[];
   const int n = EnumToArray(e, array, 0, USHORT_MAX);
   for(int i = 0; i < n; ++i)
   {
      e = (E)array[i];
      R r = get(e);
      PrintFormat("% 3d %s=%s", i, EnumToString(e), (string)r);
   }
}
```

However, due to the fact that in properties of the type *long* values of other types are actually "hidden", which should be displayed in a specific way (for example, by calling *EnumToString* for enumerations, *imeToString* for date and time, etc.), it makes sense to define another three overloaded methods that would return a string representation of the property. Let's call them *stringify*. Then in the above *list2log* draft, it is possible to use *stringify* instead of casting values to *(string)*, and the method itself will eliminate one template parameter.

```
template<typename E>
void list2log()
{
   E e = (E)0;
   int array[];
   const int n = EnumToArray(e, array, 0, USHORT_MAX);
   for(int i = 0; i < n; ++i)
   {
      e = (E)array[i];
      PrintFormat("% 3d %s=%s", i, EnumToString(e), stringify(e));
   }
}
```

For real and string types, the implementation of *stringify* looks pretty straightforward.

```
string stringify(const ENUM_SYMBOL_INFO_DOUBLE property, const string format = NUL
{
   if(format == NULL) return (string)SymbolInfoDouble(name, property);
   return StringFormat(format, SymbolInfoDouble(name, property));
}

string stringify(const ENUM_SYMBOL_INFO_STRING property) const
{
   return SymbolInfoString(name, property);
}
```

But for ENUM_SYMBOL_INFO_INTEGER, everything is a little more complicated. Of course, when the property is of type *long* or *int*, it is enough to cast it to *(string)*. All other cases need to be individually analyzed and converted within the *switch* operator.

```
string stringify(const ENUM_SYMBOL_INFO_INTEGER property) const
{
   const long v = SymbolInfoInteger(name, property);
   switch(property)
   {
      ...
   }

   return (string)v;
}
```

For example, if a property has a boolean type, it is convenient to represent it with the string "true" or "false" (thus it will be visually different from the simple numbers 1 and 0). Looking ahead, for the sake of giving an example, let's say that among the properties there is SYMBOL_EXIST, which is equivalent to the *SymbolExist* function, that is, returning a boolean indication of whether the specified character exists. For its processing and other logical properties, it makes sense to implement an auxiliary method *boolean*.

```
static string boolean(const long v)
{
   return v ? "true" : "false";
}

string stringify(const ENUM_SYMBOL_INFO_INTEGER property) const
{
   const long v = SymbolInfoInteger(name, property);
   switch(property)
   {
      case SYMBOL_EXIST:
         return boolean(v);
      ...
   }

   return (string)v;
}
```

For properties that are enumerations, the most appropriate solution would be a template method using the *EnumToString* function.

```
template<typename E>
static string enumstr(const long v)
{
   return EnumToString((E)v);
}
```

For example, the SYMBOL_SWAP_ROLLOVER3DAYS property determines on which day of the week a triple swap is charged on open positions for a symbol, and this property has the type ENUM_DAY_OF_WEEK. So, to process it, we can write the following inside *switch*:

```
      case SYMBOL_SWAP_ROLLOVER3DAYS:
         return enumstr<ENUM_DAY_OF_WEEK>(v);
```

A special case is presented by properties whose values are combinations of bit flags. In particular, for each symbol, the broker sets permissions for orders of specific types, such as market, limit, stop loss,

take profit, and others (we will consider these permissions separately). Each type of order is denoted by a constant with one bit enabled, so their superposition (combined by the bitwise OR operator '|') is stored in the SYMBOL_ORDER_MODE property, and in the absence of restrictions, all bits are enabled at the same time. For such properties, we will define our own enumerations in our header file, for example:

```
enum SYMBOL_ORDER
{
   _SYMBOL_ORDER_MARKET = 1,
   _SYMBOL_ORDER_LIMIT = 2,
   _SYMBOL_ORDER_STOP = 4,
   _SYMBOL_ORDER_STOP_LIMIT = 8,
   _SYMBOL_ORDER_SL = 16,
   _SYMBOL_ORDER_TP = 32,
   _SYMBOL_ORDER_CLOSEBY = 64,
};
```

Here, for each built-in constant, such as SYMBOL_ORDER_MARKET, a corresponding element is declared, whose identifier is the same as the constant but is preceded by an underscore to avoid naming conflicts.

To represent combinations of flags from such enumerations in the form of a string, we implement another template method, *maskstr*.

```
template<typename E>
static string maskstr(const long v)
{
   string text = "";
   for(int i = 0; ; ++i)
   {
      ResetLastError();
      const string s = EnumToString((E)(1 << i));
      if(_LastError != 0)
      {
         break;
      }
      if((v & (1 << i)) != 0)
      {
         text += s + " ";
      }
   }
   return text;
}
```

Its meaning is like *enumstr*, but the function *EnumToString* is called for each enabled bit in the property value, after which the resulting strings are "glued".

Now processing SYMBOL_ORDER_MODE in the statement *switch* is possible in a similar way:

```
      case SYMBOL_ORDER_MODE:
         return maskstr<SYMBOL_ORDER>(v);
```

Here is the full code of the *stringify* method for ENUM_SYMBOL_INFO_INTEGER. With all the properties and enumerations, we will gradually get acquainted in the following sections.

```
string stringify(const ENUM_SYMBOL_INFO_INTEGER property) const
{
   const long v = SymbolInfoInteger(name, property);
   switch(property)
   {
      case SYMBOL_SELECT:
      case SYMBOL_SPREAD_FLOAT:
      case SYMBOL_VISIBLE:
      case SYMBOL_CUSTOM:
      case SYMBOL_MARGIN_HEDGED_USE_LEG:
      case SYMBOL_EXIST:
         return boolean(v);
      case SYMBOL_TIME:
         return TimeToString(v, TIME_DATE|TIME_SECONDS);
      case SYMBOL_TRADE_CALC_MODE:
         return enumstr<ENUM_SYMBOL_CALC_MODE>(v);
      case SYMBOL_TRADE_MODE:
         return enumstr<ENUM_SYMBOL_TRADE_MODE>(v);
      case SYMBOL_TRADE_EXEMODE:
         return enumstr<ENUM_SYMBOL_TRADE_EXECUTION>(v);
      case SYMBOL_SWAP_MODE:
         return enumstr<ENUM_SYMBOL_SWAP_MODE>(v);
      case SYMBOL_SWAP_ROLLOVER3DAYS:
         return enumstr<ENUM_DAY_OF_WEEK>(v);
      case SYMBOL_EXPIRATION_MODE:
         return maskstr<SYMBOL_EXPIRATION>(v);
      case SYMBOL_FILLING_MODE:
         return maskstr<SYMBOL_FILLING>(v);
      case SYMBOL_START_TIME:
      case SYMBOL_EXPIRATION_TIME:
         return TimeToString(v);
      case SYMBOL_ORDER_MODE:
         return maskstr<SYMBOL_ORDER>(v);
      case SYMBOL_OPTION_RIGHT:
         return enumstr<ENUM_SYMBOL_OPTION_RIGHT>(v);
      case SYMBOL_OPTION_MODE:
         return enumstr<ENUM_SYMBOL_OPTION_MODE>(v);
      case SYMBOL_CHART_MODE:
         return enumstr<ENUM_SYMBOL_CHART_MODE>(v);
      case SYMBOL_ORDER_GTC_MODE:
         return enumstr<ENUM_SYMBOL_ORDER_GTC_MODE>(v);
      case SYMBOL_SECTOR:
         return enumstr<ENUM_SYMBOL_SECTOR>(v);
      case SYMBOL_INDUSTRY:
         return enumstr<ENUM_SYMBOL_INDUSTRY>(v);
      case SYMBOL_BACKGROUND_COLOR: // Bytes: Transparency Blue Green Red
         return StringFormat("TBGR(0x%08X)", v);
   }

   return (string)v;
}
```

To test the *SymbolMonitor* class, we have created a simple script *SymbolMonitor.mq5*. It logs all the properties of the working chart symbol.

```
#include <MQL5Book/SymbolMonitor.mqh>

void OnStart()
{
   SymbolMonitor m;
   m.list2log<ENUM_SYMBOL_INFO_INTEGER>();
   m.list2log<ENUM_SYMBOL_INFO_DOUBLE>();
   m.list2log<ENUM_SYMBOL_INFO_STRING>();
}
```

For example, if we run the script on the EURUSD chart, we can get the following records (given in a shortened form).

```
ENUM_SYMBOL_INFO_INTEGER Count=36
  0 SYMBOL_SELECT=true
  ...
  4 SYMBOL_TIME=2022.01.12 10:52:22
  5 SYMBOL_DIGITS=5
  6 SYMBOL_SPREAD=0
  7 SYMBOL_TICKS_BOOKDEPTH=10
  8 SYMBOL_TRADE_CALC_MODE=SYMBOL_CALC_MODE_FOREX
  9 SYMBOL_TRADE_MODE=SYMBOL_TRADE_MODE_FULL
 10 SYMBOL_TRADE_STOPS_LEVEL=0
 11 SYMBOL_TRADE_FREEZE_LEVEL=0
 12 SYMBOL_TRADE_EXEMODE=SYMBOL_TRADE_EXECUTION_INSTANT
 13 SYMBOL_SWAP_MODE=SYMBOL_SWAP_MODE_POINTS
 14 SYMBOL_SWAP_ROLLOVER3DAYS=WEDNESDAY
 15 SYMBOL_SPREAD_FLOAT=true
 16 SYMBOL_EXPIRATION_MODE=_SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY »
    _SYMBOL_EXPIRATION_SPECIFIED _SYMBOL_EXPIRATION_SPECIFIED_DAY

 ...
 26 SYMBOL_VISIBLE=true
 27 SYMBOL_CUSTOM=false
 28 SYMBOL_BACKGROUND_COLOR=TBGR(0xFF000000)
 29 SYMBOL_CHART_MODE=SYMBOL_CHART_MODE_BID
 30 SYMBOL_ORDER_GTC_MODE=SYMBOL_ORDERS_GTC
 31 SYMBOL_MARGIN_HEDGED_USE_LEG=false
 32 SYMBOL_EXIST=true
 33 SYMBOL_TIME_MSC=1641984742149
 34 SYMBOL_SECTOR=SECTOR_CURRENCY
 35 SYMBOL_INDUSTRY=INDUSTRY_UNDEFINED
ENUM_SYMBOL_INFO_DOUBLE Count=57
  0 SYMBOL_BID=1.13681
  1 SYMBOL_BIDHIGH=1.13781
  2 SYMBOL_BIDLOW=1.13552
  3 SYMBOL_ASK=1.13681
  4 SYMBOL_ASKHIGH=1.13781
  5 SYMBOL_ASKLOW=1.13552
 ...
 12 SYMBOL_POINT=1e-05
 13 SYMBOL_TRADE_TICK_VALUE=1.0
 14 SYMBOL_TRADE_TICK_SIZE=1e-05
 15 SYMBOL_TRADE_CONTRACT_SIZE=100000.0
 16 SYMBOL_VOLUME_MIN=0.01
 17 SYMBOL_VOLUME_MAX=500.0
 18 SYMBOL_VOLUME_STEP=0.01
 19 SYMBOL_SWAP_LONG=-0.7
 20 SYMBOL_SWAP_SHORT=-1.0
 21 SYMBOL_MARGIN_INITIAL=0.0
 22 SYMBOL_MARGIN_MAINTENANCE=0.0
```

```
  ...
  28 SYMBOL_TRADE_TICK_VALUE_PROFIT=1.0
  29 SYMBOL_TRADE_TICK_VALUE_LOSS=1.0
  ...
  43 SYMBOL_MARGIN_HEDGED=100000.0
  ...
  47 SYMBOL_PRICE_CHANGE=0.0132
ENUM_SYMBOL_INFO_STRING Count=15
   0 SYMBOL_BANK=
   1 SYMBOL_DESCRIPTION=Euro vs US Dollar
   2 SYMBOL_PATH=Forex\EURUSD
   3 SYMBOL_CURRENCY_BASE=EUR
   4 SYMBOL_CURRENCY_PROFIT=USD
   5 SYMBOL_CURRENCY_MARGIN=EUR
  ...
  13 SYMBOL_SECTOR_NAME=Currency
```

In particular, you can see that the symbol prices are broadcast with 5 digits (SYMBOL_DIGITS), the symbol does exist (SYMBOL_EXIST), the contract size is 100000.0 (SYMBOL_TRADE_CONTRACT_SIZE), etc. All information corresponds to the specification.

6.1.9 Checking symbol status

Earlier we looked at several functions related to the status of a symbol. Recall that *SymbolExist* is used to check for the existence of a symbol, and *SymbolSelect* is used to check for inclusion or exclusion from the *Market Watch* list. Among the properties of the symbol, there are several flags similar in purpose, the use of which has both pluses and minuses compared to the above functions.

In particular, the SYMBOL_SELECT property allows you to find out if the specified symbol is selected in *Market Watch*, while the *SymbolSelect* function changes this property.

The *SymbolExist* function, unlike the similar SYMBOL_EXIST property, additionally populates the output variable with an indication that the symbol is a user-defined one. When querying properties, it would be necessary to analyze these two attributes separately, since the attribute of the custom symbol is stored in another property, SYMBOL_CUSTOM. However, in some cases, the program may need only one property, and then the possibility of a separate query becomes a plus.

All flags are boolean values obtained through the *SymbolInfoInteger* function.

Identifier	Description
SYMBOL_EXIST	Indicates that a symbol with the given name exists
SYMBOL_SELECT	Indicates that the symbol is selected in *Market Watch*
SYMBOL_VISIBLE	Indicates that the specified symbol is displayed in *Market Watch*

Of particular interest is SYMBOL_VISIBLE. The fact is that some symbols (as a rule, these are cross rates that are necessary for calculating margin requirements and profit in the deposit currency) are selected in *Market Watch* automatically and are not displayed in the list visible to the user. Such symbols must be explicitly chosen (by the user or programmatically) to be displayed. Thus, it is the SYMBOL_VISIBLE property that allows you to determine whether a symbol is visible in the window: it

can be equal to *false* for some elements of the list, obtained using a pair of functions *SymbolsTotal* and *SymbolName* with the *selected* parameter equal to *true*.

Consider a simple script (*SymbolInvisible.mq5*), which searches the terminal for implicitly selected symbols, that is, those that are not displayed in the Market Watch (SYMBOL_VISIBLE is reset) while SYMBOL_SELECT for them is equal to *true*.

```
#define PUSH(A,V) (A[ArrayResize(A, ArraySize(A) + 1) - 1] = V)

void OnStart()
{
   const int n = SymbolsTotal(false);
   int selected = 0;
   string invisible[];
   // loop through all available symbols
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, false);
      if(SymbolInfoInteger(s, SYMBOL_SELECT))
      {
         selected++;
         if(!SymbolInfoInteger(s, SYMBOL_VISIBLE))
         {
            // collect selected but invisible symbols into an array
            PUSH(invisible, s);
         }
      }
   }
   PrintFormat("Symbols: total=%d, selected=%d, implicit=%d",
      n, selected, ArraySize(invisible));
   if(ArraySize(invisible))
   {
      ArrayPrint(invisible);
   }
}
```

Try compiling and running the script on different accounts. The situation when a symbol is implicitly selected is not always encountered. For example, if in *Market Watch* tickers of Russian blue chips that are quoted in rubles are selected, and the trading account is in a different currency (for example, dollars or euros, but not rubles), then the USDRUB symbol will be automatically selected. Of course, this assumes that it has not been previously added to the *Market Watch* explicitly. Then we get the following result in the log:

```
Symbols: total=50681, selected=49, implicit=1
"USDRUB"
```

6.1.10 Price type for building symbol charts

Bars on MetaTrader 5 price charts can be plotted based on *Bid* or *Last* prices, and the plotting type is indicated in the specification of each instrument. An MQL program can find this characteristic by calling the *SymbolInfoInteger* function for the SYMBOL_CHART_MODE property. The return value is a member of the ENUM_SYMBOL_CHART_MODE enumeration.

Identifier	Description
SYMBOL_CHART_MODE_BID	Bars are built at Bid prices
SYMBOL_CHART_MODE_LAST	Bars are built at Last prices

The mode with *Last* prices is used for symbols traded on exchanges (as opposed to the decentralized Forex market), and the Depth of Market is available for such symbols. The depth of the market can be found based on the SYMBOL_TICKS_BOOKDEPTH property.

The SYMBOL_CHART_MODE property is useful for adjusting the signals of indicators or strategies that are built, for example, at the chart's *Last* prices, while orders will be executed "at the market price", that is, at *Ask* or *Bid* prices depending on direction.

Also, the price type is required when calculating bars of the custom instrument: if it depends on standard symbols, it may make sense to consider their settings by price type. When the user enters the formula of the synthetic instrument in the *Custom Symbol* window (opened by selecting *Create Symbol* in the *Symbols* dialogue), it is possible to select price types according to the specifications of the respective standard symbols used. However, when the calculation algorithm is formed in an MQL program, precisely it is responsible for the correct choice of the price type.

First, let's collect statistics on the use of *Bid* and *Last* prices to build charts on a specific account. This is what the script *SymbolStatsByPriceType.mq5* will do.

```
const bool MarketWatchOnly = false;

void OnStart()
{
   const int n = SymbolsTotal(MarketWatchOnly);
   int k = 0;
   // loop through all available characters
   for(int i = 0; i < n; ++i)
   {
      if(SymbolInfoInteger(SymbolName(i, MarketWatchOnly), SYMBOL_CHART_MODE)
          == SYMBOL_CHART_MODE_LAST)
      {
         k++;
      }
   }
   PrintFormat("Symbols in total: %d", n);
   PrintFormat("Symbols using price types: Bid=%d, Last=%d", n - k, k);
}
```

Try it on different accounts (some may not have stock symbols). Here's what the result might look like:

```
Symbols in total: 52304
Symbols using price types: Bid=229, Last=52075
```

A more practical example is the indicator *SymbolBidAskChart.mq5*, designed to draw a diagram in the form of bars formed based on prices of the specified type. This will allow you to compare candlesticks of a chart that uses prices from the SYMBOL_CHART_MODE property for its construction with bars on an alternative price type. For example, you can see bars at the *Bid* price on the instrument chart at the price *Last* or get bars for the *Ask* price, which the standard terminal charts do not support.

As a basis for a new indicator, we will take a ready-made indicator *IndDeltaVolume.mq5* presented in the section Waiting for data and managing visibility. In that indicator, we downloaded a tick history for a certain number of bars *BarCount* and calculated the delta of volumes, that is, separately buy and sell volumes. In the new indicator, we only need to replace the calculation algorithm with the search for *Open*, *High*, *Low*, and *Close* prices based on ticks inside each bar.

Indicator settings include four buffers and one bar chart (DRAW_BARS) displayed in the main window.

```
#property indicator_chart_window
#property indicator_buffers 4
#property indicator_plots   1

#property indicator_type1   DRAW_BARS
#property indicator_color1  clrDodgerBlue
#property indicator_width1  2
#property indicator_label1  "Open;High;Low;Close;"
```

The display as bars is chosen to make them easier to read when run over the main chart candlesticks so that both versions of each bar are visible.

The new *ChartMode* input parameter allows the user to select one of three price types (note that *Ask* is our addition compared to the standard set of elements in ENUM_SYMBOL_CHART_MODE).

```
enum ENUM_SYMBOL_CHART_MODE_EXTENDED
{
   _SYMBOL_CHART_MODE_BID,  // SYMBOL_CHART_MODE_BID
   _SYMBOL_CHART_MODE_LAST, // SYMBOL_CHART_MODE_LAST
   _SYMBOL_CHART_MODE_ASK,  // SYMBOL_CHART_MODE_ASK*
};

input int BarCount = 100;
input COPY_TICKS TickType = INFO_TICKS;
input ENUM_SYMBOL_CHART_MODE_EXTENDED ChartMode = _SYMBOL_CHART_MODE_BID;
```

The former *CalcDeltaVolume* class changed its name to *CalcCustomBars* but remained almost unchanged. The differences include a new set of four buffers and the *chartMode* field which is initialized in the constructor from the input variable *ChartMode*.

```
class CalcCustomBars
{
   const int limit;
   const COPY_TICKS tickType;
   const ENUM_SYMBOL_CHART_MODE_EXTENDED chartMode;

   double open[];
   double high[];
   double low[];
   double close[];
   ...
public:
   CalcCustomBars(
      const int bars,
      const COPY_TICKS type,
      const ENUM_SYMBOL_CHART_MODE_EXTENDED mode)
      : limit(bars), tickType(type), chartMode(mode) ...
   {
      // register arrays as indicator buffers
      SetIndexBuffer(0, open);
      SetIndexBuffer(1, high);
      SetIndexBuffer(2, low);
      SetIndexBuffer(3, close);
      const static string defTitle[] = {"Open;High;Low;Close;"};
      const static string types[] = {"Bid", "Last", "Ask"};
      string name = defTitle[0];
      StringReplace(name, ";", types[chartMode] + ";");
      PlotIndexSetString(0, PLOT_LABEL, name);
      IndicatorSetInteger(INDICATOR_DIGITS, _Digits);
   }
   ...
```

Depending on the mode of *chartMode*, the auxiliary method *price* returns a specific price type from each tick.

```
protected:
   double price(const MqlTick &t) const
   {
      switch(chartMode)
      {
      case _SYMBOL_CHART_MODE_BID:
         return t.bid;
      case _SYMBOL_CHART_MODE_LAST:
         return t.last;
      case _SYMBOL_CHART_MODE_ASK:
         return t.ask;
      }
      return 0; // error
   }
   ...
```

Using the *price* method, we can easily implement the modification of the main calculation method *calc* which fills the buffers for the bar numbered *i* based on an array of *ticks* for this bar.

```
   void calc(const int i, const MqlTick &ticks[], const int skip = 0)
   {
      const int n = ArraySize(ticks);
      for(int j = skip; j < n; ++j)
      {
         const double p = price(ticks[j]);
         if(open[i] == EMPTY_VALUE)
         {
            open[i] = p;
         }

         if(p > high[i] || high[i] == EMPTY_VALUE)
         {
            high[i] = p;
         }

         if(p < low[i])
         {
            low[i] = p;
         }

         close[i] = p;
      }
   }
```

The remaining fragments of the source code and the principles of their work correspond to the description of *IndDeltaVolume.mq5*.

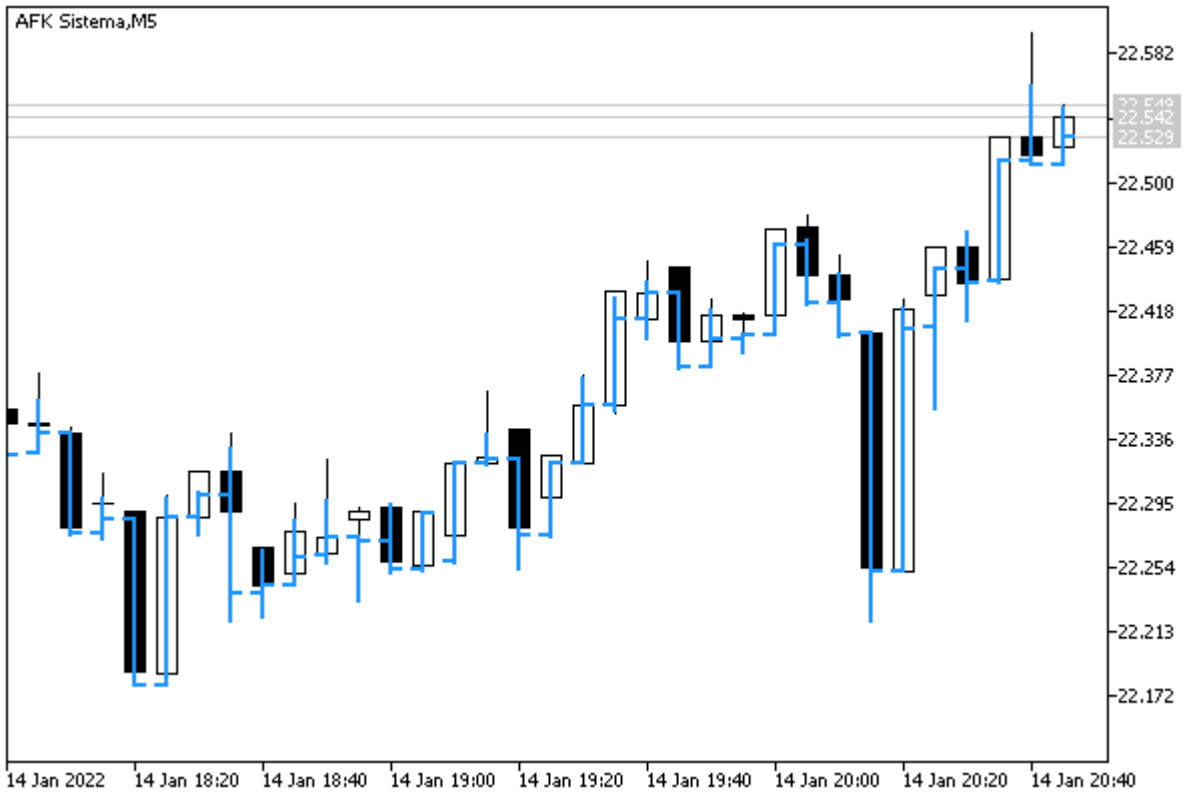
In the *OnInit* handler, we additionally display the current price type of the chart and return a warning if the user decides to build an indicator based on the *Last* price type for the instrument where the *Last* is absent.

```
int OnInit()
{
   ...
   ENUM_SYMBOL_CHART_MODE mode =
      (ENUM_SYMBOL_CHART_MODE)SymbolInfoInteger(_Symbol, SYMBOL_CHART_MODE);
   Print("Chart mode: ", EnumToString(mode));

   if(mode == SYMBOL_CHART_MODE_BID
      && ChartMode == _SYMBOL_CHART_MODE_LAST)
   {
      Alert("Last price is not available for ", _Symbol);
   }

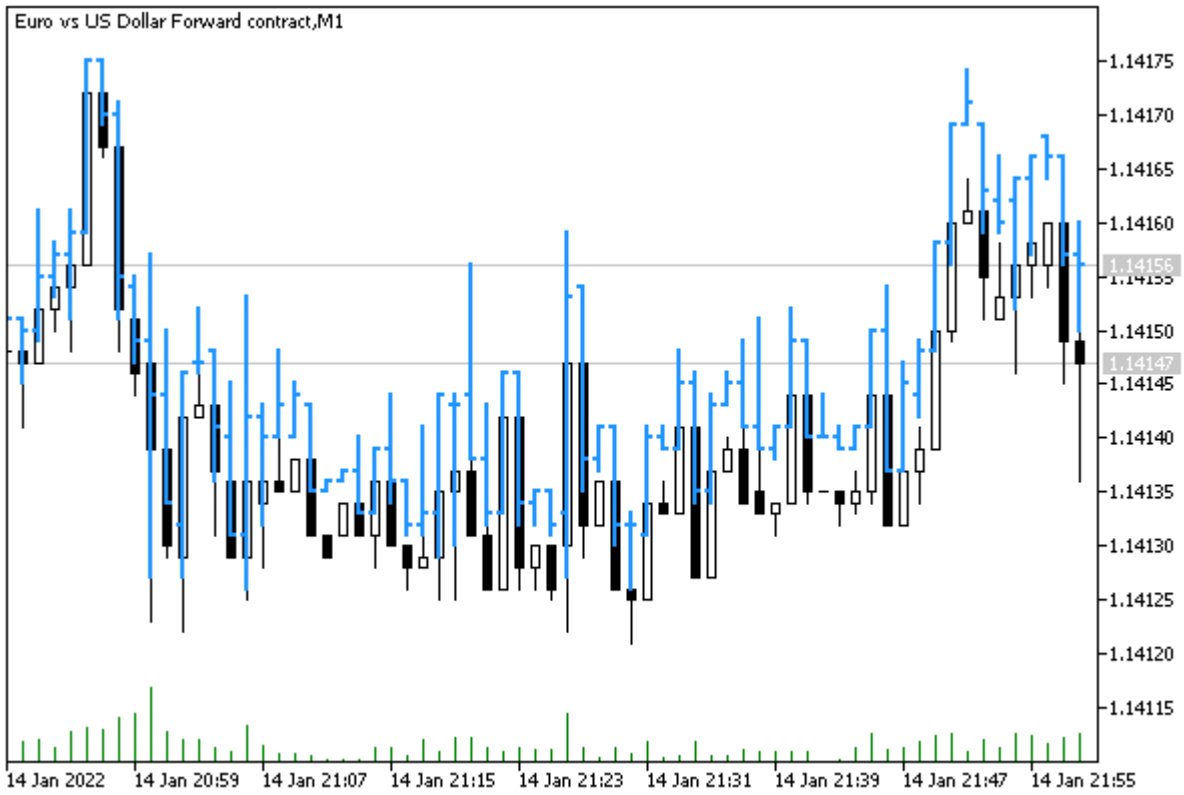
   return INIT_SUCCEEDED;
}
```

Below is a screenshot of an instrument with the chart plotting mode based on the *Last* price; an indicator with the price type *Bid* is laid over the chart.



Indicator with bars at Bid prices on the chart at Last prices

It is also interesting to look at the bars for the *Ask* price running over a regular *Bid* price chart.



Indicator with bars at Ask prices on the chart at Bid prices

During hours of low liquidity, when the spread widens, you can see a significant difference between *Bid* and *Ask* charts.

6.1.11 Base, quote, and margin currencies of the instrument

One of the most important properties of each financial instrument is its working currencies:

- The base currency in which the purchased or sold asset is expressed (for Forex instruments)
- The profit calculation (quotation) currency
- The margin calculation currency

An MQL program can get the names of these currencies using the *SymbolInfoString* function and three properties from the following table.

Identifier	Description
SYMBOL_CURRENCY_BASE	Base currency
SYMBOL_CURRENCY_PROFIT	Profit currency
SYMBOL_CURRENCY_MARGIN	Margin currency

These properties help to analyze Forex instruments, in the names of which many brokers add various prefixes and suffixes, as well as exchange instruments. In particular, the algorithm will be able to find a symbol to obtain a cross rate of two given currencies or select a portfolio of indexes with a given common quote currency.

Since searching for tools according to certain requirements is a very common task, let's create a class *SymbolFilter* (*SymbolFilter.mqh*) to build a list of suitable symbols and their selected properties. In the future, we will use this class not only to analyze currencies but also other characteristics.

First, we will consider a simplified version and then supplement it with convenient functionality.

In development, we will use ready-made auxiliary tools: an associative map array (*MapArray.mqh*) to store key-value pairs of selected types and a symbol property monitor (*SymbolMonitor.mqh*).

```
#include <MQL5Book/MapArray.mqh>
#include <MQL5Book/SymbolMonitor.mqh>
```

To simplify the statements for accumulating the results of work in arrays, we use an improved version of the PUSH macro, which we have already seen in previous examples, as well as its EXPAND version for multidimensional arrays (simple assignment is impossible in this case).

```
#define PUSH(A,V) (A[ArrayResize(A, ArraySize(A) + 1, ArraySize(A) * 2) - 1] = V)
#define EXPAND(A) (ArrayResize(A, ArrayRange(A, 0) + 1, ArrayRange(A, 0) * 2) - 1)
```

An object of the *SymbolFilter* class must have a storage for the property values which will be used to filter symbols. Therefore, we will describe three *MapArray* arrays in the class for integer, real, and string properties.

```
class SymbolFilter
{
   MapArray<ENUM_SYMBOL_INFO_INTEGER,long> longs;
   MapArray<ENUM_SYMBOL_INFO_DOUBLE,double> doubles;
   MapArray<ENUM_SYMBOL_INFO_STRING,string> strings;
   ...
```

Setting the required filter properties is done using overloaded the *let* methods.

```
public:
   SymbolFilter *let(const ENUM_SYMBOL_INFO_INTEGER property, const long value)
   {
      longs.put(property, value);
      return &this;
   }

   SymbolFilter *let(const ENUM_SYMBOL_INFO_DOUBLE property, const double value)
   {
      doubles.put(property, value);
      return &this;
   }

   SymbolFilter *let(const ENUM_SYMBOL_INFO_STRING property, const string value)
   {
      strings.put(property, value);
      return &this;
   }
   ...
```

Please note that the methods return a pointer to the filter, which allows you to write conditions as a chain: for example, if earlier in the code an object *f* of type *SymbolFilter* was described, then you can impose two conditions on the price type and the name of the profit currency as follows:

```
f.let(SYMBOL_CHART_MODE, SYMBOL_CHART_MODE_LAST).let(SYMBOL_CURRENCY_PROFIT, "USD");
```

The formation of an array of symbols that satisfy the conditions is performed by the filter object in several variants of the *select* method, the simplest of which is presented below (other options will be discussed later).

The *watch* parameter defines the search context for symbols: among those selected in *Market Watch* (*true*) or all available (*false*). The output array *symbols* will be filled with the names of matching symbols. We already know the code structure inside the method: it has a loop through the symbols for each of which a monitor object *m* is created.

```
void select(const bool watch, string &symbols[]) const
{
   const int n = SymbolsTotal(watch);
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, watch);
      SymbolMonitor m(s);
      if(match<ENUM_SYMBOL_INFO_INTEGER,long>(m, longs)
      && match<ENUM_SYMBOL_INFO_DOUBLE,double>(m, doubles)
      && match<ENUM_SYMBOL_INFO_STRING,string>(m, strings))
      {
         PUSH(symbols, s);
      }
   }
}
```

It is with the help of the monitor that we can get the value of any property in a unified way. Checking if the properties of the current symbol match the stored set of conditions in *longs*, *doubles*, and *strings* arrays is implemented by a helper method *match*. Only of all requested properties match, the symbol name will be saved in the *symbols* output array.

In the simplest case, the implementation of the *match* method is as follows (subsequently it will be changed).

```
protected:
   template<typename K,typename V>
   bool match(const SymbolMonitor &m, const MapArray<K,V> &data) const
   {
      for(int i = 0; i < data.getSize(); ++i)
      {
         const K key = data.getKey(i);
         if(!equal(m.get(key), data.getValue(i)))
         {
            return false;
         }
      }
      return true;
   }
```

If at least one of the values in the *data* array does not match the corresponding character property, the method returns *false*. If all properties match (or there are no conditions for properties of this type), the method returns *true*.

The comparison of two values is performed using the *equal*. Given the fact that among the properties there may be properties of type *double*, the implementation is not as simple as one might think.

```
template<typename V>
static bool equal(const V v1, const V v2)
{
   return v1 == v2 || eps(v1, v2);
}
```

For type *double*, the expression *v1 == v2* may not work for close numbers, and therefore the precision of the real DBL_EPSILON type should be taken into account. This is done in a separate method *eps*, overloaded separately for type *double* and all other types due to the template.

```
static bool eps(const double v1, const double v2)
{
   return fabs(v1 - v2) < DBL_EPSILON * fmax(v1, v2);
}

template<typename V>
static bool eps(const V v1, const V v2)
{
   return false;
}
```

When values of any type except *double* are equal, the template method *eps* just won't be called, and in all other cases (including when values differ), it returns *false* as required (thus, only the condition *v1 == v2*).

The filter option described above only allows you to check properties for equality. However, in practice, it is often required to analyze conditions for inequality, as well as for greater/less. For this reason, the *SymbolFilter* class has the *IS* enumeration with basic comparison operations (if desired, it can be supplemented).

```
class SymbolFilter
{
   ...
   enum IS
   {
      EQUAL,
      GREATER,
      NOT_EQUAL,
      LESS
   };
   ...
```

For each property from the ENUM_SYMBOL_INFO_INTEGER, ENUM_SYMBOL_INFO_DOUBLE, and ENUM_SYMBOL_INFO_STRING enumerations, it is required to save not only the desired property value (recall about associative arrays *longs*, *doubles*, *strings*), but also the comparing method from the new *IS* enumeration.

Since the elements of standard enumerations have non-overlapping values (there is one exception related to volumes but it is not critical), it makes sense to reserve one common map array *conditions* for the comparison method. This raises the question of which type to choose for the map key in order to technically "combine" different enumerations. To do this, we had to describe the dummy

enumeration ENUM_ANY which only denotes a certain type of generic enumeration. Recall that all enumerations have an internal representation equivalent to an integer *int*, and therefore can be reduced to one another.

```
enum ENUM_ANY
{
};

MapArray<ENUM_ANY,IS> conditions;
MapArray<ENUM_ANY,long> longs;
MapArray<ENUM_ANY,double> doubles;
MapArray<ENUM_ANY,string> strings;
...
```

Now we can complete all *let* methods which set the desired value of the property by adding the *cmp* input parameter that specifies the comparison method. By default, it sets the check for equality (EQUAL).

```
SymbolFilter *let(const ENUM_SYMBOL_INFO_INTEGER property, const long value,
   const IS cmp = EQUAL)
{
   longs.put((ENUM_ANY)property, value);
   conditions.put((ENUM_ANY)property, cmp);
   return &this;
}
```

Here's a variant for integer properties. The other two overloads change in the same way.

Taking into account new information about different ways of comparing and simultaneously eliminating different types of keys in map arrays, we modify the *match* method. In it, for each specified property, we retrieve a condition from the *conditions* array based on the key in the *data* map array, and appropriate checks are performed using the *switch* operator.

```
template<typename V>
bool match(const SymbolMonitor &m, const MapArray<ENUM_ANY,V> &data) const
{
   // dummy variable to select m.get method overload below
   static const V type = (V)NULL;
   // cycle by conditions imposed on the properties of the symbol
   for(int i = 0; i < data.getSize(); ++i)
   {
      const ENUM_ANY key = data.getKey(i);
      // choice of comparison method in the condition
      switch(conditions[key])
      {
      case EQUAL:
         if(!equal(m.get(key, type), data.getValue(i))) return false;
         break;
      case NOT_EQUAL:
         if(equal(m.get(key, type), data.getValue(i))) return false;
         break;
      case GREATER:
         if(!greater(m.get(key, type), data.getValue(i))) return false;
         break;
      case LESS:
         if(greater(m.get(key, type), data.getValue(i))) return false;
         break;
      }
   }
   return true;
}
```

The new template *greater* method is implemented simplistically.

```
template<typename V>
static bool greater(const V v1, const V v2)
{
   return v1 > v2;
}
```

Now the *match* method call can be written in a shorter form since the only remaining type of the template *V* is automatically determined by the passed *data* argument (and this is one of the arrays *longs*, *doubles*, or *strings*).

```
void select(const bool watch, string &symbols[]) const
{
   const int n = SymbolsTotal(watch);
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, watch);
      SymbolMonitor m(s);
      if(match(m, longs)
         && match(m, doubles)
         && match(m, strings))
      {
         PUSH(symbols, s);
      }
   }
}
```

This is not the final version of the *SymbolFilter* class yet, but we can already test it in action.

Let's create a script *SymbolFilterCurrency.mq5* that can filter symbols based on the properties of the base currency and profit currency; in this case, it is USD. The *MarketWatchOnly* parameter only searches in the *Market Watch* by default.

```
#include <MQL5Book/SymbolFilter.mqh>

input bool MarketWatchOnly = true;

void OnStart()
{
   SymbolFilter f;   // filter object
   string symbols[]; // array for results
   ...
```

Let's say that we want to find Forex instruments that have direct quotes, that is, "USD" appears in their names at the beginning. In order not to depend on the specifics of the formation of names for a particular broker, we will use the SYMBOL_CURRENCY_BASE property, which contains the first currency.

Let's write down the condition that the base currency of the symbol is equal to USD and apply the filter.

```
f.let(SYMBOL_CURRENCY_BASE, "USD")
.select(MarketWatchOnly, symbols);
Print("===== Base is USD =====");
ArrayPrint(symbols);
...
```

The resulting array is output to the log.

```
===== Base is USD =====
"USDCHF" "USDJPY" "USDCNH" "USDRUB" "USDCAD" "USDSEK" "SP500m" "Brent"
```

As you can see, the array includes not only Forex symbols with USD at the beginning of the ticker but also the S&P500 index and the commodity (oil). The last two symbols are quoted in dollars, but they also have the same base currency. At the same time, the quote currency of Forex symbols (it is also

the profit currency) is second and differs from USD. This allows you to supplement the filter in such a way that non-Forex symbols no longer match it.

Let's clear the array, add a condition that the profit currency is not equal to "USD", and again request suitable symbols (the previous condition was saved in the *f* object).

```
   ...
   ArrayResize(symbols, 0);

   f.let(SYMBOL_CURRENCY_PROFIT, "USD", SymbolFilter::IS::NOT_EQUAL)
   .select(MarketWatchOnly, symbols);
   Print("===== Base is USD and Profit is not USD =====");
   ArrayPrint(symbols);
}
```

This time, only the symbols you are looking for are actually displayed in the log.

```
===== Base is USD and Profit is not USD =====
"USDCHF" "USDJPY" "USDCNH" "USDRUB" "USDCAD" "USDSEK"
```

6.1.12 Price representation accuracy and change steps

Earlier, we have already met two interrelated properties of the working symbol of the chart: the minimum price change step (*Point*) and the price presentation accuracy which is expressed in the number of decimal places (*Digits*). They are also available in Predefined variables. To get similar properties of an arbitrary symbol, you should query the SYMBOL_POINT and SYMBOL_DIGITS properties, respectively. The SYMBOL_POINT property is closely related to the minimum price change (known to an MQL program as the SYMBOL_TRADE_TICK_SIZE property) and its value (SYMBOL_TRADE_TICK_VALUE), usually in the currency of the trading account (but some symbols can be configured to use the base currency; you may contact your broker for details if necessary). The table below shows the entire group of these properties.

Identifier	Description
SYMBOL_DIGITS	The number of decimal places
SYMBOL_POINT	The value of one point in the quote currency
SYMBOL_TRADE_TICK_VALUE	SYMBOL_TRADE_TICK_VALUE_PROFIT value
SYMBOL_TRADE_TICK_VALUE_PROFIT	Current tick value for a profitable position
SYMBOL_TRADE_TICK_VALUE_LOSS	Current tick value for a losing position
SYMBOL_TRADE_TICK_SIZE	Minimum price change in the quote currency

All properties except SYMBOL_DIGITS are real numbers and are requested using the *SymbolInfoDouble* function. The SYMBOL_DIGITS property is available via *SymbolInfoInteger*. To test the work with these properties, we will use ready-made classes *SymbolFilter* and *SymbolMonitor*, which will automatically call the desired function for any property.

We will also improve the *SymbolFilter* class by adding a new overload of the *select* method, which will be able to fill not only an array with the names of suitable symbols but also another array with the values of their specific property.

In a more general case, we may be interested in several properties for each symbol at once, so it is advisable to use not one of the built-in data types for the output array but a special composite type with different fields.

In programming, such types are called tuples and are somewhat equivalent to MQL5 structures.

```
template<typename T1,typename T2,typename T3> // we can describe up to 64 fields
struct Tuple3                                 // MQL5 allows 64 template parameters
{
   T1 _1;
   T2 _2;
   T3 _3;
};
```

However, structures require a preliminary description with all fields, while we do not know in advance the number and list of requested symbol properties. Therefore, in order to simplify the code, we will represent our tuple as a vector in the second dimension of a dynamic array that receives the results of the query.

```
T array[][S];
```

As a data type *T* we can use any of the built-in types and enumerations used for properties. Size *S* must match the number of properties requested.

To tell the truth, such a simplification limits us in one query to values of the same types, that is, only integers, only reals, or only strings. However, filter conditions can include any properties. We will implement the approach with tuples a little later, using the example of filters of other trading entities: orders, deals, and positions.

So the new version of the *SymbolFilter::select* method takes as an input a reference to the *property* array with property identifiers to read from the filtered symbols. The names of the symbols themselves and the values of these properties will be written to the *symbols* and *data* output arrays.

```
template<typename E,typename V>
bool select(const bool watch, const E &property[], string &symbols[],
   V &data[][], const bool sort = false) const
{
   // the size of the array of requested properties must match the output tuple
   const int q = ArrayRange(data, 1);
   if(ArraySize(property) != q) return false;

   const int n = SymbolsTotal(watch);
   // iterate over characters
   for(int i = 0; i < n; ++i)
   {
      const string s = SymbolName(i, watch);
      // access to the symbol properties is provided by the monitor
      SymbolMonitor m(s);
      // check all filter conditions
      if(match(m, longs)
      && match(m, doubles)
      && match(m, strings))
      {
         // properties of a suitable symbol are written to arrays
         const int k = EXPAND(data);
         for(int j = 0; j < q; ++j)
         {
            data[k][j] = m.get(property[j]);
         }
         PUSH(symbols, s);
      }
   }

   if(sort)
   {
      ...
   }
   return true;
}
```

Additionally, the new method can sort the output array by the first dimension (the first requested property): this functionality is left for independent study using source codes. To enable sorting, set the *sort* parameter to *true*. Arrays with symbol names and data are sorted consistently.

To avoid tuples in the calling code when only one property needs to be requested from the filtered characters, the following *select* option is implemented in *SymbolFilter*: inside it, we define intermediate arrays of properties (*properties*) and values (*tuples*) with size 1 in the second dimension, which are used to call the above full version of *select*.

```
   template<typename E,typename V>
   bool select(const bool watch, const E property, string &symbols[], V &data[],
      const bool sort = false) const
   {
      E properties[1] = {property};
      V tuples[][1];

      const bool result = select(watch, properties, symbols, tuples, sort);
      ArrayCopy(data, tuples);
      return result;
   }
```

Using the advanced filter, let's try to build a list of symbols sorted by tick value SYMBOL_TRADE_TICK_VALUE (see file *SymbolFilterTickValue.mq5*). Assuming that the deposit currency is USD, we should obtain a value equal to 1.0 for Forex instruments quoted in USD (of the type XXXUSD). For other assets, we will see non-trivial values.

```
#include <MQL5Book/SymbolFilter.mqh>

input bool MarketWatchOnly = true;

void OnStart()
{
   SymbolFilter f;      // filter object
   string symbols[];    // array with symbol names
   double tickValues[]; // array for results

   // apply the filter without conditions, fill and sort the array
   f.select(MarketWatchOnly, SYMBOL_TRADE_TICK_VALUE, symbols, tickValues, true);

   PrintFormat("===== Tick values of the symbols (%d) =====",
      ArraySize(tickValues));
   ArrayPrint(symbols);
   ArrayPrint(tickValues, 5);
}
```

Here is the result of running the script.

```
===== Tick values of the symbols (13) =====
"BTCUSD" "USDRUB" "XAUUSD" "USDSEK" "USDCNH" "USDCAD" "USDJPY" "NZDUSD" "AUDUSD" "EUR
 0.00100  0.01309  0.10000  0.10955  0.15744  0.80163  0.87319  1.00000  1.00000  1.0
```

6.1.13 Permitted volumes of trading operations

In later chapters, where we will learn how to program Expert Advisors, we will need to control many of the symbol characteristics that determine the success of sending trading orders. In particular, this applies to the part of the symbol specification that specifies the allowed scope of operations. The corresponding properties are also available in MQL5. All of them are of type *double* and are requested by the *SymbolInfoDouble* function.

Identifier	Description
SYMBOL_VOLUME_MIN	Minimum deal volume in lots
SYMBOL_VOLUME_MAX	Maximum deal volume in lots
SYMBOL_VOLUME_STEP	Minimum step for changing the deal volume in lots
SYMBOL_VOLUME_LIMIT	Maximum allowable total volume of an open position and pending orders in one direction (buy or sell)
SYMBOL_TRADE_CONTRACT_SIZE	Trading contract size = 1 lot

Attempts to buy or sell a financial instrument with a volume less than the minimum, more than the maximum, or not a multiple of a step will result in an error. In the chapter related to trading APIs, we will implement a code to unify the necessary checks and normalize volumes before calling the MQL5 API trading functions.

Among other things, the MQL program should also check SYMBOL_VOLUME_LIMIT. For example, with a limit of 5 lots, you can have an open buy position with a volume of 5 lots and place a pending order *Sell Limit* with a volume of 5 lots. However, you cannot place a pending *Buy Limit* order (because the cumulative volume in one direction will exceed the limit) or set *Sell Limit* of more than 5 lots.

As an introductory example, consider the script *SymbolFilterVolumes.mq5* which logs the values of the above properties for the selected symbols. Let's add the *MinimalContractSize* variable to the input parameters to be able to filter symbols by the SYMBOL_TRADE_CONTRACT_SIZE property: we display only those which contract size is greater than the specified one (by default, 0, that is, all symbols satisfy the condition).

```
#include <MQL5Book/SymbolFilter.mqh>

input bool MarketWatchOnly = true;
input double MinimalContractSize = 0;
```

At the beginning of *OnStart*, let's define a filter object and output arrays to get lists of property names and values as vectors *double* for four fields. The list of the four required properties is indicated in the *volumeIds* array.

```
void OnStart()
{
   SymbolFilter f;                        // filter object
   string symbols[];                      // receiving array with names
   double volumeLimits[][4];              // receiving array with data vectors

   // requested symbol properties
   ENUM_SYMBOL_INFO_DOUBLE volumeIds[] =
   {
      SYMBOL_VOLUME_MIN,
      SYMBOL_VOLUME_STEP,
      SYMBOL_VOLUME_MAX,
      SYMBOL_VOLUME_LIMIT
   };
   ...
```

Next, we apply a filter by contract size (should be greater than the specified one) and get the specification fields associated with volumes for matching symbols.

```
   f.let(SYMBOL_TRADE_CONTRACT_SIZE, MinimalContractSize, SymbolFilter::IS::GREATER)
   .select(MarketWatchOnly, volumeIds, symbols, volumeLimits);

   const int n = ArraySize(volumeLimits);
   PrintFormat("===== Volume limits of the symbols (%d) =====", n);
   string title = "";
   for(int i = 0; i < ArraySize(volumeIds); ++i)
   {
      title += "\t" + EnumToString(volumeIds[i]);
   }
   Print(title);
   for(int i = 0; i < n; ++i)
   {
      Print(symbols[i]);
      ArrayPrint(volumeLimits, 3, NULL, i, 1, 0);
   }
}
```

For default settings, the script might show results like the following (with abbreviations).

```
===== Volume limits of the symbols (13) =====
SYMBOL_VOLUME_MIN SYMBOL_VOLUME_STEP SYMBOL_VOLUME_MAX SYMBOL_VOLUME_LIMIT
EURUSD
  0.010   0.010 500.000   0.000
GBPUSD
  0.010   0.010 500.000   0.000
USDCHF
  0.010   0.010 500.000   0.000
USDJPY
  0.010   0.010 500.000   0.000
USDCNH
   0.010    0.010 1000.000    0.000
USDRUB
   0.010    0.010 1000.000    0.000
...
XAUUSD
  0.010   0.010 100.000   0.000
BTCUSD
   0.010    0.010 1000.000    0.000
SP500m
 0.100  0.100  5.000 15.000
```

Some symbols may not be limited by SYMBOL_VOLUME_LIMIT (value is 0). You can compare the results against the symbol specifications: they must match.

6.1.14 Trading permission

As a continuation of the subject related to the correct preparation of trading orders which we started in the previous section, let's turn to the following pair of properties that play a very important role in the development of Expert Advisors.

Identifier	Description
SYMBOL_TRADE_MODE	Permissions for different trading modes for the symbol (see ENUM_SYMBOL_TRADE_MODE)
SYMBOL_ORDER_MODE	Flags of allowed order types, bit mask (see further)

Both properties are of integer type and are available through the *SymbolInfoInteger* function.

We have already used the SYMBOL_TRADE_MODE property in the script *SymbolPermissions.mq5*. Its value is one of the elements of the ENUM_SYMBOL_TRADE_MODE enumeration.

Identifier	Value	Description
SYMBOL_TRADE_MODE_DISABLED	0	Trading is disabled for the symbol
SYMBOL_TRADE_MODE_LONGONLY	1	Only buy trades are allowed
SYMBOL_TRADE_MODE_SHORTONLY	2	Only sell trades are allowed
SYMBOL_TRADE_MODE_CLOSEONLY	3	Only closing operations are allowed
SYMBOL_TRADE_MODE_FULL	4	No restrictions on trading operations

Recall the *Permissions* class contains the *isTradeOnSymbolEnabled* method which checks several aspects that affect the availability of symbol trading, and one of them is the SYMBOL_TRADE_MODE property. By default, we consider that we are interested in full access to trading, that is, selling and buying: SYMBOL_TRADE_MODE_FULL. Depending on the trading strategy, the MQL program may consider sufficient, for example, permissions only to buy, only to sell, or only to close operations.

```
static bool isTradeOnSymbolEnabled(string symbol, const datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   // checking sessions
   bool found = now == 0;
   ...
   // checking the trading mode for the symbol
   return found && (SymbolInfoInteger(symbol, SYMBOL_TRADE_MODE) == mode);
}
```

In addition to the trading mode, we will need to analyze the permissions for orders of different types in the future: they are indicated by separate bits in the SYMBOL_ORDER_MODE property and can be arbitrarily combined with a logical OR ('|'). For example, the value 127 (0x7F) corresponds to all bits set, that is, the availability of all types of orders.

Identifier	Value	Description
SYMBOL_ORDER_MARKET	1	Market orders are allowed (Buy and Sell)
SYMBOL_ORDER_LIMIT	2	Limit orders are allowed (Buy Limit and Sell Limit)
SYMBOL_ORDER_STOP	4	Stop orders are allowed (Buy Stop and Sell Stop)
SYMBOL_ORDER_STOP_LIMIT	8	Stop limit orders are allowed (Buy Stop Limit and Sell Stop Limit)
SYMBOL_ORDER_SL	16	Setting Stop Loss levels is allowed
SYMBOL_ORDER_TP	32	Setting Take Profit levels is allowed
SYMBOL_ORDER_CLOSEBY	64	Permission to close a position by an opposite one for the same symbol, Close By operation

The SYMBOL_ORDER_CLOSEBY property is only set for accounts with hedging accounting (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING, see Account type).

In the test script *SymbolFilterTradeMode.mq5*, we will request a couple of described properties for symbols visible in *Market Watch*. The output of bits and their combinations as numbers is not very informative, so we will utilize the fact that in the *SymbolMonitor* class, we have a convenient method *stringify* to print enumeration members and bit masks of all properties.

```
void OnStart()
{
   SymbolFilter f;                        // filter object
   string symbols[];                      // array for names
   long permissions[][2];                 // array for data (property values)

   // list of requested symbol properties
   ENUM_SYMBOL_INFO_INTEGER modes[] =
   {
      SYMBOL_TRADE_MODE,
      SYMBOL_ORDER_MODE
   };

   // apply the filter, get arrays with results
   f.let(SYMBOL_VISIBLE, true).select(true, modes, symbols, permissions);

   const int n = ArraySize(symbols);
   PrintFormat("===== Trade permissions for the symbols (%d) =====", n);
   for(int i = 0; i < n; ++i)
   {
      Print(symbols[i] + ":");
      for(int j = 0; j < ArraySize(modes); ++j)
      {
         // display bit and number descriptions "as is"
         PrintFormat("  %s (%d)",
            SymbolMonitor::stringify(permissions[i][j], modes[j]),
            permissions[i][j]);
      }
   }
}
```

Below is part of the log resulting from running the script.

```
===== Trade permissions for the symbols (13) =====
EURUSD:
  SYMBOL_TRADE_MODE_FULL (4)
  [ _SYMBOL_ORDER_MARKET _SYMBOL_ORDER_LIMIT _SYMBOL_ORDER_STOP
  _SYMBOL_ORDER_STOP_LIMIT _SYMBOL_ORDER_SL _SYMBOL_ORDER_TP
  _SYMBOL_ORDER_CLOSEBY ] (127)
GBPUSD:
  SYMBOL_TRADE_MODE_FULL (4)
  [ _SYMBOL_ORDER_MARKET _SYMBOL_ORDER_LIMIT _SYMBOL_ORDER_STOP
  _SYMBOL_ORDER_STOP_LIMIT _SYMBOL_ORDER_SL _SYMBOL_ORDER_TP
  _SYMBOL_ORDER_CLOSEBY ] (127)
...
SP500m:
  SYMBOL_TRADE_MODE_DISABLED (0)
  [ _SYMBOL_ORDER_MARKET _SYMBOL_ORDER_LIMIT _SYMBOL_ORDER_STOP
  _SYMBOL_ORDER_STOP_LIMIT _SYMBOL_ORDER_SL _SYMBOL_ORDER_TP ] (63)
```

Please note that trading for the last symbol SP500m is completely disabled (its quotes are provided only as "indicative"). At the same time, its set of flags by order types is not 0 but does not make any difference.

Depending on the events in the market, the broker can change the properties of the symbol at their own discretion, for example, leaving only the opportunity to close positions for some time, so a correct trading robot must control these properties before each operation.

6.1.15 Symbol trading conditions and order execution modes

In this section, we will dive deeper into aspects of trading automation that depend on the settings of financial instruments. For now, we will study only the properties, while their practical application will be presented in later chapters. It is assumed that the reader is already familiar with the basic terminology such as market and pending order, trade, and position.

When sending a trade request for execution, it should be taken into account that in the financial markets there is no guarantee that at a particular moment, the entire requested volume is available for this financial instrument at the desired price. Therefore, real-time trading is regulated by price and volume execution modes. Modes, or in other words, execution policies, define the rules for cases when the price has changed or the requested volume cannot be fully executed at the current moment.

In the MQL5 API, these modes are available for each symbol as the following properties which can be obtained through the function *SymbolInfoInteger*.

Identifier	Description
SYMBOL_TRADE_EXEMODE	Trade execution modes related to the price
SYMBOL_FILLING_MODE	Flags of allowed order filling modes related to the volume (bitmask, see further)

The value of the SYMBOL_TRADE_EXEMODE property is a member of the ENUM_SYMBOL_TRADE_EXECUTION enumeration.

Identifier	Description
SYMBOL_TRADE_EXECUTION_REQUEST	Trade at the requested price
SYMBOL_TRADE_EXECUTION_INSTANT	Instant execution (trading at streamed prices)
SYMBOL_TRADE_EXECUTION_MARKET	Market execution
SYMBOL_TRADE_EXECUTION_EXCHANGE	Exchange execution

All or most of these modes should be known to terminal users from the drop-down list *Type* in the *New order* dialogue (F9). Let's briefly recall what they mean. For further details, please refer to the terminal documentation.

- Execution on request (SYMBOL_TRADE_EXECUTION_REQUEST) – execution of a market order at a price previously received from the broker. Before sending a market order, the trader requests the current price from the broker. Further execution of the order at this price can either be confirmed or rejected.
- Instant execution (SYMBOL_TRADE_EXECUTION_INSTANT) – execution of a market order at the current price. When sending a trade request for execution, the terminal automatically inserts the current prices into the order. If the broker accepts the price, the order is executed. If the broker does not accept the requested price, the broker returns the prices at which this order can be executed, which is called a requote.
- Market execution (SYMBOL_TRADE_EXECUTION_MARKET) – the broker inserts the execution price into the order without additional confirmation from the trader. Sending a market order in this mode implies an early agreement with the price at which it will be executed.
- Exchange execution (SYMBOL_TRADE_EXECUTION_EXCHANGE) – trading operations are performed at the prices of current market offers.

As for the bits in SYMBOL_FILLING_MODE that can be combined with the logical operator OR ('|'), their presence or absence indicates the following actions.

Identifier	Value	Fill policy
SYMBOL_FILLING_FOK	1	Fill Or Kill (FOK); the order must be executed exclusively in the specified volume or canceled
SYMBOL_FILLING_IOC	2	Immediate or Cancel (IOC); trade the maximum volume available on the market within the limits specified in the order or cancel
(Identifier missing)	(any, including 0)	Return; in case of partial execution, the market or limit order with the remaining volume is not canceled but stays valid

The possibility of using FOK and IOC modes is determined by the trade server.

If the SYMBOL_FILLING_FOK mode is enabled, then, while sending an order with the *OrderSend* function, the MQL program will be able to use the relevant order fill type in the *MqlTradeRequest*

structure: ORDER_FILLING_FOK. If at the same time, there is not enough volume of the financial instrument on the market, the order will not be executed. It should be taken into account that the required volume can be made up of several offers currently available on the market, resulting in several transactions.

If the SYMBOL_FILLING_IOC mode is enabled, the MQL program will have access to the ORDER_FILLING_IOC order filling method of the same name (it is also specified in the special "filling" field (*type_filling*) in the *MqlTradeRequest* structure before sending the order to the *OrderSend* function). When using this mode, in case of impossibility of full execution, the order will be executed on the available volume, and the remaining volume of the order will be canceled.

The last policy without an identifier is the default mode and is available regardless of other modes (which is why it matches zero or any other value). In other words, even if we get the value 1 (SYMBOL_FILLING_FOK), 2 (SYMBOL_FILLING_IOC), or 3 (SYMBOL_FILLING_FOK | SYMBOL_FILLING_IOC) for the SYMBOL_FILLING_MODE property, the return mode will be implied. To use this policy, when forming an order (filling in the *MqlTradeRequest* structure) we should specify the fill type ORDER_FILLING_RETURN.

> Among all SYMBOL_TRADE_EXEMODE modes, there is one specificity regarding market execution (SYMBOL_TRADE_EXECUTION_MARKET): Return orders are always prohibited in market execution mode.

Since ORDER_FILLING_FOK corresponds to the constant 0, the absence of an explicit indication of the filling type in a trade request will imply this particular mode.

We will consider all these nuances in practice when developing Expert Advisors but for now, let's check the reading of properties in a simple script *SymbolFilterExecMode.mq5*.

```
#include <MQL5Book/SymbolFilter.mqh>

void OnStart()
{
   SymbolFilter f;                        // filter object
   string symbols[];                      // array of symbol names
   long permissions[][2];                 // array with property value vectors

   // properties to read
   ENUM_SYMBOL_INFO_INTEGER modes[] =
   {
      SYMBOL_TRADE_EXEMODE,
      SYMBOL_FILLING_MODE
   };
   // apply filter - fill arrays
   f.select(true, modes, symbols, permissions);

   const int n = ArraySize(symbols);
   PrintFormat("===== Trade execution and filling modes for the symbols (%d) =====",
   for(int i = 0; i < n; ++i)
   {
      Print(symbols[i] + ":");
      for(int j = 0; j < ArraySize(modes); ++j)
      {
         // output properties as descriptions and numbers
         PrintFormat("  %s (%d)",
            SymbolMonitor::stringify(permissions[i][j], modes[j]),
            permissions[i][j]);
      }
   }
}
```

Below is a fragment of the log with the results of the script. Almost all symbols here have an immediate execution mode at prices (SYMBOL_TRADE_EXECUTION_INSTANT) except for the last SP500m (SYMBOL_TRADE_EXECUTION_MARKET). Here we can find various volume filling modes, both separate SYMBOL_FILLING_FOK, SYMBOL_FILLING_IOC, and their combination. Only BTCUSD has SYMBOL_FILLING_RETURN specified, i.e. a value of 0 was received (no FOK and IOC bits).

```
===== Trade execution and filling modes for the symbols (13) =====
EURUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK ] (1)
GBPUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK ] (1)
...
USDCNH:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK _SYMBOL_FILLING_IOC ] (3)
USDRUB:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_IOC ] (2)
AUDUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK ] (1)
NZDUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK _SYMBOL_FILLING_IOC ] (3)
...
XAUUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [ _SYMBOL_FILLING_FOK _SYMBOL_FILLING_IOC ] (3)
BTCUSD:
  SYMBOL_TRADE_EXECUTION_INSTANT (1)
  [(_SYMBOL_FILLING_RETURN)] (0)
SP500m:
  SYMBOL_TRADE_EXECUTION_MARKET (2)
  [ _SYMBOL_FILLING_FOK ] (1)
```

Recall that the underscores in the fill mode identifiers appear due to the fact that we had to define our own enumeration SYMBOL_FILLING (*SymbolMonitor.mqh*) with elements with constant values. This was done because MQL5 does not have such a built-in enumeration, but at the same time, we cannot name the elements of our enumeration exactly as built-in constants as this would cause a name conflict.

6.1.16 Margin requirements

Among the most important information about a financial instrument for a trader is the amount of funds required to open a position. Without knowing how much money is needed to buy or sell a given number of lots, it is impossible to implement a money management system within an Expert Advisor and control the account balance.

Since MetaTrader 5 is used to trade various instruments (currencies, commodities, stocks, bonds, options, and futures), the margin calculation principles differ significantly. The documentation provides details, in particular for Forex and futures, as well as exchanges.

Several properties of the MQL5 API allow you to define the type of market and the method of calculating the margin for a specific instrument.

Looking ahead, let's say that for a given combination of parameters such as the trading operation type, instrument, volume, and price, MQL5 allows you to calculate the margin using the *OrderCalcMargin*

function. This is the simplest method, but it has a significant limitation: the function does not take into account current open positions and pending orders. This, in particular, ignores possible adjustments for overlapping volumes when opposite positions are allowed on the account.

Thus, in order to obtain a breakdown of the account funds currently used as a margin for open positions and orders, an MQL program may need to analyze the following properties and calculations using formulas. Furthermore, the *OrderCalcMargin* function is prohibited for use in indicators. You can estimate the free margin in advance after the proposed transaction is completed using *OrderCheck*.

Identifier	Description
SYMBOL_TRADE_CALC_MODE	The method for calculating margin and profit (see ENUM_SYMBOL_CALC_MODE)
SYMBOL_MARGIN_HEDGED_USE_LEG	Boolean flag to enable (true) or disable (false) the hedged margin calculation mode for the largest of the overlapped positions (buy and sell)
SYMBOL_MARGIN_INITIAL	Initial margin for an exchange instrument
SYMBOL_MARGIN_MAINTENANCE	Maintenance margin for an exchange instrument
SYMBOL_MARGIN_HEDGED	Contract size or margin for one lot of covered positions (opposite positions for one symbol)

The first two properties are included in the ENUM_SYMBOL_INFO_INTEGER enumeration, and the last three are in ENUM_SYMBOL_INFO_DOUBLE, and they can be read, respectively, by functions *SymbolInfoInteger* and *SymbolInfoDouble*.

Specific margin calculation formulas depend on the SYMBOL_TRADE_CALC_MODE property and are shown in the table below. More complete information can be found in MQL5 documentation.

Please note that initial and maintenance margins are not used for Forex instruments, and these properties are always 0 for them.

The initial margin indicates the amount of required security deposit in margin currency to open a position with a volume of one lot. It is used when checking the sufficiency of the client's funds before entering the market. To get the final amount of margin charged depending on the type and direction of the order, check the margin ratios using the *SymbolInfoMarginRate* function. Thus, the broker can set an individual leverage or discount for each instrument.

The maintenance margin indicates the minimum value of funds in the instrument's margin currency to maintain an open position of one lot. It is used when checking the sufficiency of the client's funds when the account status (trading conditions) changes. If the level of funds falls below the amount of the maintenance margin of all positions, the broker will start to close them forcibly.

If the maintenance margin property is 0, then the initial margin is used. As in the case of the initial margin, to obtain the final amount of margin charged depending on the type and direction, you should check the margin ratios using the *SymbolInfoMarginRate* function.

Hedged positions, that is, multidirectional positions for the same symbol, can only exist on hedging trading accounts. Obviously, the calculation of the hedged margin together with the properties SYMBOL_MARGIN_HEDGED_USE_LEG, SYMBOL_MARGIN_HEDGED make sense only on such accounts. The hedged margin is applied for the covered volume.

The broker can choose for each instrument one of the two existing methods for calculating the margin for covered positions:

- The base calculation is applied when the longest side calculation mode is disabled, i.e. the SYMBOL_MARGIN_HEDGED_USE_LEG property is equal to *false*. In this case, the margin consists of three components: the margin for the uncovered volume of the existing position, the margin for the covered volume (if there are opposite positions and the SYMBOL_MARGIN_HEDGED property is non-zero), the margin for pending orders. If the initial margin is set for the instrument (the SYMBOL_MARGIN_INITIAL property is non-zero), then the hedged margin is specified as an absolute value (in money). If the initial margin is not set (equal to 0), then SYMBOL_MARGIN_HEDGED specifies the contract size that will be used when calculating the margin according to the formula corresponding to the type of trading instrument (SYMBOL_TRADE_CALC_MODE).
- The highest position calculation is applied when the SYMBOL_MARGIN_HEDGED_USE_LEG property is equal to *true*. The value of SYMBOL_MARGIN_HEDGED is ignored in this case. Instead, the volume of all short and long positions on the instrument is calculated, and the weighted average opening price is calculated for each side. Further, using the formulas corresponding to the instrument type (SYMBOL_TRADE_CALC_MODE), the margin for the short side and the long side is calculated. The largest value is used as the final value.

The following table lists the ENUM_SYMBOL_CALC_MODE elements and their respective margin calculation methods. The same property (SYMBOL_TRADE_CALC_MODE) is also responsible for calculating the profit/loss of a position, but we will consider this aspect later, in the chapter on MQL5 trading functions.

Identifier	Formula
SYMBOL_CALC_MODE_FOREX *Forex*	Lots * ContractSize * MarginRate / Leverage
SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE *Forex without leverage*	Lots * ContractSize * MarginRate
SYMBOL_CALC_MODE_CFD *CFD*	Lots * ContractSize * MarketPrice * MarginRate
SYMBOL_CALC_MODE_CFDLEVERAGE *CFD with leverage*	Lots * ContractSize * MarketPrice * MarginRate / Leverage
SYMBOL_CALC_MODE_CFDINDEX *CFDs on indices*	Lots * ContractSize * MarketPrice * TickPrice / TickSize * MarginRate
SYMBOL_CALC_MODE_EXCH_STOCKS *Securities on the stock exchange*	Lots * ContractSize * LastPrice * MarginRate
SYMBOL_CALC_MODE_EXCH_STOCKS_MOEX *Securities on MOEX*	Lots * ContractSize * LastPrice * MarginRate
SYMBOL_CALC_MODE_FUTURES *Futures*	Lots * InitialMargin * MarginRate
SYMBOL_CALC_MODE_EXCH_FUTURES *Futures on the stock exchange*	Lots * InitialMargin * MarginRate *or* Lots * MaintenanceMargin * MarginRate

Identifier	Formula
SYMBOL_CALC_MODE_EXCH_FUTURES_FORTS *Futures on FORTS*	Lots * InitialMargin * MarginRate *or* Lots * MaintenanceMargin * MarginRate
SYMBOL_CALC_MODE_EXCH_BONDS *Bonds on the stock exchange*	Lots * ContractSize * FaceValue * OpenPrice / 100
SYMBOL_CALC_MODE_EXCH_BONDS_MOEX *Bonds on MOEX*	Lots * ContractSize * FaceValue * OpenPrice / 100
SYMBOL_CALC_MODE_SERV_COLLATERAL	Non-tradable asset (margin not applicable)

The following notation is used in the formulas:

- Lots – position or order volume in lots (shares of the contract)
- ContractSize – contract size (one lot, SYMBOL_TRADE_CONTRACT_SIZE)
- Leverage – trading account leverage (ACCOUNT_LEVERAGE)
- InitialMargin – initial margin (SYMBOL_MARGIN_INITIAL)
- MaintenanceMargin – maintenance margin (SYMBOL_MARGIN_MAINTENANCE)
- TickPrice – tick price (SYMBOL_TRADE_TICK_VALUE)
- TickSize – tick size (SYMBOL_TRADE_TICK_SIZE)
- MarketPrice – last known *Bid/Ask* price depending on the type of transaction
- LastPrice – last known *Last* price
- OpenPrice – weighted average price of a position or order opening
- FaceValue – face value of the bond
- MarginRate – margin ratio according to the *SymbolInfoMarginRate* function, can also have 2 different values: for initial and maintenance margin

An alternative implementation of formula calculations for most types of symbols is given in the file *MarginProfitMeter.mqh* (see section Estimating the profit of a trading operation). It can also be used in indicators.

Let's make a couple of comments on some modes.

In the table above, only three of the futures formulas use the initial margin (SYMBOL_MARGIN_INITIAL). However, if this property has a non-zero value in the specification of any other symbol, then it determines the margin.

Some exchanges may impose their own specifics on margin adjustment, such as the discount system for FORTS (SYMBOL_CALC_MODE_EXCH_FUTURES_FORTS). See the MQL5 documentation and your broker for details.

In the SYMBOL_CALC_MODE_SERV_COLLATERAL mode, the value of an instrument is taken into account in Assets, which are added to Equity. Thus, open positions on such an instrument increase the amount of Free Margin and serve as an additional collateral for open positions on traded instruments. The market value of an open position is calculated based on the volume, contract size, current market price, and liquidity ratio: *Lots * ContractSize * MarketPrice * LiquidityRate* (the latter value can be obtained as the SYMBOL_TRADE_LIQUIDITY_RATE property).

As an example of working with margin-related properties, consider the script *SymbolFilterMarginStats.mq5*. Its purpose will be to calculate statistics on margin calculation methods in the list of selected symbols, as well as optionally log these properties for each symbol. We will select symbols for analysis using the already known filter class *SymbolFilter* and conditions for it supplied from the input variables.

```
#include <MQL5Book/SymbolFilter.mqh>

input bool UseMarketWatch = false;
input bool ShowPerSymbolDetails = false;
input bool ExcludeZeroInitMargin = false;
input bool ExcludeZeroMainMargin = false;
input bool ExcludeZeroHedgeMargin = false;
```

By default, information is requested for all available symbols. To limit the context to the market overview only, we should set *UseMarketWatch* to *true*.

Parameter *ShowPerSymbolDetails* allows you to enable the output of detailed information about each symbol (by default, the parameter is *false*, and only statistics are displayed).

The last three parameters are intended for filtering symbols according to the conditions of zero margin values (initial, maintenance, and hedging, respectively).

To collect and conveniently display in the log a complete set of properties for each symbol (when the *ShowPerSymbolDetails* is on), the structure *MarginSettings* is defined in the code.

```
struct MarginSettings
{
   string name;
   ENUM_SYMBOL_CALC_MODE calcMode;
   bool hedgeLeg;
   double initial;
   double maintenance;
   double hedged;
};
```

Since some of the properties are integer (SYMBOL_TRADE_CALC_MODE, SYMBOL_MARGIN_HEDGED_USE_LEG), and some are real (SYMBOL_MARGIN_INITIAL, SYMBOL_MARGIN_MAINTENANCE, SYMBOL_MARGIN_HEDGED), they will have to be requested by the filter object separately.

Now let's go directly to the working code in *OnStart*. Here, as usual, we define the filter object (*f*), output arrays for character names (*symbols*), and values of requested properties (*flags*,*values*). In addition to them, we add an array of structures *MarginSettings*.

```
void OnStart()
{
   SymbolFilter f;                  // filter object
   string symbols[];                // array for names
   long flags[][2];                 // array for integer vectors
   double values[][3];              // array for real vectors
   MarginSettings margins[];        // composite output array
   ...
```

The *stats* array map has been introduced to calculate statistics with a key like ENUM_SYMBOL_CALC_MODE and the *int* integer value for the number of times each method was encountered. Also, all cases of zero margin and the enabled calculation mode on the longer leg should be recorded in the corresponding counter variables.

```
MapArray<ENUM_SYMBOL_CALC_MODE,int> stats; // counters for each method/mode
int hedgeLeg = 0;                          // and other counters
int zeroInit = 0;                          // ...
int zeroMaintenance = 0;
int zeroHedged = 0;
...
```

Next, we specify the properties of interest to us which are related to the margin, which will be read from the symbol settings. First, integers in the *ints* array and then the real ones in the *doubles* array.

```
ENUM_SYMBOL_INFO_INTEGER ints[] =
{
   SYMBOL_TRADE_CALC_MODE,
   SYMBOL_MARGIN_HEDGED_USE_LEG
};

ENUM_SYMBOL_INFO_DOUBLE doubles[] =
{
   SYMBOL_MARGIN_INITIAL,
   SYMBOL_MARGIN_MAINTENANCE,
   SYMBOL_MARGIN_HEDGED
};
...
```

Depending on the input parameters, we will set the filtering conditions.

```
if(ExcludeZeroInitMargin) f.let(SYMBOL_MARGIN_INITIAL, 0, SymbolFilter::IS::GREATE
if(ExcludeZeroMainMargin) f.let(SYMBOL_MARGIN_MAINTENANCE, 0, SymbolFilter::IS::GR
if(ExcludeZeroHedgeMargin) f.let(SYMBOL_MARGIN_HEDGED, 0, SymbolFilter::IS::GREATE
...
```

Now everything is ready for selecting symbols by conditions and getting their properties into arrays. We do this twice, separately for integer and real properties.

```
f.select(UseMarketWatch, ints, symbols, flags);
const int n = ArraySize(symbols);
ArrayResize(symbols, 0, n);
f.select(UseMarketWatch, doubles, symbols, values);
...
```

An array with symbols has to be zeroed out after the first application of the filter so that the names do not double up. Despite two separate queries, the order of elements in all output arrays (*ints* and *doubles*) is the same, since the filtering conditions do not change.

If a detailed log is enabled by the user, we allocate memory for the *margins* array of structures.

```
if(ShowPerSymbolDetails) ArrayResize(margins, n);
```

Finally, we calculate the statistics by iterating over all the elements of the resulting arrays and optionally populate the array of structures.

```
for(int i = 0; i < n; ++i)
{
   stats.inc((ENUM_SYMBOL_CALC_MODE)flags[i].value[0]);
   hedgeLeg += (int)flags[i].value[1];
   if(values[i].value[0] == 0) zeroInit++;
   if(values[i].value[1] == 0) zeroMaintenance++;
   if(values[i].value[2] == 0) zeroHedged++;

   if(ShowPerSymbolDetails)
   {
      margins[i].name = symbols[i];
      margins[i].calcMode = (ENUM_SYMBOL_CALC_MODE)flags[i][0];
      margins[i].hedgeLeg = (bool)flags[i][1];
      margins[i].initial = values[i][0];
      margins[i].maintenance = values[i][1];
      margins[i].hedged = values[i][2];
   }
}
...
```

Now we display the statistics in the log.

```
PrintFormat("===== Margin calculation modes for %s symbols %s=====",
   (UseMarketWatch ? "Market Watch" : "all available"),
   (ExcludeZeroInitMargin || ExcludeZeroMainMargin || ExcludeZeroHedgeMargin
      ? "(with conditions) " : ""));
PrintFormat("Total symbols: %d", n);
PrintFormat("Hedge leg used in: %d", hedgeLeg);
PrintFormat("Zero margin counts: initial=%d, maintenance=%d, hedged=%d",
   zeroInit, zeroMaintenance, zeroHedged);

Print("Stats per calculation mode:");
stats.print();
...
```

Since the members of the ENUM_SYMBOL_CALC_MODE enumeration are displayed as integers (which is not very informative), we also display a text where each value has a name (from *EnumToString*).

```
      Print("Legend: key=calculation mode, value=count");
      for(int i = 0; i < stats.getSize(); ++i)
      {
         PrintFormat("%d -> %s", stats.getKey(i), EnumToString(stats.getKey(i)));
      }
      ...
```

If detailed information on the selected characters is required, we output the *margins* array of structures.

```
      if(ShowPerSymbolDetails)
      {
         Print("Settings per symbol:");
         ArrayPrint(margins);
      }
   }
```

Let's run the script a couple of times with different settings. Let's start with the default settings.

```
   ===== Margin calculation modes for all available symbols =====
   Total symbols: 131
   Hedge leg used in: 14
   Zero margin counts: initial=123, maintenance=130, hedged=32
   Stats per calculation mode:
       [key] [value]
   [0]     0     101
   [1]     4      16
   [2]     1       1
   [3]     2      11
   [4]     5       2
   Legend: key=calculation mode, value=count
   0 -> SYMBOL_CALC_MODE_FOREX
   4 -> SYMBOL_CALC_MODE_CFDLEVERAGE
   1 -> SYMBOL_CALC_MODE_FUTURES
   2 -> SYMBOL_CALC_MODE_CFD
   5 -> SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE
```

For the second run, let's set *ShowPerSymbolDetails* and *ExcludeZeroInitMargin* to *true*. This requests detailed information about all symbols that have a non-zero value of the initial margin.

```
===== Margin calculation modes for all available symbols (with conditions) =====
Total symbols: 8
Hedge leg used in: 0
Zero margin counts: initial=0, maintenance=7, hedged=0
Stats per calculation mode:
    [key] [value]
[0]     0       5
[1]     1       1
[2]     5       2
Legend: key=calculation mode, value=count
0 -> SYMBOL_CALC_MODE_FOREX
1 -> SYMBOL_CALC_MODE_FUTURES
5 -> SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE
Settings per symbol:
      [name] [calcMode] [hedgeLeg]    [initial] [maintenance]    [hedged]
[0] "XAUEUR"          0      false    100.00000       0.00000    50.00000
[1] "XAUAUD"          0      false    100.00000       0.00000   100.00000
[2] "XAGEUR"          0      false   1000.00000       0.00000  1000.00000
[3] "USDGEL"          0      false 100000.00000  100000.00000 50000.00000
[4] "SP500m"          1      false   6600.00000       0.00000  6600.00000
[5] "XBRUSD"          5      false    100.00000       0.00000    50.00000
[6] "XNGUSD"          0      false  10000.00000       0.00000 10000.00000
[7] "XTIUSD"          5      false    100.00000       0.00000    50.00000
```

6.1.17 Pending order expiration rules

When working with pending orders (including *Stop Loss* and *Take Profit* levels), an MQL program should check a couple of properties that define the rules for their expiration. Both properties are available as members of the ENUM_SYMBOL_INFO_INTEGER enumeration for the call of the *SymbolInfoInteger* function.

Identifier	Description
SYMBOL_EXPIRATION_MODE	Flags of allowed order expiration modes (bit mask)
SYMBOL_ORDER_GTC_MODE	The validity period is defined by one of the elements of the ENUM_SYMBOL_ORDER_GTC_MODE enumeration

The SYMBOL_ORDER_GTC_MODE property is taken into account only if SYMBOL_EXPIRATION_MODE contains SYMBOL_EXPIRATION_GTC (see further). GTC is an acronym for Good Till Canceled.

For each financial instrument, the SYMBOL_EXPIRATION_MODE property can specify several modes of validity (expiration) of pending orders. Each mode has a flag (bit) associated with it.

Identifier (Value)	Description
SYMBOL_EXPIRATION_GTC (1)	Order is valid according to the ENUM_SYMBOL_ORDER_GTC_MODE property
SYMBOL_EXPIRATION_DAY (2)	Order is valid until the end of the current day
SYMBOL_EXPIRATION_SPECIFIED (4)	The expiration date and time are specified in the order
SYMBOL_EXPIRATION_SPECIFIED_DAY (8)	The expiration date is specified in the order

The flags can be combined with a logical OR ('|') operation, for example, SYMBOL_EXPIRATION_GTC | SYMBOL_EXPIRATION_SPECIFIED, equivalent to 1 | 4, which is the number 5. To check whether a particular mode is enabled for a tool, perform a logical AND ('&') operation on the function result and the desired mode bit: a non-zero value means the mode is available.

In the case of SYMBOL_EXPIRATION_SPECIFIED_DAY, the order is valid until 23:59:59 of the specified day. If this time does not fall on the trading session, the expiration will occur at the nearest next trading time.

The ENUM_SYMBOL_ORDER_GTC_MODE enumeration contains the following members.

Identifier	Description
SYMBOL_ORDERS_GTC	Pending orders and Stop Loss/Take Profit levels are valid indefinitely until explicitly canceled
SYMBOL_ORDERS_DAILY	Orders are valid only within one trading day: upon its completion, all pending orders are deleted, as well as Stop Loss and Take Profit levels
SYMBOL_ORDERS_DAILY_EXCLUDING_STOPS	When changing the trading day, only pending orders are deleted, but Stop Loss and Take Profit levels are saved

Depending on the set bits in the SYMBOL_EXPIRATION_MODE property, when preparing an order for sending, an MQL program can select one of the modes corresponding to these bits. Technically, this is done by filling in the type_time field in a special structure *MqlTradeRequest* before calling the *OrderSend* function. The field value must be an element of the ENUM_ORDER_TYPE_TIME enumeration (see Pending order expiration dates): as we will see later, it has something in common with the above set of flags, that is, each flag sets the corresponding mode in the order: ORDER_TIME_GTC, ORDER_TIME_DAY, ORDER_TIME_SPECIFIED, ORDER_TIME_SPECIFIED_DAY. The expiration time or day itself must be specified in another field of the same structure.

The script *SymbolFilterExpiration.mq5* allows you to find out the statistics of the use of each of the flags in the available symbols (in the market overview or in general, depending on the input parameter *UseMarketWatch*). The second parameter in *ShowPerSymbolDetails*, being set to *true*, will cause all flags for each character to be logged, so be careful: if at the same time, the mode *UseMarketWatch* equals *false*, a very large number of log entries will be generated.

```
#property script_show_inputs

#include <MQL5Book/SymbolFilter.mqh>

input bool UseMarketWatch = false;
input bool ShowPerSymbolDetails = false;
```

In the *OnStart* function, in addition to the filter object and receiving arrays for symbol names and property values, we describe *MapArray* to calculate statistics separately for each of the SYMBOL_EXPIRATION_MODE and SYMBOL_ORDER_GTC_MODE properties.

```
void OnStart()
{
   SymbolFilter f;                // filter object
   string symbols[];              // receiving array for symbol names
   long flags[][2];               // receiving array for property values

   MapArray<SYMBOL_EXPIRATION,int> stats;        // mode counters
   MapArray<ENUM_SYMBOL_ORDER_GTC_MODE,int> gtc; // GTC counters

   ENUM_SYMBOL_INFO_INTEGER ints[] =
   {
      SYMBOL_EXPIRATION_MODE,
      SYMBOL_ORDER_GTC_MODE
   };
   ...
```

Next, apply the filter and calculate the statistics.

```
      f.select(UseMarketWatch, ints, symbols, flags);
      const int n = ArraySize(symbols);

      for(int i = 0; i < n; ++i)
      {
         if(ShowPerSymbolDetails)
         {
            Print(symbols[i] + ":");
            for(int j = 0; j < ArraySize(ints); ++j)
            {
               // properties in the form of descriptions and numbers
               PrintFormat("  %s (%d)",
                  SymbolMonitor::stringify(flags[i][j], ints[j]),
                  flags[i][j]);
            }
         }

         const SYMBOL_EXPIRATION mode = (SYMBOL_EXPIRATION)flags[i][0];
         for(int j = 0; j < 4; ++j)
         {
            const SYMBOL_EXPIRATION bit = (SYMBOL_EXPIRATION)(1 << j);
            if((mode & bit) != 0)
            {
               stats.inc(bit);
            }

            if(bit == SYMBOL_EXPIRATION_GTC)
            {
               gtc.inc((ENUM_SYMBOL_ORDER_GTC_MODE)flags[i][1]);
            }
         }
      }
      ...
```

Finally, we output the received numbers to the log.

```
      PrintFormat("===== Expiration modes for %s symbols =====",
         (UseMarketWatch ? "Market Watch" : "all available"));
      PrintFormat("Total symbols: %d", n);

      Print("Stats per expiration mode:");
      stats.print();
      Print("Legend: key=expiration mode, value=count");
      for(int i = 0; i < stats.getSize(); ++i)
      {
         PrintFormat("%d -> %s", stats.getKey(i), EnumToString(stats.getKey(i)));
      }
      Print("Stats per GTC mode:");
      gtc.print();
      Print("Legend: key=GTC mode, value=count");
      for(int i = 0; i < gtc.getSize(); ++i)
      {
         PrintFormat("%d -> %s", gtc.getKey(i), EnumToString(gtc.getKey(i)));
      }
   }
```

Let's run the script two times. The first time, with the default settings, we can get something like the following picture.

```
===== Expiration modes for all available symbols =====
Total symbols: 52357
Stats per expiration mode:
    [key] [value]
[0]     1   52357
[1]     2   52357
[2]     4   52357
[3]     8   52303
Legend: key=expiration mode, value=count
1 -> _SYMBOL_EXPIRATION_GTC
2 -> _SYMBOL_EXPIRATION_DAY
4 -> _SYMBOL_EXPIRATION_SPECIFIED
8 -> _SYMBOL_EXPIRATION_SPECIFIED_DAY
Stats per GTC mode:
    [key] [value]
[0]     0   52357
Legend: key=GTC mode, value=count
0 -> SYMBOL_ORDERS_GTC
```

Here you can see that almost all flags are allowed for most symbols, and for the SYMBOL_EXPIRATION_GTC mode, the only variant SYMBOL_ORDERS_GTC is used.

Run the script a second time by setting *UseMarketWatch* and *ShowPerSymbolDetails* to *true* (it is assumed that a limited number of symbols is selected in *Market Watch*).

```
GBPUSD:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED ] (7)
  SYMBOL_ORDERS_GTC (0)
USDCHF:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED ] (7)
  SYMBOL_ORDERS_GTC (0)
USDJPY:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED ] (7)
  SYMBOL_ORDERS_GTC (0)
...
XAUUSD:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED
  _SYMBOL_EXPIRATION_SPECIFIED_DAY ] (15)
  SYMBOL_ORDERS_GTC (0)
SP500m:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED
  _SYMBOL_EXPIRATION_SPECIFIED_DAY ] (15)
  SYMBOL_ORDERS_GTC (0)
UK100:
  [ _SYMBOL_EXPIRATION_GTC _SYMBOL_EXPIRATION_DAY _SYMBOL_EXPIRATION_SPECIFIED
  _SYMBOL_EXPIRATION_SPECIFIED_DAY ] (15)
  SYMBOL_ORDERS_GTC (0)
===== Expiration modes for Market Watch symbols =====
Total symbols: 15
Stats per expiration mode:
    [key] [value]
[0]     1      15
[1]     2      15
[2]     4      15
[3]     8       6
Legend: key=expiration mode, value=count
1 -> _SYMBOL_EXPIRATION_GTC
2 -> _SYMBOL_EXPIRATION_DAY
4 -> _SYMBOL_EXPIRATION_SPECIFIED
8 -> _SYMBOL_EXPIRATION_SPECIFIED_DAY
Stats per GTC mode:
    [key] [value]
[0]     0      15
Legend: key=GTC mode, value=count
0 -> SYMBOL_ORDERS_GTC
```

Of the 15 selected symbols, only 6 have the SYMBOL_EXPIRATION_SPECIFIED_DAY flag set. Details about the flags for each symbol can be found above.

6.1.18 Spreads and order distance from the current price

For many trading strategies, especially those based on short-term trades, information about the spread and the distance from the current price, allowing the installation or modification of orders, is important. All of these properties are part of the ENUM_SYMBOL_INFO_INTEGER enumeration and are available through the *SymbolInfoInteger* function.

Identifier	Description
SYMBOL_SPREAD	Spread size (in points)
SYMBOL_SPREAD_FLOAT	Boolean sign of a floating spread
SYMBOL_TRADE_STOPS_LEVEL	Minimum allowed distance from the current price (in points) for setting Stop Loss, Take Profit, and pending orders
SYMBOL_TRADE_FREEZE_LEVEL	Distance from the current price (in points) to freeze orders and positions

In the table above, the current price refers to the *Ask* or *Bid* price, depending on the nature of the operation being performed.

Protective *Stop Loss* and *Take Profit* levels indicate that a position should be closed. This is performed by an operation opposite to the opening. Therefore, for buy orders opened at the *Ask* price, protective levels indicate *Bid*, and for sell orders opened at *Bid*, protective levels indicate *Ask*. When placing pending orders, the open price type is selected in the standard way: buy orders (*Buy Stop*, *Buy Limit*, *Buy Stop Limit*) are based on *Ask* and sell orders (*Sell Stop*, *Sell Limit*, *Sell Stop Limit*) are based on *Bid*. Taking into account such types of prices in the context of the mentioned trading operations, the distance in points is calculated for the SYMBOL_TRADE_STOPS_LEVEL and SYMBOL_TRADE_FREEZE_LEVEL properties.

The SYMBOL_TRADE_STOPS_LEVEL property, if it is non-zero, disables modification of *Stop Loss* and *Take Profit* levels for an open position if the new level would be closer to the current price than the specified distance. Similarly, it is impossible to move the opening price of a pending order closer than SYMBOL_TRADE_STOPS_LEVEL points from the current price.

The SYMBOL_TRADE_FREEZE_LEVEL property, if it is non-zero, restricts any trading operations for a pending order or an open position within the specified distance from the current price. For a pending order, freezing occurs when the specified open price is at a distance less than SYMBOL_TRADE_FREEZE_LEVEL points from the current price (again, the type of the current price is *Ask* or *Bid*, depending on whether it is buying or selling). For a position, freezing occurs for *Stop Loss* and *Take Profit* levels, which happened to be near the current price, and therefore the measurement for them is performed for "opposite" price types.

If the SYMBOL_SPREAD_FLOAT property is *true*, the SYMBOL_SPREAD property is not part of the symbol specification but contains the actual spread, dynamically changing with each call according to market conditions. It can also be found as the difference between *Ask* and *Bid* prices in the *MqlTick* structure by calling *SymbolInfoTick*.

The script *SymbolFilterSpread.mq5* will allow you to analyze the specified properties. It defines a custom enumeration ENUM_SYMBOL_INFO_INTEGER_PART, which includes only the properties of interest to us in this context from ENUM_SYMBOL_INFO_INTEGER.

```
enum ENUM_SYMBOL_INFO_INTEGER_PART
{
   SPREAD_FIXED = SYMBOL_SPREAD,
   SPREAD_FLOAT = SYMBOL_SPREAD_FLOAT,
   STOPS_LEVEL = SYMBOL_TRADE_STOPS_LEVEL,
   FREEZE_LEVEL = SYMBOL_TRADE_FREEZE_LEVEL
};
```

The new enumeration defines the *Property* input parameter, which specifies which of the four properties will be analyzed. Parameters *UseMarketWatch* and *ShowPerSymbolDetails* control the process in the already known way, as in the previous test scripts.

```
input bool UseMarketWatch = true;
input ENUM_SYMBOL_INFO_INTEGER_PART Property = SPREAD_FIXED;
input bool ShowPerSymbolDetails = true;
```

For the convenient display of information for each symbol (property name and value in each line) using the *ArrayPrint* function, an auxiliary structure *SymbolDistance* is defined (used only when *ShowPerSymbolDetails* equals *true*).

```
struct SymbolDistance
{
   string name;
   int value;
};
```

In the *OnStart* handler, we describe the necessary objects and arrays.

```
void OnStart()
{
   SymbolFilter f;                // filter object
   string symbols[];              // receiving array for names
   long values[];                 // receiving array for values
   SymbolDistance distances[];    // array to print
   MapArray<long,int> stats;      // counters of specific values of the selected prop
   ...
```

Then we apply the filter and fill the receiving arrays with the values of the specified *Property* while also applying sorting.

```
   f.select(UseMarketWatch, (ENUM_SYMBOL_INFO_INTEGER)Property, symbols, values, true
   const int n = ArraySize(symbols);
   if(ShowPerSymbolDetails) ArrayResize(distances, n);
   ...
```

In a loop, we count the statistics and fill in the *SymbolDistance* structures, if it is needed.

```
      for(int i = 0; i < n; ++i)
      {
         stats.inc(values[i]);
         if(ShowPerSymbolDetails)
         {
            distances[i].name = symbols[i];
            distances[i].value = (int)values[i];
         }
      }
      ...
```

Finally, we output the results to the log.

```
      PrintFormat("===== Distances for %s symbols =====",
         (UseMarketWatch ? "Market Watch" : "all available"));
      PrintFormat("Total symbols: %d", n);

      PrintFormat("Stats per %s:", EnumToString((ENUM_SYMBOL_INFO_INTEGER)Property));
      stats.print();

      if(ShowPerSymbolDetails)
      {
         Print("Details per symbol:");
         ArrayPrint(distances);
      }
   }
```

Here's what you get when you run the script with default settings, which is consistent with spread analysis.

```
===== Distances for Market Watch symbols =====
Total symbols: 13
Stats per SYMBOL_SPREAD:
    [key] [value]
[0]     0       2
[1]     2       3
[2]     3       1
[3]     6       1
[4]     7       1
[5]     9       1
[6]   151       1
[7]   319       1
[8]  3356       1
[9]  3400       1
Details per symbol:
       [name] [value]
[ 0] "USDJPY"       0
[ 1] "EURUSD"       0
[ 2] "USDCHF"       2
[ 3] "USDCAD"       2
[ 4] "GBPUSD"       2
[ 5] "AUDUSD"       3
[ 6] "XAUUSD"       6
[ 7] "SP500m"       7
[ 8] "NZDUSD"       9
[ 9] "USDCNH"     151
[10] "USDSEK"     319
[11] "BTCUSD"    3356
[12] "USDRUB"    3400
```

To understand whether the spreads are floating (changing dynamically) or fixed, let's run the script with different settings: Property = SPREAD_FLOAT, ShowPerSymbolDetails = false.

```
===== Distances for Market Watch symbols =====
Total symbols: 13
Stats per SYMBOL_SPREAD_FLOAT:
    [key] [value]
[0]     1      13
```

According to this data, all symbols in the market watch have a floating spread (value 1 in the *key* key is *true* in SYMBOL_SPREAD_FLOAT). Therefore, if we run the script again and again with the default settings, we will receive new values (with an open market).

6.1.19 Getting swap sizes

For the implementation of medium-term and long-term strategies, the swap sizes become important, since they can have a significant, usually negative, impact on the financial result. However, some readers are probably fans of the "Carry Trade" strategy, which was originally built on profiting from positive swaps. MQL5 has several symbol properties that provide access to specification strings that are associated with swaps.

Identifier	Description
SYMBOL_SWAP_MODE	Swap calculation model ENUM_SYMBOL_SWAP_MODE
SYMBOL_SWAP_ROLLOVER3DAYS	Day of the week for triple swap credit ENUM_DAY_OF_WEEK
SYMBOL_SWAP_LONG	Swap size for a long position
SYMBOL_SWAP_SHORT	Swap size for a short position

The ENUM_SYMBOL_SWAP_MODE enumeration contains elements that specify options for units of measure and principles for calculating swaps. As well as SYMBOL_SWAP_ROLLOVER3DAYS, they refer to the integer properties of ENUM_SYMBOL_INFO_INTEGER.

The swap sizes are directly specified in the SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT properties as part of ENUM_SYMBOL_INFO_DOUBLE, that is, of type *double*.

Following are the elements of ENUM_SYMBOL_SWAP_MODE.

Identifier	Description
SYMBOL_SWAP_MODE_DISABLED	no swaps
SYMBOL_SWAP_MODE_POINTS	points
SYMBOL_SWAP_MODE_CURRENCY_SYMBOL	the base currency of the symbol
SYMBOL_SWAP_MODE_CURRENCY_MARGIN	symbol margin currency
SYMBOL_SWAP_MODE_CURRENCY_DEPOSIT	deposit currency
SYMBOL_SWAP_MODE_INTEREST_CURRENT	annual percentage of the price of the instrument at the time of swap calculation
SYMBOL_SWAP_MODE_INTEREST_OPEN	annual percentage of the symbol position opening price
SYMBOL_SWAP_MODE_REOPEN_CURRENT	points (with re-opening of the position at the closing price)
SYMBOL_SWAP_MODE_REOPEN_BID	points (with re-opening of the position at the Bid price of the new day). (in SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT parameters)

For the SYMBOL_SWAP_MODE_INTEREST_CURRENT and SYMBOL_SWAP_MODE_INTEREST_OPEN options, there is assumed to be 360 banking days in a year.

For the SYMBOL_SWAP_MODE_REOPEN_CURRENT and SYMBOL_SWAP_MODE_REOPEN_BID options, the position is forcibly closed at the end of the trading day, and then their behavior is different.

With SYMBOL_SWAP_MODE_REOPEN_CURRENT, the position is reopened the next day at yesterday's closing price +/- the specified number of points. With SYMBOL_SWAP_MODE_REOPEN_BID, the position is reopened the next day at the current Bid price +/- the specified number of points. In both cases, the number of points is in the SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT parameters.

Let's check the operation of the properties using the script *SymbolFilterSwap.mq5*. In the input parameters, we provide the choice of the analysis context: *Market Watch* or all symbols depending on *UseMarketWatch*. When the *ShowPerSymbolDetails* parameter is *false*, we will calculate statistics, how many times one or another mode from ENUM_SYMBOL_SWAP_MODE is used in symbols. When the *ShowPerSymbolDetails* parameter is *true*, we will output an array of all symbols with the mode specified in *mode*, and sort the array in descending order of values in the fields SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT.

```
input bool UseMarketWatch = true;
input bool ShowPerSymbolDetails = false;
input ENUM_SYMBOL_SWAP_MODE Mode = SYMBOL_SWAP_MODE_POINTS;
```

For the elements of the combined array of swaps, we describe the *SymbolSwap* structure with the symbol name and swap value. The direction of the swap will be denoted by a prefix in the name field: "+" for swaps of long positions, "-" for swaps of short positions.

```
struct SymbolSwap
{
   string name;
   double value;
};
```

By tradition, we describe the filter object at the beginning of *OnStart*. However, the following code differs significantly depending on the value of the *ShowPerSymbolDetails* variable.

```
void OnStart()
{
   SymbolFilter f;                // filter object
   PrintFormat("===== Swap modes for %s symbols =====",
      (UseMarketWatch ? "Market Watch" : "all available"));

   if(ShowPerSymbolDetails)
   {
      // summary table of swaps of the selected Mode
      ...
   }
   else
   {
      // calculation of mode statistics
      ...
   }
}
```

Let's introduce the second branch first. Here we fill arrays with symbol names using the filter (*symbols*) and swap modes (*values*) that are taken from the SYMBOL_SWAP_MODE property. The resulting values are accumulated in an array map *MapArray<ENUM_SYMBOL_SWAP_MODE,int> stats*.

```
// calculation of mode statistics
string symbols[];
long values[];
MapArray<ENUM_SYMBOL_SWAP_MODE,int> stats; // counters for each mode
// apply filter and collect mode values
f.select(UseMarketWatch, SYMBOL_SWAP_MODE, symbols, values);
const int n = ArraySize(symbols);
for(int i = 0; i < n; ++i)
{
   stats.inc((ENUM_SYMBOL_SWAP_MODE)values[i]);
}
...
```

Next, we display the collected statistics.

```
PrintFormat("Total symbols: %d", n);
Print("Stats per swap mode:");
stats.print();
Print("Legend: key=swap mode, value=count");
for(int i = 0; i < stats.getSize(); ++i)
{
   PrintFormat("%d -> %s", stats.getKey(i), EnumToString(stats.getKey(i)));
}
```

For the case of constructing a table with swap values, the algorithm is as follows. Swaps for long and short positions are requested separately, so we define paired arrays for names and values. Together they will be brought together in the *swaps* array of structures.

```
// summary table of swaps of the selected Mode
string buyers[], sellers[];    // arrays for names
double longs[], shorts[];      // arrays for swap values
SymbolSwap swaps[];            // total array to print
```

Set the condition for the selected swap mode in the filter. This is necessary to be able to compare and sort array elements.

```
f.let(SYMBOL_SWAP_MODE, Mode);
```

Then we apply the filter twice for different properties (SYMBOL_SWAP_LONG, SYMBOL_SWAP_SHORT) and fill different arrays with their values (*longs*, *shorts*). Within each call, the arrays are sorted in ascending order.

```
f.select(UseMarketWatch, SYMBOL_SWAP_LONG, buyers, longs, true);
f.select(UseMarketWatch, SYMBOL_SWAP_SHORT, sellers, shorts, true);
```

In theory, the sizes of the arrays should be the same, since the filter condition is the same, but for clarity, let's allocate a variable for each size. Since each symbol will appear in the resulting table twice, for the long and short sides, we provide a double size for the *swaps* array.

```
const int l = ArraySize(longs);
const int s = ArraySize(shorts);
const int n = ArrayResize(swaps, l + s); // should be l == s
PrintFormat("Total symbols with %s: %d", EnumToString(Mode), l);
```

Next, we join the two arrays *longs* and *shorts*, processing them in reverse order, since we need to sort from positive to negative values.

```
if(n > 0)
{
   int i = l - 1, j = s - 1, k = 0;
   while(k < n)
   {
      const double swapLong = i >= 0 ? longs[i] : -DBL_MAX;
      const double swapShort = j >= 0 ? shorts[j] : -DBL_MAX;

      if(swapLong >= swapShort)
      {
         swaps[k].name = "+" + buyers[i];
         swaps[k].value = longs[i];
         --i;
         ++k;
      }
      else
      {
         swaps[k].name = "-" + sellers[j];
         swaps[k].value = shorts[j];
         --j;
         ++k;
      }
   }
   Print("Swaps per symbols (ordered):");
   ArrayPrint(swaps);
}
```

It is interesting to run the script several times with different settings. For example, by default, we can get the following results.

```
===== Swap modes for Market Watch symbols =====
Total symbols: 13
Stats per swap mode:
    [key] [value]
[0]     1      10
[1]     0       2
[2]     2       1
Legend: key=swap mode, value=count
1 -> SYMBOL_SWAP_MODE_POINTS
0 -> SYMBOL_SWAP_MODE_DISABLED
2 -> SYMBOL_SWAP_MODE_CURRENCY_SYMBOL
```

These statistics show that 10 symbols have the swap mode SYMBOL_SWAP_MODE_POINTS, for two the swaps are disabled, SYMBOL_SWAP_MODE_DISABLED, and for one it is in the base currency SYMBOL_SWAP_MODE_CURRENCY_SYMBOL.

Let's find out what kind of symbols have SYMBOL_SWAP_MODE_POINTS and find out their swaps. For this, we will set *ShowPerSymbolDetails* to *true* (parameter *mode* already set to SYMBOL_SWAP_MODE_POINTS).

```
===== Swap modes for Market Watch symbols =====
Total symbols with SYMBOL_SWAP_MODE_POINTS: 10
Swaps per symbols (ordered):
        [name]   [value]
[ 0] "+AUDUSD"   6.30000
[ 1] "+NZDUSD"   2.80000
[ 2] "+USDCHF"   0.10000
[ 3] "+USDRUB"   0.00000
[ 4] "-USDRUB"   0.00000
[ 5] "+USDJPY"  -0.10000
[ 6] "+GBPUSD"  -0.20000
[ 7] "-USDCAD"  -0.40000
[ 8] "-USDJPY"  -0.60000
[ 9] "+EURUSD"  -0.70000
[10] "+USDCAD"  -0.80000
[11] "-EURUSD"  -1.00000
[12] "-USDCHF"  -1.00000
[13] "-GBPUSD"  -2.20000
[14] "+USDSEK"  -4.50000
[15] "-XAUUSD"  -4.60000
[16] "-USDSEK"  -4.90000
[17] "-NZDUSD"  -6.70000
[18] "+XAUUSD" -12.60000
[19] "-AUDUSD" -14.80000
```

You can compare the values with symbol specifications.

Finally, we change the Mode to SYMBOL_SWAP_MODE_CURRENCY_SYMBOL. In our case, we should get one symbol, but spaced into two lines: with a plus and a minus in the name.

```
===== Swap modes for Market Watch symbols =====
Total symbols with SYMBOL_SWAP_MODE_CURRENCY_SYMBOL: 1
Swaps per symbols (ordered):
       [name]   [value]
[0] "-SP500m" -35.00000
[1] "+SP500m" -41.41000
```

From the table, both swaps are negative.

6.1.20 Current market information (tick)

In the section Getting the last tick of a symbol, we have already seen the *SymbolInfoTick* function, which provides complete information about the last tick (price change event) in the form of the *MqlTick* structure. If necessary, the MQL program can request the values of prices and volumes corresponding to the fields of this structure separately. All of them are denoted by properties of different types that are part of the ENUM_SYMBOL_INFO_INTEGER and ENUM_SYMBOL_INFO_DOUBLE enumerations.

Identifier	Description	Property type
SYMBOL_TIME	Last quote time	datetime
SYMBOL_BID	Bid price; the best sell offer	double
SYMBOL_ASK	Ask price; the best buy offer	double
SYMBOL_LAST	Last; the price of the last deal	double
SYMBOL_VOLUME	The volume of the last deal	long
SYMBOL_TIME_MSC	The time of the last quote in milliseconds since 1970.01.01	long
SYMBOL_VOLUME_REAL	The volume of the last deal with increased accuracy	double

Note that the code for the two volume-related properties, SYMBOL_VOLUME and SYMBOL_VOLUME_REAL, is the same in both enumerations. This is the only case where the element IDs of different enumerations overlap. The thing is that they return essentially the same tick property, but with different representation accuracy.

Unlike a structure, properties do not provide an analog to the *uint flags* field, which tells what kind of changes in the market caused the tick generation. This field is only meaningful within a structure.

Let's try to request tick properties separately and compare them with the result of the *SymbolInfoTick* call. In a fast market, there is a possibility that the results will differ. A new tick (or even several ticks) may come between function calls.

```
void OnStart()
{
   PRTF(TimeToString(SymbolInfoInteger(_Symbol, SYMBOL_TIME), TIME_DATE | TIME_SECOND
   PRTF(SymbolInfoDouble(_Symbol, SYMBOL_BID));
   PRTF(SymbolInfoDouble(_Symbol, SYMBOL_ASK));
   PRTF(SymbolInfoDouble(_Symbol, SYMBOL_LAST));
   PRTF(SymbolInfoInteger(_Symbol, SYMBOL_VOLUME));
   PRTF(SymbolInfoInteger(_Symbol, SYMBOL_TIME_MSC));
   PRTF(SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_REAL));

   MqlTick tick[1];
   SymbolInfoTick(_Symbol, tick[0]);
   ArrayPrint(tick);
}
```

It is easy to verify that in a particular case, the information coincided.

```
TimeToString(SymbolInfoInteger(_Symbol,SYMBOL_TIME),TIME_DATE|TIME_SECONDS)
   =2022.01.25 13:52:51 / ok
SymbolInfoDouble(_Symbol,SYMBOL_BID)=1838.44 / ok
SymbolInfoDouble(_Symbol,SYMBOL_ASK)=1838.49 / ok
SymbolInfoDouble(_Symbol,SYMBOL_LAST)=0.0 / ok
SymbolInfoInteger(_Symbol,SYMBOL_VOLUME)=0 / ok
SymbolInfoInteger(_Symbol,SYMBOL_TIME_MSC)=1643118771166 / ok
SymbolInfoDouble(_Symbol,SYMBOL_VOLUME_REAL)=0.0 / ok
                 [time]   [bid]   [ask] [last] [volume]    [time_msc] [flags] [volume
[0] 2022.01.25 13:52:51 1838.44 1838.49   0.00        0 1643118771166       6
```

6.1.21 Descriptive symbol properties

The platform provides a group of text properties for MQL programs that describe important qualitative characteristics. For example, when developing indicators or trading strategies based on a basket of financial instruments, it may be necessary to select symbols by country of origin, economic sector, or name of the underlying asset (if the instrument is a derivative).

Identifier	Description
SYMBOL_BASIS	The name of the underlying asset for the derivative
SYMBOL_CATEGORY	The name of the category to which the financial instrument belongs
SYMBOL_COUNTRY	The country to which the financial instrument is assigned
SYMBOL_SECTOR_NAME	The sector of the economy to which the financial instrument belongs
SYMBOL_INDUSTRY_NAME	The branch of the economy or type of industry to which the financial instrument belongs
SYMBOL_BANK	Current quote source
SYMBOL_DESCRIPTION	String description of the symbol
SYMBOL_EXCHANGE	The name of the exchange or marketplace where the symbol is traded
SYMBOL_ISIN	A unique 12-digit alphanumeric code in the system of international securities identification codes - ISIN (International Securities Identification Number)
SYMBOL_PAGE	Internet page address with information on the symbol
SYMBOL_PATH	Path in symbol tree

Another case where the program can apply the analysis of these properties occurs when looking for a conversion rate from one currency to another. We already know how to find a symbol with the right combination of base and quote currency, but the difficulty is that there may be several such symbols. Reading properties like SYMBOL_SECTOR_NAME (you need to look for "Currency" or a synonym; check with your broker's specification) or SYMBOL_PATH can help in such cases.

The SYMBOL_PATH contains the entire hierarchy of folders in the symbols directory that contain the specific symbol: folder names are separated by backslashes ('\\') in the same way as the file system. The last element of the path is the name of the symbol itself.

Some string properties have integer counterparts. In particular, instead of SYMBOL_SECTOR_NAME, you can use the SYMBOL_SECTOR property, which returns an enumeration member ENUM_SYMBOL_SECTOR with all supported sectors. By analogy, for SYMBOL_INDUSTRY_NAME there is a similar property SYMBOL_INDUSTRY with the ENUM_SYMBOL_INDUSTRY enumeration type.

If necessary, an MQL program can even find the background color used when displaying a symbol in the Market Watch by simply reading the SYMBOL_BACKGROUND_COLOR property. This will allow those programs that create their own interface on the chart using graphic objects (dialog boxes, lists, etc.), to make it unified with the native terminal controls.

Consider the example script *SymbolFilterDescription.mq5*, which outputs four predefined text properties for *Market Watch* symbols. The first of them is SYMBOL_DESCRIPTION (not to be confused with the name of the symbol itself), and it is by it that the resulting list will be sorted. The other three are purely for reference: SYMBOL_SECTOR_NAME, SYMBOL_COUNTRY, SYMBOL_PATH. All values are filled in in a specific way for each broker (there may be discrepancies for the same ticker).

We haven't mentioned it, but our *SymbolFilter* class implements a special overload of the *equal* method to compare strings. It supports searching for the occurrence of a substring with a pattern in which the wildcard character '*' stands for 0 or more arbitrary characters. For example, "*ian*" will find all characters that contain the substring "ian" (anywhere), and "*Index" will only find strings ending in "Index".

This feature resembles a substring search in the *Symbols* dialog available to users. However, there is no need to specify a wildcard character, because a substring is always searched for. In the algorithm which can be found in the source codes (*SymbolFilter.mqh*), we left the possibility to search for either a full match (there are no '*' characters) or a substring (there is at least one asterisk).

The comparison is case-sensitive. If necessary, it is easy to adapt the code for comparison without distinguishing between lowercase and uppercase letters.

Given the new feature, let's define an input variable for the search string in the description of the symbols. If the variable is empty, all symbols from the *Market Watch* window will be displayed.

```
input string SearchPattern = "";
```

Further, everything is as usual.

```
void OnStart()
{
   SymbolFilter f;                        // filter object
   string symbols[];                      // array of names
   string text[][4];                      // array of vectors with data

   // properties to read
   ENUM_SYMBOL_INFO_STRING fields[] =
   {
      SYMBOL_DESCRIPTION,
      SYMBOL_SECTOR_NAME,
      SYMBOL_COUNTRY,
      SYMBOL_PATH
   };

   if(SearchPattern != "")
   {
      f.let(SYMBOL_DESCRIPTION, SearchPattern);
   }

   // apply the filter and get arrays sorted by description
   f.select(true, fields, symbols, text, true);

   const int n = ArraySize(symbols);
   PrintFormat("===== Text fields for symbols (%d) =====", n);
   for(int i = 0; i < n; ++i)
   {
      Print(symbols[i] + ":");
      ArrayPrint(text, 0, NULL, i, 1, 0);
   }
}
```

Here is a possible version of the list (with abbreviations).

```
===== Text fields for symbols (16) =====
AUDUSD:
"Australian Dollar vs US Dollar" "Currency"   ""   "Forex\AUDUSD"
EURUSD:
"Euro vs US Dollar" "Currency"   ""   "Forex\EURUSD"
UK100:
"FTSE 100 Index" "Undefined"   ""   "Indexes\UK100"
XAUUSD:
"Gold vs US Dollar" "Commodities"   ""   "Metals\XAUUSD"
JAGG:
    "JPMorgan U.S. Aggregate Bond ETF"  "Financial"
    "USA"   "ETF\United States\NYSE\JPMorgan\JAGG"
NZDUSD:
"New Zealand Dollar vs US Dollar" "Currency"   ""   "Forex\NZDUSD"
GBPUSD:
"Pound Sterling vs US Dollar" "Currency"   ""   "Forex\GBPUSD"
SP500m:
"Standard & Poor's 500" "Undefined"   ""   "Indexes\SP500m"
FIHD:
    "UBS AG FI Enhanced Global High Yield ETN" "Financial"
    "USA"   "ETF\United States\NYSE\UBS\FIHD"
...
```

If we enter the search string "*ian*" into the input variable *SearchPattern*, we get the following result.

```
===== Text fields for symbols (3) =====
AUDUSD:
"Australian Dollar vs US Dollar" "Currency"   ""   "Forex\AUDUSD"
USDCAD:
"US Dollar vs Canadian Dollar" "Currency"   ""   "Forex\USDCAD"
USDRUB:
"US Dollar vs Russian Ruble" "Currency"   ""   "Forex\USDRUB"
```

6.1.22 Depth of Market

When it comes to exchange instruments, MetaTrader 5 allows you to get not only price and volume information packed in ticks, but also the Depth of Market (order book, level II prices), that is, the distribution of volumes in placed buy and sell orders at several nearest levels around the current price. One of the integer properties of the symbol SYMBOL_TICKS_BOOKDEPTH contains the maximum number of levels shown in the Depth of Market. This amount is allowed for each of the parties, that is, the total size of the order book can be two times larger (and this does not take into account price levels with zero volumes that are not broadcast).

Depending on the market situation, the actual size of the transmitted order book may become smaller than indicated in this property. For non-exchange instruments, this property is usually equal to 0, although some brokers can broadcast the order book for Forex symbols, limited only by the orders of their clients.

The order book itself and notifications about its update must be requested by the interested MQL program using a special API, which we will discuss in the next chapter.

> It should be noted that due to the architectural features of the platform, this property is not directly related to the translation of the order book, that is, it is just a specification field filled in by

the broker. In other words, a non-zero value of the property does not mean that the order book will necessarily arrive at the terminal in an open market. This depends on other server settings and whether it has an active connection to the data provider.

Let's try to get statistics on the depth of the market for all or selected symbols using the script *SymbolFilterBookDepth.mq5*.

```
input bool UseMarketWatch = false;
input int ShowSymbolsWithDepth = -1;
```

Parameter *ShowSymbolsWithDepth*, which is equal to -1 by default, instructs to collect statistics on different Depth of Market settings among all symbols. If you set the parameter to a different value, the program will try to find all symbols with the specified order book depth.

```
void OnStart()
{
   SymbolFilter f;                // filter object
   string symbols[];              // array for symbol names
   long depths[];                 // array of property values
   MapArray<long,int> stats;      // counters of occurrences of each depth

   if(ShowSymbolsWithDepth > -1)
   {
      f.let(SYMBOL_TICKS_BOOKDEPTH, ShowSymbolsWithDepth);
   }

   // apply filter and fill arrays
   f.select(UseMarketWatch, SYMBOL_TICKS_BOOKDEPTH, symbols, depths, true);
   const int n = ArraySize(symbols);

   PrintFormat("===== Book depths for %s symbols %s=====",
      (UseMarketWatch ? "Market Watch" : "all available"),
      (ShowSymbolsWithDepth > -1 ? "(filtered by depth="
      + (string)ShowSymbolsWithDepth + ") " : ""));
   PrintFormat("Total symbols: %d", n);
   ...
```

If a specific depth is given, we simply output an array of symbols (they all satisfy the filter condition), and exit.

```
   if(ShowSymbolsWithDepth > -1)
   {
      ArrayPrint(symbols);
      return;
   }
   ...
```

Otherwise, we calculate the statistics and display them.

```
   for(int i = 0; i < n; ++i)
   {
      stats.inc(depths[i]);
   }

   Print("Stats per depth:");
   stats.print();
   Print("Legend: key=depth, value=count");
}
```

With the default settings, we can get the following picture.

```
===== Book depths for all available symbols =====
Total symbols: 52357
Stats per depth:
    [key] [value]
[0]     0   52244
[1]     5       3
[2]    10      67
[3]    16       5
[4]    20      13
[5]    32      25
Legend: key=depth, value=count
```

If you set *ShowSymbolsWithDepth* to one of the detected values, for example, 32, we get a list of symbols with this order book depth.

```
===== Book depths for all available symbols (filtered by depth=32) =====
Total symbols: 25
[ 0] "USDCNH" "USDZAR" "USDHUF" "USDPLN" "EURHUF" "EURNOK" "EURPLN" "EURSEK" "EURZAR"
[13] "NZDCAD" "NZDCHF" "USDMXN" "EURMXN" "GBPMXN" "CADMXN" "CHFMXN" "MXNJPY" "NZDMXN"
```

6.1.23 Custom symbol properties

In the introduction to this chapter, we mentioned custom symbols. These are the symbols with the quotes created directly in the terminal at the user's command or programmatically.

Custom symbols can be used, for example, to create a synthetic instrument based on a formula that includes other Market Watch symbols. This is available to the user directly in the terminal interface.

An MQL program can implement more complex scenarios in MQL5, such as merging different instruments for different periods, generating series according to a given random distribution, or receiving data (quotes, bars, or ticks) from external sources.

In order to be able to distinguish a standard symbol from a custom symbol in algorithms, MQL5 provides the SYMBOL_CUSTOM property, which is a logical sign that a symbol is custom.

If the symbol has a formula, it is available through the SYMBOL_FORMULA string property. In formulas, as you know, you can use the names of other symbols, as well as mathematical functions and operators. Here are some examples:

- Synthetic symbol: "@ESU19"/EURCAD
- Calendar spread: "Si-9.13"-"Si-6.13"

- Euro index: 34.38805726 * pow(EURUSD,0.3155) * pow(EURGBP,0.3056) * pow(EURJPY,0.1891) * pow(EURCHF,0.1113) * pow(EURSEK,0.0785)

Specifying a formula is convenient for the user, but usually not used from MQL programs since they can calculate formulas directly in the code, with non-standard functions and with more control, in particular, on each tick and not on a timer 1 time per 100ms.

Let's check the work with properties in the script *SymbolFilterCustom.mq5*: it logs all custom symbols and their formulas (if any).

```
input bool UseMarketWatch = false;

void OnStart()
{
   SymbolFilter f;                // filter object
   string symbols[];              // array for symbol names
   string formulae[];             // array for formulas

 // apply filter and fill arrays
   f.let(SYMBOL_CUSTOM, true)
   .select(UseMarketWatch, SYMBOL_FORMULA, symbols, formulae);
   const int n = ArraySize(symbols);

   PrintFormat("===== %s custom symbols =====",
      (UseMarketWatch ? "Market Watch" : "All available"));
   PrintFormat("Total symbols: %d", n);

   for(int i = 0; i < n; ++i)
   {
      Print(symbols[i], " ", formulae[i]);
   }
}
```

Below is the result with the only custom character found.

```
===== All available custom symbols =====
Total symbols: 1
synthEURUSD SP500m/UK100
```

6.1.24 Specific properties (stock exchange, derivatives, bonds)

In this final section of the chapter, we will briefly review other symbol properties that are outside the scope of the book but may be useful for implementing advanced trading strategies. Detailed information about these properties can be found in the MQL5 documentation.

As you know, MetaTrader 5 allows you to trade derivatives market instruments, including options, futures, and bonds. This is reflected in the software interface as well. The MQL5 API provides a lot of specific symbol properties related to the mentioned instrument categories.

In particular, for options, this is the circulation period (the start date SYMBOL_START_TIME and the end date SYMBOL_EXPIRATION_TIME of trading), the strike price (SYMBOL_OPTION_STRIKE), the right to buy or sell (SYMBOL_OPTION_RIGHT, Call/Put), European or American type (SYMBOL_OPTION_MODE) depending on the possibility of early exercising, day-to-day change in closing

prices (SYMBOL_PRICE_CHANGE) and volatility (SYMBOL_PRICE_VOLATILITY), as well as estimated coefficients (the Greeks) characterizing the dynamics of price behavior.

For bonds, the accumulated coupon income (SYMBOL_TRADE_ACCRUED_INTEREST), face value (SYMBOL_TRADE_FACE_VALUE), liquidity ratio (SYMBOL_TRADE_LIQUIDITY_RATE) are of particular interest.

For futures – open interest (SYMBOL_SESSION_INTEREST) and total order volumes by buy (SYMBOL_SESSION_BUY_ORDERS_VOLUME) and sell (SYMBOL_SESSION_SELL_ORDERS_VOLUME), clearing price at the close of the trading session (SYMBOL_SESSION_PRICE_SETTLEMENT).

Apart from the current market data that make up a tick, MQL5 allows you to know their daily range: the maximum and minimum values for each of the tick fields. For example, SYMBOL_BIDHIGH is the maximum *Bid* per day, and SYMBOL_BIDLOW is the minimum. Note that the properties SYMBOL_VOLUMEHIGH, SYMBOL_VOLUMELOW (of type *long*) actually duplicate, but only with less precision, the volumes in SYMBOL_VOLUMEHIGH_REAL and SYMBOL_VOLUMELOW_REAL (*double*).

Information about the *Last* prices and volumes is available, as a rule, only for exchange symbols.

Bear in mind that filling in the properties depends on the settings of the server implemented by the broker.

6.2 Depth of market

In addition to several types of up-to-date market price data (*Ask/Bid/Last*) and the last traded volumes are received in the terminal in the form of ticks, MetaTrader 5 supports the Depth of Market (order book), which is an array of records about the volumes of placed buy and sell orders around the current market price. Volumes are aggregated at several levels above and below the current price, with the smallest increment of price movement according to the symbol specification. As we have seen, the maximum order book size (number of price levels) is set in the SYMBOL_TICKS_BOOKDEPTH symbol property.

Terminal users know the Depth of Market feature in the interface and its operating principles. If you need further details, please see the documentation.

The order book contains extended market information which is commonly referred to as "market depth". Knowing it allows you to create more sophisticated trading systems.

Indeed, information about a tick is only a small slice of the order book. In a somewhat simplified sense, a tick is a 2-level order book with one nearest *Ask* price (available offer) and one nearest *Bid* price (available demand). Furthermore, ticks do not provide order volumes at these prices.

Depth of Market changes can occur much more frequently than ticks, since they affect not only the reaction to concluded deals but also changes in the volume of pending limit orders in the Depth of Market.

Usually, data providers for the order book and quotes (ticks, deals) are different instances, and tick events (*OnTick* in Expert Advisors or *OnCalculate* in indicators) do not match the Depth of Market events. Both threads arrive asynchronously and in parallel but eventually end up in the event queue of an MQL program.

It is important to note that an order book is available, as a rule, for exchange instruments, but there are exceptions both in one direction and in the other:

- Depth of Market may be missing for one reason or another for an exchange instrument
- Depth of Market can be provided by a broker for an OTC instrument based on the information they have collected about their clients' orders

In MQL5, Depth of Market data is available for Expert Advisors and indicators. By using special functions (*MarketBookAdd*, *MarketBookRelease*), programs can enable or disable their subscription to receive notifications about Depth of Market changes in the platform. To receive the notifications, the program must define the *OnBookEvent* event handler function in its code. After receiving a notification, the order book data can be read using the *MarketBookGet* function.

> The terminal maintains the history of quotes and ticks, but not of the Depth of Market data. In particular, the user or an MQL program can download the history at the required retrospective (if the broker has it) and test Expert Advisors and indicators on it.
>
> In contrast, the Depth of Market is only broadcast online and is not available in the tester. A broker does not have an archive of Depth of Market data on the server. To emulate the behavior of the order book in the tester, you should collect the Depth of Market history online and then read it from the MQL program running in the tester. You can find ready-made products in the MQL5 Market.

6.2.1 Managing subscriptions to Depth of Market events

The terminal receives the Depth of Market information on a subscription basis: an MQL program must express its intent to receive Depth of Market (order book) events or, conversely, terminate its subscription by calling the appropriate functions, *MarketBookAdd* and *MarketBookRelease*.

The *MarketBookAdd* function subscribes to receive notifications about changes in the order book for the specified instrument. Thus, you can subscribe to order books for many instruments, and not just the working instrument of the current chart.

bool MarketBookAdd(const string symbol)

Usually, this function is called from *OnInit* or in the class constructor of a long-lived object. Notifications about the order book change are sent to the program in the form of *OnBookEvent* events, therefore, to process them, the program must have a handler function of the same name.

If the specified symbol was not selected in the Market Watch before calling the function, it will be added to the window automatically.

The *MarketBookRelease* function unsubscribes from notifications about changes in the specified order book.

bool MarketBookRelease(const string symbol)

As a rule, this function should be called from *OnDeinit* or from the class destructor of a long-lived object.

Both functions return a value *true* if successful and *false* otherwise.

For all applications running on the same chart, separate subscription counters are maintained by symbols. In other words, there can be several subscriptions to different symbols on the chart, and each of them has its own counter.

Subscription or unsubscription by a single call of any of the functions changes the subscription counter only for a specific symbol, on a specific chart where the program is running. This means that two

charts can have subscriptions to *OnBookEvent* events of the same symbol, but with different values of subscription counters.

The initial value of the subscription counter is zero. On every call of *MarketBookAdd*, the subscription counter for the specified symbol on the given chart is incremented by 1 (the chart symbol and the symbol in *MarketBookAdd* do not have to match). When calling *MarketBookRelease*, the counter of subscriptions to the specified symbol within the chart decreases by 1.

OnBookEvent events for any symbol within the chart are generated as long as the subscription counter for this symbol is greater than zero. Therefore, it is important that every MQL program that contains *MarketBookAdd* calls, upon completion of its work, correctly unsubscribes from receiving events for each symbol using *MarketBookRelease*. For this, you should make sure that the number of *MarketBookAdd* calls and *MarketBookRelease* calls match. MQL5 does not allow you to find out the value of the counter.

The first example is a simple bufferless indicator *MarketBookAddRelease.mq5*, which enables a subscription to the order book at the time of launch and disables it when it is unloaded. In the *WorkSymbol* input parameter, you can specify a symbol to subscribe. If it is left empty (default value), the subscription will be initiated for the working symbol of the current chart.

```
input string WorkSymbol = ""; // WorkSymbol (empty means current chart symbol)

const string _WorkSymbol = StringLen(WorkSymbol) == 0 ? _Symbol : WorkSymbol;
string symbols[];

void OnInit()
{
   const int n = StringSplit(_WorkSymbol, ',', symbols);
   for(int i = 0; i < n; ++i)
   {
      if(!PRTF(MarketBookAdd(symbols[i])))
         PrintFormat("MarketBookAdd(%s) failed", symbols[i]);
   }
}

int OnCalculate(const int rates_total, const int prev_calculated, const int, const do
{
   return rates_total;
}

void OnDeinit(const int)
{
   for(int i = 0; i < ArraySize(symbols); ++i)
   {
      if(!PRTF(MarketBookRelease(symbols[i])))
         PrintFormat("MarketBookRelease(%s) failed", symbols[i]);
   }
}
```

As an additional feature, it is allowed to specify several instruments separated by commas. In this case, a subscription to all will be requested.

When the indicator is launched, a sign of subscription success or an error code is displayed in the log. The indicator then tries to unsubscribe from the events in the *OnDeinit* handler.

With the default settings, on the chart with the symbol for which the order book is available, we will get the following entries in the log.

```
MarketBookAdd(symbols[i])=true / ok
MarketBookRelease(symbols[i])=true / ok
```

If you put the indicator on a chart with a symbol without the order book, we will see error codes.

```
MarketBookAdd(symbols[i])=false / BOOKS_CANNOT_ADD(4901)
MarketBookAdd(XPDUSD) failed
MarketBookRelease(symbols[i])=false / BOOKS_CANNOT_DELETE(4902)
MarketBookRelease(XPDUSD) failed
```

You can experiment by specifying in the input parameter *WorkSymbol* existing or missing characters. We will consider the case of subscribing to order books of several symbols in the next section.

6.2. Receiving events about changes in the Depth of Market

The *OnBookEvent* event is generated by the terminal when the order book status changes. The event is processed by the *OnBookEvent* function defined in the source code. In order for the terminal to start sending *OnBookEvent* notifications to the MQL program for a specific symbol, you must first subscribe to receive them using the *MarketBookAdd* function.

To unsubscribe from receiving the *OnBookEvent* event for a symbol, call the *MarketBookRelease* function.

The *OnBookEvent* event is broadcast, which means that it is enough for one MQL program on the chart to subscribe to *OnBookEvent* events, and all other programs on the same chart will also start receiving the events provided they have the *OnBookEvent* handler in the code. Therefore, it is necessary to analyze the name of the symbol, which is passed to the handler as a parameter.

The *OnBookEvent* handler prototype is as follows.

```
void OnBookEvent(const string &symbol)
```

OnBookEvent events are queued even if the processing of the previous *OnBookEvent* event has not yet been completed.

It is important that the events *OnBookEvent* are only notifications and do not provide the state of the order book. To get the Depth of Market data, call the *MarketBookGet* function.

It should be noted, however, that the *MarketBookGet* call, even if it is made directly from the *OnBookEvent* handler, will receive the current state of the order book at the time when *MarketBookGet* is called, which does not necessarily match the order book state that triggered sending of the event *OnBookEvent*. This can happen when a sequence of very fast order book changes arrives at the terminal.

In this regard, in order to obtain the most complete chronology of Depth of Market changes, we need to write an implementation of *OnBookEvent* and prioritize the optimization by the execution speed.

At the same time, there is no guaranteed way to get all unique Depth of Market states in MQL5.

> If your program started receiving notifications successfully, and then they disappeared when the market was open (and ticks continue to come), this may indicate problems in the subscription. In particular, another MQL program which is poorly designed could unsubscribe more times than required. In such cases, it is recommended to resubscribe with a new *MarketBookAdd* call after a predefined timeout (for example, several tens of seconds or a minute).

An example of bufferless indicator *MarketBookEvent.mq5* allows you to track the arrival of *OnBookEvent* events and prints the symbol name and the current time (millisecond system counter) in a comment. For clarity, we use the multi-line comment function from the *Comments.mqh* file, section Displaying messages in the chart window.

Interestingly, if you leave the input parameter *WorkSymbol* empty (default value), the indicator itself will not initiate a subscription to the order book but will be able to intercept messages requested by other MQL programs on the same chart. Let's check it.

```
#include <MQL5Book/Comments.mqh>

input string WorkSymbol = ""; // WorkSymbol (if empty, intercept events initiated by

void OnInit()
{
   if(StringLen(WorkSymbol))
   {
      PRTF(MarketBookAdd(WorkSymbol));
   }
   else
   {
      Print("Start listening to OnBookEvent initiated by other programs");
   }
}

void OnBookEvent(const string &symbol)
{
   ChronoComment(symbol + " " + (string)GetTickCount());
}

void OnDeinit(const int)
{
   Comment("");
   if(StringLen(WorkSymbol))
   {
      PRTF(MarketBookRelease(WorkSymbol));
   }
}
```

Let's run *MarketBookEvent* with default settings (no own subscription) and then add the *MarketBookAddRelease* indicator from the previous section, and specify for it a list of several symbols with available order books (in the example below, this is "XAUUSD,BTCUSD,USDCNH"). It doesn't matter which chart to run the indicators on: it can be a completely different symbol, like EURUSD.

Immediately after launching *MarketBookEvent*, the chart will be empty (no comments) because there are no subscriptions yet. Once *MarketBookAddRelease* starts (three lines should appear in the log with the status of a successful subscription equal to *true*), the names of symbols will begin to appear in the

comments alternately as their order books are updated (we have not yet learned how to read the order book; this will be discussed in the next section).

Here's how it looks on the screen.

Notifications about changes in the order books of "third-party" symbols

If we now remove the *MarketBookAddRelease* indicator, it will cancel its subscriptions, and the comment will stop updating. Subsequent removal of *MarketBookEvent* will clear the comment.

Please note that some time (a second or two) passes between the request to unsubscribe and the moment when Depth of Market events actually stop updating the comment.

You can run the *MarketBookEvent* indicator alone on the chart, specifying some symbol in its *WorkSymbol* parameter to make sure notifications work within the same app. *MarketBookAddRelease* was previously used only to demonstrate the broadcast nature of notifications. In other words, enabling a subscription to order book changes in one program does affect the receipt of notifications in another.

6.2.3 Reading the current Depth of Market data

After successful execution of the *MarketBookAdd* function, an MQL program can query the order book states using the *MarketBookGet* function upon the arrival of OnBookEvent events. The *MarketBookGet* function populates the *MqlBookInfo* array of structures passed by reference with the Depth of Market values of the specified symbol.

bool MarketBookGet(string symbol, MqlBookInfo &book[])

For the receiving array, you can pre-allocate memory for a sufficient number of records. If the dynamic array has zero or insufficient size, the terminal itself will allocate memory for it.

The function returns an indication of success (*true*) or error (*false*).

MarketBookGet is usually utilized directly in the *OnBookEvent* handler code or in functions called from it.

A separate record about the Depth of Market price level is stored in the *MqlBookInfo* structure.

```
struct MqlBookInfo
{
   ENUM_BOOK_TYPE type;          // request type
   double         price;         // price
   long           volume;        // volume
   double         volume_real;   // volume with increased accuracy
};
```

The enumeration ENUM_BOOK_TYPE contains the following members.

Identifier	Description
BOOK_TYPE_SELL	Request to sell
BOOK_TYPE_BUY	Request to buy
BOOK_TYPE_SELL_MARKET	Request to sell at market price
BOOK_TYPE_BUY_MARKET	Request to buy at market price

In the order book, sell orders are located in its upper half and buy orders are placed in the lower half. As a rule, this leads to a sequence of elements from high prices to low prices. In other words, below the 0th index, there is the highest price, and the last entry is the lowest one, while between them prices decrease gradually. In this case, the minimum price step between the levels is SYMBOL_TRADE_TICK_SIZE, however, levels with zero volumes are not translated, that is, adjacent elements can be separated by a large amount.

In the terminal user interface, the order book window provides an option to enable/disable *Advanced Mode*, in which levels with zero volumes are also displayed. But by default, in the standard mode, such levels are hidden (skipped in the table).

In practice, the order book content can sometimes contradict the announced rules. In particular, some buy or sell requests may fall into the opposite half of the order book (probably, someone placed a buy at an unfavorably high price or a sell at an unfavorably low price, but the provider can also have data aggregation errors). As a result, due to the observance of the priority "all sell orders from above, all buy orders from below", the sequence of prices in the order book will be violated (see example below). In addition, repeated values of prices (levels) can be found both in one half of the order book and in the opposite ones.

In theory, the coincidence of buy and sell prices in the middle of the order book is correct. It means zero spread. However, unfortunately, duplicate levels also happen at a greater depth of the order book.

When we say "half" of the order book, it should not be taken literally. Depending on liquidity, the number of supply and demand levels may not match. In general, the book is not symmetrical.

The MQL program must check the correctness of the order book (in particular, the price sorting order) and be ready to handle potential deviations.

Less serious abnormal situations (which, nevertheless, should be taken into account in the algorithm) include:

- Consecutive identical order books, without changes
- Empty order book
- Order book with one level

Below is a fragment of a real Depth of Market received from a broker. The letters 'S' and 'B' mark, respectively, the prices of sell and buy requests.

Note that the buy and sell levels actually overlap: visually, this is not very noticeable, because all the 'S' records in the order book are specially placed up (the beginning of the receiving array), and the 'B' records are down (the end of the array). However, take a closer look: the buy prices in elements 20 and 21 are 143.23 and 138.86, respectively, and this is more than all sell offers. And, at the same time, the selling prices in elements 18 and 19 are 134.62 and 133.55, which is lower than all buy offers.

```
...
10 S 138.48 652
11 S 138.47 754
12 S 138.45 2256
13 S 138.43 300
14 S 138.42 14
15 S 138.40 1761
16 S 138.39 670    // Duplicate
17 S 138.11 200
18 S 134.62 420    // Low
19 S 133.55 10627  // Low

20 B 143.23 9564   // High
21 B 138.86 533    // High
22 B 138.39 739    // Duplicate
23 B 138.38 106
24 B 138.31 100
25 B 138.25 29
26 B 138.24 6072
27 B 138.23 571
28 B 138.21 17
29 B 138.20 201
30 B 138.19 1
...
```

In addition, the price of 138.39 is found both in the upper half at number 16 and in the lower half at number 22.

Errors in the order book are most likely to be present in extreme conditions: with strong volatility or lack of liquidity.

Let's check the receipt of the order book using the indicator *MarketBookDisplay.mq5*. It will subscribe to Depth of Market events for the specified symbol in the parameter *WorkSymbol* (if you leave an empty line there, the working symbol of the current chart is assumed).

```
input string WorkSymbol = ""; // WorkSymbol (if empty, use current chart symbol)

const string _WorkSymbol = StringLen(WorkSymbol) == 0 ? _Symbol : WorkSymbol;
int digits;

void OnInit()
{
   PRTF(MarketBookAdd(_WorkSymbol));
   digits = (int)SymbolInfoInteger(_WorkSymbol, SYMBOL_DIGITS);
   ...
}

void OnDeinit(const int)
{
   Comment("");
   PRTF(MarketBookRelease(_WorkSymbol));
}
```

The *OnBookEvent* handler is defined in the code for handling events, in which *MarketBookGet* is called, and all elements of the resulting *MqlBookInfo* array output as a multiline comment.

```
void OnBookEvent(const string &symbol)
{
   if(symbol == _WorkSymbol) // take only order books of the requested symbol
   {
      MqlBookInfo mbi[];
      if(MarketBookGet(symbol, mbi)) // getting the current order book
      {
         ...
         int half = ArraySize(mbi) / 2; // estimate of the middle of the order book
         bool correct = true;
         // collect information about levels and volumes in one line (with hyphens)
         string s = "";
         for(int i = 0; i < ArraySize(mbi); ++i)
         {
            s += StringFormat("%02d %s %s %d %g\n", i,
               (mbi[i].type == BOOK_TYPE_BUY ? "B" :
               (mbi[i].type == BOOK_TYPE_SELL ? "S" : "?")),
               DoubleToString(mbi[i].price, digits),
               mbi[i].volume, mbi[i].volume_real);

            if(i > 0) // look for the middle of the order book as a change in request
            {
               if(mbi[i - 1].type == BOOK_TYPE_SELL
                  && mbi[i].type == BOOK_TYPE_BUY)
               {
                  half = i; // this is the middle, because there has been a type chan
               }

               if(mbi[i - 1].price <= mbi[i].price)
               {
                  correct = false; // reverse order = data problem
               }
            }
         }
         Comment(s + (!correct ? "\nINCORRECT BOOK" : ""));
         ...
      }
   }
}
```

Since the order book changes rather quickly, it is not very convenient to follow the comment. Therefore, we will add a couple of buffers to the indicator, in which we will display the contents of two halves of the order book as histograms: sell and buy separately. The zero bar will correspond to the central levels that form the spread. With an increase in bar numbers, there is an increase in the "depth of the market", that is, more and more distant price levels are displayed there: in the upper histogram, this means lower prices with buy orders, and in the lower one there are higher prices with sell orders.

```
#property indicator_separate_window
#property indicator_plots 2
#property indicator_buffers 2

#property indicator_type1   DRAW_HISTOGRAM
#property indicator_color1  clrDodgerBlue
#property indicator_width1  2
#property indicator_label1  "Buys"

#property indicator_type2   DRAW_HISTOGRAM
#property indicator_color2  clrOrangeRed
#property indicator_width2  2
#property indicator_label2  "Sells"

double buys[], sells[];
```

Let's provide an opportunity to visualize the order book in standard and extended modes (that is, skip or show levels with zero volumes), as well as display the volumes themselves in fractions of lots or units. Both options have analogs in the built-in Depth of Market window.

```
input bool AdvancedMode = false;
input bool ShowVolumeInLots = false;
```

Let's set buffers and obtaining of some symbol properties (which we will need later) in *OnInit*.

```
int depth, digits;
double tick, contract;

void OnInit()
{
   ...
   // setting indicator buffers
   SetIndexBuffer(0, buys);
   SetIndexBuffer(1, sells);
   ArraySetAsSeries(buys, true);
   ArraySetAsSeries(sells, true);
   // getting the necessary symbol properties
   depth = (int)PRTF(SymbolInfoInteger(_WorkSymbol, SYMBOL_TICKS_BOOKDEPTH));
   tick = SymbolInfoDouble(_WorkSymbol, SYMBOL_TRADE_TICK_SIZE);
   contract = SymbolInfoDouble(_WorkSymbol, SYMBOL_TRADE_CONTRACT_SIZE);
}
```

Let's add buffer filling to the handler *OnBookEvent* .

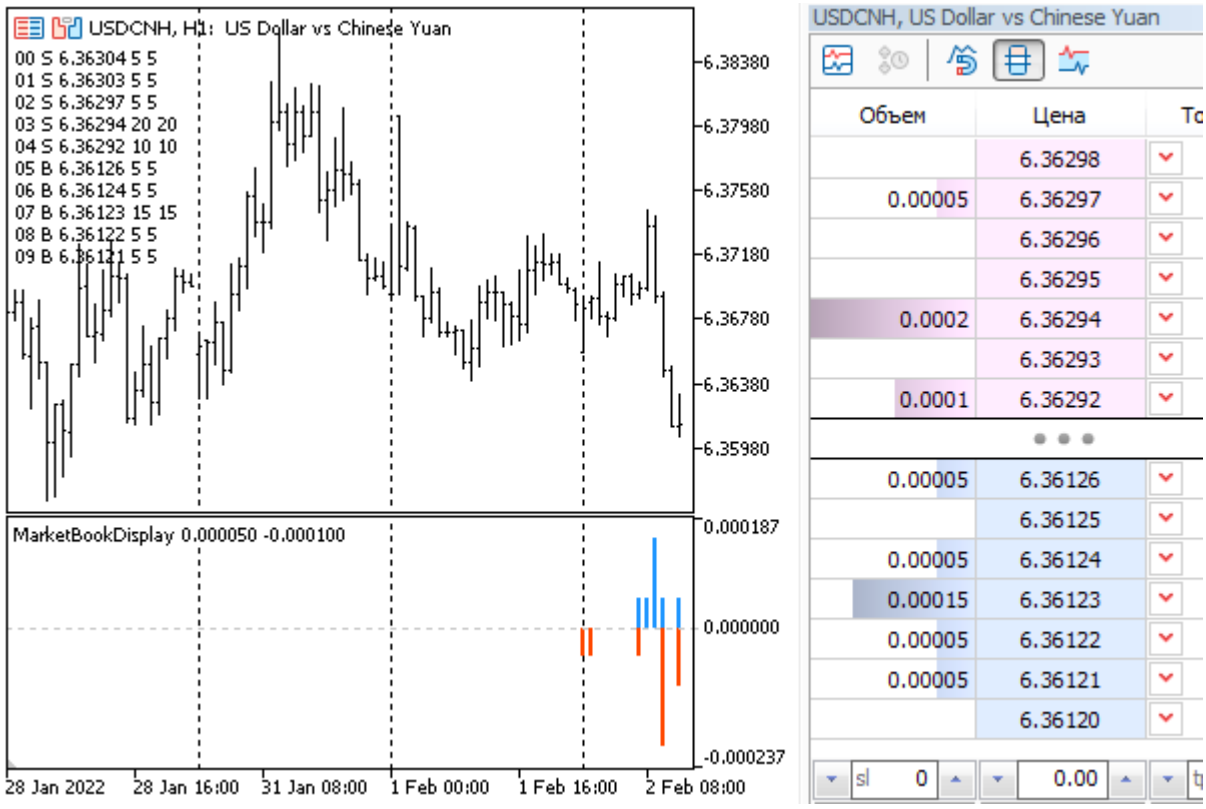
```
#define VOL(V) (ShowVolumeInLots ? V / contract : V)

void OnBookEvent(const string &symbol)
{
   if(symbol == _WorkSymbol) // take only order books of the requested symbol
   {
      MqlBookInfo mbi[];
      if(MarketBookGet(symbol, mbi)) // getting the current order book
      {
         // clear the buffers to the depth with 10 times the margin of the maximum de
         // because extended mode can have a lot of empty elements
         for(int i = 0; i <= depth * 10; ++i)
         {
            buys[i] = EMPTY_VALUE;
            sells[i] = EMPTY_VALUE;
         }
         ...// further along we form and display the comment as before
         if(!correct) return;

         // filling buffers with data
         if(AdvancedMode) // show skips enabled
         {
            for(int i = 0; i < ArraySize(mbi); ++i)
            {
               if(i < half)
               {
                  int x = (int)MathRound((mbi[i].price - mbi[half - 1].price) / tick)
                  sells[x] = -VOL(mbi[i].volume_real);
               }
               else
               {
                  int x = (int)MathRound((mbi[half].price - mbi[i].price) / tick);
                  buys[x] = VOL(mbi[i].volume_real);
               }
            }
         }
         else // standard mode: show only significant elements
         {
            for(int i = 0; i < ArraySize(mbi); ++i)
            {
               if(i < half)
               {
                  sells[half - i - 1] = -VOL(mbi[i].volume_real);
               }
               else
               {
                  buys[i - half] = VOL(mbi[i].volume_real);
               }
            }
         }
      }
```

```
      }
   }
```

The following image demonstrates how the indicator works with settings *AdvancedMode=true*, *ShowVolumeInLots=true*.



The contents of the order book in the MarketBookDisplay.mq5 indicator on the USDCNH chart

Buys are displayed as positive values (blue bar at the top), and sells are negative (red at the bottom). For clarity, there is a standard Depth of Market window on the right with the same settings (in advanced mode, volumes in lots), so you can make sure that the values match.

It should be noted that the indicator may not have time to redraw quickly enough to keep synchronization with the built-in order book. This does not mean that the MQL program did not receive the event in time, but only a side effect of asynchronous chart rendering. Working algorithms usually have analytical processing and order placing with the order book, rather than visualization.

In this case, updating the chart is implicitly requested at the time of calling the *Comment* function.

6.2.4 Using Depth of Market data in applied algorithms

The Depth of Market is considered to be a very useful technology for developing advanced trading systems. In particular, analysis of the distribution of Depth of Market volumes at levels close to the market allows you to find out in advance the average order execution price of a specific volume: simply sum up the volumes of the levels (in the opposite direction) that will ensure its filling. In a thin market, with insufficient volumes, the algorithm may refrain from opening a trade in order to avoid significant price slippage.

Based on the Depth of Market data, other strategies can also be constructed. For example, it can be important to know the price levels at which large volumes are located.

MarketBookVolumeAlert.mq5

In the next test indicator *MarketBookVolumeAlert.mq5*, we implement a simple algorithm for tracking volumes or their changes that exceed a given value.

```
#property indicator_chart_window
#property indicator_plots 0

input string WorkSymbol = ""; // WorkSymbol (if empty, use current chart symbol)
input bool CountVolumeInLots = false;
input double VolumeLimit = 0;

const string _WorkSymbol = StringLen(WorkSymbol) == 0 ? _Symbol : WorkSymbol;
```

There are no graphics in the indicator. The controlled symbol is entered in the *WorkSymbol* parameter (if left blank, the chart's working symbol is implied). The minimum threshold of tracked objects, that is, the sensitivity of the algorithm, is specified in the *VolumeLimit* parameter. Depending on the *CountVolumeInLots* parameter, the volumes are analyzed and displayed to the user in lots (*true*) or units (*false*). This also affects how the *VolumeLimit* value should be entered. The conversion from units to fractions of lots is provided by the VOL macro: the contract size used in it *contract* is initialized in *OnInit* (see below).

```
#define VOL(V) (CountVolumeInLots ? V / contract : V)
```

If large volumes are found above the threshold, the program will display a message about the corresponding level in the comment. To save the nearest history of warnings, we use the class of multi-line comments already known to us (*Comments.mqh*).

```
#define N_LINES 25                // number of lines in the comment buffer
#include <MQL5Book/Comments.mqh>
```

In the handler *OnInit* let's prepare the necessary settings and subscribe to the DOM events.

```
double contract;
int digits;

void OnInit()
{
   MarketBookAdd(_WorkSymbol);
   contract = SymbolInfoDouble(_WorkSymbol, SYMBOL_TRADE_CONTRACT_SIZE);
   digits = (int)MathRound(MathLog10(contract));
   Print(SymbolInfoDouble(_WorkSymbol, SYMBOL_SESSION_BUY_ORDERS_VOLUME));
   Print(SymbolInfoDouble(_WorkSymbol, SYMBOL_SESSION_SELL_ORDERS_VOLUME));
}
```

The SYMBOL_SESSION_BUY_ORDERS_VOLUME and SYMBOL_SESSION_SELL_ORDERS_VOLUME properties, if they are filled by your broker for the selected symbol, will help you figure out which threshold it makes sense to choose. By default, *VolumeLimit* is 0, which is why absolutely all changes in the order book will generate warnings. To filter out insignificant fluctuations, it is recommended to set *VolumeLimit* to a value that exceeds the average size of volumes at all levels (look in advance in the built-in order book or in the *MarketBookDisplay.mq5* indicator).

In the usual way, we implement the finalization.

```
void OnDeinit(const int)
{
   MarketBookRelease(_WorkSymbol);
   Comment("");
}
```

The main work is done by the *OnBookEvent* processor. It describes a static array *MqlBookInfo mbp* to store the previous version of the order book (since the last function call).

```
void OnBookEvent(const string &symbol)
{
   if(symbol != _WorkSymbol) return; // process only the requested symbol

   static MqlBookInfo mbp[];      // previous table/book
   MqlBookInfo mbi[];
   if(MarketBookGet(symbol, mbi)) // read the current book
   {
      if(ArraySize(mbp) == 0) // first time we just save, because nothing to compare
      {
         ArrayCopy(mbp, mbi);
         return;
      }
      ...
```

If there is an old and a new order book, we compare the volumes at their levels with each other in nested loops by *i* and *j*. Recall that an increase in the index means a decrease in price.

```
int j = 0;
for(int i = 0; i < ArraySize(mbi); ++i)
{
   bool found = false;
   for( ; j < ArraySize(mbp); ++j)
   {
      if(MathAbs(mbp[j].price - mbi[i].price) < DBL_EPSILON * mbi[i].price)
      {       // mbp[j].price == mbi[i].price
         if(VOL(mbi[i].volume_real - mbp[j].volume_real) >= VolumeLimit)
         {
            NotifyVolumeChange("Enlarged", mbp[j].price,
               VOL(mbp[j].volume_real), VOL(mbi[i].volume_real));
         }
         else
         if(VOL(mbp[j].volume_real - mbi[i].volume_real) >= VolumeLimit)
         {
            NotifyVolumeChange("Reduced", mbp[j].price,
               VOL(mbp[j].volume_real), VOL(mbi[i].volume_real));
         }
         found = true;
         ++j;
         break;
      }
      else if(mbp[j].price > mbi[i].price)
      {
         if(VOL(mbp[j].volume_real) >= VolumeLimit)
         {
            NotifyVolumeChange("Removed", mbp[j].price,
               VOL(mbp[j].volume_real), 0.0);
         }
         // continue the loop increasing ++j to lower prices
      }
      else // mbp[j].price < mbi[i].price
      {
         break;
      }
   }
   if(!found) // unique (new) price
   {
      if(VOL(mbi[i].volume_real) >= VolumeLimit)
      {
         NotifyVolumeChange("Added", mbi[i].price, 0.0, VOL(mbi[i].volume_real)
      }
   }
}
...
```

Here, the emphasis is not on the type of level, but on the volume value only. However, if you wish, you can easily add the designation of buys or sells to notifications, depending on the *type* field of that level where the important change took place.

Finally, we save a new copy of *mbi* in a static array *mbp* to compare against it on the next function call.

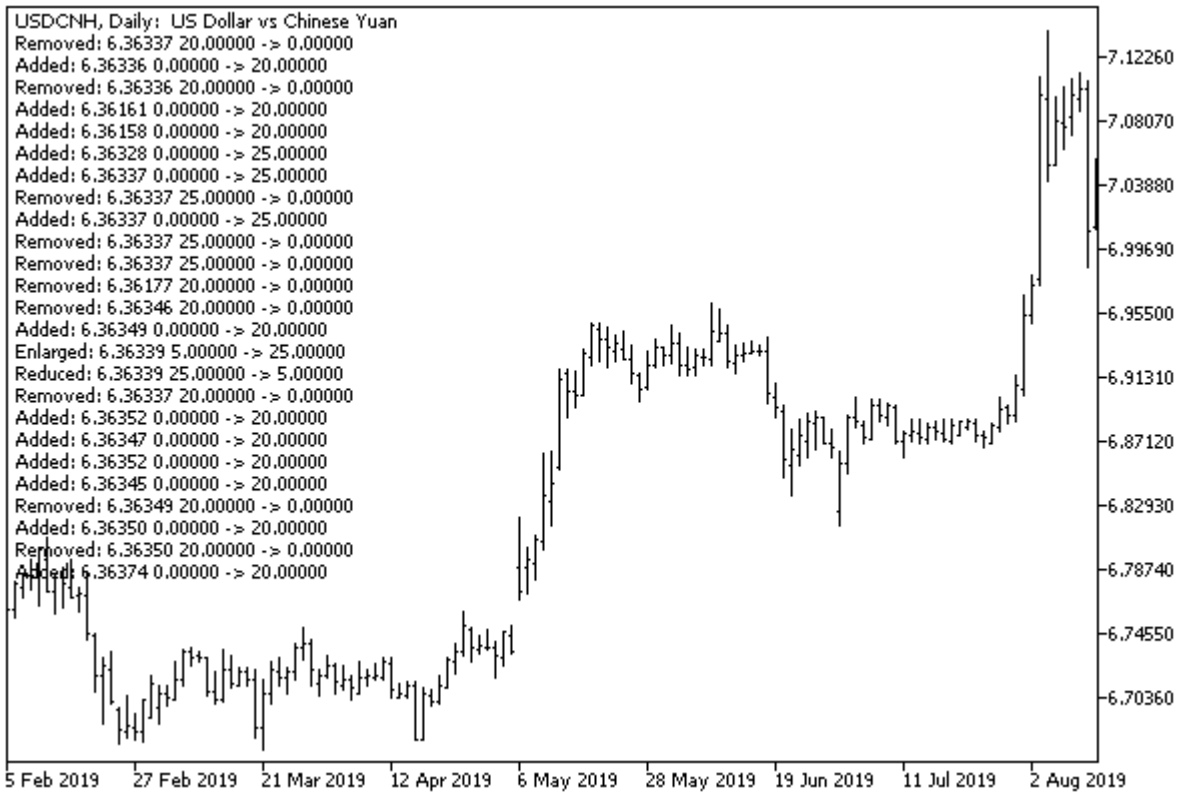
```
      if(ArrayCopy(mbp, mbi) <= 0)
      {
         Print("ArrayCopy failed:", _LastError);
      }
      if(ArrayResize(mbp, ArraySize(mbi)) <= 0) // shrink if needed
      {
         Print("ArrayResize failed:", _LastError);
      }
   }
}
```

ArrayCopy does not automatically shrink a dynamic destination array if it happens to be larger than the source array, so we explicitly set its exact size with *ArrayResize*.

An auxiliary function *NotifyVolumeChange* simply adds information about the found change to the comment.

```
void NotifyVolumeChange(const string action, const double price,
   const double previous, const double volume)
{
   const string message = StringFormat("%s: %s %s -> %s",
      action,
      DoubleToString(price, (int)SymbolInfoInteger(_WorkSymbol, SYMBOL_DIGITS)),
      DoubleToString(previous, digits),
      DoubleToString(volume, digits));
   ChronoComment(message);
}
```

The following image shows the result of the indicator for settings *CountVolumeInLots=false*, *VolumeLimit=20*.



Notifications about volume changes in the order book

MarketBookQuasiTicks.mq5

As a second example of the possible use of the order book, let's turn to the problem of obtaining multicurrency ticks. We have already touched on it in the section Generation of custom events, where we have seen one of the possible solutions and the indicator *EventTickSpy.mq5*. Now, after getting acquainted with the Depth of Market API, we can implement an alternative.

Let's create an indicator *MarketBookQuasiTicks.mq5*, which will subscribe to order books of a given list of instruments and find the prices of the best offer and demand in them, that is, pairs of prices around the spread, which are just prices *Ask* and *Bid*.

Of course, this information is not a complete equivalent of standard ticks (recall that trade/tick and order book flows can come from completely different providers), but it provides an adequate and timely view of the market.

New values of prices by symbols will be displayed in a multi-line comment.

The list of working symbols is specified in the *SymbolList* input parameter as a comma-separated list. Enabling and disabling subscriptions to Depth of Market events is done in the *OnInit* and *OnDeinit* handlers.

```
#define N_LINES 25                 // number of lines in the comment buffer
#include <MQL5Book/Comments.mqh>

input string SymbolList = "EURUSD,GBPUSD,XAUUSD,USDJPY"; // SymbolList (comma,separat

const string WorkSymbols = StringLen(SymbolList) == 0 ? _Symbol : SymbolList;
string symbols[];

void OnInit()
{
   const int n = StringSplit(WorkSymbols, ',', symbols);
   for(int i = 0; i < n; ++i)
   {
      if(!MarketBookAdd(symbols[i]))
      {
         PrintFormat("MarketBookAdd(%s) failed with code %d", symbols[i], _LastError)
      }
   }
}

void OnDeinit(const int)
{
   for(int i = 0; i < ArraySize(symbols); ++i)
   {
      if(!MarketBookRelease(symbols[i]))
      {
         PrintFormat("MarketBookRelease(%s) failed with code %d", symbols[i], _LastEr
      }
   }
   Comment("");
}
```

The analysis of each new order book is carried out in *OnBookEvent*.

```
void OnBookEvent(const string &symbol)
{
   MqlBookInfo mbi[];
   if(MarketBookGet(symbol, mbi)) // getting the current order book
   {
      int half = ArraySize(mbi) / 2; // estimate the middle of the order book
      bool correct = true;
      for(int i = 0; i < ArraySize(mbi); ++i)
      {
         if(i > 0)
         {
            if(mbi[i - 1].type == BOOK_TYPE_SELL
               && mbi[i].type == BOOK_TYPE_BUY)
            {
               half = i; // specify the middle of the order book
            }

            if(mbi[i - 1].price <= mbi[i].price)
            {
               correct = false;
            }
         }
      }

      if(correct) // retrieve the best Bid/Ask prices from the correct order book
      {
         // mbi[half - 1].price // Ask
         // mbi[half].price     // Bid
         OnSymbolTick(symbol, mbi[half].price);
      }
   }
}
```

Found market *Ask/Bid* prices are passed to helper function *OnSymbolTick* to be displayed in a comment.

```
void OnSymbolTick(const string &symbol, const double price)
{
   const string message = StringFormat("%s %s",
      symbol, DoubleToString(price, (int)SymbolInfoInteger(symbol, SYMBOL_DIGITS)));
   ChronoComment(message);
}
```

If you wish, you can make sure that our synthesized ticks do not differ much from the standard ticks.

This is how information about incoming quasi-ticks looks on the chart.

Multi-symbol quasi-ticks based on order book events

At the same time, it should be noted once again that order book events are available on the platform online only, but not in the tester. If the trading system is built exclusively on quasi-ticks from the order book, its testing will require the use of third-party solutions that ensure the collection and playback of order books in the tester.

6.3 Trading account information

In this chapter, we will study the last important aspect of the trading environment of MQL programs and, specifically, Expert Advisors, which we will develop in detail in the next few chapters. Let's talk about a trading account.

Having a valid account and an active connection to it are a necessary condition for the functioning of most MQL programs. Until now, we have not focused on this, but getting quotes, ticks, and, in general, the ability to open a workable chart implies a successful connection to a trading account.

In the context of Expert Advisors, an account additionally reflects the financial condition of the client, accumulates the trading history and determines the specific modes allowed for trading.

The MQL5 API allows you to get the properties of an account, starting with its number and ending with the current profit. All of them are read-only in the terminal and are installed by the broker on the server.

The terminal can only be connected to one account at a time. All MQL programs work with this account. As we have already noted in the section Features of starting and stopping programs of various types, switching an account initiates a reload of the indicators and Expert Advisors attached to the charts. However, in the *OnDeinit* handler, the program can find the reason for deinitialization, which, when switching the account, will be equal to REASON_ACCOUNT.

6.3.1 Overview of functions for getting account properties

The full set of account properties is logically divided into three groups depending on their type. String properties are summarized in the ENUM_ACCOUNT_INFO_STRING enumeration and are queried by the *AccountInfoString* function. Real-type properties are combined in the ENUM_ACCOUNT_INFO_DOUBLE enumeration, and the function that works for them is *AccountInfoDouble*. The ENUM_ACCOUNT_INFO_INTEGER enumeration used in the *AccountInfoInteger* function contains identifiers of integer and boolean properties (flags), as well as several applied ENUM_ACCOUNT_INFO enumerations.

double AccountInfoDouble(ENUM_ACCOUNT_INFO_DOUBLE property)
long AccountInfoInteger(ENUM_ACCOUNT_INFO_INTEGER property)
string AccountInfoString(ENUM_ACCOUNT_INFO_STRING property)

We have created the *AccountMonitor* class (*AccountMonitor.mqh*) to simplify the reading of properties. By overloading *get* methods, the class provides the automatic call of the required API function depending on the element of a specific enumeration passed in the parameter.

```
class AccountMonitor
{
public:
   long get(const ENUM_ACCOUNT_INFO_INTEGER property) const
   {
      return AccountInfoInteger(property);
   }

   double get(const ENUM_ACCOUNT_INFO_DOUBLE property) const
   {
      return AccountInfoDouble(property);
   }

   string get(const ENUM_ACCOUNT_INFO_STRING property) const
   {
      return AccountInfoString(property);
   }

   long get(const int property, const long) const
   {
      return AccountInfoInteger((ENUM_ACCOUNT_INFO_INTEGER)property);
   }

   double get(const int property, const double) const
   {
      return AccountInfoDouble((ENUM_ACCOUNT_INFO_DOUBLE)property);
   }

   string get(const int property, const string) const
   {
      return AccountInfoString((ENUM_ACCOUNT_INFO_STRING)property);
   }
   ...
```

In addition, it has several overloads of the *stringify* method, which form a user-friendly string representation of property values (in particular, it is useful for applied enumerations, which would otherwise be displayed as uninformative numbers). The features of each property will be discussed in the following sections.

```
static string boolean(const long v)
{
   return v ? "true" : "false";
}

template<typename E>
static string enumstr(const long v)
{
   return EnumToString((E)v);
}

// "decode" properties according to subtype inside integer values
static string stringify(const long v, const ENUM_ACCOUNT_INFO_INTEGER property)
{
   switch(property)
   {
      case ACCOUNT_TRADE_ALLOWED:
      case ACCOUNT_TRADE_EXPERT:
      case ACCOUNT_FIFO_CLOSE:
         return boolean(v);
      case ACCOUNT_TRADE_MODE:
         return enumstr<ENUM_ACCOUNT_TRADE_MODE>(v);
      case ACCOUNT_MARGIN_MODE:
         return enumstr<ENUM_ACCOUNT_MARGIN_MODE>(v);
      case ACCOUNT_MARGIN_SO_MODE:
         return enumstr<ENUM_ACCOUNT_STOPOUT_MODE>(v);
   }

   return (string)v;
}

string stringify(const ENUM_ACCOUNT_INFO_INTEGER property) const
{
   return stringify(AccountInfoInteger(property), property);
}

string stringify(const ENUM_ACCOUNT_INFO_DOUBLE property, const string format = NU
{
   if(format == NULL) return DoubleToString(AccountInfoDouble(property),
      (int)get(ACCOUNT_CURRENCY_DIGITS));
   return StringFormat(format, AccountInfoDouble(property));
}

string stringify(const ENUM_ACCOUNT_INFO_STRING property) const
{
   return AccountInfoString(property);
}
...
```

Finally, there is a template method *list2log* that allows getting comprehensive information about the account.

```
   // list of names and values of all properties of enum type E
   template<typename E>
   void list2log()
   {
      E e = (E)0; // suppress warning 'possible use of uninitialized variable'
      int array[];
      const int n = EnumToArray(e, array, 0, USHORT_MAX);
      Print(typename(E), " Count=", n);
      for(int i = 0; i < n; ++i)
      {
         e = (E)array[i];
         PrintFormat("% 3d %s=%s", i, EnumToString(e), stringify(e));
      }
   }
};
```

We'll test the new class in action in the next section.

6.3.2 Identifying the account, client, server, and broker

Perhaps the most important properties of an account are its number and identification data: the name of the server and the broker's company, as well as the name of the client. All of these properties, except for the number, are string properties.

Identifier	Description
ACCOUNT_LOGIN	Account number (long)
ACCOUNT_NAME	Client name
ACCOUNT_SERVER	Trade server name
ACCOUNT_COMPANY	Name of the company servicing the account

Let's use the *AccountMonitor* class from the previous section to log these and many other properties that will be discussed in a moment. Let's create the corresponding object and call its properties in the script *AccountInfo.mq5*.

```
#include <MQL5Book/AccountMonitor.mqh>

void OnStart()
{
   AccountMonitor m;
   m.list2log<ENUM_ACCOUNT_INFO_INTEGER>();
   m.list2log<ENUM_ACCOUNT_INFO_DOUBLE>();
   m.list2log<ENUM_ACCOUNT_INFO_STRING>();
}
```

Here is an example of a possible result of the script.

```
ENUM_ACCOUNT_INFO_INTEGER Count=10
  0 ACCOUNT_LOGIN=30000003
  1 ACCOUNT_TRADE_MODE=ACCOUNT_TRADE_MODE_DEMO
  2 ACCOUNT_TRADE_ALLOWED=true
  3 ACCOUNT_TRADE_EXPERT=true
  4 ACCOUNT_LEVERAGE=100
  5 ACCOUNT_MARGIN_SO_MODE=ACCOUNT_STOPOUT_MODE_PERCENT
  6 ACCOUNT_LIMIT_ORDERS=200
  7 ACCOUNT_MARGIN_MODE=ACCOUNT_MARGIN_MODE_RETAIL_HEDGING
  8 ACCOUNT_CURRENCY_DIGITS=2
  9 ACCOUNT_FIFO_CLOSE=false
ENUM_ACCOUNT_INFO_DOUBLE Count=14
  0 ACCOUNT_BALANCE=10000.00
  1 ACCOUNT_CREDIT=0.00
  2 ACCOUNT_PROFIT=-78.76
  3 ACCOUNT_EQUITY=9921.24
  4 ACCOUNT_MARGIN=1000.00
  5 ACCOUNT_MARGIN_FREE=8921.24
  6 ACCOUNT_MARGIN_LEVEL=992.12
  7 ACCOUNT_MARGIN_SO_CALL=50.00
  8 ACCOUNT_MARGIN_SO_SO=30.00
  9 ACCOUNT_MARGIN_INITIAL=0.00
 10 ACCOUNT_MARGIN_MAINTENANCE=0.00
 11 ACCOUNT_ASSETS=0.00
 12 ACCOUNT_LIABILITIES=0.00
 13 ACCOUNT_COMMISSION_BLOCKED=0.00
ENUM_ACCOUNT_INFO_STRING Count=4
  0 ACCOUNT_NAME=Vincent Silver
  1 ACCOUNT_COMPANY=MetaQuotes Software Corp.
  2 ACCOUNT_SERVER=MetaQuotes-Demo
  3 ACCOUNT_CURRENCY=USD
```

Pay attention to the properties of this section (ACCOUNT_LOGIN, ACCOUNT_NAME, ACCOUNT_COMPANY, ACCOUNT_SERVER). In this case, the script was executed on the account of the demo server "MetaQuotes-Demo". Obviously, this should be a demo account, and this is indicated not only by the name of the server but also by another property, ACCOUNT_TRADE_MODE, which will be discussed in the next section.

Account identifiers are usually used to link MQL programs to a specific trading environment. An example of such an algorithm was presented in the Services section.

6.3.3 Account type: real, demo or contest

MetaTrader 5 supports several types of accounts that can be opened for a client. The ACCOUNT_TRADE_MODE property, which is part of ENUM_ACCOUNT_INFO_INTEGER, allows you to find out the current account type. Possible values for this property are described in the ENUM_ACCOUNT_TRADE_MODE enumeration.

Identifier	Description
ACCOUNT_TRADE_MODE_DEMO	Demo trading account
ACCOUNT_TRADE_MODE_CONTEST	Contest trading account
ACCOUNT_TRADE_MODE_REAL	Real trading account

This property is convenient for building demo (free) versions of MQL programs. A full-featured, paid version may require linking to an account number, and the account must be real.

As we saw in the example of running the script *AccountInfo.mq5* in the previous section, the account on the "MetaQuotes-Demo" server is of the ACCOUNT_TRADE_MODE_DEMO type.

6.3.4 Account currency

Balance, profit, margin, commissions, and other financial indicators are always converted to the account currency in the end, even if the specifications for some trades require settlement in other currencies, for example, in the margin currency of a Forex pair.

The MQL5 API provides two properties that describe the account currency: its name and the accuracy of the representation, that is, the size of the minimum unit of measurement (such as cents).

Identifier	Description
ACCOUNT_CURRENCY	Deposit currency (string)
ACCOUNT_CURRENCY_DIGITS	Number of decimal places for account currency required for the accurate display of trading results (integer)

For example, for the demo account used to test the *AccountInfo* script in the section on Account identification, the ACCOUNT_CURRENCY property was "USD", and the accuracy of ACCOUNT_CURRENCY_DIGITS was 2 decimal places. We have used the ACCOUNT_CURRENCY_DIGITS property in the *AccountMonitor* class in the *stringify* method for values of type *double* (in the characteristics of the account, they are all associated with money).

6.3.5 Account type: netting or hedging

MetaTrader 5 supports several types of accounts, in particular, netting and hedging. For netting, it is allowed to have only one position for each symbol. For hedging, you can open several positions for a symbol, including multidirectional ones. Orders, trades, and positions will be discussed in detail in the following chapters.

An MQL program determines the account type by querying the ACCOUNT_MARGIN_MODE property using the *AccountInfoInteger* function. As you can understand from the name of the property, it describes not only the account type but also the margin calculation mode. Its possible values are specified in the ENUM_ACCOUNT_MARGIN_MODE enumeration.

Identifier	Description
ACCOUNT_MARGIN_MODE_RETAIL_NETTING	OTC market, considering positions in the netting mode. Margin calculation is based on the SYMBOL_TRADE_CALC_MODE property.
ACCOUNT_MARGIN_MODE_EXCHANGE	Exchange market, considering positions in the netting mode. The margin is calculated based on the rules of the exchange with the possibility of discounts specified by the broker in the instrument settings.
ACCOUNT_MARGIN_MODE_RETAIL_HEDGING	OTC market with independent consideration of positions in the hedging mode. Margin calculation is based on the SYMBOL_TRADE_CALC_MODE symbol property while considering the size of the hedged margin SYMBOL_MARGIN_HEDGED.

For example, running the *AccountInfo* script in the section Account identification showed that the account is of type ACCOUNT_MARGIN_MODE_RETAIL_HEDGING.

6.3.6 Restrictions and permissions for account operations

Among the properties of the account, there are restrictions on trading operations, including completely disabled trading. All of these properties belong to the ENUM_ACCOUNT_INFO_INTEGER enumeration and are boolean flags, except ACCOUNT_LIMIT_ORDERS.

Identifier	Description
ACCOUNT_TRADE_ALLOWED	Permission to trade on a current account
ACCOUNT_TRADE_EXPERT	Permission for algorithmic trading using Expert Advisors and scripts
ACCOUNT_LIMIT_ORDERS	Maximum allowed number of valid pending orders
ACCOUNT_FIFO_CLOSE	Requirement to close positions only according to the FIFO rule

Since our book is about MQL5 programming, which includes algorithmic trading, it should be noted that the disabled ACCOUNT_TRADE_EXPERT permission is just as critical as the general prohibition to trade when ACCOUNT_TRADE_ALLOWED is equal to *false*. The broker has the ability to prohibit trading using Expert Advisors and scripts while allowing manual trading.

The ACCOUNT_TRADE_ALLOWED property is usually equal to *false* if the connection to the account was made using the investment password.

If the value of the ACCOUNT_FIFO_CLOSE property is *true*, positions for each symbol can only be closed in the same order in which they were opened, that is, first you close the oldest order, then the newer one, and so on until the last one. If you try to close positions in a different order, you will receive an error. For accounts without position hedging, that is, if the ACCOUNT_MARGIN_MODE property is not equal to ACCOUNT_MARGIN_MODE_RETAIL_HEDGING, the ACCOUNT_FIFO_CLOSE property is always *false*.

In the Permissions and Schedules of trading and quoting sessions sections, we have already started developing a class for detecting trade operations available to the MQL program. Now we can supplement it with account permission checks and bring it to the final version (*Permissions.mqh*).

Restriction levels are provided in the TRADE_RESTRICTIONS enumeration, which, after adding two new elements related to account properties, takes the following form.

```
class Permissions
{
   enum TRADE_RESTRICTIONS
   {
      NO_RESTRICTIONS = 0,
      TERMINAL_RESTRICTION = 1, // user's restriction for all programs
      PROGRAM_RESTRICTION = 2,  // user's restriction for a specific program
      SYMBOL_RESTRICTION = 4,   // the symbol is not traded according to the specific
      SESSION_RESTRICTION = 8,  // the market is closed according to the session sche
      ACCOUNT_RESTRICTION = 16, // investor password or broker restriction
      EXPERTS_RESTRICTION = 32, // broker restricted algorithmic trading
   };
   ...
```

During the check, the MQL program may detect several restrictions for various reasons, and therefore the elements are encoded by separate bits. The final result can represent their superposition.

The last two restrictions just correspond to the new properties and are set in the *getTradeRestrictionsOnAccount* method. The general bitmask of detected restrictions (if any) is formed in the *lastRestrictionBitMask* variable.

```
private:
   static uint lastRestrictionBitMask;
   static bool pass(const uint bitflag)
   {
      lastRestrictionBitMask |= bitflag;
      return lastRestrictionBitMask == 0;
   }

public:
   static uint getTradeRestrictionsOnAccount()
   {
      return (AccountInfoInteger(ACCOUNT_TRADE_ALLOWED) ? 0 : ACCOUNT_RESTRICTION)
         | (AccountInfoInteger(ACCOUNT_TRADE_EXPERT) ? 0 : EXPERTS_RESTRICTION);
   }

   static bool isTradeOnAccountEnabled()
   {
      lastRestrictionBitMask = 0;
      return pass(getTradeRestrictionsOnAccount());
   }
   ...
```

If the calling code is not interested in the reason for restriction but only needs to determine the possibility of performing trading operations, it is more convenient to use the *isTradeOnAccountEnabled* method which returns a boolean sign (*true/false*).

Checks of symbol and terminal properties have been reorganized according to a similar principle. For example, the *getTradeRestrictionsOnSymbol* method contains the source code already familiar from the previous version of the class (checking the symbol's trading sessions and trading modes) but returns a flags mask. If at least one bit is set, it describes the source of the restriction.

```
static uint getTradeRestrictionsOnSymbol(const string symbol, datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   if(now == 0) now = TimeTradeServer();
   bool found = false;
   // checking the symbol trading sessions and setting 'found' to 'true',
   // if the 'now' time is inside one of the sessions
   ...

   // in addition to sessions, check the trading mode
   const ENUM_SYMBOL_TRADE_MODE m = (ENUM_SYMBOL_TRADE_MODE)SymbolInfoInteger(symb
   return (found ? 0 : SESSION_RESTRICTION)
      | (((m & mode) != 0) || (m == SYMBOL_TRADE_MODE_FULL) ? 0 : SYMBOL_RESTRICTI
}

static bool isTradeOnSymbolEnabled(const string symbol, const datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   lastRestrictionBitMask = 0;
   return pass(getTradeRestrictionsOnSymbol(symbol, now, mode));
}
...
```

Finally, a general check of all potential "instances", including (in addition to the previous levels) the settings of the terminal and the program, is performed in the *getTradeRestrictions* and *isTradeEnabled* methods.

```
static uint getTradeRestrictions(const string symbol = NULL, const datetime now =
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   return (TerminalInfoInteger(TERMINAL_TRADE_ALLOWED) ? 0 : TERMINAL_RESTRICTION)
       | (MQLInfoInteger(MQL_TRADE_ALLOWED) ? 0 : PROGRAM_RESTRICTION)
       | getTradeRestrictionsOnSymbol(symbol == NULL ? _Symbol : symbol, now, mode
       | getTradeRestrictionsOnAccount();
}

static bool isTradeEnabled(const string symbol = NULL, const datetime now = 0,
   const ENUM_SYMBOL_TRADE_MODE mode = SYMBOL_TRADE_MODE_FULL)
{
   lastRestrictionBitMask = 0;
   return pass(getTradeRestrictions(symbol, now, mode));
}
```

A comprehensive check of trade permissions with a new class is demonstrated by the script *AccountPermissions.mq5*.

```
#include <MQL5Book/Permissions.mqh>

void OnStart()
{
   PrintFormat("Run on %s", _Symbol);
   if(!Permissions::isTradeEnabled()) // checking for current character, default
   {
      Print("Trade is disabled for the following reasons:");
      Print(Permissions::explainLastRestrictionBitMask());
   }
   else
   {
      Print("Trade is enabled");
   }
}
```

If restrictions are found, their bit mask can be displayed in a clear string representation using the *explainLastRestrictionBitMask* method.

Here are some script results. In the first two cases, trading was disabled in the global settings of the terminal (properties TERMINAL_TRADE_ALLOWED and MQL_TRADE_ALLOWED were equal to *false*, which corresponds to the TERMINAL_RESTRICTION and PROGRAM_RESTRICTION bits).

When run on USDRUB during the hours when the market is closed, we will additionally receive SESSION_RESTRICTION:

```
Trade is disabled for USDRUB following reasons:
TERMINAL_RESTRICTION PROGRAM_RESTRICTION SESSION_RESTRICTION
```

For the symbol SP500m, for which trading is totally disabled, the SYMBOL_RESTRICTION flag appears.

```
Trade is disabled for SP500m following reasons:
TERMINAL_RESTRICTION PROGRAM_RESTRICTION SYMBOL_RESTRICTION SESSION_RESTRICTION
```

Finally, having allowed trading in the terminal but having logged into the account under the investor's password, we will see ACCOUNT_RESTRICTION on any symbol.

```
Run on XAUUSD
Trade is disabled for following reasons:
ACCOUNT_RESTRICTION
```

Early check of permissions in the MQL program helps avoid serial unsuccessful attempts to send trading orders.

6.3.7 Account margin settings

For trading robots, it is important to control the amount of margin blocked and the amount available to secure new trades. In particular, if there are not enough free funds, the program will not be able to execute a trade. When maintaining open unprofitable positions, first a Margin Call is received, and if it is not fulfilled, the positions are forcedly closed by the broker (Stop Out). All associated account properties are included in the ENUM_ACCOUNT_INFO_DOUBLE enumeration.

Identifier	Description
ACCOUNT_MARGIN	Current reserved margin on the account in the deposit currency
ACCOUNT_MARGIN_FREE	Current free margin on the account in the deposit currency, available for opening a position
ACCOUNT_MARGIN_LEVEL	Margin level on the account in percent (equity/margin*100)
ACCOUNT_MARGIN_SO_CALL	The minimum margin level at which account replenishment will be required (Margin Call)
ACCOUNT_MARGIN_SO_SO	The minimum margin level at which the most unprofitable position will be forced to close (Stop Out)
ACCOUNT_MARGIN_INITIAL	Funds reserved on the account to provide margin for all pending orders
ACCOUNT_MARGIN_MAINTENANCE	Funds reserved on the account to provide the minimum required margin for all open positions

ACCOUNT_MARGIN_SO_CALL and ACCOUNT_MARGIN_SO_SO are expressed as a percentage or deposit currency depending on the set ACCOUNT_MARGIN_SO_MODE (see further). This property, with the possibility to measure margin thresholds for the Margin Call or Stop Out, is included in the ENUM_ACCOUNT_INFO_INTEGER enumeration. In addition, the total leverage (used to calculate the margin for certain types of instruments) is also indicated there.

Identifier	Description
ACCOUNT_LEVERAGE	The leverage amount
ACCOUNT_MARGIN_SO_MODE	The mode for setting the minimum allowable margin level from the ENUM_ACCOUNT_STOPOUT_MODE enumeration

And here are the elements of the ENUM_ACCOUNT_STOPOUT_MODE enumeration.

Identifier	Description
ACCOUNT_STOPOUT_MODE_PERCENT	The level is set as a percentage
ACCOUNT_STOPOUT_MODE_MONEY	The level is set in the account currency

For example, for the ACCOUNT_STOPOUT_MODE_PERCENT option, the specified percentage (Margin Call or Stop Out) should be checked against the ratio of equity to the value of the ACCOUNT_MARGIN property:

```
AccountInfoDouble(ACCOUNT_EQUITY) / AccountInfoDouble(ACCOUNT_MARGIN) * 100
   > AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL)
```

In the next section, you will find more details about the ACCOUNT_EQUITY property and other financial indicators of the account.

However, the current margin level in percent is already provided in the ACCOUNT_MARGIN_LEVEL property. This is easy to check using the *AccountInfo.mq5* script which logs all account properties, including those listed above.

We have already run this script in the section Account identification. At that moment, one position was opened (1 lot USDRUB, equal to 100,000 USD), and the financials were as follows:

```
0 ACCOUNT_BALANCE=10000.00
1 ACCOUNT_CREDIT=0.00
2 ACCOUNT_PROFIT=-78.76
3 ACCOUNT_EQUITY=9921.24
4 ACCOUNT_MARGIN=1000.00
5 ACCOUNT_MARGIN_FREE=8921.24
6 ACCOUNT_MARGIN_LEVEL=992.12
7 ACCOUNT_MARGIN_SO_CALL=50.00
8 ACCOUNT_MARGIN_SO_SO=30.00
```

With a margin of 1000.00 USD, it is easy to check that the leverage of the account, ACCOUNT_LEVERAGE, is indeed 100 (according to the formula for calculating margin for Forex and margin ratio which is equal to 1.0). The margin amount does not need to be converted at the current rate into the account currency, since it is the same as the base currency of the instrument.

To get 992.12 in ACCOUNT_MARGIN_LEVEL, just divide 9921.24 by 1000.00 and multiply by 100%.

Then another 1 lot position was opened, and the quotes went in an unfavorable direction, as a result of which the situation changed:

```
0 ACCOUNT_BALANCE=10000.00
1 ACCOUNT_CREDIT=0.00
2 ACCOUNT_PROFIT=-1486.07
3 ACCOUNT_EQUITY=8513.93
4 ACCOUNT_MARGIN=2000.00
5 ACCOUNT_MARGIN_FREE=6513.93
6 ACCOUNT_MARGIN_LEVEL=425.70
```

We can see a loss in the ACCOUNT_PROFIT column and a corresponding decrease in equity ACCOUNT_EQUITY. The margin ACCOUNT_MARGIN increased proportionally from 1000 to 2000, free margin and margin level decreased (but still far from the 50% and 30% limits). Again, the level 425.70 is obtained as the result of calculating the expression 8513.93 / 2000.00 * 100.

It is more practical to use this formula to calculate the future margin level before opening a new position. In this case, it is necessary to increase the amount of the existing margin by the additional margin of *X*. In addition, if a market entry deal involves an instant commission deduction *C*, then, strictly speaking, it should also be taken into account (although usually it has a size significantly less than the margin and it can be neglected, plus the API does not provide a way to find out the commission in advance, before performing a trade: it can only be estimated by the commissions of already completed trades in trading history).

```
(AccountInfoDouble(ACCOUNT_EQUITY) - C) / (AccountInfoDouble(ACCOUNT_MARGIN) + X) * 1
   > AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL)
```

Later we will learn how to obtain the *X* value using the *OrderCalcMargin* function, but in addition to it, adjustments may be required according to the rules announced in the Margin Requirements section, in particular, taking into account the possible position hedging, discounts, and margin adjustments.

For the option of setting the margin limit in money (ACCOUNT_STOPOUT_MODE_MONEY), the check for sufficient funds must be different.

```
AccountInfoDouble(ACCOUNT_EQUITY) > AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL)
```

Here the commission is omitted. Please note that the margin *X* for a new position being prepared for opening 'now' does not affect the assessment of the 'future' margin in any way.

However, in any case, it is desirable not to load the deposit so much that the inequalities are barely fulfilled. The values of ACCOUNT_MARGIN_SO_CALL and ACCOUNT_MARGIN_SO_SO are quite close, and although the margin at the ACCOUNT_MARGIN_SO_CALL level is just a warning to the trader, it is easy to get a forced closing. That is why the formulas use the ACCOUNT_MARGIN_SO_CALL property.

6.3.8 Current financial performance of the account

The MQL5 API allows control over several account properties via its main financial indicators. They are all included in the ENUM_ACCOUNT_INFO_DOUBLE enumeration.

Identifier	Description
ACCOUNT_BALANCE	Account balance in the deposit currency
ACCOUNT_PROFIT	The amount of current profit on the account in the deposit currency
ACCOUNT_EQUITY	Account equity in the deposit currency
ACCOUNT_CREDIT	The amount of the credit provided by the broker in the deposit currency
ACCOUNT_ASSETS	Current amount of assets on the account
ACCOUNT_LIABILITIES	Current amount of liabilities on the account
ACCOUNT_COMMISSION_BLOCKED	The current amount of blocked commissions on the account

In the previous sections, we saw examples of the values of these properties when running the *AccountInfo.mq5* script under different conditions. Try to compare these properties for your different accounts.

In the trading process, we will be primarily interested in the first three properties: balance, profit (or loss if the value is negative), and equity, which together cover the account balance, credit, profit, and overhead costs (swap and commission).

Commissions can be considered in different ways, depending on the broker's settings. If commissions are immediately deducted from the account balance at the time of trades and are reflected in the deal properties, the account property ACCOUNT_COMMISSION_BLOCKED will be equal to 0. However, if the commission calculation is postponed until the end of the period (for example, a day or a month), the amount blocked for the commission will appear in this property. Then, when the final commission amount is determined and deducted from the balance at the end of the period, the property will be reset.

The properties ACCOUNT_ASSETS and ACCOUNT_LIABILITIES are filled, as a rule, only for exchange trading. They reflect the current value of long and short positions in securities.

6.4 Creating Expert Advisors

In this chapter, we begin to study the MQL5 trading API used to implement Expert Advisors. This type of program is perhaps the most complex and demanding in terms of error-free coding and the number and variety of technologies involved. In particular, we will need to utilize many of the skills acquired from the previous chapters, ranging from OOP to the applied aspects of working with graphical objects, indicators, symbols, and software environment settings.

Depending on the chosen trading strategy, the Expert Advisor developer may need to pay special attention to the following:

- Decision-making and order-sending speed (for HFT, High-Frequency Trading)
- Selecting the optimal portfolio of instruments based on their correlations and volatility (for cluster trading)
- Dynamically calculating lots and distance between orders (for martingale and grid strategies)
- Analysis of news or external data sources (this will be discussed in the 7th part of the book)

All such features should be optimally applied by the developer to the described trading mechanisms provided by the MQL5 API.

Next, we will consider in detail built-in functions for managing trading activity, the Expert Advisor event model, and specific data structures, and recall the basic principles of interaction between the terminal and the server, as well as the basic concepts for algorithmic trading in MetaTrader 5: order, deal, and position.

At the same time, due to the versatility of the material, many important nuances of Expert Advisor development, such as testing and optimization, are highlighted in the next chapter.

We have previously considered the Design of MQL programs of various types, including Expert Advisors, as well as started Features of starting and stopping programs. Despite the fact that an Expert Advisor is launched on a specific chart, for which a working symbol is defined, there are no obstacles to centrally manage trading of an arbitrary set of financial instruments. Such Expert Advisors are traditionally referred to as multicurrency, although in fact, their portfolio may include CFDs, stocks, commodities, and tickers of other markets.

In Expert Advisors, as well as in indicators, there are Key events *OnInit* and *OnDeinit*. They are not mandatory, but, as a rule, they are present in the code for the preparation and regular completion of the program: we used them and will continue using them in the examples. In a separate section, we provided an Overview of all event handling functions: we have already studied some of them in detail by now (for example, *OnCalculate* indicator events and the *OnTimer* timer). Expert Advisor-specific events (*OnTick*, *ontrade*, *OnTradeTransaction*) will be described in this chapter.

Expert Advisors can use the widest range of source data as trading signals: quotes, tics, depth of market, trading account history, or indicator readings. In the latter case, the principles of creating indicator instances and reading values from their buffers are no different from those discussed in the chapter Using ready-made indicators from MQL programs. In the Expert Advisor examples in the following sections, we will demonstrate most of these tricks.

It should be noted that trading functions can be used not only in Expert Advisors but also in scripts. We will see examples for both options.

6.4.1 Expert Advisors main event: OnTick

The *OnTick* event is generated by the terminal for Expert Advisors when a new tick appears containing the price of the current chart's working symbol on which the Expert Advisor is running. To handle this event, the *OnTick* function must be defined in the Expert Advisor code. It has the following prototype.

```
void OnTick(void)
```

As you can see, the function has no parameters. If necessary, the very value of the new price and other tick characteristics should be requested by calling *SymbolInfoTick*.

From the point of view of the reaction to the new tick event, this handler is similar to *OnCalculate* in indicators. However, *OnCalculate* can only be defined in indicators, and *OnTick* only in Expert Advisors (to be more precise, the *OnTick* function in the code of an indicator, script, or service will be simply ignored).

At the same time, the Expert Advisor does not have to contain the *OnTick* handler. In addition to this event, Expert Advisors can process the *OnTimer*, *OnBookEvent*, and *OnChartEvent* events and perform all necessary trading operations from them.

All events in Expert Advisors are processed one after the other in the order they arrive, since Expert Advisors, like all other MQL programs, are single-threaded. If there is already an *OnTick* event in the queue or such an event is being processed, then new *OnTick* events are not queued.

An *OnTick* event is generated regardless of whether automatic trading is disabled or enabled (*Algo trading* button in the terminal interface). Disabled automatic trading means only restriction on sending trade requests from the Expert Advisors but does not prevent the Expert Advisor from running.

It should be remembered that tick events are generated only for one symbol, which is the symbol of the current chart. If the Expert Advisor is multicurrency, then getting ticks from other symbols should be organized in some alternative way, for example, using a spy indicator *EventTickSpy.mq5* or subscription to market book events, as in *MarketBookQuasiTicks.mq5*.

As a simple example, consider the Expert Advisor *ExpertEvents.mq5*. It defines handlers for all events that are usually used to launch trading algorithms. We will study some other events (*OnTrade*, *OnTradeTransaction*, as well as tester events) later.

All handlers call the *display* helper function which outputs the current time (millisecond system counter label) and handler name in a multi-line comment.

```
#define N_LINES 25
#include <MQL5Book/Comments.mqh>

void Display(const string message)
{
   ChronoComment((string)GetTickCount() + ": " + message);
}
```

The *OnTick* event will be called automatically upon the arrival of new ticks. For timer and order book events, you need to activate the corresponding handlers using *EventSetTimer* and *MarketBookAdd* calls from *OnInit*.

```
void OnInit()
{
   Print(__FUNCTION__);
   EventSetTimer(2);
   if(!MarketBookAdd(_Symbol))
   {
      Print("MarketBookAdd failed:", _LastError);
   }
}

void OnTick()
{
   Display(__FUNCTION__);
}

void OnTimer()
{
   Display(__FUNCTION__);
}

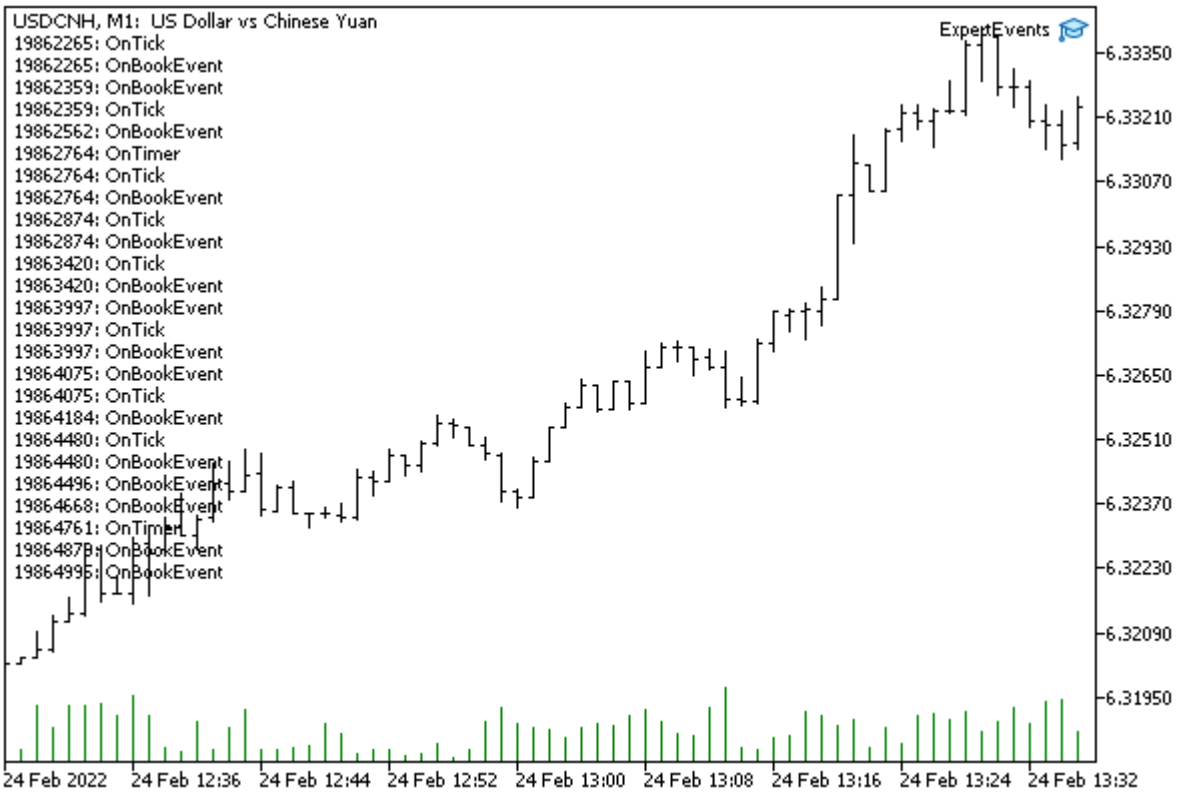
void OnBookEvent(const string &symbol)
{
   if(symbol == _Symbol) // react only to order book of "our" symbol
   {
      Display(__FUNCTION__);
   }
}
```

The chart change event is also available: it can be used to trade on markup based on graphical objects, by pressing buttons or hotkeys, as well as upon the arrival of custom events from other programs, for example, indicators like *EventTickSpy.mq5*.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   Display(__FUNCTION__);
}

void OnDeinit(const int)
{
   Print(__FUNCTION__);
   MarketBookRelease(_Symbol);
   Comment("");
}
```

The following screenshot shows the result of the Expert Advisor operation on the chart.



Comments with events of various types in the Expert Advisor

Please note that the *OnBookEvent* event (if it is broadcast for a symbol) arrives more often than *OnTick*.

6.4.2 Basic principles and concepts: order, deal, and position

Before starting to study the development of Expert Advisors in MQL5, let's recall the general architecture of the platform and the basic concepts that formalize trading activity.

MetaTrader 5 is a client terminal connected to a multi-level server part distributed between the computers of a broker, dealer or exchange. Once a user fills out an order to execute a trade, it goes through several stages of forwarding and verification, after which it is registered or rejected by the dealer or exchange. Then an order registered in the market may or may not be executed depending on circumstances such as liquidity, rate of price change, pause in symbol trading, or technical issues.

General scheme for processing a trade request

Here, green arrows indicate the successful execution of a trade operation as it moves from the terminal to the market, and red arrows indicate a potential rejection.

Orders generated by MQL programs also go through similar instances. In case of an unfavorable outcome, the MQL5 API will allow us to learn the reason for the failure through the error code.

This whole process is expressed (and documented in reports) in three fundamental terms: order, deal, and position.

An order is a trader's instruction to a brokerage company to buy or sell a financial instrument. MetaTrader 5 supports several types of orders, but in a simplified form they can be conditionally divided into market, pending, and special protective levels *Take Profit* and *Stop Loss*.

As a result of the successful execution of an order, a deal occurs in the trading system. Specifically, a deal can be concluded at the current price in the case of a market order, or when a pending order is triggered when the price reaches the value specified in the order. In other words, a deal is a fact of buying or selling a particular financial instrument.

It should be taken into account that in some conditions, an order execution may result in several deals. For example, if the order book does not contain a sufficient amount of symbol liquidity, then a buy order can be executed through various counter orders, including those at a slightly different price.

A financial instrument bought or sold according to a deal forms a long or short position, respectively, which is reflected in the assets/liabilities of the trading account. As a result of the subsequent change in the price of the position instrument, a floating profit or loss is formed on the account, which can be fixed by closing the position through reverse trading operations (orders and deals). Depending on the type of trading account (netting or hedging), deals for the same instrument modify a single net position or create/delete independent positions.

More information can be found in the terminal user manual.

All orders, deals, and positions are included in the trading history of the account.

Next, we will look at the software API, which includes functions for sending trade orders, getting the current state of the portfolio in the account, checking the margin load and potential profit/loss, as well as analyzing the trading history.

6.4.3 Types of trading operations

Trading in MQL5 is implemented by sending orders using the *OrderSend* function. We will study it in one of the following sections because its description requires you to first become familiar with several concepts.

The very first new concept will be the trading operation type. Each trade request contains an indication of the type of the requested trade and allows you to perform actions such as opening and closing positions, as well as placing, modifying, and deleting pending orders. All types of trading operations are described in the ENUM_TRADE_REQUEST_ACTIONS enumeration.

Identifier	Description
TRADE_ACTION_DEAL	Place a trading order for an immediate trade with the specified parameters (place a market order)
TRADE_ACTION_PENDING	Place a trading order to execute a trade under the specified conditions (pending order)
TRADE_ACTION_SLTP	Change the *Stop Loss* and *Take Profit* values of an open position
TRADE_ACTION_MODIFY	Change the parameters of a previously placed order
TRADE_ACTION_REMOVE	Delete a previously placed pending order
TRADE_ACTION_CLOSE_BY	Close a position with an opposite one

When requesting TRADE_ACTION_DEAL and TRADE_ACTION_PENDING, the program will need to specify a specific order type. This is another important concept that has its own reflection in the MQL5 API, and we will consider it in the next section.

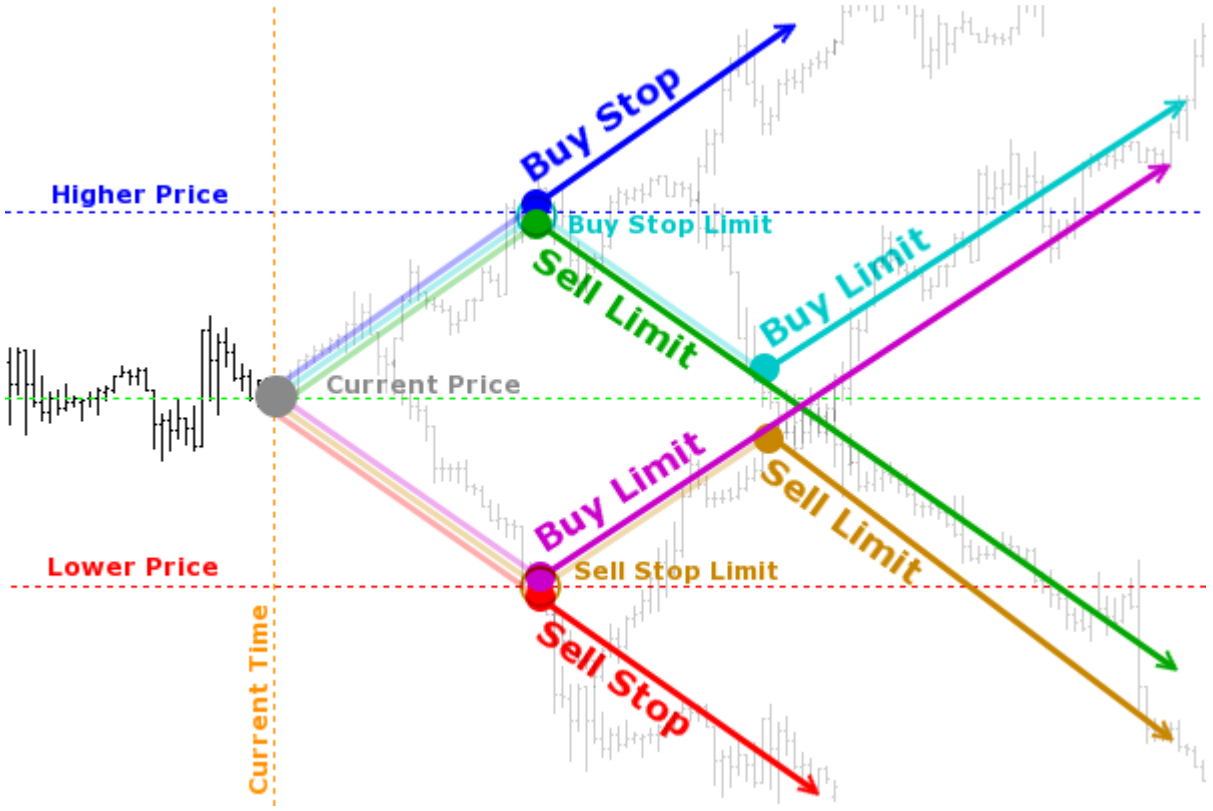
6.4.4 Order types

As you know, MetaTrader 5 supports several order types: two market orders for buying and selling at the current price, and six pending ones with predefined activation levels above and below the market. All these types are available in the MQL5 API and are described by the elements of the ENUM_ORDER_TYPE enumeration. Later we will consider how to create an order of a particular type in a program. For now, let's get acquainted with the enumeration.

Identifier	Description
ORDER_TYPE_BUY	Market buy order
ORDER_TYPE_SELL	Market sell order
ORDER_TYPE_BUY_LIMIT	*Buy Limit* pending order
ORDER_TYPE_SELL_LIMIT	*Sell Limit* pending order
ORDER_TYPE_BUY_STOP	*Buy Stop* pending order
ORDER_TYPE_SELL_STOP	*Sell Stop* pending order
ORDER_TYPE_BUY_STOP_LIMIT	*Buy Limit* pending order to be placed when the price reaches the specified upper level
ORDER_TYPE_SELL_STOP_LIMIT	*Sell Limit* pending order to be placed when the price reaches the specified lower level
ORDER_TYPE_CLOSE_BY	Order to close one position with an oppositely directed position

The last element corresponds to the action to close opposite positions: this possibility exists only on hedging accounts and for the financial instruments having properties that allow such operations (SYMBOL_ORDER_CLOSEBY).

The following picture may remind you of the general pending order activation principles. It shows the expected future price movements in gray. But at the current time, it is not known which forecast will turn out to be correct.



Scheme of activation of pending orders

Buy Stop and *Sell Stop* pending orders follow the level breakdown principle: for *Buy Stop*, this level should be located above the current price, and it should be below the current price for *Sell Stop*. In other words, at a given level, we want a buy or sell operation to be executed expecting further trading in the trend direction.

Buy Limit and *Sell Limit* implement the strategy of rebounding from the level, and in this case, the buy activation price is below the current price, and the sell price is higher. This implies a change in trend or fluctuation in the corridor. In the diagram above, the same upper (Higher Price) and lower (Lower Price) activation levels of pending orders are used to illustrate both a breakout and a rebound.

Pending orders can be placed at the current price, and they will most likely be executed immediately. In addition, this technique applied to limit orders guarantees a trade price that is no worse than the requested one, unlike a market order.

Order of *Buy Stop Limit* and *Sell Stop Limit* types are not sent to the market as a result of their activation, but they place set pending orders, *Buy Limit* or *Sell Limit*, at some additional levels specified in the original order.

For exchange instruments, limit orders (*Buy Limit*, *Sell Limit*) are usually directly displayed in the order book and are visible to other market participants.

In contrast, *Stop* and *Stop Limit* orders (*Buy Stop*, *Sell Stop*, *Buy Stop Limit*, and *Sell Stop Limit*) are not output directly to the external trading system. Until the stop price is reached, these types of orders are processed within the MetaTrader 5 platform. When the stop price specified in the Buy Stop or Sell Stop order is reached, the corresponding market operation is executed. Upon reaching the stop price specified in the *Buy Stop Limit* or *Sell Stop Limit* order, a corresponding limit order is placed.

In exchange execution mode, the price specified when placing limit orders is not checked. It can be specified above the current *Ask* price (for buy orders) and below the *Bid* price (for sell orders). When placing an order with such a price, it almost immediately gets triggered and turns into a market one.

Please note that not all types of orders may be allowed for a specific financial instrument: the SYMBOL_ORDER_MODE property describes flags of allowed order types.

6.4.5 Order execution modes by price and volume

When sending trade requests, we will need to specify the buying/selling price and volume in the algorithm in a special way. At the same time, it should be taken into account that in the financial markets there is no guarantee that at the moment the entire requested volume is available for the financial instrument at the desired price. Therefore, trading operations are regulated by price and volume execution modes (or policies). They define the rules for cases when the price has changed during the process of sending the request, or it cannot be fully satisfied.

In the chapter on symbols, in the section Trading conditions and order execution modes, we have already discussed the settings for order execution by price (SYMBOL_TRADE_EXEMODE) and order filling by volume (SYMBOL_FILLING_MODE), which are set by the broker. In accordance with the available SYMBOL_FILLING_MODE modes, the MQL program must select the fill mode for the newly formed order in a special structure *MqlTradeRequest* (soon we will see this in practice).

Versions are provided in the ENUM_ORDER_TYPE_FILLING enumeration: their identifiers echo those of SYMBOL_FILLING_MODE.

Execution policy (Values)	Description
ORDER_FILLING_FOK (0)	Fill or Kill
ORDER_FILLING_IOC (1)	Immediate or Cancel
ORDER_FILLING_RETURN (2)	Return

With the ORDER_FILLING_FOK policy, an order can only be filled in the specified volume. If there is not enough volume of the financial instrument on the market at the moment, the order will not be executed. The required volume can be made up of several offers currently available on the market. The ability to use FOK orders is determined by the presence of the SYMBOL_FILLING_FOK permission.

With the ORDER_FILLING_IOC policy, the trader agrees to make a deal on the maximum volume available on the market within the limits specified in the order. If full coverage is not possible, the order will be executed on the available volume, and the missing volume will be canceled. The ability to use IOC orders is determined by the presence of the SYMBOL_FILLING_IOC permission.

With the ORDER_FILLING_RETURN policy, in case of partial execution, the order with the remaining volume is not canceled but continues to operate. This is the default mode and is always available.

However, there is one exception: Return orders are not allowed in market execution mode (SYMBOL_TRADE_EXECUTION_MARKET in the SYMBOL_TRADE_EXEMODE symbol property).

Thus, before sending a market (not pending) order, the MQL program should correctly set one of the ORDER_TYPE_FILLING policies based on the SYMBOL_FILLING_MODE property of the corresponding financial instrument: this property contains a combination of bit flags of allowed modes.

For pending orders, regardless of the SYMBOL_TRADE_EXEMODE execution mode, you must use the ORDER_FILLING_RETURN policy, since such orders will be filled with volume later and according to the rules that the broker sets at that time.

> Unlike the volume fill policy, the order execution mode at a price cannot be selected as it is predetermined by the broker for each symbol. This affects which fields of the *MqlTradeRequest* structure should be filled in before submitting a trade request.

The application of fill policies depending on the execution modes can be represented as a table ('+' – allowed, '-' – disabled, '±' – depends on the symbol settings):

Fill policy Execution mode	ORDER_FILLING_FOK	ORDER_FILLING_IOC	ORDER_FILLING_RETURN
SYMBOL_TRADE_EXECUTION_INSTANT	+	+	+
SYMBOL_TRADE_EXECUTION_REQUEST	+	+	+
SYMBOL_TRADE_EXECUTION_MARKET	±	±	-
SYMBOL_TRADE_EXECUTION_EXCHANGE	±	±	+
Pending	-	-	+

In the SYMBOL_TRADE_EXECUTION_INSTANT and SYMBOL_TRADE_EXECUTION_REQUEST execution modes, all volume filling policies are allowed.

6.4.6 Pending order expiration dates

For pending orders, an important characteristic is their expiration mode. In the MQL5 API, the order validity period can be set in the *type_time* field of the special *MqlTradeRequest* structure when sending a trade request via the *OrderSend* function. Acceptable values are described in the ENUM_ORDER_TYPE_TIME enumeration.

Identifier (Value)	Description
ORDER_TIME_GTC (0)	The order will be in the queue until it is canceled
ORDER_TIME_DAY (1)	The order will be valid only during the current trading day
ORDER_TIME_SPECIFIED (2)	The order will be valid until the expiration date
ORDER_TIME_SPECIFIED_DAY (3)	The order will be valid until 23:59:59 of the specified day (if this time does not fall within the trading session, the expiration will occur at the nearest next trading time)

It should be noted that each financial instrument has two properties SYMBOL_EXPIRATION_MODE and SYMBOL_ORDER_GTC_MODE, which determine Pending order expiration rules for this instrument. When forming an order, an MQL program can choose one of the allowed modes. We will consider an example after studying the *OrderSend* function.

6.4.7 Margin calculation for a future order: OrderCalcMargin

Before sending a trade request to the server, an MQL program can calculate the margin required for a planned trade using the *OrderCalcMargin* function. It is recommended to always do this in order to avoid excessive deposit load.

```
bool OrderCalcMargin(ENUM_ORDER_TYPE action, const string symbol,
  double volume, double price, double &margin)
```

The function calculates the margin required for the specified *action* order type and the *symbol* financial instrument with *volume* lots. This aligns with the settings of the current account but does not consider existing pending orders and open positions. The ENUM_ORDER_TYPE enumeration was introduced in the Order types section.

The margin value (in the account currency) is written to the *margin* parameter passed by reference.

It should be emphasized that this is an estimate of the margin for a single new position or order, and not the total value of the collateral, which it will become after execution. Moreover, the evaluation is done as if there were no other pending orders and open positions on the current account. In reality, the value of the margin depends on many factors, including other orders and positions, and may change as the market environment (such as leverage) changes.

The function returns an indicator of success (*true*) or error (*false*). The error code can be obtained in the usual way from the variable *_LastError*.

> The *OrderCalcMargin* function can only be used in Expert Advisors and scripts. To calculate the margin in indicators, you need to implement an alternative method, for example, launch an auxiliary Expert Advisor in a chart object, pass parameters to it. and get the result through the event mechanism, or independently describe calculations in MQL5 using formulas according to the types of instruments. In the next section, we will give an example of such an implementation, along with an estimate of the potential profit/loss.

We could write a simple script that calls *OrderCalcMargin* for symbols from *Market Watch*, and compare margin values for them. Instead, let's slightly complicate the task and consider the header file *LotMarginExposure.mqh*, which allows the evaluation of the deposit load and the margin level after opening a position with a predetermined risk level. A little later we will discuss the *OrderCheck* function

which is capable of providing similar information. However, our algorithm will additionally be able to solve the inverse problem of choosing the lot size according to the given load or risk levels.

The use of new features is demonstrated in a non-trading Expert Advisor *LotMarginExposureTable.mq5*.

> In theory, the fact that an MQL program is implemented as an Expert Advisor does not mean that trading operations must be performed in it. Very often, as in our case, various utilities are created in the form of an Expert Advisor. Their advantage over scripts is that they remain on the chart and can perform their functions indefinitely in response to certain events.

In the new Expert Advisor, we use the skills of creating an interactive graphical interface using objects. To say it in a simpler way, for a given list of symbols, the Expert Advisor will display a table with several columns of margin indicators on the chart, and the table can be sorted by each of the columns. We will provide the list of columns a little later.

Since the analysis of lots, margin, and deposit load is a common task, we will separate the implementation into a separate header file *LotMarginExposure.mqh*.

All file functions are grouped in a namespace to avoid conflicts and for the sake of clarity (indicating the context before calling an internal function informs about the origin and location of this function).

```
namespace LEMLR
{
   ...
};
```

The abbreviation *LEMLR* means "Lot, Exposure, Margin Level, Risk".

The main calculations are performed in the *Estimate* function. Considering a prototype of the built-in *OrderCalcMargin* function, in the *Estimate* function parameters we need to pass the symbol name, order type, volume, and price. But that's not all we need.

```
bool Estimate(const ENUM_ORDER_TYPE type, const string symbol, const double lot,
   const double price,...)
```

We intend to evaluate several indicators of a trading operation, which are interconnected and can be calculated in different directions, depending on what the user entered as initial data and what they want to calculate. For example, using the above parameters, it is easy to find the new margin level and account load. Their formulas are exactly the opposite:

```
Ml = money / margin * 100
Ex = margin / money * 100
```

Here the *margin* variable indicates the amount of margin, for which it is enough to call *OrderCalcMargin*.

However, traders often prefer to start from a predetermined load or margin level and calculate the volume for that. Moreover, there is an equally popular risk-based lot calculation approach. Risk is understood as the amount of potential loss from trading in case of an unfavorable price movement, as a result of which the content of another variable from the above formulas will decrease, that is, *money*.

To calculate the loss, it is important to know the volatility of the financial instrument during the trading period (the duration of the strategy) or the distance of the stop loss assumed by the user.

Therefore, the list of parameters of the *Estimate* function expands.

```
bool Estimate(const ENUM_ORDER_TYPE type, const string symbol, const double lot,
   const double price,
   const double exposure, const double riskLevel, const int riskPoints,
   const ENUM_TIMEFRAMES riskPeriod, double money,...)
```

In the *exposure* parameter, we specify the desired deposit load as a percentage, and in the *riskLevel* parameter, we indicate the part of the deposit (also in percentage) that we are willing to risk. For risk-based calculations, you can pass the stop loss size in points in the *riskPoints* parameter. When it is equal to 0, the *riskPeriod* parameter comes into play: it specifies the period for which the algorithm will automatically calculate the range of symbol quotes in points. Finally, in the *money* parameter, we can specify an arbitrary amount of free margin for lot evaluation. Some traders conditionally divide the deposit between several robots. When *money* is 0, the function will fill this variable with the *AccountInfoDouble(ACCOUNT_MARGIN_FREE)* property.

Now we need to decide how to return the results of the function. Since it is able to evaluate many trading indicators and several volume options, it makes sense to define the *SymbolLotExposureRisk* structure.

```
struct SymbolLotExposureRisk
{
   double lot;                      // requested volume (or minimum)
   int atrPointsNormalized;         // price range normalized by tick size
   double atrValue;                 // range as the amount of profit/loss for 1 lo
   double lotFromExposureRaw;       // not normalized ( can be less than the minim
   double lotFromExposure;          // normalized lot from deposit loading
   double lotFromRiskOfStopLossRaw; // not normalized (can be less than the minimu
   double lotFromRiskOfStopLoss;    // normalized lot from risk
   double exposureFromLot;          // loading based on the volume of 'lot
   double marginLevelFromLot;       // margin level from 'lot' volume
   int lotDigits;                   // number of digits in normalized lots
};
```

The *lot* field in the structure contains the lot passed to the *Exposure* function if the lot is not equal to 0. If the passed lot is zero, the symbol property SYMBOL_VOLUME_MIN is substituted instead.

Two fields are allocated for the calculated values of volumes based on the load of the deposit and the risk: with the suffix *Raw* (*lotFromExposureRaw*, *lotFromRiskOfStopLossRaw*), and without it (*lotFromExposure*, *lotFromRiskOfStopLoss*). *Raw* fields contain a "pure arithmetic" result, which may not match the symbol specification. In the fields without a suffix, lots are normalized considering the minimum, maximum, and step. Such duplication is useful, in particular, for those cases when the calculation gives values less than the minimum lot (for example, *lotFromExposureRaw* equals 0.023721 with a minimum of 0.1, due to which *lotFromExposure* is reduced to zero): then from the content of *Raw* fields, you can evaluate how much money to add or how much to increase the risk to get to the minimum lot.

Let's describe the last output parameter of the *Estimate* function as a reference to this structure. We will gradually fill in all the fields in the function body. First of all, we get the margin for one lot by calling *OrderCalcMargin* and save it to a local variable *lot1margin*.

```
bool Estimate(const ENUM_ORDER_TYPE type, const string symbol, const double lot,
   const double price, const double exposure,
   const double riskLevel, const int riskPoints, const ENUM_TIMEFRAMES riskPeriod,
   double money, SymbolLotExposureRisk &r)
{
   double lot1margin;
   if(!OrderCalcMargin(type, symbol, 1.0,
      price == 0 ? GetCurrentPrice(symbol, type) : price,
      lot1margin))
   {
      Print("OrderCalcMargin ", symbol, " failed: ", _LastError);
      return false;
   }
   if(lot1margin == 0)
   {
      Print("Margin ", symbol, " is zero, ", _LastError);
      return false;
   }
   ...
```

If the entry price is not specified, i.e. *price* equals 0, the helper function *GetCurrentPrice* returns a suitable price based on order type: for buys, the symbol property SYMBOL_ASK will be taken, and for sells it will be SYMBOL_BID. This and other helper functions are omitted here, their content can be found in the attached source code.

If the margin calculation fails, or a zero value is received, the *Estimate* function will return *false*.

Keep in mind that zero margin may be the norm, but it also may be an error, depending on the instrument and order type. So for exchange tickers, pending orders are subject to deposit, but not for OTC tickers (i.e., deposit 0 is correct). This point should be taken into account in the calling code: it should request margin only for such combinations of symbols and types of operations for which it makes sense and is assumed to be non-zero.

Having a deposit for one lot, we can calculate the number of lots to ensure a given load of the deposit.

```
   double usedMargin = 0;
   if(money == 0)
   {
      money = AccountInfoDouble(ACCOUNT_MARGIN_FREE);
      usedMargin = AccountInfoDouble(ACCOUNT_MARGIN);
   }

   r.lotFromExposureRaw = money * exposure / 100.0 / lot1margin;
   r.lotFromExposure = NormalizeLot(symbol, r.lotFromExposureRaw);
   ...
```

The helper function *NormalizeLot* is shown below.

In order to get a lot depending on the risk and volatility, a little more calculation is required.

```
      const double tickValue = SymbolInfoDouble(symbol, SYMBOL_TRADE_TICK_VALUE);
      const int pointsInTick = (int)(SymbolInfoDouble(symbol, SYMBOL_TRADE_TICK_SIZE)
         / SymbolInfoDouble(symbol, SYMBOL_POINT));
      const double pointValue = tickValue / pointsInTick;
      const int atrPoints = (riskPoints > 0) ? (int)riskPoints :
         (int)(((MathMax(iHigh(symbol, riskPeriod, 1), iHigh(symbol, riskPeriod, 0))
         -  MathMin(iLow(symbol, riskPeriod, 1), iLow(symbol, riskPeriod, 0)))
         / SymbolInfoDouble(symbol, SYMBOL_POINT)));
      // rounding by tick size
      r.atrPointsNormalized = atrPoints / pointsInTick * pointsInTick;
      r.atrValue = r.atrPointsNormalized * pointValue;

      r.lotFromRiskOfStopLossRaw = money * riskLevel / 100.0
         / (pointValue * r.atrPointsNormalized);
      r.lotFromRiskOfStopLoss = NormalizeLot(symbol, r.lotFromRiskOfStopLossRaw);
      ...
```

Here we find the cost of one pip of the instrument and the range of its changes for the specified period, after which we already calculate the lot.

Finally, we get the account load and margin level for the given lot.

```
      r.lot = lot <= 0 ? SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN) : lot;
      double margin = r.lot * lot1margin;

      r.exposureFromLot = (margin + usedMargin) / money * 100.0;
      r.marginLevelFromLot = margin > 0 ? money / (margin + usedMargin) * 100.0 : 0;
      r.lotDigits = (int)MathLog10(1.0 / SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN))

      return true;
   }
```

In case of successful calculation, the function will return *true*.

Here is the shortened view of the *NormalizeLot* function (all checks for 0 are omitted for simplicity). Details about the corresponding properties can be found in the section Permitted volumes of trading operations.

```
   double NormalizeLot(const string symbol, const double lot)
   {
      const double stepLot = SymbolInfoDouble(symbol, SYMBOL_VOLUME_STEP);
      const double newLotsRounded = MathFloor(lot / stepLot) * stepLot;
      const double minLot = SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN);
      if(newLotsRounded < minLot) return 0;
      const double maxLot = SymbolInfoDouble(symbol, SYMBOL_VOLUME_MAX);
      if(newLotsRounded > maxLot) return maxLot;
      return newLotsRounded;
   }
```

The above implementation of *Estimate* does not take into account adjustments for overlapping positions. As a rule, they lead to a decrease in the deposit, so the current estimate of account load and margin level may be more pessimistic than it turns out in reality, but this provides additional protection. Those interested can add a code to analyze the composition of already frozen account funds (their total amount is contained in the ACCOUNT_MARGIN account property) broken down by positions and

orders: then it will be possible to take into account the potential effect of a new order on the margin (for example, only the largest position from the opposite ones will be taken into account or a reduced hedged margin rate will be applied, see details in the section Margin requirements).

Now it's time to put margin and lot estimation into practice in *LotMarginExposureTable.mq5*. Considering the fact that *Raw* fields will be shown only in those cases when the normalization of lots led to their zeroing, the total number of columns in the resulting table of indicators is 8.

```
#include <MQL5Book/LotMarginExposure.mqh>
#define TBL_COLUMNS 8
```

In the input parameters, we will provide the possibility to specify the order type, the list of symbols to be analyzed (a list separated by commas), available funds, as well as the lot, the target deposit load, the level of margin, and risk.

```
input ENUM_ORDER_TYPE Action = ORDER_TYPE_BUY;
input string WorkList = "";                  // Symbols (comma,separated,list)
input double Money = 0;                      // Money (0 = free margin)
input double Lot = 0;                        // Lot (0 = min lot)
input double Exposure = 5.0;                 // Exposure (%)
input double RiskLevel = 5.0;                // RiskLevel (%)
input int RiskPoints = 0;                    // RiskPoints/SL (0 = auto-range of Ris
input ENUM_TIMEFRAMES RiskPeriod = PERIOD_W1;
```

For pending order types, it is necessary to select stock symbols, since for other symbols a zero margin will be obtained, which will cause an error in the *Estimate* function. If the list of symbols is left empty, the Expert Advisor will process only the symbol of the current chart. Zero default values in parameters *Money* and *Lot* mean, respectively, the current amount of free funds on the account and the minimum lot for each symbol.

The 0 value in the *RiskPoints* parameter means getting a range of prices during *RiskPeriod* (default is a week).

The input parameter *UpdateFrequency* sets the recalculation frequency in seconds. If you leave it equal to zero, the recalculation is performed on each new bar.

```
input int UpdateFrequency = 0; // UpdateFrequency (sec, 0 - once per bar)
```

Described in the global context are: an array of symbols (later populated by parsing the input parameter *WorkList*) and the timestamp of the last successful calculation.

```
string symbols[];
datetime lastTime;
```

At startup, we turn on the second timer.

```
void OnInit()
{
   Comment("Starting...");
   lastTime = 0;
   EventSetTimer(1);
}
```

In the timer handler, we provide the first call to the main calculation in *OnTick*, if *OnTick* has not yet been called upon the arrival of a tick. This situation can happen, for example, on weekends or during a calm market. Also, *OnTimer* is the entry point for recalculations at a given frequency.

```
void OnTimer()
{
   if(lastTime == 0) // calculation for the first time (if OnTick did have time to tr
   {
      OnTick();
      Comment("Started");
   }
   else if(lastTime != -1)
   {
      if(UpdateFrequency <= 0) // if there is no frequency, we work on new bars in On
      {
         EventKillTimer();     // and the timer is no longer needed
      }
      else if(TimeCurrent() - lastTime >= UpdateFrequency)
      {
         lastTime = LONG_MAX; // prevent re-entering this 'if' branch
         OnTick();
         if(lastTime != -1)   // completed without error
         {
 lastTime = TimeCurrent();// update timestamp
         }
      }
      Comment("");
   }
}
```

In the *OnTick* handler, we first check the input parameters and convert the list of symbols into an array of strings. If problems are found, the sign of the error is written in *lastTime*: the value -1, and the processing of subsequent ticks is interrupted at the very beginning.

```
void OnTick()
{
   if(lastTime == -1) return; // already had an error, exit

   if(UpdateFrequency <= 0)   // if the update rate is not set
   {
      if(lastTime == iTime(NULL, 0, 0)) return; // waiting for a new bar
   }
   else if(TimeCurrent() - lastTime < UpdateFrequency)
   {
      return;
   }

   const int ns = StringSplit((WorkList == "" ? _Symbol : WorkList), ',', symbols);
   if(ns <= 0)
   {
      Print("Empty symbols");
      lastTime = -1;
      return;
   }

   if(Exposure > 100 || Exposure <= 0)
   {
      Print("Percent of Exposure is incorrect: ", Exposure);
      lastTime = -1;
      return;
   }

   if(RiskLevel > 100 || RiskLevel <= 0)
   {
      Print("Percent of RiskLevel is incorrect: ", RiskLevel);
      lastTime = -1;
      return;
   }
   ...
```

In particular, it is considered an error if the input values *Exposure* and *Risk Level* are beyond the range of 0 to 100, as it should be for percentages. In case of normal input data, we update the timestamp, describe the structure *LEMLR::SymbolLotExposureRisk* to receive calculated indicators from the function *LEMLR::Estimate* (one symbol each), as well as a two-dimensional array *LME* (from "Lot Margin Exposure") to collect indicators for all symbols.

```
   lastTime = UpdateFrequency > 0 ? TimeCurrent() : iTime(NULL, 0, 0);

   LEMLR::SymbolLotExposureRisk r = {};

   double LME[][13];
   ArrayResize(LME, ns);
   ArrayInitialize(LME, 0);
   ...
```

In a loop through symbols, we call the *LEMLR::Estimate* function and fill the *LME* array.

```
   for(int i = 0; i < ns; i++)
   {
      if(!LEMLR::Estimate(Action, symbols[i], Lot, 0,
         Exposure, RiskLevel, RiskPoints, RiskPeriod, Money, r))
      {
        Print("Calc failed (will try on the next bar, or refresh manually)");
        return;
      }

      LME[i][eLot] = r.lot;
      LME[i][eAtrPointsNormalized] = r.atrPointsNormalized;
      LME[i][eAtrValue] = r.atrValue;
      LME[i][eLotFromExposureRaw] = r.lotFromExposureRaw;
      LME[i][eLotFromExposure] = r.lotFromExposure;
      LME[i][eLotFromRiskOfStopLossRaw] = r.lotFromRiskOfStopLossRaw;
      LME[i][eLotFromRiskOfStopLoss] = r.lotFromRiskOfStopLoss;
      LME[i][eExposureFromLot] = r.exposureFromLot;
      LME[i][eMarginLevelFromLot] = r.marginLevelFromLot;
      LME[i][eLotDig] = r.lotDigits;
      LME[i][eMinLot] = SymbolInfoDouble(symbols[i], SYMBOL_VOLUME_MIN);
      LME[i][eContract] = SymbolInfoDouble(symbols[i], SYMBOL_TRADE_CONTRACT_SIZE);
      LME[i][eSymbol] = pack2double(symbols[i]);
   }
   ...
```

Elements of the special enumeration LME_FIELDS are used as array indexes, which simultaneously provide names and numbers for indicators from the structure.

```
enum LME_FIELDS // 10 fields + 3 additional symbol properties
{
   eLot,
   eAtrPointsNormalized,
   eAtrValue,
   eLotFromExposureRaw,
   eLotFromExposure,
   eLotFromRiskOfStopLossRaw,
   eLotFromRiskOfStopLoss,
   eExposureFromLot,
   eMarginLevelFromLot,
   eLotDig,
   eMinLot,
   eContract,
   eSymbol
};
```

The properties of SYMBOL_VOLUME_MIN and SYMBOL_TRADE_CONTRACT_SIZE are added for reference. The symbol name is "packed" into an approximate value of type *double* using the *pack2double* function, in order to subsequently implement a unified sorting by any of the fields, including the names.

```
double pack2double(const string s)
{
   double r = 0;
   for(int i = 0; i < StringLen(s); i++)
   {
      r = (r * 255) + (StringGetCharacter(s, i) % 255);
   }
   return r;
}
```

At this stage, we could already run the Expert Advisor and print the results in a log, something like this.

```
ArrayPrint(LME);
```

But looking into a log all the time is not convenient. Besides, unified formatting of values from different columns, and even more so the presentation of "packed" rows in *double*, can't be called user-friendly. Therefore, the scoreboard class was developed (*Tableau.mqh*) to display an arbitrary table on the chart. In addition to the fact that when preparing a table, we can control the format of each field ourselves (in the future, highlight it in a different color), this class allows you to interactively sort the table by any column: the first mouse click sorts in one direction, the second click sorts in the opposite direction, and the third one cancels sorting.

Here we will not describe the class in detail but you can study its source code. It is only important to note that the interface is based on graphical objects. In fact, the table cells are formed by objects of the OBJ_LABEL type, and all their properties are already familiar to the reader. However, some of the techniques used in the source code of the scoreboard, in particular, working with graphic resources and measuring the display text, will be presented later, in the seventh part.

The constructor of the class *tableau* takes several parameters:

- prefix – prefix for the names of the created graphical objects
- rows – number of rows
- cols – number of columns
- height – line height in pixels (-1 means double the font size)
- width – cell width in pixels
- c – an angle of the chart for anchoring objects
- g – the gap in pixels between cells
- f – font size
- font – font name for regular cells
- bold – the name of the bold font for headings
- bgc – background color
- bgt – background transparency

```
class Tableau
{
public:
   Tableau(const string prefix, const int rows, const int cols,
      const int height = 16, const int width = 100,
      const ENUM_BASE_CORNER c = CORNER_RIGHT_LOWER, const int g = 8,
      const int f = 8, const string font = "Consolas", const string bold = "Arial Bla
      const int mask = TBL_FLAG_COL_0_HEADER,
      const color bgc = 0x808080, const uchar bgt = 0xC0)
      ...
};
```

Most of these parameters can be set by the user in the input variables of the *LotMarginExposureTable.mq5* Expert Advisor.

```
input ENUM_BASE_CORNER Corner = CORNER_RIGHT_LOWER;
input int Gap = 16;
input int FontSize = 8;
input string DefaultFontName = "Consolas";
input string TitleFontName = "Arial Black";
input string MotoTypeFontsHint = "Consolas/Courier/Courier New/Lucida Console/Lucida
input color BackgroundColor = 0x808080;
input uchar BackgroundTransparency = 0xC0; // BackgroundTransparency (255 - opaque, 0
```

The number of columns in the table is predetermined, the number of lines is equal to the number of symbols, plus the top line with headings.

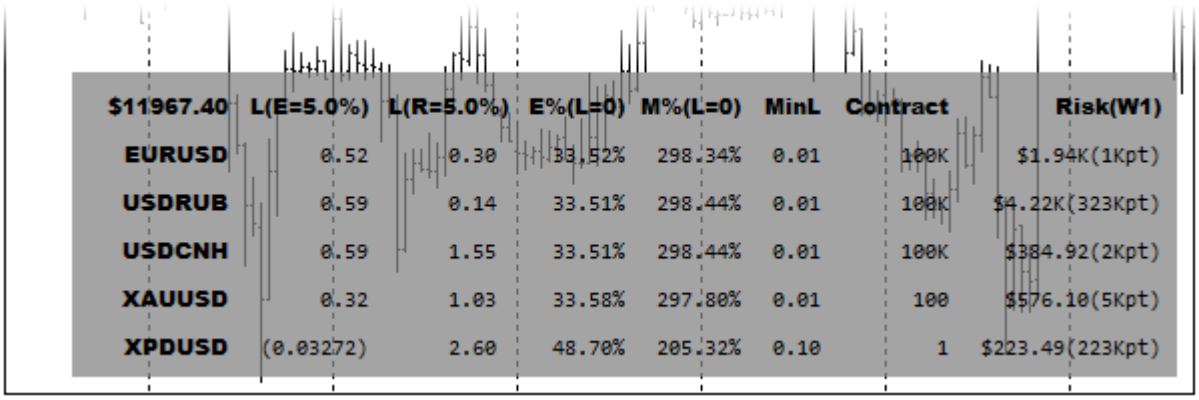
It is important to note that fonts for the table should be selected without proportional lettering, so in the variable *MotoTypeFontsHint* a tooltip is provided with a set of standard Windows monospace fonts.

The created graphical objects are populated using the *fill* method of the *Tableau* class.

```
bool fill(const string &data[], const string &hint[]) const;
```

Our Expert Advisor passes the *data* array of strings which are obtained from the *LME* array through a series of transformations through *StringFormat*, as well as the *hint* array with tooltips for titles.

The following image shows a part of the chart with the running Expert Advisor with default settings but with a specified list of symbols "EURUSD,USDRUB,USDCNH,XAUUSD,XPDUSD".



$11967.40	L(E=5.0%)	L(R=5.0%)	E%(L=0)	M%(L=0)	MinL	Contract	Risk(W1)
EURUSD	0.52	0.30	33.52%	298.34%	0.01	100K	$1.94K(1Kpt)
USDRUB	0.59	0.14	33.51%	298.44%	0.01	100K	$4.22K(323Kpt)
USDCNH	0.59	1.55	33.51%	298.44%	0.01	100K	$384.92(2Kpt)
XAUUSD	0.32	1.03	33.58%	297.80%	0.01	100	$576.10(5Kpt)
XPDUSD	(0.03272)	2.60	48.70%	205.32%	0.10	1	$223.49(223Kpt)

Deposit and margin loading levels with a minimum lot for each symbol

Symbol names are displayed in the left column. As the heading of the first column, the funds amount is displayed (in this case, free on the account at the current moment, because in the input parameter

Money is left at 0). When you hover your mouse over the column name, you can see a tooltip with an explanation.

In the following columns:

- L(E) – lot calculated for loading level E of the 5% deposit after the deal
- L(R) – lot calculated at risk R for 5% of the deposit after unsuccessful trading (range in points and risk amount – in the last column)
- E% – deposit loading after entry with a minimum lot
- M% – margin level after entry with the minimum lot
- MinL – minimum lot for each symbol
- Contract – contract size (1 lot) for each symbol
- Risk – profit/loss in money when trading 1 lot and the same range in points

In columns E% and M%, in this case, the minimum lots are used, since the input parameter *Lot* is 0 (default).

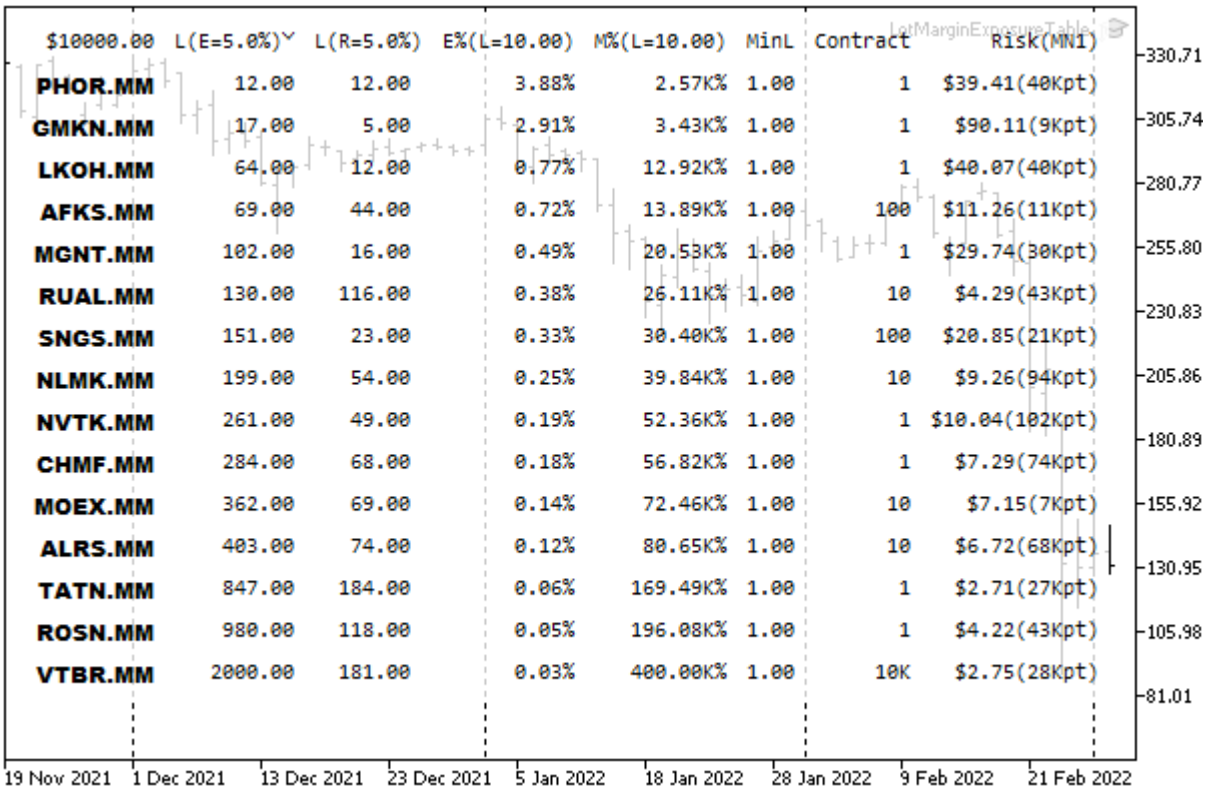
When loading a 5% of the deposit, trading is possible for all selected symbols except for "XPDUSD". For the latter, the volume turned out to be 0.03272, which is less than the minimum lot of 0.1, and therefore the result is enclosed in brackets. If we allow loading of 20% (enter 20 in the parameter *Exposure*), we get the minimum lot for "XPDUSD" 0.1.

If we enter the value of 1 in the *Lot* parameter, we will see updated values in the E% and M% columns in the table (the load will increase, and the margin level will fall).

$11787.04	L(E=5.0%)	L(R=5.0%)	E%(L=1)	M%(L=1)	MinL	Contract	Risk(W1)
EURUSD	0.52	0.30	43.54%	229.69%	0.01	100K	$1.94K(1Kpt)
USDRUB	0.58	0.13	42.42%	235.74%	0.01	100K	$4.22K(323Kpt)
USDCNH	0.58	1.53	42.42%	235.74%	0.01	100K	$384.95(2Kpt)
XAUUSD	0.31	1.02	49.73%	201.09%	0.01	100	$576.10(5Kpt)
XPDUSD	(0.032)	2.60	190.20%	52.58%	0.10	1	$223.49(223Kpt)

Deposit and margin loading levels for a single lot for each symbol

The last screenshot illustrating the work of the Expert Advisor shows a large set of blue chips of the Russian exchange MOEX sorted by volume calculated for a 5% deposit load (2nd column). Among the non-standard settings, it can be noted that *Lot=10*, and the period for calculating the price range and risk is equal to MN1. The background is made translucent white, the anchoring is to the upper left corner of the chart.



Lots, deposit loading and margin level for MOEX instruments

6.4.8 Estimating the profit of a trading operation: OrderCalcProfit

One of the MQL5 API functions, *OrderCalcProfit*, allows you to pre-evaluate the financial result of a trading operation if the expected conditions are met. For example, using this function you can find out the amount of profit when reaching the *Take Profit* level, and the amount of loss when *Stop Loss* is triggered.

```
bool OrderCalcProfit(ENUM_ORDER_TYPE action, const string symbol, double volume,
   double openPrice, double closePrice, double &profit)
```

The function calculates the profit or loss in the account currency for the current market environment based on the passed parameters.

The order type is specified in the *action* parameter. Only market orders ORDER_TYPE_BUY or ORDER_TYPE_SELL from the ENUM_ORDER_TYPE enumeration are allowed. The name of the financial instrument and its volume are passed in the parameters *symbol* and *volume*. The market entry and exit prices are set by the parameters *openPrice* and *closePrice*, respectively. The *profit* variable is passed by reference as the last parameter, and the profit value will be written in it.

The function returns an indicator of success (*true*) or error (*false*).

The formula for calculating the financial result used inside *OrderCalcProfit* depends on the symbol type.

Identifier	Formula
SYMBOL_CALC_MODE_FOREX	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_CFD	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_CFDINDEX	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_CFDLEVERAGE	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_EXCH_STOCKS	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_EXCH_STOCKS_MOEX	(ClosePrice - OpenPrice) * ContractSize * Lots
SYMBOL_CALC_MODE_FUTURES	(ClosePrice - OpenPrice) * Lots * TickPrice / TickSize
SYMBOL_CALC_MODE_EXCH_FUTURES	(ClosePrice - OpenPrice) * Lots * TickPrice / TickSize
SYMBOL_CALC_MODE_EXCH_FUTURES_FORTS	(ClosePrice - OpenPrice) * Lots * TickPrice / TickSize
SYMBOL_CALC_MODE_EXCH_BONDS	Lots * ContractSize * (ClosePrice * FaceValue + AccruedInterest)
SYMBOL_CALC_MODE_EXCH_BONDS_MOEX	Lots * ContractSize * (ClosePrice * FaceValue + AccruedInterest)
SYMBOL_CALC_MODE_SERV_COLLATERAL	Lots * ContractSize * MarketPrice * LiqudityRate

The following notation is used in the formulas:

- Lots – position volume in lots (contract shares)
- ContractSize – contract size (one lot, SYMBOL_TRADE_CONTRACT_SIZE)
- TickPrice – tick price (SYMBOL_TRADE_TICK_VALUE)
- TickSize – tick size (SYMBOL_TRADE_TICK_SIZE)
- MarketPrice – last known price *Bid/Ask* depending on the type of transaction
- OpenPrice – position opening price
- ClosePrice – position closing price
- FaceValue – face value of the bond (SYMBOL_TRADE_FACE_VALUE)
- LiqudityRate – liquidity ratio (SYMBOL_TRADE_LIQUIDITY_RATE)
- AccruedInterest – accumulated coupon income (SYMBOL_TRADE_ACCRUED_INTEREST)

The *OrderCalcProfit* function can only be used in Expert Advisors and scripts. To calculate potential profit/loss in indicators, you need to implement an alternative method, for example, independent calculations using formulas.

To bypass the restriction on the use of the *OrderCalcProfit* and *OrderCalcMargin* functions in indicators, we have developed a set of functions that perform calculations using the formulas from this section, as well as the section Margin requirements. The functions are in the header file *MarginProfitMeter.mqh*, inside the common namespace *MPM* (from "Margin Profit Meter").

In particular, to calculate the financial result, it is important to have the value of one point of a particular instrument. In the above formulas, it indirectly participates in the difference between the opening and closing prices *(ClosePrice - OpenPrice)*.

The function calculates the value of one price point *PointValue*.

```
namespace MPM
{
   double PointValue(const string symbol, const bool ask = false,
      const datetime moment = 0)
   {
      const double point = SymbolInfoDouble(symbol, SYMBOL_POINT);
      const double contract = SymbolInfoDouble(symbol, SYMBOL_TRADE_CONTRACT_SIZE);
      const ENUM_SYMBOL_CALC_MODE m =
         (ENUM_SYMBOL_CALC_MODE)SymbolInfoInteger(symbol, SYMBOL_TRADE_CALC_MODE);
      ...
```

At the beginning of the function, we request all the symbol properties needed for the calculation. Then, depending on the type of symbol, we obtain profit/loss in the currency of the profit of this instrument. Please note that there are no bonds here, the formulas of which take into account the nominal price and coupon income.

```
      double result = 0;
      switch(m)
      {
      case SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE:
      case SYMBOL_CALC_MODE_FOREX:
      case SYMBOL_CALC_MODE_CFD:
      case SYMBOL_CALC_MODE_CFDINDEX:
      case SYMBOL_CALC_MODE_CFDLEVERAGE:
      case SYMBOL_CALC_MODE_EXCH_STOCKS:
      case SYMBOL_CALC_MODE_EXCH_STOCKS_MOEX:
         result = point * contract;
         break;

      case SYMBOL_CALC_MODE_FUTURES:
      case SYMBOL_CALC_MODE_EXCH_FUTURES:
      case SYMBOL_CALC_MODE_EXCH_FUTURES_FORTS:
         result = point * SymbolInfoDouble(symbol, SYMBOL_TRADE_TICK_VALUE)
            / SymbolInfoDouble(symbol, SYMBOL_TRADE_TICK_SIZE);
         break;
      default:
         PrintFormat("Unsupported symbol %s trade mode: %s", symbol, EnumToString(m))
      }
      ...
```

Finally, we convert the amount to the account currency, if it differs.

```
         string account = AccountInfoString(ACCOUNT_CURRENCY);
         string current = SymbolInfoString(symbol, SYMBOL_CURRENCY_PROFIT);

         if(current != account)
         {
            if(!Convert(current, account, ask, result, moment)) return 0;
         }

         return result;
      }
      ...
   };
```

The helper function *Convert* is used to convert amounts. It, in turn, depends on the *FindExchangeRate* function, which searches among all available symbols for one that contains the rate from the *current* currency into the *account* currency.

```
   bool Convert(const string current, const string account,
      const bool ask, double &margin, const datetime moment = 0)
   {
      string rate;
      int dir = FindExchangeRate(current, account, rate);
      if(dir == +1)
      {
         margin *= moment == 0 ?
            SymbolInfoDouble(rate, ask ? SYMBOL_BID : SYMBOL_ASK) :
            GetHistoricPrice(rate, moment, ask);
      }
      else if(dir == -1)
      {
         margin /= moment == 0 ?
            SymbolInfoDouble(rate, ask ? SYMBOL_ASK : SYMBOL_BID) :
            GetHistoricPrice(rate, moment, ask);
      }
      else
      {
         static bool once = false;
         if(!once)
         {
            Print("Can't convert ", current, " -> ", account);
            once = true;
         }
      }
      return true;
   }
```

The *FindExchangeRate* function looks up characters in *Market Watch* and returns the name of the first matching Forex symbol, if there are several of them, in the *result* parameter. If the quote corresponds to the direct order of currencies "*current/account*", the function will return +1, and if the opposite, it will be "*account/current*", i.e. -1.

```
int FindExchangeRate(const string current, const string account, string &result)
{
   for(int i = 0; i < SymbolsTotal(true); i++)
   {
      const string symbol = SymbolName(i, true);
      const ENUM_SYMBOL_CALC_MODE m =
         (ENUM_SYMBOL_CALC_MODE)SymbolInfoInteger(symbol, SYMBOL_TRADE_CALC_MODE);
      if(m == SYMBOL_CALC_MODE_FOREX || m == SYMBOL_CALC_MODE_FOREX_NO_LEVERAGE)
      {
         string base = SymbolInfoString(symbol, SYMBOL_CURRENCY_BASE);
         string profit = SymbolInfoString(symbol, SYMBOL_CURRENCY_PROFIT);
         if(base == current && profit == account)
         {
            result = symbol;
            return +1;
         }
         else
         if(base == account && profit == current)
         {
            result = symbol;
            return -1;
         }
      }
   }
   return 0;
}
```

The full code of the functions can be found in the attached file *MarginProfitMeter.mqh*.

Let's check the performance of the *OrderCalcProfit* function and the group of functions *MPM* with a test script *ProfitMeter.mq5*: we will calculate the profit/loss estimate for virtual trades for all symbols of the Market Watch, and we will do it using two methods: built-in and ours.

In the input parameters of the script, you can select the type of operation *Action* (buy or sell), lot size *Lot* and the position holding time in bars *Duration*. The financial result is calculated for the quotes of the last *Duration* bars of the current timeframe.

```
#property script_show_inputs

input ENUM_ORDER_TYPE Action = ORDER_TYPE_BUY; // Action (only Buy/Sell allowed)
input float Lot = 1;
input int Duration = 20; // Duration (bar number in past)
```

In the body of the script, we connect the header files and display the header with the parameters.

```
#include <MQL5Book/MarginProfitMeter.mqh>
#include <MQL5Book/Periods.mqh>

void OnStart()
{
   // guarantee that the operation will only be a buy or a sell
   ENUM_ORDER_TYPE type = (ENUM_ORDER_TYPE)(Action % 2);
   const string text[] = {"buying", "selling"};
   PrintFormat("Profits/Losses for %s %s lots"
      " of %d symbols in Market Watch on last %d bars %s",
      text[type], (string)Lot, SymbolsTotal(true),
      Duration, PeriodToString(_Period));
   ...
```

Then, in a loop through symbols, we perform the calculations in two ways and print the results for comparison.

```
   for(int i = 0; i < SymbolsTotal(true); i++)
   {
      const string symbol = SymbolName(i, true);
      const double enter = iClose(symbol, _Period, Duration);
      const double exit = iClose(symbol, _Period, 0);

      double profit1, profit2; // 2 adopted variables

      // standard method
      if(!OrderCalcProfit(type, symbol, Lot, enter, exit, profit1))
      {
         PrintFormat("OrderCalcProfit(%s) failed: %d", symbol, _LastError);
         continue;
      }

      // our own method
      const int points = (int)MathRound((exit - enter)
         / SymbolInfoDouble(symbol, SYMBOL_POINT));
      profit2 = Lot * points * MPM::PointValue(symbol);
      profit2 = NormalizeDouble(profit2,
         (int)AccountInfoInteger(ACCOUNT_CURRENCY_DIGITS));
      if(type == ORDER_TYPE_SELL) profit2 *= -1;

      // output to the log for comparison
      PrintFormat("%s: %f %f", symbol, profit1, profit2);
   }
}
```

Try running the script for different accounts and instrument sets.

```
Profits/Losses for buying 1.0 lots of 13 symbols in Market Watch on last 20 bars H1
EURUSD: 390.000000 390.000000
GBPUSD: 214.000000 214.000000
USDCHF: -254.270000 -254.270000
USDJPY: -57.930000 -57.930000
USDCNH: -172.570000 -172.570000
USDRUB: 493.360000 493.360000
AUDUSD: 84.000000 84.000000
NZDUSD: 13.000000 13.000000
USDCAD: -97.480000 -97.480000
USDSEK: -682.910000 -682.910000
XAUUSD: -1706.000000 -1706.000000
SP500m: 5300.000000 5300.000000
XPDUSD: -84.030000 -84.030000
```

Ideally, the numbers in each line should match.

6.4.9 MqlTradeRequest structure

MQL5 API trading functions, in particular *OrderCheck* and *OrderSend*, operate on several built-in structures. Therefore, we will have to consider these structures before moving on to the functions themselves.

Let's start with the *MqlTradeRequest* structure which contains all the fields required for executing trades.

```
struct MqlTradeRequest
{
   ENUM_TRADE_REQUEST_ACTIONS action;       // Type of action to perform
   ulong                      magic;        // Unique Expert Advisor number
   ulong                      order;        // Order ticket
   string                     symbol;       // Name of the trading instrument
   double                     volume;       // Requested trade volume in lots
   double                     price;        // Price
   double                     stoplimit;    // StopLimit order level
   double                     sl;           // Stop Loss order level
   double                     tp;           // Take Profit order level
   ulong                      deviation;    // Maximum deviation from the given price
   ENUM_ORDER_TYPE            type;         // Order type
   ENUM_ORDER_TYPE_FILLING    type_filling; // Order type by execution
   ENUM_ORDER_TYPE_TIME       type_time;    // Order type by duration
   datetime                   expiration;   // Order expiration date
   string                     comment;      // Comment to the order
   ulong                      position;     // Position ticket
   ulong                      position_by;  // Opposite position ticket
};
```

You should not be afraid of a large number of fields: the structure is designed to serve absolutely all possible types of trade requests, however, in each specific case, only a few fields are usually used.

Before filling in the fields, it is recommended to nullify the structure either by explicit initialization in its definition or by calling the *ZeroMemory* function.

```
MqlTradeRequest request = {};
...
ZeroMemory(request);
```

This way it will avoid potential errors and side effects from passing random values to the API functions in those fields that were not explicitly assigned.

The following table provides a brief description of the fields. We will see how to fill them when describing trading operations.

Field	Description
action	Trading operation type from ENUM_TRADE_REQUEST_ACTIONS
magic	Expert ID (optional)
order	Pending order ticket for which modification is requested
symbol	Trading instrument name
volume	Requested trade volume in lots
price	The price at which the order must be executed
stoplimit	The price where a limit order will be placed when the ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT orders are activated
sl	Price at which *Stop Loss* order will be triggered when the price moves in an unfavorable direction
tp	Price at which *Take Profit* order will be triggered when the price moves in a favorable direction
deviation	Maximum acceptable deviation from the asked price, in points
type	Order type from ENUM_ORDER_TYPE
type_filling	Order filling type from ENUM_ORDER_TYPE_FILLING
type_time	Pending order expiration type from ENUM_ORDER_TYPE_TIME
expiration	Pending order expiration date
comment	Comment to the order
position	Position ticket
position_by	Opposite position ticket for the TRADE_ACTION_CLOSE_BY operation

To send orders for trading operations, it is necessary to fill in a different set of fields, depending on the nature of the operation. Some fields are required, and some are optional (can be omitted when filling out). Next, we'll take a closer look at the field requirements in the context of specific actions.

The program can check a formed *MqlTradeRequest* structure for correctness using the *OrderCheck* function or send it to the server using the *OrderSend* function. If successful, the requested operation will be performed.

The *action* field is the only one required for all trading activities.

A unique number in the *magic* field is usually indicated only for market buy/sell requests or when creating a new pending order. This leads to the subsequent marking of completed transactions and positions with this number, which allows for organizing the analytical processing of trading actions. When modifying the price levels of a position or pending orders, as well as deleting them, this field has no effect.

When manually performing trading operations from the MetaTrader 5 interface, the magic identifier cannot be set, and therefore it is equal to zero. This provides a popular but not entirely reliable way to distinguish between manual and automated trading when analyzing history. In fact, Expert Advisors can also use a zero identifier. Therefore, to find out who and how performed specific trading actions, use the corresponding properties of orders (ORDER_REASON), deals (DEAL_REASON), and positions (POSITION_REASON).

Each Expert Advisor can set its own unique ID or even use several IDs for different purposes (broken down by trading strategies, signals, etc.). The *magic* number of the position corresponds to the *magic* number of the last deal involved in the formation of the position.

Symbol name in the *symbol* field is important only for opening or increasing positions, as well as when placing pending orders. In cases of modifying and closing orders and positions, it will be ignored, but there is a small exception here. Since only one position can exist on netting accounts for each symbol, the *symbol* field can be used to identify a position in a request to change its protective price levels (*Stop Loss* and *Take Profit*).

The *volume* field is used in the same way: it is needed in immediate buy/sell orders or when creating pending orders. It should be taken into account that the actual volume in the operation will depend on the execution mode and may differ from what is requested.

The *price* field also has some limitations: when sending market orders (TRADE_ACTION_DEAL in the *action*) for instruments with execution mode SYMBOL_TRADE_EXECUTION_MARKET or SYMBOL_TRADE_EXECUTION_EXCHANGE, this field is ignored.

The *stoplimit* field makes sense only when setting stop-limit orders, i.e., when the *type* field contains ORDER_TYPE_BUY_STOP_LIMIT or ORDER_TYPE_SELL_STOP_LIMIT. It specifies the price at which a pending limit order will be placed when the price reaches the *price* value (this fact is tracked by the MetaTrader 5 server, and until this moment a pending order is not displayed in the trading system).

When placing pending orders, their expiration rules are set in a pair of fields: *type_time* and *expiration*. The latter contains a value of type *datetime*, which is taken into account only if *type_time* is equal to ORDER_TIME_SPECIFIED or ORDER_TIME_SPECIFIED_DAY.

Finally, the last couple of fields are related to the identification of positions in queries. Each new position created on the basis of orders (manually or programmatically) gets a ticket assigned by the system, a unique number. As a rule, it corresponds to the ticket of the order, as a result of which the position is opened, but may change subject to service operations on the server, for example, accrual of swaps by reopening a position.

We will talk about obtaining the properties of positions, deals, and orders in separate sections. Here, for now, it is important for us that the *position* field should be filled in when changing and closing a position in order to unambiguously identify it. In theory, on netting accounts, it is enough to indicate the position symbol in the *symbol* field, but for the unification of algorithms, it is better to leave the *position* field in work.

The *position_by* field is used for closing opposite positions (TRADE_ACTION_CLOSE_BY). It should indicate a position opened for the same symbol but in the opposite direction in relation to *position* (this is only possible on hedging accounts).

The *deviation* field affects the execution of market orders only in the Instant Execution and Request Execution modes.

Examples of filling in the structure for trading operations of each type will be given in the relevant sections.

6.4.10 MqlTradeCheckResul structure

Before sending a request for a trading operation to the trade server, it is recommended to check that it is completed without formal errors. The check is carried out by the *OrderCheck* function, to which we pass the request in the *MqlTradeRequest* structure and the receiving variable of the *MqlTradeCheckResult* structure type.

In addition to the correctness of the request, the structure enables the evaluation of the account state after the execution of a trading operation, in particular, the balance, funds, and margin.

```
struct MqlTradeCheckResult
{
   uint   retcode;      // Response code
   double balance;      // Balance after the transaction
   double equity;       // Equity after the transaction
   double profit;       // Floating profit
   double margin;       // Margin requirements
   double margin_free;  // Free margin
   double margin_level; // Margin level
   string comment;      // Comment to the response code (description of the error)
};
```

The following table describes the fields.

Field	Description
retcode	Assumed return code
balance	The value of the balance, which will be observed after the execution of the trade operation
equity	The value of own funds, which will be observed after the execution of the trade operation
profit	The value of the floating profit, which will be observed after the execution of the trade operation
margin	Total locked margin after a trade
margin_free	The volume of free own funds that will remain after the execution of the trade operation
margin_level	The margin level that will be set after the execution of a trade operation
comment	Comment on the response code, description of the error

In the structure which is filled by calling *OrderCheck*, the *retcode* field will contain a result code from among those that the platform supports for processing real trade requests and puts in a similar *retcode* field of the *MqlTradeResult* structure after calling trading functions *OrderSend* and *OrderSendAsync*.

Return code constants are presented in MQL5 documentation. For their more visual output to the log when debugging Expert Advisors, the applied enumeration TRADE_RETCODE was defined in the file *TradeRetcode.mqh*. All elements in it have identifiers that match the built-in constants but without the common "TRADE_RETCODE_" prefix. For example,

```
enum TRADE_RETCODE
{
   OK_0           = 0,      // no standard constant
   REQUOTE        = 10004,  // TRADE_RETCODE_REQUOTE
   REJECT         = 10006,  // TRADE_RETCODE_REJECT
   CANCEL         = 10007,  // TRADE_RETCODE_CANCEL
   PLACED         = 10008,  // TRADE_RETCODE_PLACED
   DONE           = 10009,  // TRADE_RETCODE_DONE
   DONE_PARTIAL   = 10010,  // TRADE_RETCODE_DONE_PARTIAL
   ERROR          = 10011,  // TRADE_RETCODE_ERROR
   TIMEOUT        = 10012,  // TRADE_RETCODE_TIMEOUT
   INVALID        = 10013,  // TRADE_RETCODE_INVALID
   INVALID_VOLUME = 10014,  // TRADE_RETCODE_INVALID_VOLUME
   INVALID_PRICE  = 10015,  // TRADE_RETCODE_INVALID_PRICE
   INVALID_STOPS  = 10016,  // TRADE_RETCODE_INVALID_STOPS
   TRADE_DISABLED = 10017,  // TRADE_RETCODE_TRADE_DISABLED
   MARKET_CLOSED  = 10018,  // TRADE_RETCODE_MARKET_CLOSED
   ...
};

#define TRCSTR(X) EnumToString((TRADE_RETCODE)(X))
```

So, the use of *TRCSTR(r.retcode)*, where *r* is a structure, will provide a minimal description of the numeric code.

We will consider an example of applying a macro and analyzing a structure in the next section about the *OrderCheck* function.

6.4.11 Request validation: OrderCheck

To perform any trading operation, the MQL program must first fill the *MqlTradeRequest* structure with the necessary data. Before sending it to the server using trading functions, it makes sense to check it for formal correctness and evaluate the consequences of the request, in particular, the amount of margin that will be required and the remaining free funds. This check is performed by the *OrderCheck* function.

bool OrderCheck(const MqlTradeRequest &request, MqlTradeCheckResult &result)

If there are not enough funds if the parameters are filled incorrectly, the function returns *false*. In addition, the function also reacts with a refusal when the trading is disabled, both in the terminal as a whole and for a specific program. For the error code check the *retcode* field of the *result* structure.

Successful check of structure *request* and the trading environment ends with the status *true*, however, this does not guarantee that the requested operation will certainly succeed if it is repeated using the functions *OrderSend* or *OrderSendAsync*. Trading conditions may change between calls or the broker on the server may have settings applied for a specific external trading system that cannot be satisfied in the formal verification algorithm that is performed by *OrderCheck*.

To obtain a description of the expected financial result, you should analyze the fields of the structure *result*.

Unlike the *OrderCalcMargin* function which calculates the estimated margin required for only one proposed position or order, *OrderCheck* takes into account, albeit in a simplified mode, the general

state of the trading account. So it fills the *margin* field in the *MqlTradeCheckResult* structure and other related fields (*margin_free*, *margin_level*) with cumulative variables that will be formed after the execution of the order. For example, if a position is already open for any instrument at the time of the *OrderCheck* call and the request being checked increases the position, the *margin* field will reflect the amount of deposit, including previous margin liabilities. If the new order contains an operation in the opposite direction, the margin will not increase (in reality, it should decrease, because a position should be closed completely on a netting account and the hedging margin should be applied for opposite positions on a hedging account; however, the function does not perform such accurate calculations).

First of all, *OrderCheck* is useful for programmers at the initial stage of getting acquainted with the trading API in order to experiment with requests without sending them to the server.

Let's test the performance of the f*OrderCheck* unction using a simple non-trading Expert Advisor *CustomOrderCheck.mq5*. We made it an Expert Advisor and not a script for ease of use: this way it will remain on the chart after being launched with the current settings, which can be easily edited by changing individual input parameters. With a script, we would have to start over by setting the fields each time from the default values.

To run the check, let's set a timer in *OnInit*.

```
void OnInit()
{
   // initiate pending execution
   EventSetTimer(1);
}
```

As for the timer handler, the main algorithm will be implemented there. At the very beginning we cancel the timer since we need the code to be executed once, and then wait for the user to change the parameters.

```
void OnTimer()
{
   // execute the code once and wait for new user settings
   EventKillTimer();
   ...
}
```

The Expert Advisor's input parameters completely repeat the set of fields of the trade request structure.

```
input ENUM_TRADE_REQUEST_ACTIONS Action = TRADE_ACTION_DEAL;
input ulong Magic;
input ulong Order;
input string Symbol;     // Symbol (empty = current _Symbol)
input double Volume;     // Volume (0 = minimal lot)
input double Price;      // Price (0 = current Ask)
input double StopLimit;
input double SL;
input double TP;
input ulong Deviation;
input ENUM_ORDER_TYPE Type;
input ENUM_ORDER_TYPE_FILLING Filling;
input ENUM_ORDER_TYPE_TIME ExpirationType;
input datetime ExpirationTime;
input string Comment;
input ulong Position;
input ulong PositionBy;
```

Many of them do not affect the check and financial performance but are left so that you can be sure of this.

By default, the state of the variables corresponds to the request to open a position with the minimum lot of the current instrument. In particular, the *Type* parameter without explicit initialization will get the value of 0, which is equal to the ORDER_TYPE_BUY member of the ENUM_ORDER_TYPE structure. In the *Action* parameter, we specified an explicit initialization because 0 does not correspond to any element of the ENUM_TRADE_REQUEST_ACTIONS enumeration (the first element of TRADE_ACTION_DEAL is 1).

```
void OnTimer()
{
   ...
   // initialize structures with zeros
   MqlTradeRequest request = {};
   MqlTradeCheckResult result = {};

   // default values
   const bool kindOfBuy = (Type & 1) == 0;
   const string symbol = StringLen(Symbol) == 0 ? _Symbol : Symbol;
   const double volume = Volume == 0 ?
      SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN) : Volume;
   const double price = Price == 0 ?
      SymbolInfoDouble(symbol, kindOfBuy ? SYMBOL_ASK : SYMBOL_BID) : Price;
   ...
```

Let's fill in the structure. Real robots usually only need to assign a few fields, but since this test is generic, we must ensure that any parameters that the user enters are passed.

```
request.action = Action;
request.magic = Magic;
request.order = Order;
request.symbol = symbol;
request.volume = volume;
request.price = price;
request.stoplimit = StopLimit;
request.sl = SL;
request.tp = TP;
request.deviation = Deviation;
request.type = Type;
request.type_filling = Filling;
request.type_time = ExpirationType;
request.expiration = ExpirationTime;
request.comment = Comment;
request.position = Position;
request.position_by = PositionBy;
...
```

Please note that here we do not normalize prices and lots yet, although it is required in the real program. Thus, this test makes it possible to enter "uneven" values and make sure that they lead to an error. In the following examples, normalization will be enabled.

Then we call *OrderCheck* and log the *request* and *result* structures. We are only interested in the *retcode* field of the latter, so it is additionally printed with "decryption" as text, macro TRCSTR (*TradeRetcode.mqh*). You can also analyze a string field *comment*, but its format may change so that it is more suitable for display to the user.

```
ResetLastError();
PRTF(OrderCheck(request, result));
StructPrint(request, ARRAYPRINT_HEADER);
Print(TRCSTR(result.retcode));
StructPrint(result, ARRAYPRINT_HEADER, 2);
...
```

The output of structures is provided by a helper function *StructPrint* which is based on *ArrayPrint*. Because of this, we will still get a "raw" display of data. In particular, the elements of enumerations are represented by numbers "as is". Later we will develop a function for a more transparent (user-friendly) *MqlTradeRequest* structure output (see *TradeUtils.mqh*).

To facilitate the analysis of the results, at the beginning of the *OnTimer* function we will display the current state of the account, and at the end, for comparison, we will calculate the margin for a given trading operation using the function *OrderCalcMargin*.

```
void OnTimer()
{
   PRTF(AccountInfoDouble(ACCOUNT_EQUITY));
   PRTF(AccountInfoDouble(ACCOUNT_PROFIT));
   PRTF(AccountInfoDouble(ACCOUNT_MARGIN));
   PRTF(AccountInfoDouble(ACCOUNT_MARGIN_FREE));
   PRTF(AccountInfoDouble(ACCOUNT_MARGIN_LEVEL));
   ...
   // filling in the structure MqlTradeRequest
   // calling OrderCheck and printing results
   ...
   double margin = 0;
   ResetLastError();
   PRTF(OrderCalcMargin(Type, symbol, volume, price, margin));
   PRTF(margin);
}
```

Below is an example of logs for XAUUSD with default settings.

```
AccountInfoDouble(ACCOUNT_EQUITY)=15565.22 / ok
AccountInfoDouble(ACCOUNT_PROFIT)=0.0 / ok
AccountInfoDouble(ACCOUNT_MARGIN)=0.0 / ok
AccountInfoDouble(ACCOUNT_MARGIN_FREE)=15565.22 / ok
AccountInfoDouble(ACCOUNT_MARGIN_LEVEL)=0.0 / ok
OrderCheck(request,result)=true / ok
[action] [magic] [order] [symbol] [volume] [price] [stoplimit] [sl] [tp] [deviation]
       1       0       0 "XAUUSD"     0.01 1899.97        0.00 0.00 0.00           0

 »              0           0 1970.01.01 00:00:00 ""                 0             0
OK_0
[retcode] [balance] [equity] [profit] [margin] [margin_free] [margin_level] [comment]
        0  10000.87  9999.54    -0.83   158.26       9841.28        6318.43 "Done"
OrderCalcMargin(Type,symbol,volume,price,margin)=true / ok
margin=79.04000000000001 / ok
```

Try changing any request parameters and see if the request is successful. Incorrect parameter combinations will cause error codes from the standard list, but since there are many more invalid options than reserved ones (the most common errors), the function can often return the generic code TRADE_RETCODE_INVALID (10013). In this regard, it is recommended to implement your own structure checks with a greater degree of diagnostics.

When sending real requests to the server, the same TRADE_RETCODE_INVALID code is used under various unforeseen circumstances, for example, when trying to re-edit an order whose modification operation has already been started (but has not yet been completed) in the external trading system.

6.4.12 Request sending result: MqlTradeResult structure

In response to a trade request executed by the *OrderSend* or *OrderSendAsync* functions, which we'll cover in the next section, the server returns the request processing results. For this purpose, a special predefined structure is used *MqlTradeResult*.

```
struct MqlTradeResult
{
   uint     retcode;          // Operation result code
   ulong    deal;             // Transaction ticket, if it is completed
   ulong    order;            // Order ticket, if it is placed
   double   volume;           // Trade volume confirmed by the broker
   double   price;            // Trade price confirmed by the broker
   double   bid;              // Current market bid price
   double   ask;              // Current market offer price
   string   comment;          // Broker's comment on the operation
   uint     request_id;       // Request identifier, set by the terminal when sending
   uint     retcode_external; // Response code of the external trading system
};
```

The following table describes its fields.

Field	Description
retcode	Trade server return code
deal	Deal ticket if it is performed (during the TRADE_ACTION_DEAL trading operation)
order	Order ticket if it is placed (during the TRADE_ACTION_PENDING trading operation)
volume	Trade volume confirmed by the broker (depends on the order execution modes)
price	The price in the deal confirmed by the broker (depends on the *deviation* field in the trade request, execution mode, and the trading operation)
bid	Current market bid price
ask	Current market ask price
comment	Broker's comment on the trade (by default, it is filled in with the decryption of the trade server return code)
request_id	Request ID which is set by the terminal when sending it to the trade server
retcode_external	Error code returned by the external trading system

As we will see below when conducting trading operations, a variable of type *MqlTradeResult* is passed as the second parameter by reference in the *OrderSend* or *OrderSendAsync* function. It returns the result.

When sending a trade request to the server, the terminal sets the *request_id* identifier to a unique value. This is necessary for the analysis of subsequent trading events, which is required if an asynchronous function *OrderSendAsync* is used. This identifier allows you to associate the sent request with the result of its processing passed to the *OnTradeTransaction* event handler.

The presence and types of errors in the *retcode_external* field depend on the broker and the external trading system into which trading operations are forwarded.

Request results are analyzed in different ways, depending on the trading operations and the way they are sent. We will deal with this in subsequent sections on specific actions: market buy and sell, placing and deleting pending orders, and modifying and closing positions.

6.4.13 Sending a trade request: OrderSend and OrderSendAsync

To perform trading operations, the MQL5 API provides two functions: *OrderSend* and *OrderSendAsync*. Just like *OrderCheck*, they perform a formal check of the request parameters passed in the form of the *MqlTradeRequest* structure and then, if successful, send a request to the server.

The difference between the two functions is as follows. *OrderSend* expects for the order to be queued for processing on the server and receives meaningful data from it into the fields of the *MqlTradeResult* structure which is passed as the second function parameter. *OrderSendAsync* immediately returns control to the calling code regardless of how the server responds. At the same time, from all fields of

the *MqlTradeResult* structure except *retcode*, important information is filled only into *request_id*. Using this request identifier, an MQL program can receive further information about the progress of processing this request in the *OnTradeTransaction* event. An alternative approach is to periodically analyze the lists of orders, deals, and positions. This can also be done in a loop, setting some timeout in case of communication problems.

It's important to note that despite the "Async" suffix in the second function's name, the first function without this suffix is also not fully synchronous. The fact is that the result of order processing by the server, in particular, the execution of a deal (or, probably, several deals based on one order) and the opening of a position, generally occurs asynchronously in an external trading system. So the *OrderSend* function also requires delayed collection and analysis of the consequences of request execution, which MQL programs must, if necessary, implement themselves. We'll look at an example of truly synchronous sending of a request and receiving all of its results later (see *MqlTradeSync.mqh*).

bool OrderSend(const MqlTradeRequest &request, MqlTradeResult &result)

The function returns *true* in case of a successful basic check of the *request* structure in the terminal and a few additional checks on the server. However, this only indicates the acceptance of the order by the server and does not guarantee a successful execution of the trade operation.

The trade server can fill the field *deal* or *order* values in the returned *result* structure if this data is known at the time the server formats an answer to the *OrderSend* call. However, in the general case, the events of deal execution or placing limit orders corresponding to an order can occur after the response is sent to the MQL program in the terminal. Therefore, for any type of trade request, when receiving the execution *OrderSend* result, it is necessary to check the trade server return code *retcode* and external trading system response code *retcode_external* (if necessary) which are available in the returned *result* structure. Based on them, you should decide whether to wait for pending actions on the server or take your own actions.

Each accepted order is stored on the trade server pending processing until any of the following events that affect its life cycle occurs:

- execution when a counter request appears
- triggered when the execution price arrives
- expiration date
- cancellation by the user or MQL program
- removal by the broker (for example, in case of clearing or shortage of funds, *Stop Out*)

The *OrderSendAsync* prototype completely repeats that of *OrderSend*.

bool OrderSendAsync(const MqlTradeRequest &request, MqlTradeResult &result)

The function is intended for high-frequency trading, when, according to the conditions of the algorithm, it is unacceptable to waste time waiting for a response from the server. The use of *OrderSendAsync* does not speed up request processing by the server or request sending to the external trading system.

> Attention! In the tester, the *OrderSendAsync* function works like *OrderSend*. This makes it difficult to debug the pending processing of asynchronous requests.

The function returns *true* upon a successful sending of the request to the MetaTrader 5 server. However, this does not mean that the request reached the server and was accepted for processing. At the same time, the response code in the receiving *result* structure contains the TRADE_RETCODE_PLACED (10008) value, that is, "the order has been placed".

When processing the received request, the server will send a response message to the terminal about a change in the current state of positions, orders and deals, which leads to the generation of the *OnTrade* event in an MQL program. There, the program can analyze the new trading environment and account history. We will look at relevant examples below.

Also, the details of the trader request execution on the server can be tracked using the *OnTradeTransaction* handler. At the same time, it should be considered that as a result of the execution of one trade request, the *OnTradeTransaction* handler will be called multiple times. For example, when sending a market buy request, it is accepted for processing by the server, a corresponding 'buy' order is created for the account, the order is executed and the trader is performed, as a result of which it is removed from the list of open orders and added to the history of orders. Then the trade is added to the history and a new position is created. For each of these events, the *OnTradeTransaction* function will be called.

Let's start with a simple Expert Advisor example *CustomOrderSend.mq5*. It allows you to set all fields of the request in the input parameters, which is similar to *CustomOrderCheck.mq5*, but further differs in that it sends a request to the server instead of a simple check in the terminal. Run the Expert Advisor on your demo account. After completing the experiments, don't forget to remove the Expert Advisor from the chart or close the chart so that you don't send a test request every next launch of the terminal.

The new example has several other improvements. First of all the input parameter *Async* is added.

```
input bool Async = false;
```

This option allows selecting the function that will send the request to the server. By default, the parameter equals to *false* and the *OrderSend* function is used. If you set it to *true*, *OrderSendAsync* will be called.

In addition, with this example, we will begin to describe and complete a special set of functions in the header file *TradeUtils.mqh*, which will come in handy to simplify the coding of robots. All functions are placed in the namespace TU (from "Trade Utilities"), and first, we introduce functions for convenient output to the structure log *MqlTradeRequest* and *MqlTradeResult*.

```
namespace TU
{
   string StringOf(const MqlTradeRequest &r)
   {
      SymbolMetrics p(r.symbol);

      // main block: action, type, symbol
      string text = EnumToString(r.action);
      if(r.symbol != NULL) text += ", " + r.symbol;
      text += ", " + EnumToString(r.type);
      // volume block
      if(r.volume != 0) text += ", V=" + p.StringOf(r.volume, p.lotDigits);
      text += ", " + EnumToString(r.type_filling);
      // block of all prices
      if(r.price != 0) text += ", @ " + p.StringOf(r.price);
      if(r.stoplimit != 0) text += ", X=" + p.StringOf(r.stoplimit);
      if(r.sl != 0) text += ", SL=" + p.StringOf(r.sl);
      if(r.tp != 0) text += ", TP=" + p.StringOf(r.tp);
      if(r.deviation != 0) text += ", D=" + (string)r.deviation;
      // pending orders expiration block
      if(IsPendingType(r.type)) text += ", " + EnumToString(r.type_time);
      if(r.expiration != 0) text += ", " + TimeToString(r.expiration);
      // modification block
      if(r.order != 0) text += ", #=" + (string)r.order;
      if(r.position != 0) text += ", #P=" + (string)r.position;
      if(r.position_by != 0) text += ", #b=" + (string)r.position_by;
      // auxiliary data
      if(r.magic != 0) text += ", M=" + (string)r.magic;
      if(StringLen(r.comment)) text += ", " + r.comment;

      return text;
   }

   string StringOf(const MqlTradeResult &r)
   {
      string text = TRCSTR(r.retcode);
      if(r.deal != 0) text += ", D=" + (string)r.deal;
      if(r.order != 0) text += ", #=" + (string)r.order;

      if(r.price != 0) text += ", @ " + (string)r.price;
      if(r.bid != 0) text += ", Bid=" + (string)r.bid;
      if(r.ask != 0) text += ", Ask=" + (string)r.ask;
      if(StringLen(r.comment)) text += ", " + r.comment;
      if(r.request_id != 0) text += ", Req=" + (string)r.request_id;
      if(r.retcode_external != 0) text += ", Ext=" + (string)r.retcode_external;

      return text;
   }
   ...
};
```

The purpose of the functions is to provide all significant (non-empty) fields in a concise but convenient form: they are displayed in one line with a unique designation for each.

As you can see, the function uses the *SymbolMetrics* class for *MqlTradeRequest*. It facilitates the normalization of multiple prices or volumes for the same instrument. Don't forget that the normalization of prices and volumes is a prerequisite for preparing a correct trade request.

```
class SymbolMetrics
{
public:
   const string symbol;
   const int digits;
   const int lotDigits;

   SymbolMetrics(const string s): symbol(s),
      digits((int)SymbolInfoInteger(s, SYMBOL_DIGITS)),
      lotDigits((int)MathLog10(1.0 / SymbolInfoDouble(s, SYMBOL_VOLUME_STEP)))
   { }

   double price(const double p)
   {
      return TU::NormalizePrice(p, symbol);
   }

   double volume(const double v)
   {
      return TU::NormalizeLot(v, symbol);
   }

   string StringOf(const double v, const int d = INT_MAX)
   {
      return DoubleToString(v, d == INT_MAX ? digits : d);
   }
};
```

The direct normalization of values is entrusted to auxiliary functions *NormalizePrice* and *NormalizeLot* (the scheme of the latter is identical to what we saw in the file *LotMarginExposure.mqh*).

```
double NormalizePrice(const double price, const string symbol = NULL)
{
   const double tick = SymbolInfoDouble(symbol, SYMBOL_TRADE_TICK_SIZE);
   return MathRound(price / tick) * tick;
}
```

If we connect *TradeUtils.mqh*, the example *CustomOrderSend.mq5* has the following form (the omitted code fragments '...' remained unchanged from *CustomOrderCheck.mq5*).

```
void OnTimer()
{
   ...
   MqlTradeRequest request = {};
   MqlTradeCheckResult result = {};

   TU::SymbolMetrics sm(symbol);

   // fill in the request structure
   request.action = Action;
   request.magic = Magic;
   request.order = Order;
   request.symbol = symbol;
   request.volume = sm.volume(volume);
   request.price = sm.price(price);
   request.stoplimit = sm.price(StopLimit);
   request.sl = sm.price(SL);
   request.tp = sm.price(TP);
   request.deviation = Deviation;
   request.type = Type;
   request.type_filling = Filling;
   request.type_time = ExpirationType;
   request.expiration = ExpirationTime;
   request.comment = Comment;
   request.position = Position;
   request.position_by = PositionBy;

   // send the request and display the result
   ResetLastError();
   if(Async)
   {
      PRTF(OrderSendAsync(request, result));
   }
   else
   {
      PRTF(OrderSend(request, result));
   }
   Print(TU::StringOf(request));
   Print(TU::StringOf(result));
}
```

Due to the fact that prices and volume are now normalized, you can try to enter uneven values into the corresponding input parameters. They are often obtained in programs during calculations, and our code converts them according to the symbol specification.

With default settings, the Expert Advisor creates a request to buy the minimum lot of the current instrument by market and makes it using the *OrderSend* function.

```
OrderSend(request,result)=true / ok
TRADE_ACTION_DEAL, EURUSD, ORDER_TYPE_BUY, V=0.01, ORDER_FILLING_FOK, @ 1.12462
DONE, D=1250236209, #=1267684253, V=0.01, @ 1.12462, Bid=1.12456, Ask=1.12462, Reques
```

As a rule, with allowed trading, this operation should be completed successfully (status DONE, comment "Request executed"). In the *result* structure, we immediately received the deal number *D*.

If we open Expert Advisor settings and replace the value of the parameter *Async* with *true*, we will send a similar request but with the *OrderSendAsync* function.

```
OrderSendAsync(request,result)=true / ok
TRADE_ACTION_DEAL, EURUSD, ORDER_TYPE_BUY, V=0.01, ORDER_FILLING_FOK, @ 1.12449
PLACED, Order placed, Req=2
```

In this case, the status is PLACED, and the trade number at the time the function returns is not known. We only know the unique request ID *Req=2*. To get the deal and position number, you need to intercept the TRADE_TRANSACTION_REQUEST message with the same request ID in the *OnTradeTransaction* handler, where the filled structure will be received as a *MqlTradeResult* parameter.

From the user's point of view, both requests should be equally fast.

It will be possible to compare the performance of these two functions directly in the code of an MQL program using another example of an Expert Advisor (see the section on synchronous and asynchronous requests), which we will consider after studying the model of trading events.

> It should be noted that trading events are sent to the *OnTradeTransaction* handler (if present in the code), regardless of which function is used to send requests, *OrderSend* or *OrderSendAsync*. The situation is as follows: in case of applying *OrderSend* some or all information about the execution of the order is immediately available in the receiving *MqlTradeResult* structure. However, in the general case, the result is distributed over time and volume, for example, when one order is "filled" into several deals. Then complete information can be obtained from trading events or by analyzing the history of transactions and orders.

If you try to send a deliberately incorrect request, for example, change the order type to a pending ORDER_TYPE_BUY_STOP, you will get an error message, because for such orders you should use the TRADE_ACTION_PENDING action. Furthermore, they should be located at a distance from the current price (we use the market price by default). Before this test, it is important not to forget to change the query mode back to synchronous (*Async=false*) to immediately see the error in the *MqlTradeResult* structure after ending the *OrderSend* call. Otherwise, *OrderSendAsync* would return *true*, but the order would still not be set, and the program could receive information about this only in *OnTradeTransaction* which we don't have yet.

```
OrderSend(request,result)=false / TRADE_SEND_FAILED(4756)
TRADE_ACTION_DEAL, EURUSD, ORDER_TYPE_BUY_STOP, V=0.01, ORDER_FILLING_FOK, @ 1.12452,
REQUOTE, Bid=1.12449, Ask=1.12452, Requote, Req=5
```

In this case, the error reports an invalid Requote price.

Examples of using functions to perform specific trading actions will be presented in the following sections.

6.4.14 Buying and selling operations

In this section, we finally begin to study the application of MQL5 functions for specific trading tasks. The purpose of these functions is to fill in the *MqlTradeRequest* structure in a special way and call the *OrderSend* or *OrderSendAsync* function.

The first action we will learn is buying or selling a financial instrument at the current market price. The procedure for performing this action includes:

- Creating a market order based on a submitted order
- Executing a deal (one or several) under an order
- The result should be an open position

As we saw in the section on types of trading operations, instant buy/sell corresponds to the TRADE_ACTION_DEAL element in the ENUM_TRADE_REQUEST_ACTIONS enumeration. Therefore, when filling the *MqlTradeRequest* structure, write TRADE_ACTION_DEAL in the *action* field.

The trade direction is set using the *type* field which should contain one of the order types: ORDER_TYPE_BUY or ORDER_TYPE_SELL.

Of course, to buy or sell, you need to specify the name of the symbol in the *symbol* field and its desired volume in the *volume* field.

The *type_filling* field must be filled with one of the fill policies from the enumeration ENUM_ORDER_TYPE_FILLING, which is chosen based on the character property SYMBOL_FILLING_MODE with allowed policies.

Optionally, the program can fill in the fields with protective price levels (*sl* and *tp*), a comment (*comment*), and an Expert Advisor ID (*magic*).

The contents of other fields are set differently depending on the price execution mode for the selected symbol. In some modes, certain fields have no effect. For example, in the Request Execution and Instant Execution modes, the field with the *price* must be filled in with a suitable price (the last known *Ask* for buying and *Bid* for selling), and the *deviation* field may contain the maximum allowable deviation of the price from the set price for the successful execution of a deal. In Exchange Execution and Market Execution, these fields are ignored. In order to simplify the source code, you can fill in the price and slippage uniformly in all modes, but in the last two options, the price will still be selected and substituted by the trade server according to the rules of the modes.

Other fields of the *MqlTradeRequest* structure not mentioned here are not used for these trading operations.

The following table summarizes the rules for filling the fields for different execution modes. The required fields are marked with an asterisk, while optional fields are marked with a plus.

Field	Request	Instant	Exchange	Market
action	*	*	*	*
symbol	*	*	*	*
volume	*	*	*	*
type	*	*	*	*
type_filling	*	*	*	*
price	*	*		
sl	+	+	+	+
tp	+	+	+	+
deviation	+	+		
magic	+	+	+	+
comment	+	+	+	+

Depending on server settings, it may be forbidden to fill in fields with protective *sl* and *tp* levels at the moment of opening a position. This is often the case for exchange execution or market execution modes, but the MQL5 API does not provide properties for clarifying this circumstance in advance. In such cases, *Stop Loss* and *Take Profit* should be set by modifying an already open position. By the way, this method can be recommended for all execution modes, since it is the only one that allows you to accurately postpone the protective levels from the real position opening price. On the other hand, creating and setting up a position in two moves can lead to a situation where the position is open, but the second request to set protective levels failed for one reason or another.

Regardless of the trade direction (buy/sell), the *Stop Loss* order is always placed as a stop order (ORDER_TYPE_BUY_STOP or ORDER_TYPE_SELL_STOP), and the *Take Profit* order is placed as a limit order (ORDER_TYPE_BUY_LIMIT or ORDER_TYPE_SELL_LIMIT). Moreover, stop orders are always controlled by the MetaTrader 5 server and only when the price reaches the specified level, they are sent to the external trading system. In contrast, limit orders can be output directly to an external trading system. Specifically, this is usually the case for exchange-traded instruments.

In order to simplify the coding of trading operations, not only buying and selling but also all others, we will start from this section by developing classes, or rather structures that provide automatic and correct filling of fields for trade requests, as well as a truly synchronous waiting for the result. The latter is especially important, given that the *OrderSend* and *OrderSendAsync* functions return control to the calling code before the trading action is completed in full. In particular, for market buy and sell, the algorithm usually needs to know not the ticket number of the order created on the server, but whether

the position is open or not. Depending on this, it can, for example, modify the position by setting *Stop Loss* and *Take Profit* if it has opened or repeat attempts to open it if the order was rejected.

A little later we will learn about the *OnTrade* and *OnTradeTransaction* trading events, which inform the program about changes in the account state, including the status of orders, deals, and positions. However, dividing the algorithm into two fragments – separately generating orders according to certain signals or rules, and separately analyzing the situation in event handlers – makes the code less understandable and maintainable.

In theory, the asynchronous programming paradigm is not inferior to the synchronous one either in speed or in ease of coding. However, the ways of its implementation can be different, for example, based on direct pointers to callback functions (a basic technique in Java, JavaScript, and many other languages) or events (as in MQL5), which predetermines some features, which will be discussed in the *OnTradeTransaction* section. Asynchronous mode allows you to speed up the sending of requests due to deferred control over their execution. But this control will still need to be done sooner or later in the same thread, so the average performance of the circuits is the same.

All new structures will be placed in the *MqlTradeSync.mqh* file. In order not to "reinvent the wheel", let's take the built-in MQL5 structures as a starting point and describe our structures as child structures. For example, to get query results, let's define *MqlTradeResultSync*, which is derived from *MqlTradeResult*. Here we will add useful fields and methods, in particular, the *position* field to store an open position ticket as a result of a market buy or sell operation.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ulong position;
   ...
};
```

The second important improvement will be a constructor that resets all fields (this saves us from having to specify explicit initialization when describing variables of a structure type).

```
   MqlTradeResultSync()
   {
      ZeroMemory(this);
   }
```

Next, we will introduce a universal synchronization mechanism, i.e., waiting for the results of a request (each type of request will have its own rules for checking readiness).

Let's define the type of the *condition* callback function. A function of this type must take the *MqlTradeResultSync* structure parameter and return *true* if successful: the result of the operation is received.

```
   typedef bool (*condition)(MqlTradeResultSync &ref);
```

Functions like this are meant to be passed to the *wait* method, which implements a cyclic check for the readiness of the result during a predefined timeout in milliseconds.

```
bool wait(condition p, const ulong msc = 1000)
{
   const ulong start = GetTickCount64();
   bool success;
   while(!(success = p(this)) && GetTickCount64() - start < msc);
   return success;
}
```

Let's clarify right away that the timeout is the maximum waiting time: even if it is set to a very large value, the loop will end immediately as soon as the result is received, which can happen instantly. Of course, a meaningful timeout should last no more than a few seconds.

Let's see an example of a method that will be used to synchronously wait for an order to appear on the server (it doesn't matter with what status: status analysis is the task of the calling code).

```
static bool orderExist(MqlTradeResultSync &ref)
{
   return OrderSelect(ref.order) || HistoryOrderSelect(ref.order);
}
```

Two built-in MQL5 API functions are applied here, *OrderSelect* and *HistoryOrderSelect*: they search and logically select an order by its ticket in the internal trading environment of the terminal. First, this confirms the existence of an order (if one of the functions returned *true*), and second, it allows you to read its properties using other functions, which is not important to us yet. We will cover all these features in separate sections. The two functions are written in conjunction because a market order can be filled so quickly that its active phase (falling into *OrderSelect*) will immediately flow into history (*HistoryOrderSelect*).

Note that the method is declared static. This is due to the fact that MQL5 does not support pointers to object methods. If this were the case, we could declare the method non-static while using the prototype of the pointer to the *condition* callback functions without the parameter referencing to *MqlTradeResultSync* (since all fields are present inside the *this* object).

The waiting mechanism can be started as follows:

```
if(wait(orderExist))
{
   // there is an order
}
else
{
   // timeout
}
```

Of course, this fragment must be executed after we receive a result from the server with the status TRADE_RETCODE_DONE or TRADE_RETCODE_DONE_PARTIAL, and the *order* field in the *MqlTradeResultSync* structure is guaranteed to contain an order ticket. Please note that due to the system's distributed nature, an order from the server may not immediately be displayed in the terminal environment. That's why you need waiting time.

As long as the *orderExist* function returns *false* into the *wait* method, the wait loop inside runs until the timeout expires. Under normal circumstances, we will almost instantly find an order in the terminal environment, and the loop will end with a sign of success (*true*).

The *positionExist* function that checks the presence of an open position in a similar but a little more complicated way. Since the previous *orderExist* function has completed checking the order, its ticket contained in the field *ref.order* of the structure is confirmed as working.

```
static bool positionExist(MqlTradeResultSync &ref)
{
   ulong posid, ticket;
   if(HistoryOrderGetInteger(ref.order, ORDER_POSITION_ID, posid))
   {
      // in most cases, the position ID is equal to the ticket,
      // but not always: the full code implements getting a ticket by ID,
      // for which there are no built-in MQL5 tools
      ticket = posid;

      if(HistorySelectByPosition(posid))
      {
         ref.position = ticket;
         ...
         return true;
      }
   }
   return false;
}
```

Using the built-in *HistoryOrderGetInteger* and *HistorySelectByPosition* functions, we get the ID and ticket of the position based on the order.

Later we will see the use of *orderExist* and *positionExist* when verifying a buy/sell request, but now let's turn to another structure: *MqlTradeRequestSync*. It is also inherited from the built-in one and contains additional fields, in particular, a structure with a result (so as not to describe it in the calling code) and a timeout for synchronous requests.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   MqlTradeResultSync result;
   ulong timeout;
   ...
```

Since the inherited fields of the new structure are public, the MQL program can assign values to them explicitly, just as it was done with the standard *MqlTradeRequest* structure. The methods that we will add to perform trading operations will consider, check and, if necessary, correct these values for the valid ones.

In the constructor, we reset all fields and set the symbol to the default value if the parameter is omitted.

```
MqlTradeRequestSync(const string s = NULL, const ulong t = 1000): timeout(t)
{
   ZeroMemory(this);
   symbol = s == NULL ? _Symbol : s;
}
```

In theory, due to the fact that all fields of the structure are public, they can technically be assigned directly, but this is not recommended for those fields that require validation and for which we

implement setter methods: they will be called before performing trading operations. The first of these methods is *setSymbol*.

It fills the *symbol* field making sure the transmitted ticker exists and initiates the subsequent setting of the volume filling mode.

```
bool setSymbol(const string s)
{
   if(s == NULL)
   {
      if(symbol == NULL)
      {
         Print("symbol is NULL, defaults to " + _Symbol);
         symbol = _Symbol;
         setFilling();
      }
      else
      {
         Print("new symbol is NULL, current used " + symbol);
      }
   }
   else
   {
      if(SymbolInfoDouble(s, SYMBOL_POINT) == 0)
      {
         Print("incorrect symbol " + s);
         return false;
      }
      if(symbol != s)
      {
         symbol = s;
         setFilling();
      }
   }
   return true;
}
```

So, changing the symbol with *setSymbol* will automatically pick up the correct filling mode via a nested call of *setFilling*.

The *setFilling* method provides the automatic specification of the volume filling method based on the SYMBOL_FILLING_MODE and SYMBOL_TRADE_EXEMODE symbol properties (see the section Trading conditions and order execution modes).

```
private:
   void setFilling()
   {
      const int filling = (int)SymbolInfoInteger(symbol, SYMBOL_FILLING_MODE);
      const bool market = SymbolInfoInteger(symbol, SYMBOL_TRADE_EXEMODE)
         == SYMBOL_TRADE_EXECUTION_MARKET;

      // the field may already be filled
      // and bit match means a valid mode
      if(((type_filling + 1) & filling) != 0
         || (type_filling == ORDER_FILLING_RETURN && !market)) return;

      if((filling & SYMBOL_FILLING_FOK) != 0)
      {
         type_filling = ORDER_FILLING_FOK;
      }
      else if((filling & SYMBOL_FILLING_IOC) != 0)
      {
         type_filling = ORDER_FILLING_IOC;
      }
      else
      {
         type_filling = ORDER_FILLING_RETURN;
      }
   }
```

This method implicitly (without errors and messages) corrects the *type_filling* field if the Expert Advisor has set it incorrectly. If your algorithm requires a guaranteed specific fill method, without which trading is impossible, make appropriate edits to interrupt the process.

> For the set of structures being developed, it is assumed that, in addition to the *type_filling* field, you can directly set only optional fields without specific requirements for their content, such as *magic* or *comment*.

In what follows, many of the methods are provided in a shorter form for the sake of simplicity. They have parts for the types of operations we'll look at later, as well as branched error checking.

For the buy and sell operations, we need the *price* and *volume* fields; both these values should be normalized and checked for the acceptable range. This is done by the *setVolumePrices* method.

```
bool setVolumePrices(const double v, const double p,
   const double stop, const double take)
{
   TU::SymbolMetrics sm(symbol);
   volume = sm.volume(v);

   if(p != 0) price = sm.price(p);
   else price = sm.price(TU::GetCurrentPrice(type, symbol));

   return setSLTP(stop, take);
}
```

If the transaction price is not set (*p == 0*), the program will automatically take the current price of the correct type, depending on the direction, which is read from the *type* field.

Although the *Stop Loss* and *Take Profit* levels are not required, they should also be normalized if present, which is why they are added to the parameters of this method.

The abbreviation TU is already known to us. It stands for the namespace in the file *TradeUtilits.mqh* with a lot of useful functions, including those for the normalization of prices and volumes.

Processing of *sl* and *tp* fields is performed by the separate *setSLTP* method because this is needed not only in the buy and sell operations but also when modifying an existing position.

```
bool setSLTP(const double stop, const double take)
{
   TU::SymbolMetrics sm(symbol);
   TU::TradeDirection dir(type);

   if(stop != 0)
   {
      sl = sm.price(stop);
      if(!dir.worse(sl, price))
      {
         PrintFormat("wrong SL (%s) against price (%s)",
            TU::StringOf(sl), TU::StringOf(price));
         return false;
      }
   }
   else
   {
      sl = 0; // remove SL
   }

   if(take != 0)
   {
      tp = sm.price(take);
      if(!dir.better(tp, price))
      {
         PrintFormat("wrong TP (%s) against price (%s)",
            TU::StringOf(tp), TU::StringOf(price));
         return false;
      }
   }
   else
   {
      tp = 0; // remove TP
   }
   return true;
}
```

In addition to normalizing and assigning values to *sl* and *tp* fields, this method checks the mutual correct location of the levels relative to the *price*. For this purpose, the *TradeDirection* class is described in the space TU.

Its constructors allow you to specify the analyzed direction of trade: buying or selling, in the context of which it is easy to identify a profitable or unprofitable mutual arrangement of two prices. With this class, the analysis is performed in a unified way and the checks in the code are reduced by 2 times

since there is no need to separately process buy and sell operations. In particular, the *worse* method has two price parameters *p1*, *p2*, and returns *true* if the price *p1* is placed worse, i.e., unprofitable, in relation to the price *p2*. A similar method *better* represents reverse logic: it will return *true* if the price *p1* is better than price *p2*. For example, for a sale, the best price is placed lower because *Take Profit* is below the current price.

```
TU::TradeDirection dir(ORDER_TYPE_SELL);
Print(dir.better(100, 200)); // true
```

Now, if an order is placed incorrectly, the *setSLTP* function logs a warning and aborts the verification process without attempting to correct the values since the appropriate response may vary in different programs. For example, from the two passed *stop* and *take* levels only one can be wrong, and then it probably makes sense to use the second (correct) one.

You can change the behavior, for example, by skipping the assignment of invalid values (then the protection levels simply will not be changed) or adding a field with an error flag to the structure (for such a structure, an attempt to send a request should be suppressed so as not to load the server with obviously impossible requests). Sending an invalid request will end with the *retcode* error code equal to TRADE_RETCODE_INVALID_STOPS.

The *setSLTP* method also checks to make sure that the protective levels are not located closer to the current price than the number of points in the SYMBOL_TRADE_STOPS_LEVEL property of the symbol (if this property is set, i.e. greater than 0), and position modification is not requested when it is inside the SYMBOL_TRADE_FREEZE_LEVEL freeze area (if it is set). These nuances are not shown here: they can be found in the source code.

Now we are ready to implement a group of trading methods. For example, for buying and selling with the most complete set of fields, we define *buy* and *sell* methods.

```
public:
   ulong buy(const string name, const double lot, const double p = 0,
      const double stop = 0, const double take = 0)
   {
      type = ORDER_TYPE_BUY;
      return _market(name, lot, p, stop, take);
   }
   ulong sell(const string name, const double lot, const double p = 0,
      const double stop = 0, const double take = 0)
   {
      type = ORDER_TYPE_SELL;
      return _market(name, lot, p, stop, take);
   }
```

As already mentioned, to set optional fields like *deviation*, *comment*, and *magic* should do a direct assignment before calling *buy/sell*. This is all the more convenient since *deviation* and *magic* in most cases are set once, and used in subsequent queries.

The methods return an order ticket, but below we will show in action the mechanism of "synchronous" receipt of a position ticket, and this will be a ticket of a created or modified position (if position increase or partial closing was done).

Methods *buy* and *sell* differ only in the *type* field value, while everything else is the same. This is why the general part is framed as a separate method *_market*. This is where we set *action* in TRADE_ACTION_DEAL, and call *setSymbol* and *setVolumePrices*.

```
private:
   ulong _market(const string name, const double lot, const double p = 0,
      const double stop = 0, const double take = 0)
   {
      action = TRADE_ACTION_DEAL;
      if(!setSymbol(name)) return 0;
      if(!setVolumePrices(lot, p, stop, take)) return 0;
      ...
```

Next, we could just call *OrderSend*, but given the possibility of requotes (price updates on the server during the time the order was sent), let's wrap the call in a loop. Due to this, the method will be able to retry several times, but no more than the preset number of times MAX_REQUOTES (the macro is chosen to be 10 in the code).

```
      int count = 0;
      do
      {
         ZeroMemory(result);
         if(OrderSend(this, result)) return result.order;
         // automatic price selection means automatic processing of requotes
         if(result.retcode == TRADE_RETCODE_REQUOTE)
         {
            Print("Requote N" + (string)++count);
            if(p == 0)
            {
               price = TU::GetCurrentPrice(type, symbol);
            }
         }
      }
      while(p == 0 && result.retcode == TRADE_RETCODE_REQUOTE
         && ++count < MAX_REQUOTES);
      return 0;
   }
```

Since the financial instrument is set in the structure constructor by default, we can provide a couple of simplified overloads of *buy/sell* methods without the *symbol* parameter.

```
public:
   ulong buy(const double lot, const double p = 0,
      const double stop = 0, const double take = 0)
   {
      return buy(symbol, lot, p, stop, take);
   }

   ulong sell(const double lot, const double p = 0,
      const double stop = 0, const double take = 0)
   {
      return sell(symbol, lot, p, stop, take);
   }
```

Thus, in a minimal configuration, it will be enough for the program to call *request.buy(1.0)* in order to make a one-lot buy operation.

Now let's get back to the problem of obtaining the final result of the request, which in the case of the operation TRADE_ACTION_DEAL means the position ticket. In the *MqlTradeRequestSync* structure, this problem is solved by the *completed* method: for each type of operation, it must ask for the nested *MqlTradeResultSync* structure to wait for its filling in accordance with the type of operation.

```
bool completed()
{
   if(action == TRADE_ACTION_DEAL)
   {
      const bool success = result.opened(timeout);
      if(success) position = result.position;
      return success;
   }
   ...
   return false;
}
```

Position opening is controlled by the *opened* method. Inside we will find a couple of calls to the *wait* method described above: the first one is for *orderExist*, and the second one is for *positionExist*.

```
bool opened(const ulong msc = 1000)
{
   if(retcode != TRADE_RETCODE_DONE
      && retcode != TRADE_RETCODE_DONE_PARTIAL)
   {
      return false;
   }

   if(!wait(orderExist, msc))
   {
      Print("Waiting for order: #" + (string)order);
   }

   if(deal != 0)
   {
      if(HistoryDealGetInteger(deal, DEAL_POSITION_ID, position))
      {
         return true;
      }
      Print("Waiting for position for deal D=" + (string)deal);
   }

   if(!wait(positionExist, msc))
   {
      Print("Timeout");
      return false;
   }
   position = result.position;

   return true;
}
```

Of course, it makes sense to wait for an order and a position to appear only if the status of the *retcode* indicates success. Other statuses refer to errors or cancellation of the operation, or to specific intermediate codes (TRADE_RETCODE_PLACED, TRADE_RETCODE_TIMEOUT) that are not accompanied by useful information in other fields. In both cases, this prevents further processing within this "synchronous" framework.

It is important to note that we are using *OrderSync* and therefore we rely on the obligatory presence of the order ticket in the structure received from the server.

In some cases, the system sends not only an order ticket but also a deal ticket at the same time. Then from the deal, you can find the position faster. But even if there is information about the deal, the trading environment of the terminal may temporarily not have information about the new position. That is why you should wait for it with *wait(positionExist)*.

Let's sum up for the intermediate result. The created structures allow you to write the following code to buy 1 lot of the current symbol:

```
MqlTradeRequestSync request;
if(request.buy(1.0) && request.completed())
{
   Print("OK Position: P=", request.result.position);
}
```

We get inside the block of the conditional operator only with a guaranteed open position, and we know its ticket. If we used only *buy/sell* methods, they would receive an order ticket at their output and would have to check the execution themselves. In case of an error, we will not get inside the *if* block, and the server code will be contained in *request.result.retcode*.

When we implement methods for other trades in the following sections, they can be executed in a similar "blocking" mode, for example, to modify stop levels:

```
if(request.adjust(SL, TP) && request.completed())
{
   Print("OK Adjust")
}
```

Of course, you are not required to call *completed* if you don't want to check the result of the operation in blocking mode. Instead, you can stick to the asynchronous paradigm and analyze the environment in trading events handlers. But even in this case, the *MqlTradeRequestAsync* structure can be useful for checking and normalizing operation parameters.

Let's write a test Expert Advisor *MarketOrderSend.mq5* to put all this together. The input parameters will provide input of values for the main and some optional fields of the trade request.

```
enum ENUM_ORDER_TYPE_MARKET
{
   MARKET_BUY = ORDER_TYPE_BUY,  // ORDER_TYPE_BUY
   MARKET_SELL = ORDER_TYPE_SELL // ORDER_TYPE_SELL
};

input string Symbol;          // Symbol (empty = current _Symbol)
input double Volume;          // Volume (0 = minimal lot)
input double Price;           // Price (0 = current Ask)
input ENUM_ORDER_TYPE_MARKET Type;
input string Comment;
input ulong Magic;
input ulong Deviation;
```

The ENUM_ORDER_TYPE_MARKET enumeration is a subset of the standard ENUM_ORDER_TYPE and is introduced in order to limit the available types of operations to only two: market buy and sell.

The action will run once on a timer, in the same way as in the previous examples.

```
void OnInit()
{
   // scheduling a delayed start
   EventSetTimer(1);
}
```

In the timer handler, we disable the timer so that the request is executed only once. For the next launch, you will need to change the Expert Advisor parameters.

```
void OnTimer()
{
   EventKillTimer();
   ...
```

Let's describe a variable of type *MqlTradeRequestSync* and prepare the values for the main fields.

```
   const bool wantToBuy = Type == MARKET_BUY;
   const string symbol = StringLen(Symbol) == 0 ? _Symbol : Symbol;
   const double volume = Volume == 0 ?
      SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN) : Volume;

   MqlTradeRequestSync request(symbol);
   ...
```

Optional fields will be filled in directly.

```
   request.magic = Magic;
   request.deviation = Deviation;
   request.comment = Comment;
   ...
```

Among the optional fields, you can select the fill mode (*type_filling*). By default, *MqlTradeRequestSync* automatically writes to this field the first of the allowed modes ENUM_ORDER_TYPE_FILLING. Recall that the structure has a special method *setFilling* for this.

Next, we call the *buy* or *sell* method with parameters, and if it returns an order ticket, we wait for an open position to appear.

```
   ResetLastError();
   const ulong order = (wantToBuy ?
      request.buy(volume, Price) :
      request.sell(volume, Price));
   if(order != 0)
   {
      Print("OK Order: #=", order);
      if(request.completed()) // waiting for an open position
      {
         Print("OK Position: P=", request.result.position);
      }
   }
   Print(TU::StringOf(request));
   Print(TU::StringOf(request.result));
}
```

At the end of the function, the query and result structures are logged for reference.

If we run the Expert Advisor with the default parameters (buying the current symbol with the minimum lot), we can get the following result for "XTIUSD".

```
OK Order: #=218966930
Waiting for position for deal D=215494463
OK Position: P=218966930
TRADE_ACTION_DEAL, XTIUSD, ORDER_TYPE_BUY, V=0.01, ORDER_FILLING_FOK, @ 109.340, P=21
DONE, D=215494463, #=218966930, V=0.01, @ 109.35, Request executed, Req=8
```

Pay attention to the warning about the temporary absence of a position: it will always appear due to the distributed processing of requests (the warnings themselves can be disabled by removing the SHOW_WARNINGS macro in the Expert Advisor code, but the situation will remain). But thanks to the developed new structures, the applied code is not diverted by these internal complexities and is written in the form of a sequence of simple steps, where each next one is "confident" in the success of the previous ones.

On a netting account, we can achieve an interesting effect of position reversal by subsequent selling with a doubled minimum lot (0.02 in this case).

```
OK Order: #=218966932
Waiting for position for deal D=215494468
Position ticket <> id: 218966932, 218966930
OK Position: P=218966932
TRADE_ACTION_DEAL, XTIUSD, ORDER_TYPE_SELL, V=0.02, ORDER_FILLING_FOK, @ 109.390, P=2
DONE, D=215494468, #=218966932, V=0.02, @ 109.39, Request executed, Req=9
```

It is important to note that after the reversal, the position ticket ceases to be equal to the position identifier: the identifier remains from the first order, and the ticket remains from the second. We deliberately bypassed the task of finding the position ticket by its identifier in order to simplify the presentation. In most cases, the ticket and ID are the same, but for precise control, use the *TU::PositionSelectById* function. Those interested can study the attached source code.

Identifiers are constant as long as the position exists (until it closes to zero in terms of volume) and are useful for analyzing the account history. Tickets describe positions while they are open (there is no concept of a position ticket in history) and are used in some types of requests, in particular, to modify protection levels or close with an opposite position. But there are nuances associated with pouring in parts. We'll talk more about position properties in a separate section.

When making a buy or sell operation, our *buy/sell* methods allow you to immediately set the *Stop Loss* and/or *Take Profit* levels. To do this, simply pass them as additional parameters obtained from input variables or calculated using some formulas. For example,

```
input double SL;
input double TP;
...
void OnTimer()
{
   ...
   const ulong order = (wantToBuy ?
      request.buy(symbol, volume, Price, SL, TP) :
      request.sell(symbol, volume, Price, SL, TP));
   ...
```

All methods of the new structures provide automatic normalization of the passed parameters, so there is no need to use *NormalizeDouble* or something else.

It has already been noted above that some server settings may prohibit the setting of protective levels at the position opening time. In this case, you should set the *sl* and *tp* fields via a separate request.

Exactly the same request is also used in those cases when it is required to modify already set levels, in particular, to implement trailing stop or trailing profit.

In the next section, we will complete the current example with a delayed setting of *sl* and *tp* with the second request after the successful opening of a position.

6.4.15 Modifying Stop Loss and/or Take Profit levels of a position

An MQL program can change protective *Stop Loss* and *Take Profit* price levels for an open position. The TRADE_ACTION_SLTP element in the ENUM_TRADE_REQUEST_ACTIONS enumeration is intended for this purpose, that is, when filling the *MqlTradeRequest* structure, we should write TRADE_ACTION_SLTP in the *action* field.

This is the only required field. The need to fill in other fields is determined by the account operation mode ENUM_ACCOUNT_MARGIN_MODE. On hedging accounts, you should fill in the *symbol* field, but you can omit the position ticket. On hedging accounts, on the contrary, it is mandatory to indicate the *position* position ticket, but you can omit the symbol. This is due to the specifics of position identification on accounts of different types. During netting, only one position can exist for each symbol.

In order to unify the code, it is recommended to fill in both fields if information is available.

Protective price levels are set in the *sl* and *tp* fields. It is possible to est only one of the fields. To remove protective levels, assign zero values to them.

The following table summarizes the requirements for filling in the fields depending on the counting modes. Required fields are marked with an asterisk, optional fields are marked with a plus.

Field	Netting	Hedging
action	*	*
symbol	*	+
position	+	*
sl	+	+
tp	+	+

To perform the operation of modifying protective levels, we introduce several overloads of the *adjust* method in the *MqlTradeRequestSync* structure.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool adjust(const ulong pos, const double stop = 0, const double take = 0);
   bool adjust(const string name, const double stop = 0, const double take = 0);
   bool adjust(const double stop = 0, const double take = 0);
   ...
};
```

As we saw above, depending on the environment, modification can be done only by ticket or only by position symbol. These options are taken into account in the first two prototypes.

In addition, since the structure may have already been used for previous requests, it may have filled *position* and *symbols* fields. Then you can call the method with the last prototype.

We do not yet show the implementation of these three methods, because it is clear that it must have a common body with sending a request. This part is framed as a private helper method *_adjust* with a full set of options. Here its code is given with some abbreviations that do not affect the logic of work.

```
private:
   bool _adjust(const ulong pos, const string name,
      const double stop = 0, const double take = 0)
   {
      action = TRADE_ACTION_SLTP;
      position = pos;
      type = (ENUM_ORDER_TYPE)PositionGetInteger(POSITION_TYPE);
      if(!setSymbol(name)) return false;
      if(!setSLTP(stop, take)) return false;
      ZeroMemory(result);
      return OrderSend(this, result);
   }
```

We fill in all the fields of the structure according to the above rules, calling the previously described *setSymbol* and *setSLTP* methods, and then send a request to the server. The result is a success status (*true*) or errors (*false*).

Each of the overloaded *adjust* methods separately prepares source parameters for the request. This is how it is done in the presence of a position ticket.

```
public:
   bool adjust(const ulong pos, const double stop = 0, const double take = 0)
   {
      if(!PositionSelectByTicket(pos))
      {
         Print("No position: P=" + (string)pos);
         return false;
      }
      return _adjust(pos, PositionGetString(POSITION_SYMBOL), stop, take);
   }
```

Here, using the built-in *PositionSelectByTicket* function, we check for the presence of a position and its selection in the trading environment of the terminal, which is necessary for the subsequent reading of its properties, in this case, the symbol (*PositionGetString(POSITION_SYMBOL)*). Then the universal variant is called *adjust*.

When modifying a position by symbol name (which is only available on a netting account), you can use another option *adjust*.

```
bool adjust(const string name, const double stop = 0, const double take = 0)
{
   if(!PositionSelect(name))
   {
      Print("No position: " + s);
      return false;
   }

   return _adjust(PositionGetInteger(POSITION_TICKET), name, stop, take);
}
```

Here, position selection is done using the built-in *PositionSelect* function, and the ticket number is obtained from its properties (*PositionGetInteger(POSITION_TICKET)*).

All of these features will be discussed in detail in their respective sections on working with positions and position properties.

The *adjust* method version with the most minimalist set of parameters, i.e. with only *stop* and *take* levels, is as follows.

```
bool adjust(const double stop = 0, const double take = 0)
{
   if(position != 0)
   {
      if(!PositionSelectByTicket(position))
      {
         Print("No position with ticket P=" + (string)position);
         return false;
      }
      const string s = PositionGetString(POSITION_SYMBOL);
      if(symbol != NULL && symbol != s)
      {
         Print("Position symbol is adjusted from " + symbol + " to " + s);
      }
      symbol = s;
   }
   else if(AccountInfoInteger(ACCOUNT_MARGIN_MODE)
      != ACCOUNT_MARGIN_MODE_RETAIL_HEDGING
      && StringLen(symbol) > 0)
   {
      if(!PositionSelect(symbol))
      {
         Print("Can't select position for " + symbol);
         return false;
      }
      position = PositionGetInteger(POSITION_TICKET);
   }
   else
   {
      Print("Neither position ticket nor symbol was provided");
      return false;
   }
   return _adjust(position, symbol, stop, take);
}
```

This code ensures that the *position* and *symbols* fields are filled correctly in various modes or that it exits early with an error message in the log. At the end, the private version of *_adjust* is called, which sends the request via *OrderSend*.

Similar to *buy/sell* methods, the set of *adjust* methods works "asynchronously": upon their completion, only the request sending status is known, but there is no confirmation of the modification of the levels. As we know, for the stock exchange, the *Take Profit* level can be forwarded as a limit order. Therefore, in the *MqlTradeResultSync* structure, we should provide a "synchronous" wait until the changes take effect.

The general wait mechanism formed as the *MqlTradeResultSync::wait* method is already ready and has been used to wait for the opening of a position. The *wait* method receives as the first parameter a pointer to another method with a predefined prototype *condition* to poll in a loop until the required condition is met or a timeout occurs. In this case, this *condition*-compatible method should perform an applied check of the stop levels in the position.

Let's add such a new method called *adjusted*.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   bool adjusted(const ulong msc = 1000)
   {
      if(retcode != TRADE_RETCODE_DONE || retcode != TRADE_RETCODE_PLACED)
      {
         return false;
      }

      if(!wait(checkSLTP, msc))
      {
         Print("SL/TP modification timeout: P=" + (string)position);
         return false;
      }

      return true;
   }
```

First of all, of course, we check the status in the field *retcode*. If there is a standard status, we continue checking the levels themselves, passing to *wait* an auxiliary method *checkSLTP*.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   static bool checkSLTP(MqlTradeResultSync &ref)
   {
      if(PositionSelectByTicket(ref.position))
      {
         return TU::Equal(PositionGetDouble(POSITION_SL), /*.?.*/)
            && TU::Equal(PositionGetDouble(POSITION_TP), /*.?.*/);
      }
      else
      {
         Print("PositionSelectByTicket failed: P=" + (string)ref.position);
      }
      return false;
   }
```

This code ensures that the position is selected by ticket in the trading environment of the terminal using *PositionSelectByTicket* and reads the position properties POSITION_SL and POSITION_TP, which should be compared with what was in the request. The problem is that here we don't have access to the request object and we must somehow pass here a couple of values for the places marked with '.?.'.

Basically, since we are designing the *MqlTradeResultSync* structure, we can add *sl* and *tp* fields to it and fill them with values from *MqlTradeRequestSync* before sending the request (the kernel does not "know" about our added fields and will leave them untouched during the*OrderSend* call). But for simplicity, we will use what is already available. The *bid* and *ask* fields in the *MqlTradeResultSync* structure are only used to report requote prices (TRADE_RETCODE_REQUOTE status), which is not related to the TRADE_ACTION_SLTP request, so we can store the *sl* and *tp* from the completed *MqlTradeRequestSync* in them.

It is logical to make this in the *completed* method of the *MqlTradeRequestSync* structure which starts a blocking wait for the trading operation results with a predefined timeout. So far, its code has only had one branch for the TRADE_ACTION_DEAL action. To continue, let's add a branch for TRADE_ACTION_SLTP.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool completed()
   {
      if(action == TRADE_ACTION_DEAL)
      {
         const bool success = result.opened(timeout);
         if(success) position = result.position;
         return success;
      }
      else if(action == TRADE_ACTION_SLTP)
      {
         // pass the original request data for comparison with the position propertie
         // by default they are not in the result structure
         result.position = position;
         result.bid = sl; // bid field is free in this result type, use under StopLos
         result.ask = tp; // ask field is free in this type of result, we use it unde
         return result.adjusted(timeout);
      }
      return false;
   }
```

As you can see, after setting the position ticket and price levels from the request, we call the *adjusted* method discussed above which checks *wait(checkSLTP)*. Now we can return to the helper method *checkSLTP* in the *MqlTradeResultSync* structure and bring it to its final form.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   static bool checkSLTP(MqlTradeResultSync &ref)
   {
      if(PositionSelectByTicket(ref.position))
      {
         return TU::Equal(PositionGetDouble(POSITION_SL), ref.bid) // sl from request
            && TU::Equal(PositionGetDouble(POSITION_TP), ref.ask); // tp from request
      }
      else
      {
         Print("PositionSelectByTicket failed: P=" + (string)ref.position);
      }
      return false;
   }
```

This completes the extension of the functionality of structures *MqlTradeRequestSync* and *MqlTradeResultSync* for the of *Stop Loss* and *Take Profit* modification operation.

With this in mind, let's continue with the example of the Expert Advisor *MarketOrderSend.mq5* which we started in the previous section. Let's add to it an input parameter *Distance2SLTP*, which allows you to specify the distance in points to the levels *Stop Loss* and *Take Profit*.

```
input int Distance2SLTP = 0; // Distance to SL/TP in points (0 = no)
```

When it is zero, no guard levels will be set.

In the working code, after receiving confirmation of opening a position, we calculate the values of the levels in the SL and TP variables and perform a synchronous modification: *request.adjust(SL, TP) && request.completed()*.

```
   ...
   const ulong order = (wantToBuy ?
      request.buy(symbol, volume, Price) :
      request.sell(symbol, volume, Price));
   if(order != 0)
   {
      Print("OK Order: #=", order);
      if(request.completed()) // waiting for position opening
      {
         Print("OK Position: P=", request.result.position);
         if(Distance2SLTP != 0)
         {
            // position "selected" in the trading environment of the terminal inside
            // so it is not required to do this explicitly on the ticket
            // PositionSelectByTicket(request.result.position);

            // with the selected position, you can find out its properties, but we ne
            // to step back from it by a given number of points
            const double price = PositionGetDouble(POSITION_PRICE_OPEN);
            const double point = SymbolInfoDouble(symbol, SYMBOL_POINT);
            // we count the levels using the auxiliary class TradeDirection
            TU::TradeDirection dir((ENUM_ORDER_TYPE)Type);
            // SL is always "worse" and TP is always "better" of the price: the code
            const double SL = dir.negative(price, Distance2SLTP * point);
            const double TP = dir.positive(price, Distance2SLTP * point);
            if(request.adjust(SL, TP) && request.completed())
            {
               Print("OK Adjust");
            }
         }
      }
   }
   Print(TU::StringOf(request));
   Print(TU::StringOf(request.result));
}
```

In the first call of *completed* after a successful buy or sell operation, the position ticket is saved in the *position* field of the request structure. Therefore, to modify stops, only price levels are sufficient, and the symbol and ticket of the position are already present in *request*.

Let's try to execute a buy operation using the Expert Advisor with default settings but with *Distance2SLTP* set at 500 points.

```
OK Order: #=1273913958
Waiting for position for deal D=1256506526
OK Position: P=1273913958
OK Adjust
TRADE_ACTION_SLTP, EURUSD, ORDER_TYPE_BUY, V=0.01, ORDER_FILLING_FOK, @ 1.10889, »
»  SL=1.10389, TP=1.11389, P=1273913958
DONE, Bid=1.10389, Ask=1.11389, Request executed, Req=26
```

The last two lines correspond to the debug output to the log of the contents of the *request* and *request.result* structures, initiated at the end of the function. In these lines, it is interesting that the fields store a symbiosis of values from two queries: first, a position was opened, and then it was modified. In particular, the fields with volume (0.01) and price (1.10889) in the request remained after TRADE_ACTION_DEAL, but did not prevent the execution of TRADE_ACTION_SLTP. In theory, it is easy to get rid of this by resetting the structure between two requests, however, we preferred to leave them as they are, because among the filled fields there are also useful ones: the *position* field received the ticket we need to request the modification. If we reset the structure, then we would need to introduce a variable for intermediate storage of the ticket.

In general cases, of course, it is desirable to adhere to a strict data initialization policy, but knowing how to use them in specific scenarios (such as two or more related requests of a predefined type) allows you to optimize your code.

Also, one should not be surprised that in the structure with the result, we see the requested levels *sl* and *tp* in the fields for the *Bid* and *Ask* prices: they were written there by the *MqlTradeRequestSync::completed* method for the purpose of comparison with the actual position changes. When executing the request, the system kernel filled only *retcode* (DONE), *comment* ("Request executed"), and *request_id* (26) in the *result* structure.

Next, we will consider another example of level modification that implements the trailing stop.

6.4.16 Trailing stop

One of the most common tasks where the ability to change protective price levels is used is to sequentially shift *Stop Loss* at a better price as the favorable trend continues. This is the trailing stop. We implement it using new structures *MqlTradeRequestSync* and *MqlTradeResultSync* from previous sections.

To be able to connect the mechanism to any Expert Advisor, let's declare it as the *Trailing Stop* class (see the file *TrailingStop.mqh*). We will store the number of the controlled position, its symbol, and the size of the price point, as well as the required distance of the stop loss level from the current price, and the step of level changes in the personal variables of the class.

```
#include <MQL5Book/MqlTradeSync.mqh>

class TrailingStop
{
   const ulong ticket;  // ticket of controlled position
   const string symbol; // position symbol
   const double point;  // symbol price pip size
   const uint distance; // distance to the stop in points
   const uint step;     // movement step (sensitivity) in points
   ...
```

The distance is only needed for the standard position tracking algorithm provided by the base class. Derived classes will be able to move the protective level according to other principles, such as moving averages, channels, the SAR indicator, and others. After getting acquainted with the base class, we will give an example of a derived class with a moving average.

Let's create the *level* variable for the current stop price level. In the *ok* variable, we will maintain the current status of the position: *true* if the position still exists and *false* if an error occurred and the position was closed.

```
protected:
   double level;
   bool ok;
   virtual double detectLevel()
   {
      return DBL_MAX;
   }
```

A virtual method *detectLevel* is intended for overriding in descendant classes, where the stop price should be calculated according to an arbitrary algorithm. In this implementation, a special value DBL_MAX is returned, indicating the work according to the standard algorithm (see below).

In the constructor, fill in all the fields with the values of the corresponding parameters. The *PositionSelectByTicket* function checks for the existence of a position with a given ticket and allocates it in the program environment so that the subsequent call of *PositionGetString* returns its string property with the symbol name.

```
public:
   TrailingStop(const ulong t, const uint d, const uint s = 1) :
      ticket(t), distance(d), step(s),
      symbol(PositionSelectByTicket(t) ? PositionGetString(POSITION_SYMBOL) : NULL),
      point(SymbolInfoDouble(symbol, SYMBOL_POINT))
   {
      if(symbol == NULL)
      {
         Print("Position not found: " + (string)t);
         ok = false;
      }
      else
      {
         ok = true;
      }
   }

   bool isOK() const
   {
      return ok;
   }
```

Now let's consider the main public method of the *trail* class. The MQL program will need to call it on every tick or by timer to keep track of the position. The method returns *true* while the position exists.

```
   virtual bool trail()
   {
      if(!PositionSelectByTicket(ticket))
      {
         ok = false;
         return false; // position closed
      }

      // find out prices for calculations: current quote and stop level
      const double current = PositionGetDouble(POSITION_PRICE_CURRENT);
      const double sl = PositionGetDouble(POSITION_SL);
      ...
```

Here and below we use the position properties reading functions. They will be discussed in detail in a separate section. In particular, we need to find out the direction of trade – buying and selling – in order to know in which direction the stop level should be set.

```
      // POSITION_TYPE_BUY  = 0 (false)
      // POSITION_TYPE_SELL = 1 (true)
      const bool sell = (bool)PositionGetInteger(POSITION_TYPE);
      TU::TradeDirection dir(sell);
      ...
```

For calculations and checks, we will use the helper class *TU::TradeDirection* and its object *dir*. For example, its *negative* method allows you to calculate the price located at a specified distance from the current price in a losing direction, regardless of the type of operation. This simplifies the code because otherwise you would have to do "mirror" calculations for buys and sells.

```
      level = detectLevel();
      // we can't trail without a level: removing the stop level must be done by the
      if(level == 0) return true;
      // if there is a default value, make a standard offset from the current price
      if(level == DBL_MAX) level = dir.negative(current, point * distance);
      level = TU::NormalizePrice(level, symbol);

      if(!dir.better(current, level))
      {
         return true; // you can't set a stop level on the profitable side<
      }
      ...
```

The *better* method of the *TU::TradeDirection* class checks that the received stop level is located on the right side of the price. Without this method, we would need to write the check twice again (for buys and sells).

We may get an incorrect stop level value since the *detectLevel* method can be overridden in derived classes. With the standard calculation, this problem is eliminated because the level is calculated by the *dir* object.

Finally, when the level is calculated, it is necessary to apply it to the position. If the position does not already have a stop loss, any valid level will do. If the stop loss has already been set, then the new value should be better than the previous one and differ by more than the specified step.

```
      if(sl == 0)
      {
         PrintFormat("Initial SL: %f", level);
         move(level);
      }
      else
      {
         if(dir.better(level, sl) && fabs(level - sl) >= point * step)
         {
            PrintFormat("SL: %f -> %f", sl, level);
            move(level);
         }
      }

      return true; // success
   }
```

Sending of a position modification request is implemented in the *move* method which uses the familiar *adjust* method of the *MqlTradeRequestSync* structure (see the section Modifying Stop Loss and/or Take Profit levels).

```
   bool move(const double sl)
   {
      MqlTradeRequestSync request;
      request.position = ticket;
      if(request.adjust(sl, 0) && request.completed())
      {
         Print("OK Trailing: ", TU::StringOf(sl));
         return true;
      }
      return false;
   }
};
```

Now everything is ready to add trailing to the test Expert Advisor *TrailingStop.mq5*. In the input parameters, you can specify the trading direction, the distance to the stop level in points, and the step in points. The *TrailingDistance* parameter equals 0 by default, which means automatic calculation of the daily range of quotes and using half of it as a distance.

```
#include <MQL5Book/MqlTradeSync.mqh>
#include <MQL5Book/TrailingStop.mqh>

enum ENUM_ORDER_TYPE_MARKET
{
   MARKET_BUY = ORDER_TYPE_BUY,    // ORDER_TYPE_BUY
   MARKET_SELL = ORDER_TYPE_SELL   // ORDER_TYPE_SELL
};

input int TrailingDistance = 0;   // Distance to Stop Loss in points (0 = autodetect)
input int TrailingStep = 10;      // Trailing Step in points
input ENUM_ORDER_TYPE_MARKET Type;
input string Comment;
input ulong Deviation;
input ulong Magic = 1234567890;
```

When launched, the Expert Advisor will find if there is a position on the current symbol with the specified *Magic* number and will create it if it doesn't exist.

Trailing will be carried out by an object of the *TrailingStop* class wrapped in a smart pointer *AutoPtr*. Thanks to the latter, we don't need to manually delete the old object when it needs a new tracking object to replace it for the new position being created. When a new object is assigned to a smart pointer, the old object is automatically deleted. Recall that dereferencing a smart pointer, i.e., accessing the work object stored inside, is done using the overloaded [] operator.

```
#include <MQL5Book/AutoPtr.mqh>

AutoPtr<TrailingStop> tr;
```

In the *OnTick* handler, we check if there is an object. If there is one, check whether a position exists (the attribute is returned from the *trail* method). Immediately after the program starts, the object is not there, and the pointer is NULL. In this case, you should either create a new position or find an already open one and create a *Trailing Stop* object for it. This is done by the *Setup* function. On subsequent calls of *OnTick*, the object starts and continues tracking, preventing the program from going inside the *if* block while the position is "alive".

```
void OnTick()
{
   if(tr[] == NULL || !tr[].trail())
   {
      // if there is no trailing yet, create or find a suitable position
      Setup();
   }
}
```

And here is the *Setup* function.

```
void Setup()
{
   int distance = 0;
   const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);

   if(trailing distance == 0) // auto-detect the daily range of prices
   {
      distance = (int)((iHigh(_Symbol, PERIOD_D1, 1) - iLow(_Symbol, PERIOD_D1, 1))
         / point / 2);
      Print("Autodetected daily distance (points): ", distance);
   }
   else
   {
      distance = TrailingDistance;
   }

   // process only the position of the current symbol and our Magic
   if(GetMyPosition(_Symbol, Magic))
   {
      const ulong ticket = PositionGetInteger(POSITION_TICKET);
      Print("The next position found: ", ticket);
      tr = new TrailingStop(ticket, distance, TrailingStep);
   }
   else // there is no our position
   {
      Print("No positions found, lets open it...");
      const ulong ticket = OpenPosition();
      if(ticket)
      {
         tr = new TrailingStop(ticket, distance, TrailingStep);
      }
   }

   if(tr[] != NULL)
   {
      // Execute trailing for the first time immediately after creating or finding a
      tr[].trail();
   }
}
```

The search for a suitable open position is implemented in the *GetMyPosition* function, and opening a new position is done by the *OpenPosition* function. Both are presented below. In any case, we get a position ticket and create a trailing object for it.

```
bool GetMyPosition(const string s, const ulong m)
{
   for(int i = 0; i < PositionsTotal(); ++i)
   {
      if(PositionGetSymbol(i) == s && PositionGetInteger(POSITION_MAGIC) == m)
      {
         return true;
      }
   }
   return false;
}
```

The purpose and the general meaning of the algorithm should be clear from the names of the built-in functions. In the loop through all open positions (*PositionsTotal*), we sequentially select each of them using *PositionGetSymbol* and get its symbol. If the symbol matches the requested one, we read and compare the position property POSITION_MAGIC with the passed "magic". All functions for working with positions will be discussed in a separate section.

The function will return *true* as soon as the first matching position is found. At the same time, the position will remain selected in the trading environment of the terminal which makes it possible for the rest of the code to read its other properties if necessary.

We already know the algorithm for opening a position.

```
ulong OpenPosition()
{
   MqlTradeRequestSync request;

   // default values
   const bool wantToBuy = Type == MARKET_BUY;
   const double volume = SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN);
   // optional fields are filled directly in the structure
   request.magic = Magic;
   request.deviation = Deviation;
   request.comment = Comment;
   ResetLastError();
   // execute the selected trade operation and wait for its confirmation
   if((bool)(wantToBuy ? request.buy(volume) : request.sell(volume))
      && request.completed())
   {
      Print("OK Order/Deal/Position");
   }

   return request.position; // non-zero value - sign of success
}
```

For clarity, let's see how this program works in the tester, in visual mode.

After compilation, let's open the strategy tester panel in the terminal, on the *Review* tab, and choose the first option: *Single test*.

In the *Settings* tab, select the following:

- in the drop-down list *Expert Advisor*: MQL5Book\p6\TralingStop

- *Symbol*: EURUSD
- *Timeframe*: H1
- *Interval*: last year, month, or custom
- *Forward*: No
- *Delays*: disabled
- *Modeling*: based on real or generated ticks
- *Optimization*: disabled
- *Visual mode*: enabled

Once you press *Start*, you will see something like this in a separate tester window:

Standard trailing stop in the tester

The log will show entries that look like this:

```
2022.01.10 00:02:00   Autodetected daily distance (points): 373
2022.01.10 00:02:00   No positions found, let's open it...
2022.01.10 00:02:00   instant buy 0.01 EURUSD at 1.13612 (1.13550 / 1.13612 / 1.13550
2022.01.10 00:02:00   deal #2 buy 0.01 EURUSD at 1.13612 done (based on order #2)
2022.01.10 00:02:00   deal performed [#2 buy 0.01 EURUSD at 1.13612]
2022.01.10 00:02:00   order performed buy 0.01 at 1.13612 [#2 buy 0.01 EURUSD at 1.13
2022.01.10 00:02:00   Waiting for position for deal D=2
2022.01.10 00:02:00   OK Order/Deal/Position
2022.01.10 00:02:00   Initial SL: 1.131770

2022.01.10 10:06:38   order performed sell 0.01 at 1.13221 [#3 sell 0.01 EURUSD at 1.
2022.01.10 10:06:38   Autodetected daily distance (points): 373
2022.01.10 10:06:38   No positions found, let's open it...
```

Look how the algorithm shifts the SL level up with a favorable price movement, up to the moment when the position is closed by stop loss. Immediately after liquidating a position, the program opens a new one.

To check the possibility of using non-standard tracking mechanisms, we implement an example of an algorithm on a moving average. To do this, let's go back to the file *TrailingStop.mqh* and describe the derived class *TrailingStopByMA*.

```
class TrailingStopByMA: public TrailingStop
{
   int handle;

public:
   TrailingStopByMA(const ulong t, const int period,
      const int offset = 1,
      const ENUM_MA_METHOD method = MODE_SMA,
      const ENUM_APPLIED_PRICE type = PRICE_CLOSE): TrailingStop(t, 0, 1)
   {
      handle = iMA(_Symbol, PERIOD_CURRENT, period, offset, method, type);
   }

   virtual double detectLevel() override
   {
      double array[1];
      ResetLastError();
      if(CopyBuffer(handle, 0, 0, 1, array) != 1)
      {
         Print("CopyBuffer error: ", _LastError);
         return 0;
      }
      return array[0];
   }
};
```

It creates the *iMA* indicator instance in the constructor: the period, the averaging method, and the price type are passed via parameters.

In the overridden *detectLevel* method, we read the value from the indicator buffer, and by default, this is done with an offset of 1 bar, i.e., the bar is closed, and its readings do not change when ticks arrive. Those who wish can take the value from the zero bar, but such signals are unstable for all price types, except for PRICE_OPEN.

To use a new class in the same test Expert Advisor *TrailingStop.mq5*, let's add another input parameter *MATrailingPeriod* with a moving period (we will leave other parameters of the indicator unchanged).

```
input int MATrailingPeriod = 0;   // Period for Trailing by MA (0 = disabled)
```

The value of 0 in this parameter disables the trailing moving average. If it is enabled, the distance settings in the *TrailingDistance* parameter are ignored.

Depending on this parameter, we will create either a standard trailing object *TrailingStop* or the one derivative from *iMA* –*TrailingStopByMA*.

```
      ...
      tr = MATrailingPeriod > 0 ?
         new TrailingStopByMA(ticket, MATrailingPeriod) :
         new TrailingStop(ticket, distance, TrailingStep);
      ...
```

Let's see how the updated program behaves in the tester. In the Expert Advisor settings, set a non-zero period for MA, for example, 10.

Trailing stop on the moving average in the tester

Please note that in those moments when the average comes close to the price, there is an effect of frequent stop-loss triggering and closing the position. When the average is above the quotes, a protective level is not set at all, because this is not correct for buying. This is a consequence of the fact that our Expert Advisor does not have any strategy and always opens positions of the same type, regardless of the situation on the market. For sales, the same paradoxical situation will occasionally arise when the average goes below the price, which means the market is growing, and the robot "stubbornly" gets into a short position.

In working strategies, as a rule, the direction of the position is chosen taking into account the movement of the market, and the moving average is located on the right side of the current price, where placing a stop loss is allowed.

6.4.17 Closing a position: full and partial

Technically, closing a position can be thought of as a trading operation that is opposite to the one used to open it. For example, to exit a buy, you need to make a sell operation (ORDER_TYPE_SELL in the *type* field) and to exit the sell one you need to buy (ORDER_TYPE_BUY in the *type* field).

The trading operation type in the *action* field of the *MqlTradeTransaction* structure remains the same: TRADE_ACTION_DEAL.

On a hedging account, the position to be closed must be specified using a ticket in the *position* field. For netting accounts, you can specify only the name of the symbol in the *symbol* field since only one symbol position is possible on them. However, you can also close positions by ticket here.

In order to unify the code, it makes sense to fill in both *position* and *symbol* fields regardless of account type.

Also, be sure to set the volume in the *volume* field. If it is equal to the position volume, it will be closed completely. However, by specifying a lower value, it is possible to close only part of the position.

In the following table, all mandatory structure fields are marked with an asterisk and optional fields are marked with a plus.

Field	Netting	Hedging
action	*	*
symbol	*	+
position	+	*
type	*	*
type_filling	*	*
volume	*	*
price	*'	*'
deviation	±	±
magic	+	+
comment	+	+

The *price* field marked is with an asterisk with a tick because it is required only for symbols with the *Request* and *Instant* execution modes), while for the *Exchange* and *Market* execution, the price in the structure is not taken into account.

For a similar reason, the *deviation* field is marked with '±'. It has effect only for *Instant* and *Request* modes.

To simplify the programmatic implementation of closing a position, let's return to our extended structure *MqlTradeRequestSync* in the file *MqlTradeSync.mqh*. The method for closing a position by ticket has the following code.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   double partial; // volume after partial closing
   ...
   bool close(const ulong ticket, const double lot = 0)
   {
      if(!PositionSelectByTicket(ticket)) return false;

      position = ticket;
      symbol = PositionGetString(POSITION_SYMBOL);
      type = (ENUM_ORDER_TYPE)(PositionGetInteger(POSITION_TYPE) ^ 1);
      price = 0;
      ...
```

Here we first check for the existence of a position by calling the *PositionSelectByTicket* function. Additionally, this call makes the position selected in the trading environment of the terminal, which allows you to read its properties using the subsequent functions. In particular, we find out the symbol of a position from the POSITION_SYMBOL property and "reverse" its type from POSITION_TYPE to the opposite one in order to get the required order type.

The position types in the ENUM_POSITION_TYPE enum are POSITION_TYPE_BUY (value 0) and POSITION_TYPE_SELL (value 1). In the enumeration of order types ENUM_ORDER_TYPE, exactly the same values are occupied by market operations: ORDER_TYPE_BUY and ORDER_TYPE_SELL. That is why we can bring the first enumeration to the second one, and to get the opposite direction of trading, it is enough to switch the zero bit using the exclusive OR operation ('^'): we get 1 from 0, and 0 from 1.

Zeroing the *price* field means automatic selection of the correct current price (*Ask* or *Bid*) before sending the request: this is done a little later, inside the helper method *setVolumePrices*, which is called further along the algorithm, from the *market* method.

The *_market* method call occurs a couple of lines below. The *_market* method generates a market order for the full volume or a part, taking into account all the completed fields of the structure.

```
      const double total = lot == 0 ? PositionGetDouble(POSITION_VOLUME) : lot;
      partial = PositionGetDouble(POSITION_VOLUME) - total;
      return _market(symbol, total);
   }
```

This fragment is slightly simplified compared to the current source code. The full code contains the handling of a rare but possible situation when the position volume exceeds the maximum allowed volume in one order per symbol (SYMBOL_VOLUME_MAX property). In this case, the position has to be closed in parts, via several orders.

Also note that since the position can be closed partially, we had to add a field to the *partial* structure, where the planned balance of the volume after the operation is placed. Of course, for a complete closure, this will be 0. This information will be required to further verify the completion of the operation.

For netting accounts, there is a version of the *close* method that identifies the position by symbol name. It selects a position by symbol, gets its ticket, and then refers to the previous version of *close*.

```
bool close(const string name, const double lot = 0)
{
   if(!PositionSelect(name)) return false;
   return close(PositionGetInteger(POSITION_TICKET), lot);
}
```

In the *MqlTradeRequestSync* structure, we have the *completed* method that provides a synchronous wait for the completion of the operation, if necessary. Now we need to supplement it to close positions, in the branch where *action* equals TRADE_ACTION_DEAL. We will distinguish between opening a position and closing by a zero value in the *position* field: it has no ticket when opening a position and has one when closing.

```
bool completed()
{
   if(action == TRADE_ACTION_DEAL)
   {
      if(position == 0)
      {
         const bool success = result.opened(timeout);
         if(success) position = result.position;
         return success;
      }
      else
      {
         result.position = position;
         result.partial = partial;
         return result.closed(timeout);
      }
   }
```

To check the actual closing of a position, we have added the *closed* method into the *MqlTradeResultSync* structure. Before calling it, we write the position ticket in the *result.position* field so that the result structure can track the moment when the corresponding ticket disappears from the trading environment of the terminal, or when the volume equals *result.partial* in case of partial closure.

Here is the *closed* method. It is built on a well-known principle: first checking the success of the server return code, and then waiting with the *wait* method for some condition to fulfill.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   bool closed(const ulong msc = 1000)
   {
      if(retcode != TRADE_RETCODE_DONE)
      {
         return false;
      }
      if(!wait(positionRemoved, msc))
      {
         Print("Position removal timeout: P=" + (string)position);
      }

      return true;
   }
```

In this case, to check the condition for the position to disappear, we had to implement a new function *positionRemoved*.

```
   static bool positionRemoved(MqlTradeResultSync &ref)
   {
      if(ref.partial)
      {
         return PositionSelectByTicket(ref.position)
            && TU::Equal(PositionGetDouble(POSITION_VOLUME), ref.partial);
      }
      return !PositionSelectByTicket(ref.position);
   }
```

We will test the operation of closing positions using the Expert Advisor *TradeClose.mq5*, which implements a simple trading strategy: enter the market if there are two consecutive bars in the same direction, and as soon as the next bar closes in the opposite direction to the previous trend, we exit the market. Repetitive signals during continuous trends will be ignored, that is, there will be a maximum of one position (minimum lot) or none in the market.

The Expert Advisor will not have any adjustable parameters: only the (*Deviation*) and a unique number (*Magic*). The implicit parameters are the timeframe and the working symbol of the chart.

To track the presence of an already open position, we use the *GetMyPosition* function from the previous example *TradeTrailing.mq5*: it searches among positions by symbol and Expert Advisor number and returns a logical *true* if a suitable position is found.

We also take the almost unchanged function *OpenPosition*: it opens a position according to the market order type passed in the single parameter. Here, this parameter will come from the trend detection algorithm, and earlier (in *TrailingStop.mq5*) the order type was set by the user through an input variable.

A new function that implements closing a position is *ClosePosition*. Because the header file *MqlTradeSync.mqh* took over the whole routine, we only need to call the *request.close(ticket)* method for the submitted position ticket and wait for the deletion to complete by *request.completed()*.

In theory, the latter can be avoided if the Expert Advisor analyzes the situation at each tick. In this case, a potential problem with deleting the position will promptly reveal itself on the next tick, and the

Expert Advisor can try to delete it again. However, this Expert Advisor has trading logic based on bars, and therefore it makes no sense to analyze every tick. Next, we implement a special mechanism for bar-by-bar work, and in this regard, we synchronously control the removal, otherwise, the position would remain "hanging" for a whole bar.

```
ulong LastErrorCode = 0;

ulong ClosePosition(const ulong ticket)
{
   MqlTradeRequestSync request; // empty structure

   // optional fields are filled directly in the structure
   request.magic = Magic;
   request.deviation = Deviation;

   ResetLastError();
   // perform close and wait for confirmation
   if(request.close(ticket) && request.completed())
   {
      Print("OK Close Order/Deal/Position");
   }
   else // print diagnostics in case of problems
   {
      Print(TU::StringOf(request));
      Print(TU::StringOf(request.result));
      LastErrorCode = request.result.retcode;
      return 0; // error, code to parse in LastErrorCode
   }

   return request.position; // non-zero value - success
}
```

We could force the *ClosePosition* functions to return 0 in case of successful deletion of the position and an error code otherwise. This seemingly efficient approach would make the behavior of the two functions *OpenPosition* and *ClosePosition* different: in the calling code, it would be necessary to nest the calls of these functions in logical expressions that are opposite in meaning, and this would introduce confusion. In addition, we would require the global variable *LastErrorCode* in any case, in order to add information about the error inside the *OpenPosition* function. Also, the *if(condition)* check is more organically interpreted as success than *if(!condition)*.

The function that generates trading signals according to the above strategy is called *GetTradeDirection*.

```
ENUM_ORDER_TYPE GetTradeDirection()
{
   if(iClose(_Symbol, _Period, 1) > iClose(_Symbol, _Period, 2)
      && iClose(_Symbol, _Period, 2) > iClose(_Symbol, _Period, 3))
   {
      return ORDER_TYPE_BUY; // open a long position
   }

   if(iClose(_Symbol, _Period, 1) < iClose(_Symbol, _Period, 2)
      && iClose(_Symbol, _Period, 2) < iClose(_Symbol, _Period, 3))
   {
      return ORDER_TYPE_SELL; // open a short position
   }

   return (ENUM_ORDER_TYPE)-1; // close
}
```

The function returns a value of the ENUM_ORDER_TYPE type with two standard elements (ORDER_TYPE_BUY and ORDER_TYPE_SELL) triggering buys and sells, respectively. The special value -1 (not in the enumeration) will be used as a close signal.

To activate the Expert Advisor based on the trading algorithm, we use the *OnTick* handler. As we remember, other options are suitable for other strategies, for example, a timer for trading on the news or Depth of Market events for volume trading.

First, let's analyze the function in a simplified form, without handling potential errors. At the very beginning, there is a block that ensures that the further algorithm is triggered only when a new bar is opened.

```
void OnTick()
{
   static datetime lastBar = 0;
   if(iTime(_Symbol, _Period, 0) == lastBar) return;
   lastBar = iTime(_Symbol, _Period, 0);
   ...
```

Next, we get the current signal from the *GetTradeDirection* function.

```
   const ENUM_ORDER_TYPE type = GetTradeDirection();
```

If there is a position, we check whether a signal to close it has been received and call *ClosePosition* if necessary. If there is no position yet and there is a signal to enter the market, we call *OpenPosition*.

```
      if(GetMyPosition(_Symbol, Magic))
      {
         if(type != ORDER_TYPE_BUY && type != ORDER_TYPE_SELL)
         {
            ClosePosition(PositionGetInteger(POSITION_TICKET));
         }
      }
      else if(type == ORDER_TYPE_BUY || type == ORDER_TYPE_SELL)
      {
         OpenPosition(type);
      }
   }
```

To analyze errors, you will need to enclose *OpenPosition* and *ClosePosition* calls into conditional statements and take some action to restore the working state of the program. In the simplest case, it is enough to repeat the request at the next tick, but it is desirable to do this a limited number of times. Therefore, we will create static variables with a counter and an error limit.

```
   void OnTick()
   {
      static int errors = 0;
      static const int maxtrials = 10; // no more than 10 attempts per bar

      // expect a new bar to appear if there were no errors
      static datetime lastBar = 0;
      if(iTime(_Symbol, _Period, 0) == lastBar && errors == 0) return;
      lastBar = iTime(_Symbol, _Period, 0);
      ...
```

The bar-by-bar mechanism is temporarily disabled if errors appear since it is desirable to overcome them as soon as possible.

Errors are counted in conditional statements around *ClosePosition* and *OpenPosition*.

```
      const ENUM_ORDER_TYPE type = GetTradeDirection();

      if(GetMyPosition(_Symbol, Magic))
      {
         if(type != ORDER_TYPE_BUY && type != ORDER_TYPE_SELL)
         {
            if(!ClosePosition(PositionGetInteger(POSITION_TICKET)))
            {
               ++errors;
            }
            else
            {
               errors = 0;
            }
         }
      }
      else if(type == ORDER_TYPE_BUY || type == ORDER_TYPE_SELL)
      {
         if(!OpenPosition(type))
         {
            ++errors;
         }
         else
         {
            errors = 0;
         }
      }
    // too many errors per bar
      if(errors >= maxtrials) errors = 0;
    // error serious enough to pause
      if(IS_TANGIBLE(LastErrorCode)) errors = 0;
   }
```

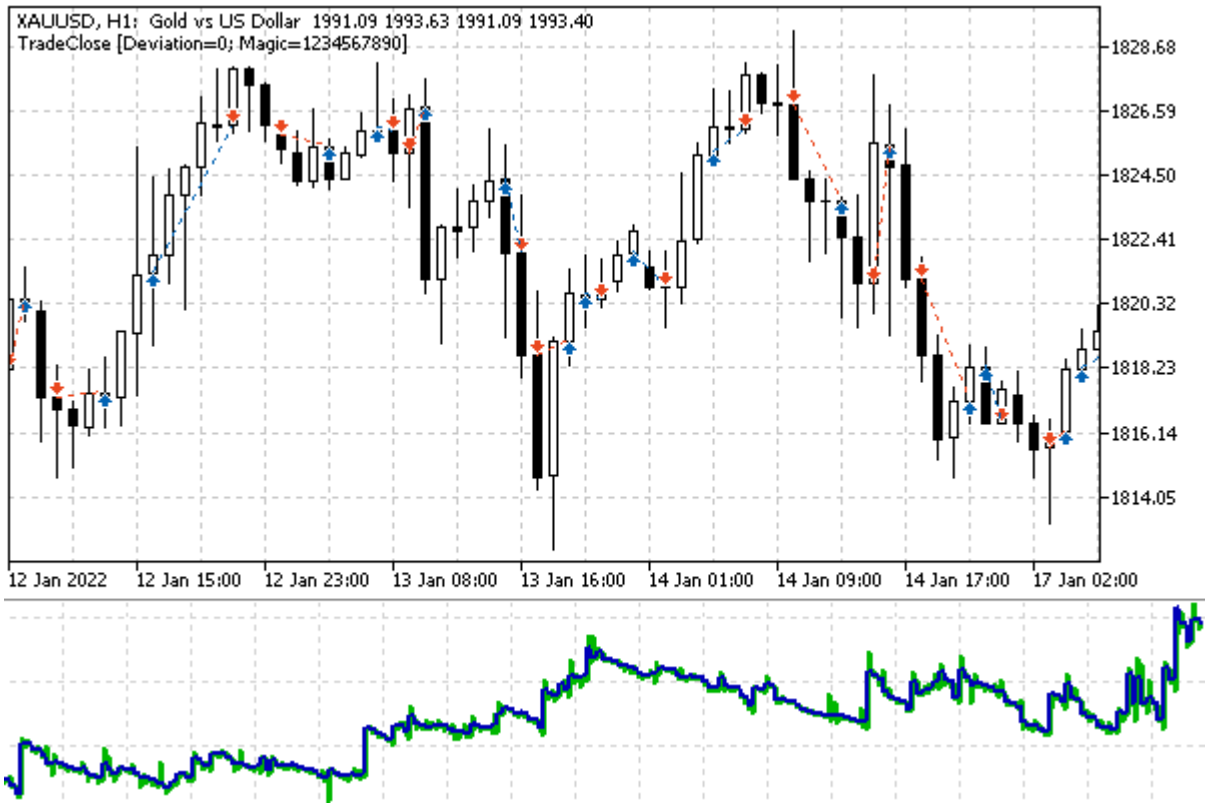
Setting the *errors* variable to 0 turns on the bar-by-bar mechanism again and stops attempts to repeat the request until the next bar.

The macro IS_TANGIBLE is defined in *TradeRetcode.mqh* as:

```
#define IS_TANGIBLE(T) ((T) >= TRADE_RETCODE_ERROR)
```

Errors with smaller codes are operational, that is, normal in a sense. Large codes require analysis and different actions, depending on the cause of the problem: incorrect request parameters, permanent or temporary bans in the trading environment, lack of funds, and so on. We will present an improved error classifier in the section Pending order modification.

Let's run the Expert Advisor in the tester on XAUUSD, H1 from the beginning of 2022, simulating real ticks. The next collage shows a fragment of a chart with deals, as well as the balance curve.



TradeClose testing results on XAUUSD, H1

Based on the report and the log, we can see that the combination of our simple trading logic and the two operations of opening and closing positions is working properly.

In addition to simply closing a position, the platform supports the possibility of mutual closing of two opposite positions on hedging accounts.

6.4.18 Closing opposite positions: full and partial (hedging)

On hedging accounts, it is allowed to open several positions at the same time, and in most cases, these positions can be in the opposite direction. In some jurisdictions, hedging accounts are restricted: you can only have positions in one direction at a time. In this case, you will receive the TRADE_RETCODE_HEDGE_PROHIBITED error code when trying to execute an opposite trading operation. Also, this restriction often correlates with the setting of the ACCOUNT_FIFO_CLOSE account property to *true*.

When two opposite positions are opened at the same time, the platform supports the mechanism of their simultaneous mutual closing using the TRADE_ACTION_CLOSE_BY operation. To perform this action, you should fill two more fields in the *MqlTradeTransaction* structure in addition to the *action* field: *position* and *position_by* must contain the tickets of positions to be closed.

The availability of this feature depends on the SYMBOL_ORDER_MODE property of the financial instrument: SYMBOL_ORDER_CLOSEBY (64) must be present in the allowed flags bitmask.

This operation not only simplifies closing (one operation instead of two) but also saves one spread.

As you know, any new position starts trading with a loss equal to the spread. For example, when buying a financial instrument, a transaction is concluded at the *Ask* price, but for an exit deal, that is, a sale,

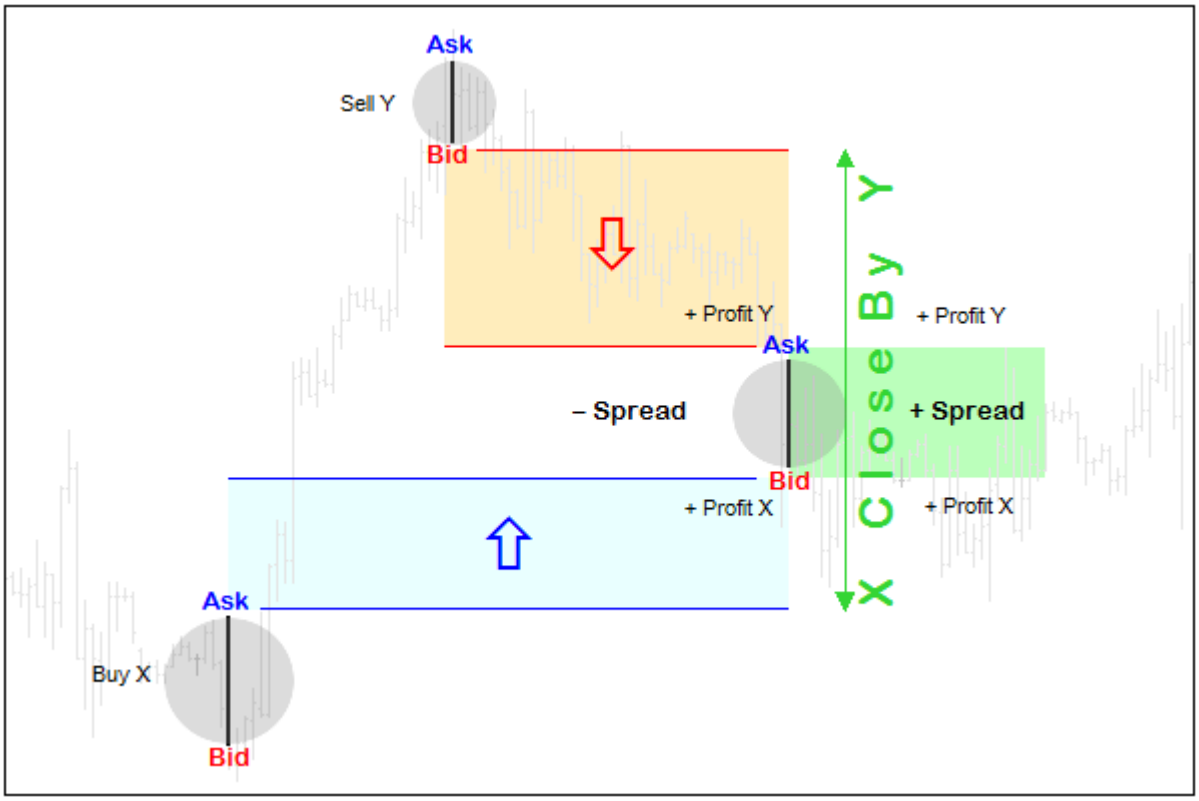
the actual price is *Bid*. For a short position, the situation is reversed: immediately after entering at the *Bid* price, we start tracking the price *Ask* for a potential exit.

If you close positions at the same time in a regular way, their exit prices will be at a distance of the current spread from each other. However, if you use the TRADE_ACTION_CLOSE_BY operation, then both positions will be closed without taking into account the current prices. The price at which positions are offset is equal to the opening price of the *position_by* position (in the request structure). It is specified in the ORDER_TYPE_CLOSE_BY order generated by the TRADE_ACTION_CLOSE_BY request.

Unfortunately, in the reports in the context of deals and positions, the closing and opening prices of opposite positions/deals are displayed in pairs of identical values, in a mirror direction, which gives the impression of a double profit or loss. In fact, the financial result of the operation (the difference between prices adjusted for the lot) is recorded only for the first position exit trade (the *position* field in the request structure). The result of the second exit trade is always 0, regardless of the price difference.

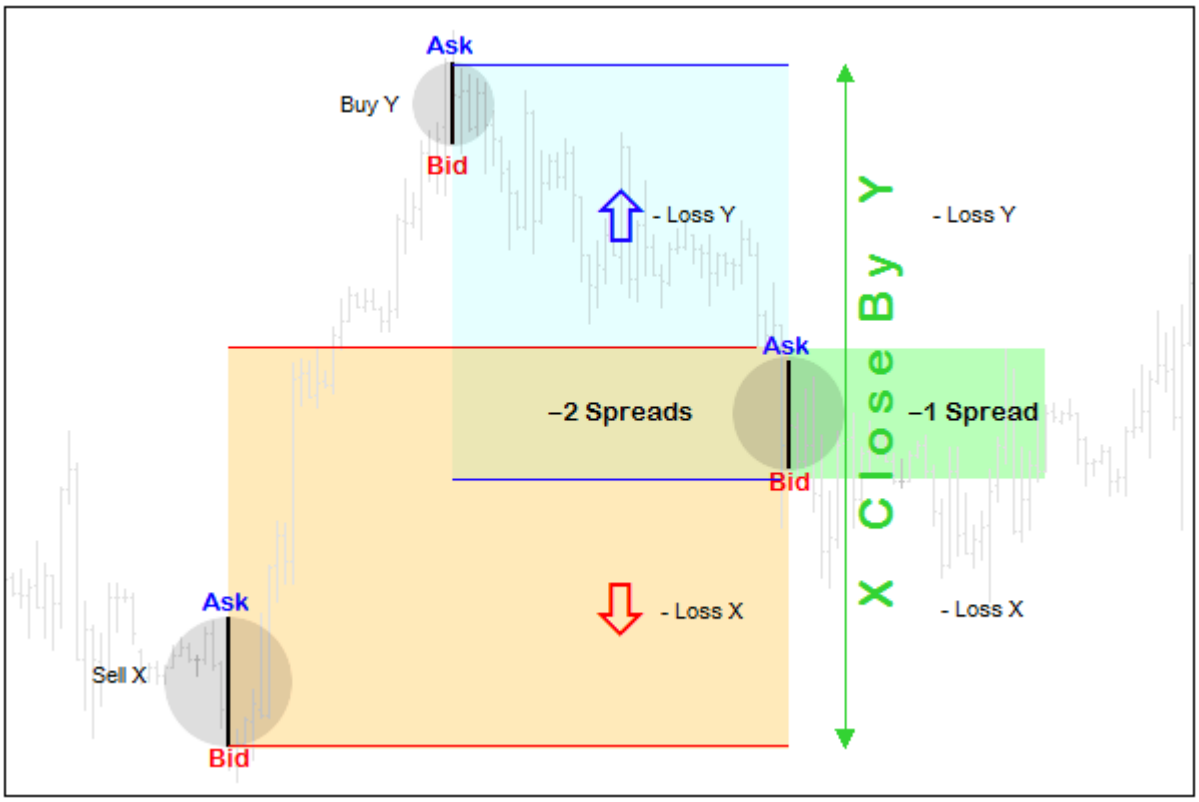
Another consequence of this asymmetry is that from changing the places of tickets in the *position* and *position_by* fields, the profit and loss statistics in the context of long and short trades changes in the trading report, for example, profitable long trades can increase exactly as much as the number of profitable short trades decreases. But this, in theory, should not affect the overall result, if we assume that the delay in the execution of the order does not depend on the order of transfer of tickets.

The following diagram shows a graphical explanation of the process (spreads are intentionally exaggerated).



Spread accounting when closing profitable positions

Here is a case of a profitable pair of positions. If the positions had opposite directions and were at a loss, then when they were closed separately, the spread would be taken into account twice (in each). Counter closing allows you to reduce the loss by one spread.



Accounting for the spread when closing unprofitable positions

Reversed positions do not have to be of equal size. The opposite closing operation will work on the minimum of the two volumes.

In the *MqlTradeSync.mqh* file, the close-by operation is implemented using the *closeby* method with two parameters for position tickets.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool closeby(const ulong ticket1, const ulong ticket2)
   {
      if(!PositionSelectByTicket(ticket1)) return false;
      double volume1 = PositionGetDouble(POSITION_VOLUME);
      if(!PositionSelectByTicket(ticket2)) return false;
      double volume2 = PositionGetDouble(POSITION_VOLUME);

      action = TRADE_ACTION_CLOSE_BY;
      position = ticket1;
      position_by = ticket2;

      ZeroMemory(result);
      if(volume1 != volume2)
      {
         // remember which position should disappear
         if(volume1 < volume2)
            result.position = ticket1;
         else
            result.position = ticket2;
      }
      return OrderSend(this, result);
   }
```

To control the result of the closure, we store the ticket of a smaller position in the *result.position* variable. Everything in the *completed* method and in the *MqlTradeResultSync* structure is ready for synchronous position closing tracking: the same algorithm worked for a normal closing of a position.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool completed()
   {
      ...
      else if(action == TRADE_ACTION_CLOSE_BY)
      {
         return result.closed(timeout);
      }
      return false;
   }
```

Opposite positions are usually used as a replacement for a stop order or an attempt to take profit on a short-term correction while remaining in the market and following the main trend. The option of using a pseudo-stop order allows you to postpone the decision to actually close positions for some time, continuing the analysis of market movements expecting the price to reverse in the right direction. However, it should be kept in mind that "locked" positions require increased deposits and are subject to swaps. That is why it is difficult to imagine a trading strategy built on opposite positions in its pure form, which could serve as an example for this section.

Let's develop the idea of the price-action bar-based strategy outlined in the previous example. The new Expert Advisor is *TradeCloseBy.mq5*.

We will use the previous signal to enter the market upon detection of two consecutive candles that closed in the same direction. A function responsible for its formation is again *GetTradeDirection*. However, let's allow re-entries if the trend continues. The total maximum allowed number of positions will be set in the input variable *PositionLimit*, the default is 5.

The *GetMyPositions* function will undergo some changes: it will have two parameters, which will be references to arrays that accept position tickets: buy and sell separately.

```
#define PUSH(A,V) (A[ArrayResize(A, ArraySize(A) + 1, ArraySize(A) * 2) - 1] = V)

int GetMyPositions(const string s, const ulong m,
   ulong &ticketsLong[], ulong &ticketsShort[])
{
   for(int i = 0; i < PositionsTotal(); ++i)
   {
      if(PositionGetSymbol(i) == s && PositionGetInteger(POSITION_MAGIC) == m)
      {
         if((ENUM_POSITION_TYPE)PositionGetInteger(POSITION_TYPE) == POSITION_TYPE_BU
            PUSH(ticketsLong, PositionGetInteger(POSITION_TICKET));
         else
            PUSH(ticketsShort, PositionGetInteger(POSITION_TICKET));
      }
   }

   const int min = fmin(ArraySize(ticketsLong), ArraySize(ticketsShort));
   if(min == 0) return -fmax(ArraySize(ticketsLong), ArraySize(ticketsShort));
   return min;
}
```

The function returns the size of the smallest array of the two. When it is greater than zero, we have the opportunity to close opposite positions.

If the minimum array is zero size, the function will return the size of another array, but with a minus sign, just to let the calling code know that all positions are in the same direction.

If there are no positions in either direction, the function will return 0.

Opening positions will remain under the control of the function *OpenPosition* - no changes here.

Closing will be carried out only in the mode of two opposite positions in the new function *CloseByPosition*. In other words, this Expert Advisor is not capable of closing positions one at a time, in the usual way. Of course, in a real robot, such a principle is unlikely to occur, but as an example of an oncoming closure, it fits very well. If we need to close a single position, it is enough to open an opposite position for it (at this moment the floating profit or loss is fixed) and call *CloseByPosition* for two.

```
bool CloseByPosition(const ulong ticket1, const ulong ticket2)
{
   MqlTradeRequestSync request;
   request.magic = Magic;

   ResetLastError();
   // send a request and wait for it to complete
   if(request.closeby(ticket1, ticket2))
   {
      Print("Positions collapse initiated");
      if(request.completed())
      {
         Print("OK CloseBy Order/Deal/Position");
         return true; // success
      }
   }

   Print(TU::StringOf(request));
   Print(TU::StringOf(request.result));

   return false; // error
}
```

The code uses the *request.closeby* method described above. The *position*, and *position_by* fields are filled and *OrderSend* is called.

The trading logic is described in the *OnTick* handler which analyzes the price configuration only at the moment of the formation of a new bar and receives a signal from the *GetTradeDirection* function.

```
void OnTick()
{
   static bool error = false;
   // waiting for the formation of a new bar, if there is no error
   static datetime lastBar = 0;
   if(iTime(_Symbol, _Period, 0) == lastBar && !error) return;
   lastBar = iTime(_Symbol, _Period, 0);

   const ENUM_ORDER_TYPE type = GetTradeDirection();
   ...
```

Next, we fill the *ticketsLong* and *ticketsShort* arrays with position tickets of the working symbol and with the given *Magic* number. If the *GetMyPositions* function returns a value greater than zero, it gives the number of formed pairs of opposite positions. They can be closed in a loop using the *CloseByPosition* function. The combination of pairs in this case is chosen randomly (in the order of positions in the terminal environment), however, in practice, it may be important to select pairs by volume or in such a way that the most profitable ones are closed first.

```
      ulong ticketsLong[], ticketsShort[];
      const int n = GetMyPositions(_Symbol, Magic, ticketsLong, ticketsShort);
      if(n > 0)
      {
         for(int i = 0; i < n; ++i)
         {
            error = !CloseByPosition(ticketsShort[i], ticketsLong[i]) && error;
         }
      }
      ...
```

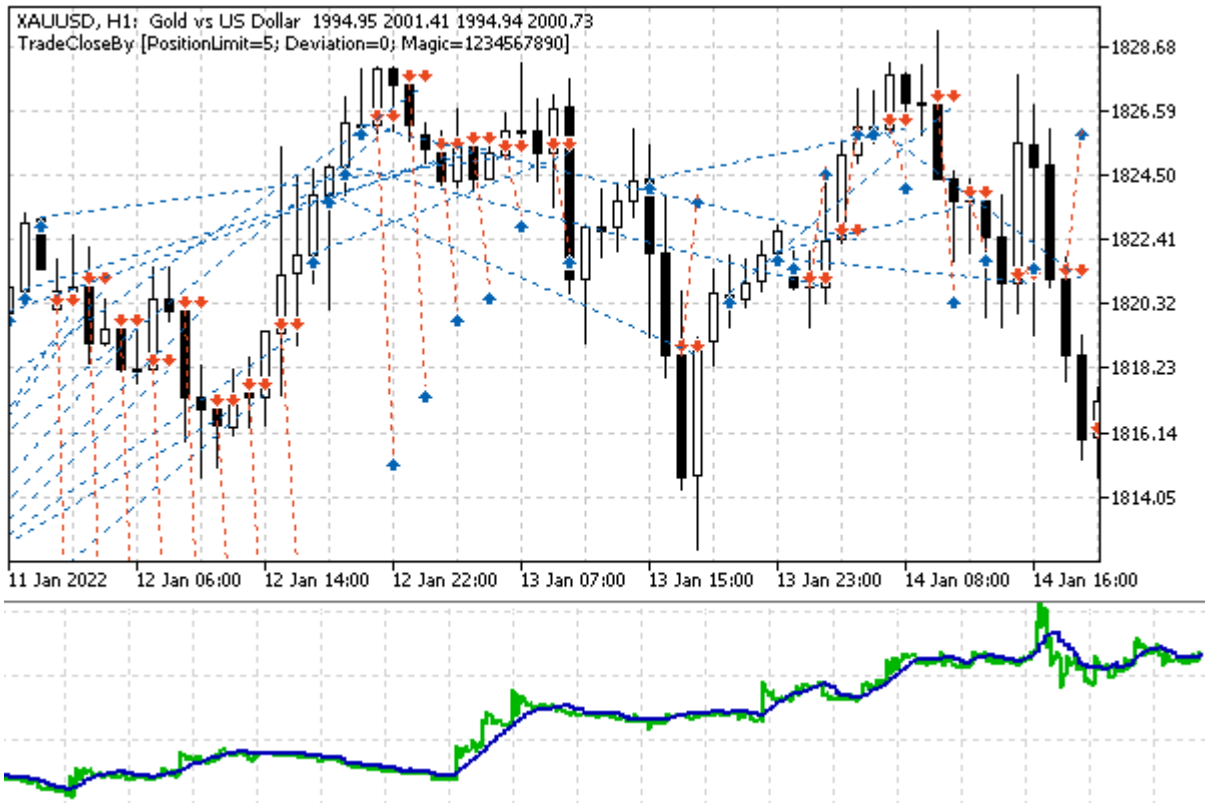
For any other value of *n*, you should check if there is a signal (possibly repeated) to enter the market and execute it by calling *OpenPosition*.

```
      else if(type == ORDER_TYPE_BUY || type == ORDER_TYPE_SELL)
      {
         error = !OpenPosition(type);
      }
      ...
```

Finally, if there are still open positions, but they are in the same direction, we check if their number has reached the limit, in which case we form an opposite position in order to "collapse" two of them on the next bar (thus closing one of any position from the old ones).

```
      else if(n < 0)
      {
         if(-n >= (int)PositionLimit)
         {
            if(ArraySize(ticketsLong) > 0)
            {
               error = !OpenPosition(ORDER_TYPE_SELL);
            }
            else // (ArraySize(ticketsShort) > 0)
            {
               error = !OpenPosition(ORDER_TYPE_BUY);
            }
         }
      }
   }
```

Let's run the Expert Advisor in the tester on XAUUSD, H1 from the beginning of 2022, with default settings. Below is the chart with positions in the process of the program, as well as the balance curve.

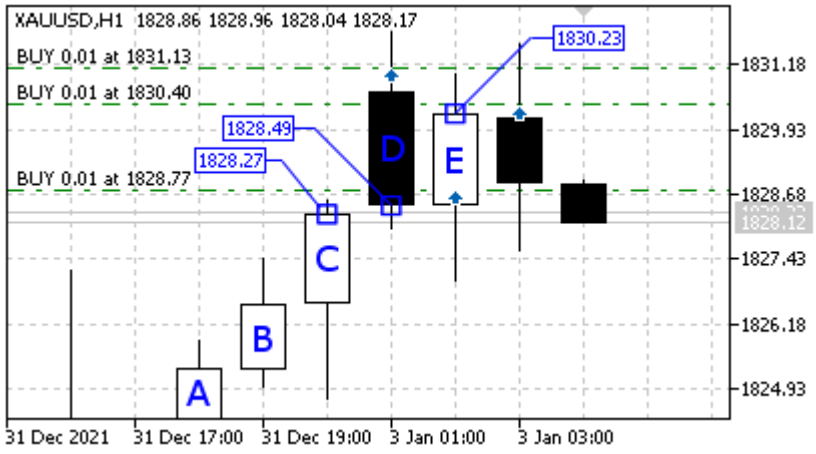


TradeCloseBy test results on XAUUSD, H1

It is easy to find in the log the moments of time when one trend ends (buying with tickets from #2 to #4), and transactions start being generated in the opposite direction (selling #5), after which a counter close is triggered.

```
2022.01.03 01:05:00   instant buy 0.01 XAUUSD at 1831.13 (1830.63 / 1831.13 / 1830.63
2022.01.03 01:05:00   deal #2 buy 0.01 XAUUSD at 1831.13 done (based on order #2)
2022.01.03 01:05:00   deal performed [#2 buy 0.01 XAUUSD at 1831.13]
2022.01.03 01:05:00   order performed buy 0.01 at 1831.13 [#2 buy 0.01 XAUUSD at 1831
2022.01.03 01:05:00   Waiting for position for deal D=2
2022.01.03 01:05:00   OK New Order/Deal/Position
2022.01.03 02:00:00   instant buy 0.01 XAUUSD at 1828.77 (1828.47 / 1828.77 / 1828.47
2022.01.03 02:00:00   deal #3 buy 0.01 XAUUSD at 1828.77 done (based on order #3)
2022.01.03 02:00:00   deal performed [#3 buy 0.01 XAUUSD at 1828.77]
2022.01.03 02:00:00   order performed buy 0.01 at 1828.77 [#3 buy 0.01 XAUUSD at 1828
2022.01.03 02:00:00   Waiting for position for deal D=3
2022.01.03 02:00:00   OK New Order/Deal/Position
2022.01.03 03:00:00   instant buy 0.01 XAUUSD at 1830.40 (1830.16 / 1830.40 / 1830.16
2022.01.03 03:00:00   deal #4 buy 0.01 XAUUSD at 1830.40 done (based on order #4)
2022.01.03 03:00:00   deal performed [#4 buy 0.01 XAUUSD at 1830.40]
2022.01.03 03:00:00   order performed buy 0.01 at 1830.40 [#4 buy 0.01 XAUUSD at 1830
2022.01.03 03:00:00   Waiting for position for deal D=4
2022.01.03 03:00:00   OK New Order/Deal/Position
2022.01.03 05:00:00   instant sell 0.01 XAUUSD at 1826.22 (1826.22 / 1826.45 / 1826.2
2022.01.03 05:00:00   deal #5 sell 0.01 XAUUSD at 1826.22 done (based on order #5)
2022.01.03 05:00:00   deal performed [#5 sell 0.01 XAUUSD at 1826.22]
2022.01.03 05:00:00   order performed sell 0.01 at 1826.22 [#5 sell 0.01 XAUUSD at 18
2022.01.03 05:00:00   Waiting for position for deal D=5
2022.01.03 05:00:00   OK New Order/Deal/Position
2022.01.03 06:00:00   close position #5 sell 0.01 XAUUSD by position #2 buy 0.01 XAUU
2022.01.03 06:00:00   deal #6 buy 0.01 XAUUSD at 1831.13 done (based on order #6)
2022.01.03 06:00:00   deal #7 sell 0.01 XAUUSD at 1826.22 done (based on order #6)
2022.01.03 06:00:00   Positions collapse initiated
2022.01.03 06:00:00   OK CloseBy Order/Deal/Position
```

Transaction #3 is an interesting artifact. An attentive reader will notice that it opened lower than the previous one, seemingly violating our strategy. In fact, there is no error here, and this is a consequence of the fact that the conditions of the signals are written as simply as possible: only based on the closing prices of the bars. Therefore, a bearish reversal candle (D), which opened with a gap up and closed above the end of the previous bullish candle (C), generated a buy signal. This situation is illustrated in the following screenshot.



Transactions on an uptrend at closing prices

All candles in sequence A, B, C, D, and E close higher than the previous one and encourage continued buying. To exclude such artifacts, one should additionally analyze the direction of the bars themselves.

The last thing to pay attention to in this example is the *OnInit* function. Since the Expert Advisor uses the TRADE_ACTION_CLOSE_BY operation, checks are made here for the relevant account and working symbol settings.

```
int OnInit()
{
   ...
   if(AccountInfoInteger(ACCOUNT_MARGIN_MODE) != ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
   {
      Alert("An account with hedging is required for this EA!");
      return INIT_FAILED;
   }

   if((SymbolInfoInteger(_Symbol, SYMBOL_ORDER_MODE) & SYMBOL_ORDER_CLOSEBY) == 0)
   {
      Alert("'Close By' mode is not supported for ", _Symbol);
      return INIT_FAILED;
   }

   return INIT_SUCCEEDED;
}
```

If one of the properties does not support cross-closing, the Expert Advisor will not be able to continue working. When creating working robots, these checks, as a rule, are carried out inside the trading algorithm and switch the program to alternative modes, in particular, to a single closing of positions and maintaining an aggregate position in case of netting.

6.4.19 Placing a pending order

In Types of orders, we theoretically considered all options for placing pending orders supported by the platform. From a practical point of view, orders are created using *OrderSend/OrderSendAsync* functions, for which the request structure *MqlTradeRequest* is prefilled according to special rules. Specifically, the *action* field must contain the TRADE_ACTION_PENDING value from the ENUM_TRADE_REQUEST_ACTIONS enumeration. With this in mind, the following fields are mandatory:

- action
- symbol
- volume
- price
- type (default value 0 corresponds to ORDER_TYPE_BUY)
- type_filling (default 0 corresponds to ORDER_FILLING_FOK)
- type_time (default value 0 corresponds to ORDER_TIME_GTC)
- expiration (default 0, not used for ORDER_TIME_GTC)

If zero defaults are suitable for the task, some of the last four fields can be skipped.

The *stoplimit* field is mandatory only for orders of types ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT.

The following fields are optional:

- sl
- tp
- magic
- comment

Zero values in *sl* and *tp* indicate the absence of protective levels.

Let's add the methods for checking values and filling fields into our structures in the *MqlTradeSync.mqh* file. The principle of formation of all types of orders is the same, so let's consider a couple of special cases of placing limit buy and sell orders. The remaining types will differ only in the value of the field type. Public methods with a full set of required fields, as well as protective levels, are named according to types: *buyLimit* and *sellLimit*.

```
ulong buyLimit(const string name, const double lot, const double p,
   const double stop = 0, const double take = 0,
   ENUM_ORDER_TYPE_TIME duration = ORDER_TIME_GTC, datetime until = 0)
{
   type = ORDER_TYPE_BUY_LIMIT;
   return _pending(name, lot, p, stop, take, duration, until);
}

ulong sellLimit(const string name, const double lot, const double p,
   const double stop = 0, const double take = 0,
   ENUM_ORDER_TYPE_TIME duration = ORDER_TIME_GTC, datetime until = 0)
{
   type = ORDER_TYPE_SELL_LIMIT;
   return _pending(name, lot, p, stop, take, duration, until);
}
```

Since the structure contains the *symbol* field which is optionally initialized in the constructor, there are similar methods without the *name* parameter: they call the above methods by passing *symbol* as the first parameter. Thus, to create an order with minimal effort, write the following:

```
MqlTradeRequestSync request; // by default uses the current chart symbol
request.buyLimit(volume, price);
```

The general part of the code for checking the passed values, normalizing them, saving them in structure fields, and creating a pending order has been moved to the helper method *_pending*. It returns the order ticket on success or 0 on failure.

```
ulong _pending(const string name, const double lot, const double p,
   const double stop = 0, const double take = 0,
   ENUM_ORDER_TYPE_TIME duration = ORDER_TIME_GTC, datetime until = 0,
   const double origin = 0)
{
   action = TRADE_ACTION_PENDING;
   if(!setSymbol(name)) return 0;
   if(!setVolumePrices(lot, p, stop, take, origin)) return 0;
   if(!setExpiration(duration, until)) return 0;
   if((SymbolInfoInteger(name, SYMBOL_ORDER_MODE) & (1 << (type / 2))) == 0)
   {
      Print(StringFormat("pending orders %s not allowed for %s",
         EnumToString(type), name));
      return 0;
   }
   ZeroMemory(result);
   if(OrderSend(this, result)) return result.order;
   return 0;
}
```

We already know how to fill the *action* field and how to call the *setSymbol* and *setVolumePrices* methods from previous trading operations.

The multi-string *if* operator ensures that the operation being prepared is present among the allowed symbol operations specified in the SYMBOL_ORDER_MODE property. Integer type division *type* which divides in half and shifts the resulting value by 1, sets the correct bit in the mask of allowed order types. This is due to the combination of constants in the ENUM_ORDER_TYPE enumeration and the SYMBOL_ORDER_MODE property. For example, ORDER_TYPE_BUY_STOP and ORDER_TYPE_SELL_STOP have the values 4 and 5, which when divided by 2 both give 2 (with decimals removed). Operation *1 << 2* has a result 4 equal to SYMBOL_ORDER_STOP.

A special feature of pending orders is the processing of the expiration date. The *setExpiration* method deals with it. In this method, it should be ensured that the specified expiration mode ENUM_ORDER_TYPE_TIME of *duration* is allowed for the symbol and the date and time in *until* are filled in correctly.

```
bool setExpiration(ENUM_ORDER_TYPE_TIME duration = ORDER_TIME_GTC, datetime until
{
   const int modes = (int)SymbolInfoInteger(symbol, SYMBOL_EXPIRATION_MODE);
   if(((1 << duration) & modes) != 0)
   {
      type_time = duration;
      if((duration == ORDER_TIME_SPECIFIED || duration == ORDER_TIME_SPECIFIED_DAY
         && until == 0)
      {
         Print(StringFormat("datetime is 0, "
            "but it's required for order expiration mode %s",
            EnumToString(duration)));
         return false;
      }
      if(until > 0 && until <= TimeTradeServer())
      {
         Print(StringFormat("expiration datetime %s is in past, server time is %s"
            TimeToString(until), TimeToString(TimeTradeServer())));
         return false;
      }
      expiration = until;
   }
   else
   {
      Print(StringFormat("order expiration mode %s is not allowed for %s",
         EnumToString(duration), symbol));
      return false;
   }
   return true;
}
```

The bitmask of allowed modes is available in the SYMBOL_EXPIRATION_MODE property. The combination of bits in the mask and the constants ENUM_ORDER_TYPE_TIME is such that we just need to evaluate the expression *1 << duration* and superimpose it on the mask: a non-zero value indicates the presence of the mode.

For the ORDER_TIME_SPECIFIED and ORDER_TIME_SPECIFIED_DAY modes, the *expiration* field with the specific *datetime* value cannot be empty. Also, the specified date and time cannot be in the past.

Since the *_pending* method presented earlier sends a request to the server using *OrderSend* in the end, our program must make sure that the order with the received ticket was actually created (this is especially important for limit orders that can be output to an external trading system). Therefore, in the *completed* method, which is used for "blocking" control of the result, we will add a branch for the TRADE_ACTION_PENDING operation.

```
bool completed()
{
   // old processing code
   // TRADE_ACTION_DEAL
   // TRADE_ACTION_SLTP
   // TRADE_ACTION_CLOSE_BY
   ...
   else if(action == TRADE_ACTION_PENDING)
   {
      return result.placed(timeout);
   }
   ...
   return false;
}
```

In the *MqlTradeResultSync* structure, we add the *placed* method.

```
bool placed(const ulong msc = 1000)
{
   if(retcode != TRADE_RETCODE_DONE
      && retcode != TRADE_RETCODE_DONE_PARTIAL)
   {
      return false;
   }

   if(!wait(orderExist, msc))
   {
      Print("Waiting for order: #" + (string)order);
      return false;
   }
   return true;
}
```

Its main task is to wait for the order to appear using the wait in the *orderExist* function: it has already been used in the first stage of verification of position opening.

To test the new functionality, let's implement the Expert Advisor *PendingOrderSend.mq5*. It enables the selection of the pending order type and all its attributes using input variables, after which a confirmation request is executed.

```
enum ENUM_ORDER_TYPE_PENDING
{                                                    // UI interface strings
   PENDING_BUY_STOP = ORDER_TYPE_BUY_STOP,           // ORDER_TYPE_BUY_STOP
   PENDING_SELL_STOP = ORDER_TYPE_SELL_STOP,         // ORDER_TYPE_SELL_STOP
   PENDING_BUY_LIMIT = ORDER_TYPE_BUY_LIMIT,         // ORDER_TYPE_BUY_LIMIT
   PENDING_SELL_LIMIT = ORDER_TYPE_SELL_LIMIT,       // ORDER_TYPE_SELL_LIMIT
   PENDING_BUY_STOP_LIMIT = ORDER_TYPE_BUY_STOP_LIMIT,    // ORDER_TYPE_BUY_STOP_LIMIT
   PENDING_SELL_STOP_LIMIT = ORDER_TYPE_SELL_STOP_LIMIT, // ORDER_TYPE_SELL_STOP_LIMI
};

input string Symbol;             // Symbol (empty = current _Symbol)
input double Volume;             // Volume (0 = minimal lot)
input ENUM_ORDER_TYPE_PENDING Type = PENDING_BUY_STOP;
input int Distance2SLTP = 0;     // Distance to SL/TP in points (0 = no)
input ENUM_ORDER_TYPE_TIME Expiration = ORDER_TIME_GTC;
input datetime Until = 0;
input ulong Magic = 1234567890;
input string Comment;
```

The Expert Advisor will create a new order every time it is launched or parameters are changed. Automatic order removal is not yet provided. We will discuss this operation type later. In this regard, do not forget to delete orders manually.

A one-time order placement is performed, as in some previous examples, based on a timer (therefore, you should first make sure that the market is open).

```
void OnTimer()
{
   // execute once and wait for the user to change the settings
   EventKillTimer();

   const string symbol = StringLen(Symbol) == 0 ? _Symbol : Symbol;
   if(PlaceOrder((ENUM_ORDER_TYPE)Type, symbol, Volume,
      Distance2SLTP, Expiration, Until, Magic, Comment))
   {
      Alert("Pending order placed - remove it manually, please");
   }
}
```

The *PlaceOrder* function accepts all settings as parameters, sends a request, and returns a success indicator (non-zero ticket). Orders of all supported types are provided with pre-filled distances from the current price which are calculated as part of the daily range of quotes.

```
ulong PlaceOrder(const ENUM_ORDER_TYPE type,
   const string symbol, const double lot,
   const int sltp, ENUM_ORDER_TYPE_TIME expiration, datetime until,
   const ulong magic = 0, const string comment = NULL)
{
   static double coefficients[] = // indexed by order type
   {
      0  ,   // ORDER_TYPE_BUY - not used
      0  ,   // ORDER_TYPE_SELL - not used
     -0.5,   // ORDER_TYPE_BUY_LIMIT - slightly below the price
     +0.5,   // ORDER_TYPE_SELL_LIMIT - slightly above the price
     +1.0,   // ORDER_TYPE_BUY_STOP - far above the price
     -1.0,   // ORDER_TYPE_SELL_STOP - far below the price
     +0.7,   // ORDER_TYPE_BUY_STOP_LIMIT - average above the price
     -0.7,   // ORDER_TYPE_SELL_STOP_LIMIT - average below the price
      0  ,   // ORDER_TYPE_CLOSE_BY - not used
   };
   ...
```

For example, the coefficient of -0.5 for ORDER_TYPE_BUY_LIMIT means that the order will be placed below the current price by half of the daily range (rebound inside the range), and the coefficient of +1.0 for ORDER_TYPE_BUY_STOP means that the order will be at the upper border of the range (breakout).

The daily range itself is calculated as follows.

```
   const double range = iHigh(symbol, PERIOD_D1, 1) - iLow(symbol, PERIOD_D1, 1);
   Print("Autodetected daily range: ", (float)range);
   ...
```

We find the volume and point values that will be required below.

```
   const double volume = lot == 0 ? SymbolInfoDouble(symbol, SYMBOL_VOLUME_MIN) : lot
   const double point = SymbolInfoDouble(symbol, SYMBOL_POINT);
```

The price level for placing an order is calculated in the *price* variable based on the given coefficients from the total range.

```
   const double price = TU::GetCurrentPrice(type, symbol) + range * coefficients[type
```

The *stoplimit* field must be filled only for *_STOP_LIMIT orders. The values for it are stored in the *origin* variable.

```
   const bool stopLimit =
      type == ORDER_TYPE_BUY_STOP_LIMIT ||
      type == ORDER_TYPE_SELL_STOP_LIMIT;
   const double origin = stopLimit ? TU::GetCurrentPrice(type, symbol) : 0;
```

When these two types of orders are triggered, a new pending order will be placed at the current price. Indeed, in this scenario, the price moves from the current value to the *price* level, where the order is activated, and therefore the "former current" price becomes the correct rebound level indicated by a limit order. We will illustrate this situation below.

Protective levels are determined using the *TU::TradeDirection* object. For stop-limit orders, we calculated starting from *origin*.

```
TU::TradeDirection dir(type);
const double stop = sltp == 0 ? 0 :
   dir.negative(stopLimit ? origin : price, sltp * point);
const double take = sltp == 0 ? 0 :
   dir.positive(stopLimit ? origin : price, sltp * point);
```

Next, the structure is described and the optional fields are filled in.

```
MqlTradeRequestSync request(symbol);

request.magic = magic;
request.comment = comment;
// request.type_filling = SYMBOL_FILLING_FOK;
```

Here you can select the fill mode. By default, *MqlTradeRequestSync* automatically selects the first of the allowed modes, ENUM_ORDER_TYPE_FILLING.

Depending on the order type chosen by the user, we call one or another trading method.

```
ResetLastError();
// fill in and check the required fields, send the request
ulong order = 0;
switch(type)
{
case ORDER_TYPE_BUY_STOP:
   order = request.buyStop(volume, price, stop, take, expiration, until);
   break;
case ORDER_TYPE_SELL_STOP:
   order = request.sellStop(volume, price, stop, take, expiration, until);
   break;
case ORDER_TYPE_BUY_LIMIT:
   order = request.buyLimit(volume, price, stop, take, expiration, until);
   break;
case ORDER_TYPE_SELL_LIMIT:
   order = request.sellLimit(volume, price, stop, take, expiration, until);
   break;
case ORDER_TYPE_BUY_STOP_LIMIT:
   order = request.buyStopLimit(volume, price, origin, stop, take, expiration, unt
   break;
case ORDER_TYPE_SELL_STOP_LIMIT:
   order = request.sellStopLimit(volume, price, origin, stop, take, expiration, un
   break;
}
...
```

If the ticket is received, we wait for it to appear in the trading environment of the terminal.

```
      if(order != 0)
      {
         Print("OK order sent: #=", order);
         if(request.completed()) // expect result (order confirmation)
         {
            Print("OK order placed");
         }
      }
      Print(TU::StringOf(request));
      Print(TU::StringOf(request.result));
      return order;
   }
```

Let's run the Expert Advisor on the EURUSD chart with default settings and additionally select the distance to the protective levels of 1000 points. We will see the following entries in the log (assuming that the default settings match the permissions for EURUSD in your account).

```
Autodetected daily range: 0.01413
OK order sent: #=1282106395
OK order placed
TRADE_ACTION_PENDING, EURUSD, ORDER_TYPE_BUY_STOP, V=0.01, ORDER_FILLING_FOK, »
  » @ 1.11248, SL=1.10248, TP=1.12248, ORDER_TIME_GTC, M=1234567890
DONE, #=1282106395, V=0.01, Request executed, Req=91
Alert: Pending order placed - remove it manually, please
```

Here is what it looks like on the chart:

Pending order ORDER_TYPE_BUY_STOP

Let's delete the order manually and change the order type to ORDER_TYPE_BUY_STOP_LIMIT. The result is a more complex picture.

Pending order ORDER_TYPE_BUY_STOP_LIMIT

The price where the upper pair of dash-dotted lines is located is the order trigger price, as a result of which an ORDER_TYPE_BUY_LIMIT order will be placed at the current price level, with *Stop Loss* and *Take Profit* values marked with red lines. The *Take Profit* level of the future ORDER_TYPE_BUY_LIMIT order practically coincides with the activation level of the newly created preliminary order ORDER_TYPE_BUY_STOP_LIMIT.

As an additional example for self-study, an Expert Advisor *AllPendingsOrderSend.mq5* is included with the book; the Expert Advisor sets 6 pending orders at once: one of each type.

Pending orders of all types

As a result of running it with default settings, you may get log entries as follows:

```
Autodetected daily range: 0.01413
OK order placed: #=1282032135
TRADE_ACTION_PENDING, EURUSD, ORDER_TYPE_BUY_LIMIT, V=0.01, ORDER_FILLING_FOK, »

Alert: 6 pending orders placed - remove them manually, please
```

6.4.20 Modifying a pending order

MetaTrader 5 allows you to modify certain properties of a pending order, including the activation price, protection levels, and expiration date. The main properties such as order type or volume cannot be changed. In such cases, you should delete the order and replace it with another one. The only case where the order type can be changed by the server itself is the activation of a stop limit order, which turns into the corresponding limit order.

Programmatic modification of orders is performed by the TRADE_ACTION_MODIFY operation: it is this constant that needs to be written in the field *action* of the structure *MqlTradeRequest* before sending to the server by the function *OrderSend* or *OrderSendAsync*. The ticket of the modified order is indicated in the field *order*. Taking into account *action* and *order*, the full list of required fields for this operation includes:

- action
- order
- price
- type_time (default value 0 corresponds to ORDER_TIME_GTC)
- expiration (default 0, not important for ORDER_TIME_GTC)
- type_filling (default 0 corresponds to ORDER_FILLING_FOK)
- stoplimit (only for orders of types ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT)

Optional fields:

- sl
- tp

If protective levels have already been set for the order, they should be specified so they can be saved. Zero values indicate deletion of *Stop Loss* and/or *Take Profit*.

In the *MqlTradeRequestSync* structure (*MqlTradeSync.mqh*), the implementation of order modification is placed in the *modify* method.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool modify(const ulong ticket,
      const double p, const double stop = 0, const double take = 0,
      ENUM_ORDER_TYPE_TIME duration = ORDER_TIME_GTC, datetime until = 0,
      const double origin = 0)
   {
      if(!OrderSelect(ticket)) return false;

      action = TRADE_ACTION_MODIFY;
      order = ticket;

      // the following fields are needed for checks inside subfunctions
      type = (ENUM_ORDER_TYPE)OrderGetInteger(ORDER_TYPE);
      symbol = OrderGetString(ORDER_SYMBOL);
      volume = OrderGetDouble(ORDER_VOLUME_CURRENT);

      if(!setVolumePrices(volume, p, stop, take, origin)) return false;
      if(!setExpiration(duration, until)) return false;
      ZeroMemory(result);
      return OrderSend(this, result);
   }
```

The actual execution of the request is again done in the *completed* method, in the dedicated branch of the *if* operator.

```
   bool completed()
   {
      ...
      else if(action == TRADE_ACTION_MODIFY)
      {
         result.order = order;
         result.bid = sl;
         result.ask = tp;
         result.price = price;
         result.volume = stoplimit;
         return result.modified(timeout);
      }
      ...
   }
```

For the *MqlTradeResultSync* structure to know the new values of the properties of the edited order and to be able to compare them with the result, we write them in free fields (they are not filled by the server in this type of request). Further in the *modified* method, the result structure is waiting for the modification to be applied.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   bool modified(const ulong msc = 1000)
   {
      if(retcode != TRADE_RETCODE_DONE && retcode != TRADE_RETCODE_PLACED)
      {
         return false;
      }

      if(!wait(orderModified, msc))
      {
         Print("Order not found in environment: #" + (string)order);
         return false;
      }
      return true;
   }

   static bool orderModified(MqlTradeResultSync &ref)
   {
      if(!(OrderSelect(ref.order) || HistoryOrderSelect(ref.order)))
      {
         Print("OrderSelect failed: #=" + (string)ref.order);
         return false;
      }
      return TU::Equal(ref.bid, OrderGetDouble(ORDER_SL))
         && TU::Equal(ref.ask, OrderGetDouble(ORDER_TP))
         && TU::Equal(ref.price, OrderGetDouble(ORDER_PRICE_OPEN))
         && TU::Equal(ref.volume, OrderGetDouble(ORDER_PRICE_STOPLIMIT));
   }
```

Here we see how the order properties are read using the *OrderGetDouble* function and compared with the specified values. All this happens according to the already familiar procedure, in a loop inside the wait function, within a certain timeout of *msc* (1000 milliseconds by default).

As an example, let's use the Expert Advisor *PendingOrderModify.mq5*, while inheriting some code fragments from *PendingOrderSend.mq5*. In particular, a set of input parameters and the *PlaceOrder* function to create a new order. It is used at the first launch if there is no order for the given combination of the symbol and *Magic* number, thus ensuring that the Expert Advisor has something to modify.

A new function was required to find a suitable order: *GetMyOrder*. It is very similar to the *GetMyPosition* function, which was used in the example with position tracking (*TrailingStop.mq5*) to find a suitable position. The purpose of the built-in MQL5 API functions used inside *GetMyOrder* should be generally clear from their names, and the technical description will be presented in separate sections.

```
ulong GetMyOrder(const string name, const ulong magic)
{
   for(int i = 0; i < OrdersTotal(); ++i)
   {
      ulong t = OrderGetTicket(i);
      if(OrderGetInteger(ORDER_MAGIC) == magic
         && OrderGetString(ORDER_SYMBOL) == name)
      {
         return t;
      }
   }

   return 0;
}
```

The input parameter *Distance2SLTP* is now missing. Instead, the new Expert Advisor will automatically calculate the daily range of prices and place protective levels at a distance of half of this range. At the beginning of each day, the range and the new levels in the *sl* and *tp* fields will be recalculated. Order modification requests will be generated based on the new values.

Those pending orders that trigger and turn into positions will be closed upon reaching *Stop Loss* or *Take Profit*. The terminal can inform the MQL program about the activation of pending orders and the closing of positions if you describe trading event handlers in it. This would allow, for example, to avoid the creation of a new order if there is an open position. However, the current strategy can also be used. So, we will deal with events later.

The main logic of the Expert Advisor is implemented in the *OnTick* handler.

```
void OnTick()
{
   static datetime lastDay = 0;
   static const uint DAYLONG = 60 * 60 * 24; // number of seconds in a day
   //discard the "fractional" part, i.e. time
   if(TimeTradeServer() / DAYLONG * DAYLONG == lastDay) return;
   ...
```

Two lines at the beginning of the function ensure that the algorithm runs once at the beginning of each day. To do this, we calculate the current date without time and compare it with the value of the *lastDay* variable which contains the last successful date. The success or error status of course becomes clear at the end of the function, so we'll come back to it later.

Next, the price range for the previous day is calculated.

```
   const string symbol = StringLen(Symbol) == 0 ? _Symbol : Symbol;
   const double range = iHigh(symbol, PERIOD_D1, 1) - iLow(symbol, PERIOD_D1, 1);
   Print("Autodetected daily range: ", (float)range);
   ...
```

Depending on whether there is an order or not in the *GetMyOrder* function, we will either create a new order via *PlaceOrder* or edit the existing one using *ModifyOrder*.

```
   uint retcode = 0;
   ulong ticket = GetMyOrder(symbol, Magic);
   if(!ticket)
   {
      retcode = PlaceOrder((ENUM_ORDER_TYPE)Type, symbol, Volume,
         range, Expiration, Until, Magic);
   }
   else
   {
      retcode = ModifyOrder(ticket, range, Expiration, Until);
   }
   ...
```

Both functions, *PlaceOrder* and *ModifyOrder*, work on the basis of the Expert Advisor's input parameters and the found price range. They return the status of the request, which will need to be analyzed in some way to decide which action to take:

- Update the *lastDay* variable if the request is successful (the order has been updated and the Expert Advisor sleeps until the beginning of the next day)
- Leave the old day in *lastDay* for some time to try again on the next ticks if there are temporary problems (for example, the trading session has not started yet)
- Stop the Expert Advisor if serious problems are detected (for example, the selected order type or trade direction is not allowed on the symbol)

```
   ...
   if(/* some kind of retcode analysis */)
   {
      lastDay = TimeTradeServer() / DAYLONG * DAYLONG;
   }
}
```

In the section Closing a position: full and partial, we used a simplified analysis with the IS_TANGIBLE macro which gave an answer in the categories of "yes" and "no" to indicate whether there was an error or not. Obviously, this approach needs to be improved, and we will return to this issue soon. For now, we will focus on the main functionality of the Expert Advisor.

The source code of the *PlaceOrder* function remained virtually unchanged from the previous example. *ModifyOrder* is shown below.

Recall that we determined the location of orders based on the daily range, to which the table of coefficients was applied. The principle has not changed, however, since we now have two functions that work with orders, *PlaceOrder* and *ModifyOrder*, the *Coefficients* table is placed in a global context. We will not repeat it here and will go straight to the *ModifyOrder* function.

```
uint ModifyOrder(const ulong ticket, const double range,
   ENUM_ORDER_TYPE_TIME expiration, datetime until)
{
   // default values
   const string symbol = OrderGetString(ORDER_SYMBOL);
   const double point = SymbolInfoDouble(symbol, SYMBOL_POINT);
   ...
```

Price levels are calculated depending on the order type and the passed range.

```
      const ENUM_ORDER_TYPE type = (ENUM_ORDER_TYPE)OrderGetInteger(ORDER_TYPE);
      const double price = TU::GetCurrentPrice(type, symbol) + range * Coefficients[type

      // origin is filled only for orders *_STOP_LIMIT
      const bool stopLimit =
         type == ORDER_TYPE_BUY_STOP_LIMIT ||
         type == ORDER_TYPE_SELL_STOP_LIMIT;
      const double origin = stopLimit ? TU::GetCurrentPrice(type, symbol) : 0;

      TU::TradeDirection dir(type);
      const int sltp = (int)(range / 2 / point);
      const double stop = sltp == 0 ? 0 :
         dir.negative(stopLimit ? origin : price, sltp * point);
      const double take = sltp == 0 ? 0 :
         dir.positive(stopLimit ? origin : price, sltp * point);
      ...
```

After calculating all the values, we create an object of the *MqlTradeRequestSync* structure and execute the request.

```
      MqlTradeRequestSync request(symbol);

      ResetLastError();
      // pass the data for the fields, send the order and wait for the result
      if(request.modify(ticket, price, stop, take, expiration, until, origin)
         && request.completed())
      {
         Print("OK order modified: #=", ticket);
      }

      Print(TU::StringOf(request));
      Print(TU::StringOf(request.result));
      return request.result.retcode;
   }
```

To analyze *retcode* which we have to execute in the calling block inside *OnTick*, a new mechanism was developed that supplemented the file *TradeRetcode.mqh*. All server return codes are divided into several "severity" groups, described by the elements of the TRADE_RETCODE_SEVERITY enumeration.

```
enum TRADE_RETCODE_SEVERITY
{
   SEVERITY_UNDEFINED,    // something non-standard - just output to the log
   SEVERITY_NORMAL,       // normal operation
   SEVERITY_RETRY,        // try updating environment/prices again (probably several t
   SEVERITY_TRY_LATER,    // we should wait and try again
   SEVERITY_REJECT,       // request denied, probably(!) you can try again
                          //
   SEVERITY_INVALID,      // need to fix the request
   SEVERITY_LIMITS,       // need to check the limits and fix the request
   SEVERITY_PERMISSIONS, // it is required to notify the user and change the program/
   SEVERITY_ERROR,        // stop, output information to the log and to the user
};
```

In a simplistic way, the first half corresponds to recoverable errors: it is usually enough to wait a while and retry the request. The second half requires you to change the content of the request, check the account or symbol settings, the permissions for the program, and in the worst case, stop trading. Those who wish can draw a conditional separator line not after SEVERITY_REJECT, as it is visually highlighted now, but before it.

The division of all codes into groups is performed by the *TradeCodeSeverity* function (given with abbreviations).

```
TRADE_RETCODE_SEVERITY TradeCodeSeverity(const uint retcode)
{
   static const TRADE_RETCODE_SEVERITY severities[] =
   {
      ...
      SEVERITY_RETRY,       // REQUOTE (10004)
      SEVERITY_UNDEFINED,
      SEVERITY_REJECT,      // REJECT (10006)
      SEVERITY_NORMAL,      // CANCEL (10007)
      SEVERITY_NORMAL,      // PLACED (10008)
      SEVERITY_NORMAL,      // DONE (10009)
      SEVERITY_NORMAL,      // DONE_PARTIAL (10010)
      SEVERITY_ERROR,       // ERROR (10011)
      SEVERITY_RETRY,       // TIMEOUT (10012)
      SEVERITY_INVALID,     // INVALID (10013)
      SEVERITY_INVALID,     // INVALID_VOLUME (10014)
      SEVERITY_INVALID,     // INVALID_PRICE (10015)
      SEVERITY_INVALID,     // INVALID_STOPS (10016)
      SEVERITY_PERMISSIONS, // TRADE_DISABLED (10017)
      SEVERITY_TRY_LATER,   // MARKET_CLOSED (10018)
      SEVERITY_LIMITS,      // NO_MONEY (10019)
      ...
   };

   if(retcode == 0) return SEVERITY_NORMAL;
   if(retcode < 10000 || retcode > HEDGE_PROHIBITED) return SEVERITY_UNDEFINED;
   return severities[retcode - 10000];
}
```

Thanks to this functionality, the *OnTick* handler can be supplemented with "smart" error handling. A static variable *RetryFrequency* stores the frequency with which the program will try to repeat the request in case of non-critical errors. The last time such an attempt was made is stored in the *RetryRecordTime* variable.

```
void OnTick()
{
   ...
   const static int DEFAULT_RETRY_TIMEOUT = 1; // seconds
   static int RetryFrequency = DEFAULT_RETRY_TIMEOUT;
   static datetime RetryRecordTime = 0;
   if(TimeTradeServer() - RetryRecordTime < RetryFrequency) return;
   ...
```

Once the *PlaceOrder* or *ModifyOrder* function returns the value of *retcode*, we learn how severe it is and, based on the severity, we choose one of three alternatives: stopping the Expert Advisor, waiting for a timeout, or regular operation (marking the successful modification of the order by the current day in *lastDay*).

```
   const TRADE_RETCODE_SEVERITY severity = TradeCodeSeverity(retcode);
   if(severity >= SEVERITY_INVALID)
   {
      Alert("Can't place/modify pending order, EA is stopped");
      RetryFrequency = INT_MAX;
   }
   else if(severity >= SEVERITY_RETRY)
   {
      RetryFrequency += (int)sqrt(RetryFrequency + 1);
      RetryRecordTime = TimeTradeServer();
      PrintFormat("Problems detected, waiting for better conditions "
         "(timeout enlarged to %d seconds)",
         RetryFrequency);
   }
   else
   {
      if(RetryFrequency > DEFAULT_RETRY_TIMEOUT)
      {
         RetryFrequency = DEFAULT_RETRY_TIMEOUT;
         PrintFormat("Timeout restored to %d second", RetryFrequency);
      }
      lastDay = TimeTradeServer() / DAYLONG * DAYLONG;
   }
```

In case of repeated problems that are classified as solvable, the *RetryFrequency* timeout gradually increases with each subsequent error but resets to 1 second when the request is successfully processed.

It should be noted that the methods of the applied structure *MqlTradeRequestSync* check a large number of combinations of parameters for correctness and, if problems are found, interrupt the process prior to the *SendRequest* call. This behavior is enabled by default, but it can be disabled by defining an empty RETURN(X) macro before the directive *#include* with *MqlTradeSync.mqh*.

```
#define RETURN(X)
#include <MQL5Book/MqlTradeSync.mqh>
```

With this macro definition, checks will only print warnings to the log but will continue to execute methods until the *SendRequest* call.

In any case, after calling one or another method of the *MqlTradeResultSync* structure, the error code will be added to *retcode*. This will be done either by the server or by the *MqlTradeRequestSync* structure's checking algorithms (here we utilize the fact that the *MqlTradeResultSync* instance is included inside *MqlTradeRequestSync*). I do not provide here the description of the return of error codes and the use of the RETURN macro in the *MqlTradeRequestSync* methods for the sake of brevity. Those interested can see the full source code in the *MqlTradeSync.mqh* file.

Let's run the Expert Advisor *PendingOrderModify.mq5* in the tester, with the visual mode enabled, using the data of XAUUSD, H1 (all ticks or real ticks mode). With the default settings, the Expert Advisor will place orders of the ORDER_TYPE_BUY_STOP type with a minimum lot. Let's make sure from the log and trading history that the program places pending orders and modifies them at the beginning of each day.

```

```

The order can be triggered at any moment, after which the position is closed after some time by the stop loss or take profit (as in the code above).

In some cases, a situation may arise when the position still exists at the beginning of the next day, and then a new order will be created in addition to it, as in the screenshot below.

The Expert Advisor with a trading strategy based on pending orders in the tester

Please note that due to the fact that we request quotes of the PERIOD_D1 timeframe to calculate the daily range, the visual tester opens the corresponding chart, in addition to the current working one. Such a service works not only for timeframes other than the working one but also for other symbols. This will be useful, in particular, when developing multicurrency Expert Advisors.

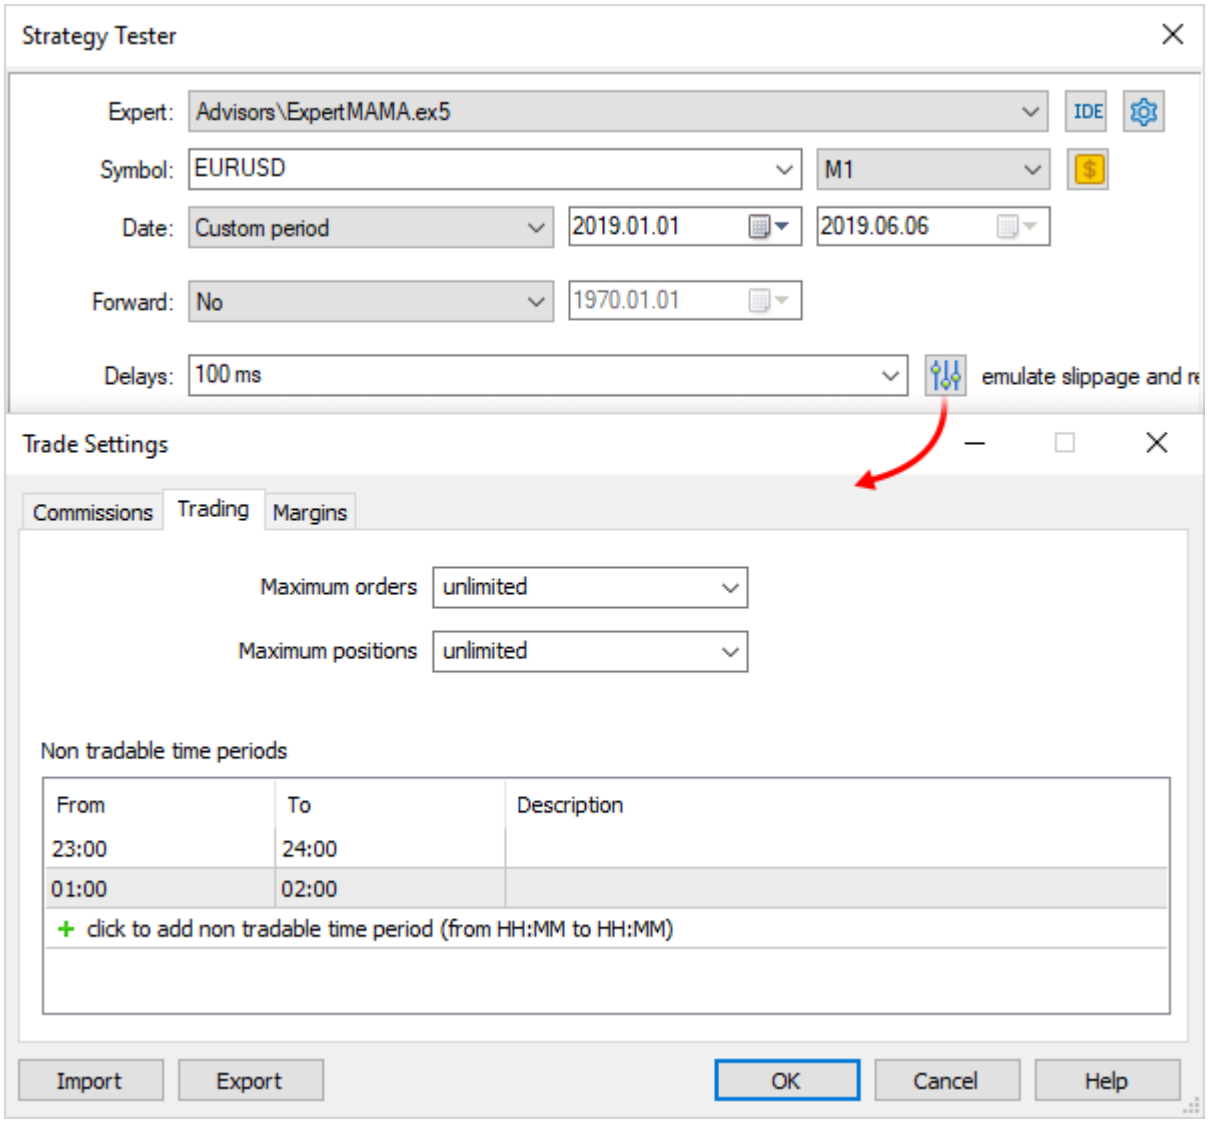
To check how error handling works, try disabling trading for the Expert Advisor. The log will contain the following:

```
Autodetected daily range: 34.48
TRADE_ACTION_PENDING, XAUUSD, ORDER_TYPE_BUY_STOP, V=0.01, ORDER_FILLING_FOK, »
  » @ 1975.73, SL=1958.49, TP=1992.97, ORDER_TIME_GTC, M=1234567890
CLIENT_DISABLES_AT, AutoTrading disabled by client
Alert: Can't place/modify pending order, EA is stopped
```

This error is critical, and the Expert Advisor stops working.

To demonstrate one of the easier errors, we could use the *OnTimer* handler instead of *OnTick*. Then launching the same Expert Advisor on symbols where trading sessions take only a part of a day would periodically generate a sequence of non-critical errors about a closed market ("Market closed"). In this case, the Expert Advisor would keep trying to start trading, constantly increasing the waiting time.

This, in particular, is easy to check in the tester, which allows you to set up arbitrary trading sessions for any symbol. On the *Settings* tab, to the right of the *Delays* dropdown list, there is a button that opens the *Trade setup* dialog. There, you should include the option *Use your settings* and on the *Trade* tab add at least one record to the table *Non-trading periods*.



Setting up non-trading periods in the tester

Please note that it is non-trading periods that are set here, not trading sessions, i.e., this setting acts exactly the opposite in comparison with the symbol specification.

Many potential errors related to trade restrictions can be eliminated by preliminary analysis of the environment using a class like *Permissions* presented in the section Restrictions and permissions for account transactions.

6.4.21 Deleting a pending order

Deletion of a pending order is performed at the program level using the TRADE_ACTION_REMOVE operation: this constant should be assigned to the *action* field of the *MqlTradeRequest* structure before calling one of the versions of the *OrderSend* function. The only required field in addition to *action* is *order* to specify the ticket of the order to be deleted.

The *remove* method in *MqlTradeRequestSync* application structure from the *MqlTradeSync.mqh* file is pretty basic.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   bool remove(const ulong ticket)
   {
      if(!OrderSelect(ticket)) return false;
      action = TRADE_ACTION_REMOVE;
      order = ticket;
      ZeroMemory(result);
      return OrderSend(this, result);
   }
```

Checking the fact of deleting an order is traditionally done in the *completed* method.

```
   bool completed()
   {
      ...
      else if(action == TRADE_ACTION_REMOVE)
      {
         result.order = order;
         return result.removed(timeout);
      }
      ...
   }
```

Waiting for the actual removal of the order is performed in the *removed* method of the *MqlTradeResultSync* structure.

```
struct MqlTradeResultSync: public MqlTradeResult
{
   ...
   bool removed(const ulong msc = 1000)
   {
      if(retcode != TRADE_RETCODE_DONE)
      {
         return false;
      }

      if(!wait(orderRemoved, msc))
      {
         Print("Order removal timeout: #=" + (string)order);
         return false;
      }

      return true;
   }

   static bool orderRemoved(MqlTradeResultSync &ref)
   {
      return !OrderSelect(ref.order) && HistoryOrderSelect(ref.order);
   }
```

An example of the Expert Advisor (*PendingOrderDelete.mq5*) demonstrating the removal of an order we will build almost entirely based on *PendingOrderSend.mq5*. This is due to the fact that it is easier to guarantee the existence of an order before deletion. Thus, immediately after the launch, the Expert Advisor will create a new order with the specified parameters. The order will then be deleted in the *OnDeinit* handler. If you change the Expert Advisor input parameters, the symbol, or the chart timeframe, the old order will also be deleted, and a new one will be created.

The *OwnOrder* global variable has been added to store the order ticket. It is filled as a result of the *PlaceOrder* call (the function itself is unchanged).

```
ulong OwnOrder = 0;

void OnTimer()
{
   // execute the code once for the current parameters
   EventKillTimer();

   const string symbol = StringLen(Symbol) == 0 ? _Symbol : Symbol;
   OwnOrder = PlaceOrder((ENUM_ORDER_TYPE)Type, symbol, Volume,
      Distance2SLTP, Expiration, Until, Magic, Comment);
}
```

Here is a simple deletion function *RemoveOrder*, which creates the *request* object and sequentially calls the *remove* and *completed* methods for it.

```
void OnDeinit(const int)
{
   if(OwnOrder != 0)
   {
      RemoveOrder(OwnOrder);
   }
}

void RemoveOrder(const ulong ticket)
{
   MqlTradeRequestSync request;
   if(request.remove(ticket) && request.completed())
   {
      Print("OK order removed");
   }
   Print(TU::StringOf(request));
   Print(TU::StringOf(request.result));
}
```

The following log shows the entries that appeared as a result of placing the Expert Advisor on the EURUSD chart, after which the symbol was switched to XAUUSD, and then the Expert Advisor was deleted.

```
(EURUSD,H1)   Autodetected daily range: 0.0094
(EURUSD,H1)   OK order placed: #=1284920879
(EURUSD,H1)   TRADE_ACTION_PENDING, EURUSD, ORDER_TYPE_BUY_STOP, V=0.01, ORDER_FILLIN
                » @ 1.11011, ORDER_TIME_GTC, M=1234567890
(EURUSD,H1)   DONE, #=1284920879, V=0.01, Request executed, Req=1
(EURUSD,H1)   OK order removed
(EURUSD,H1)   TRADE_ACTION_REMOVE, EURUSD, ORDER_TYPE_BUY, ORDER_FILLING_FOK, #=12849
(EURUSD,H1)   DONE, #=1284920879, Request executed, Req=2
(XAUUSD,H1)   Autodetected daily range: 47.45
(XAUUSD,H1)   OK order placed: #=1284921672
(XAUUSD,H1)   TRADE_ACTION_PENDING, XAUUSD, ORDER_TYPE_BUY_STOP, V=0.01, ORDER_FILLIN
                » @ 1956.68, ORDER_TIME_GTC, M=1234567890
(XAUUSD,H1)   DONE, #=1284921672, V=0.01, Request executed, Req=3
(XAUUSD,H1)   OK order removed
(XAUUSD,H1)   TRADE_ACTION_REMOVE, XAUUSD, ORDER_TYPE_BUY, ORDER_FILLING_FOK, #=12849
(XAUUSD,H1)   DONE, #=1284921672, Request executed, Req=4
```

We will look at another example of deleting orders to implement the "One Cancel Other" (OCO) strategy in the *OnTrade* events section.

6.4.22 Getting a list of active orders

Expert Advisor programs often need to enumerate existing active orders and analyze their properties. In particular, in the section on pending order modifications, in the example *PendingOrderModify.mq5*, we have created a special function *GetMyOrder* to find the orders belonging to the Expert Advisor in to modify this order. There, the analysis was carried out by symbol name and Expert Advisor ID (*Magic*). In theory, the same approach should have been applied in the example of deleting a pending order *PendingOrderDelete.mq5* from the previous section.

In the latter case, for simplicity, we created an order and stored its ticket in a global variable. But this cannot be done in the general case because the Expert Advisor and the entire terminal can be stopped or restarted at any time. Therefore, the Expert Advisor must contain an algorithm for restoring the internal state, including the analysis of the entire trading environment, along with orders, deals, positions, account balance, and so on.

In this section, we will study the MQL5 functions for obtaining a list of active orders and selecting any of them in the trading environment, which makes it possible to read all its properties.

int OrdersTotal()

The *OrdersTotal* function returns the number of currently active orders. These include pending orders, as well as market orders that have not yet been executed. As a rule, a market order is executed promptly, and therefore it is not often possible to catch it in the active phase, but if there is not enough liquidity in the market, this can happen. As soon as the order is executed (a deal is concluded), it is transferred from the category of active ones to history. We will talk about working with order history in a separate section.

> Please note that only orders can be active and historical. This significantly distinguishes orders from deals which are always created in history and from positions that exist only online. To restore the history of positions, you should analyze the history of deals.

ulong OrderGetTicket(uint index)

The *OrderGetTicket* function returns the order ticket by its number in the list of orders in the terminal's trading environment. The *index* parameter must be between 0 and the *OrdersTotal()-1* value inclusive. The way in which orders are organized is not regulated.

The *OrderGetTicket* function selects an order, that is, copies data about it to some internal cache so that the MQL program can read all its properties using the subsequent calls of the *OrderGetDouble*, *OrderGetInteger*, or *OrderGetString* function, which will be discussed in a separate section.

The presence of such a cache indicates that the data received from it can become obsolete: the order may no longer exist or may have been modified (for example, it may have a different status, open price, *Stop Loss* or *Take Profit* levels and expiration). Therefore, to guarantee the receipt of relevant data about the order, it is recommended to call the *OrderGetTicket* function immediately prior to requesting the data. Here is how this is done in the example of *PendingOrderModify.mq5*.

```
ulong GetMyOrder(const string name, const ulong magic)
{
   for(int i = 0; i < OrdersTotal(); ++i)
   {
      ulong t = OrderGetTicket(i);
      if(OrderGetInteger(ORDER_MAGIC) == magic
      && OrderGetString(ORDER_SYMBOL) == name)
      {
         return t;
      }
   }
   return 0;
}
```

Each MQL program maintains its own cache (trading environment context), which includes the selected order. In the following sections, we will learn that in addition to orders, an MQL program can select positions and history fragments with deals and orders into the active context.

The *OrderSelect* function performs a similar selection of an order with copying of its data to the internal cache.

bool OrderSelect(ulong ticket)

The function checks for the presence of an order and prepares the possibility of further reading its properties. In this case, the order is specified not by a serial number but by a ticket which must be received by the MQL program earlier in one way or another, in particular, as a result of executing *OrderSend/OrderSendAsync*.

The function returns *true* in case of success. If *false* is received, it usually means that there is no order with the specified ticket. The most common reason for this is when order status has changed from active to history, for example, as a result of execution or cancellation (we will learn how to determine the exact status later). Orders can be selected in history using the relevant functions.

Previously we used the *OrderSelect* function in the *MqlTradeResultSync* structure for tracking creation and removal of pending orders.

6.4.23 Order properties (active and history)

In the sections related to trading operations, in particular to making buying/selling, closing a position, and placing a pending order, we have seen that requests are sent to the server based on the filling of specific fields of the *MqlTradeRequest* structure, most of which directly define the properties of the resulting orders. The MQL5 API allows you to learn these and some other properties set by the trading system itself, such as ticket, registration time, and status.

It is important to note that the list of order properties is common for both active and historical orders, although, of course, the values of many properties will differ for them.

Order properties are grouped in MQL5 according to the principle already familiar to us based on the type of values: integer (compatible with *long/ulong*), real (*double*), and strings. Each property group has its own enumeration.

Integer properties are summarized in ENUM_ORDER_PROPERTY_INTEGER and are presented in the following table.

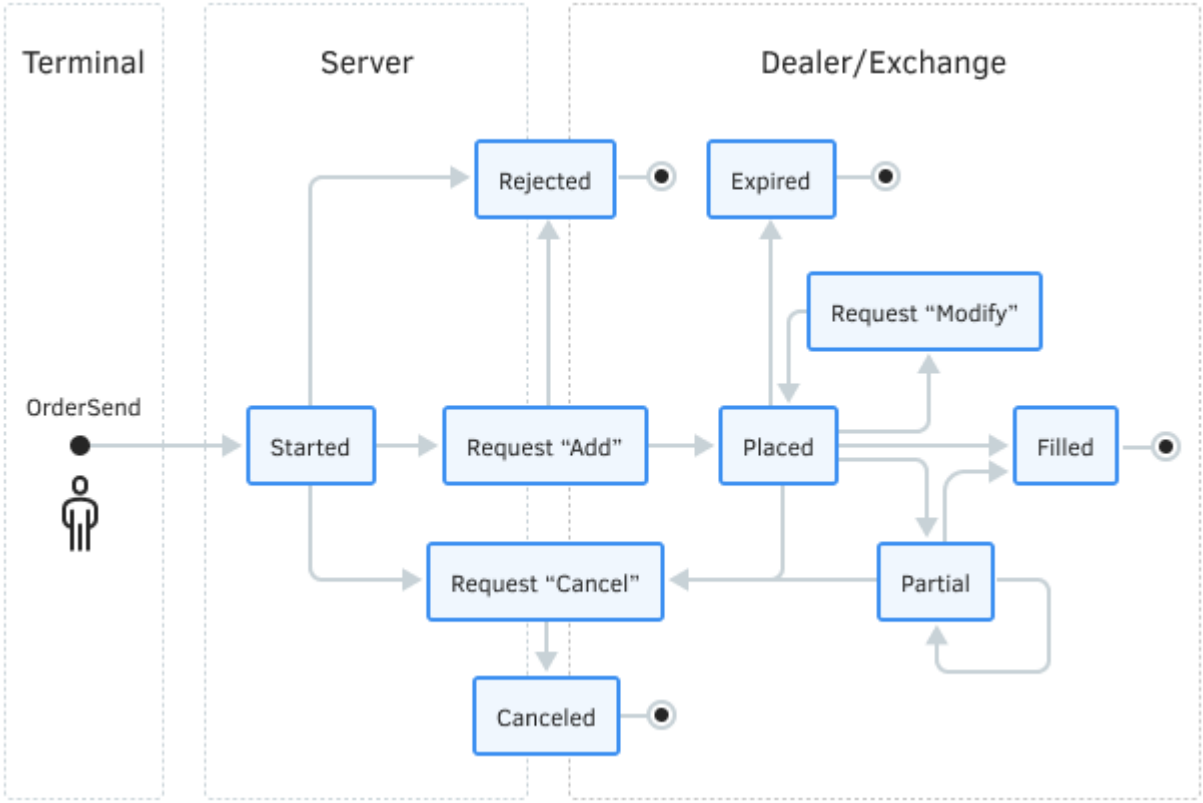
Identifier	Description	Type
ORDER_TYPE	Order type	ENUM_ORDER_TYPE
ORDER_TYPE_FILLING	Execution type by volume	ENUM_ORDER_TYPE_FILLING
ORDER_TYPE_TIME	Order lifetime (pending)	ENUM_ORDER_TYPE_TIME
ORDER_TIME_EXPIRATION	Order expiration time (pending)	datetime
ORDER_MAGIC	Arbitrary identifier set by the Expert Advisor that placed the order	ulong
ORDER_TICKET	Order ticket; a unique number assigned by the server to each order	ulong

Identifier	Description	Type
ORDER_STATE	Order status	ENUM_ORDER_STATE (see below)
ORDER_REASON	Reason or source for the order	ENUM_ORDER_REASON (see below)
ORDER_TIME_SETUP	Order placement time	datetime
ORDER_TIME_DONE	Order execution or withdrawal time	datetime
ORDER_TIME_SETUP_MSC	Time of order placement for execution in milliseconds	ulong
ORDER_TIME_DONE_MSC	Order execution/withdrawal time in milliseconds	ulong
ORDER_POSITION_ID	ID of the position that the order generated or modified upon execution	ulong
ORDER_POSITION_BY_ID	Opposite position identifier for orders of type ORDER_TYPE_CLOSE_BY	ulong

Each executed order generates a deal that opens a new or changes an existing position. The ID of this position is assigned to the executed order in the ORDER_POSITION_ID property.

The ENUM_ORDER_STATE enumeration contains elements that describe order statuses. See a simplified scheme (state diagram) of orders below.

Identifier	Description
ORDER_STATE_STARTED	The order has been checked for correctness but has not yet been accepted by the server
ORDER_STATE_PLACED	The order has been accepted by the server
ORDER_STATE_CANCELED	The order has been canceled by the client (user or MQL program)
ORDER_STATE_PARTIAL	The order has been partially executed
ORDER_STATE_FILLED	The order has been filled in full
ORDER_STATE_REJECTED	The order has been rejected by the server
ORDER_STATE_EXPIRED	The order has been canceled upon expiration
ORDER_STATE_REQUEST_ADD	The order is being registered (being placed in the trading system)
ORDER_STATE_REQUEST_MODIFY	The order is being modified (its parameters are being changed)
ORDER_STATE_REQUEST_CANCEL	The order is being deleted (removing from the trading system)



Order status diagram

Changing the state is possible only for active orders. For historical orders (filled or canceled), the status is fixed.

You can cancel an order that has already been partially fulfilled, and then its status in the history will be ORDER_STATE_CANCELED.

ORDER_STATE_PARTIAL occurs only for active orders. Executed (historical) orders always have the status ORDER_STATE_FILLED.

The ENUM_ORDER_REASON enumeration specifies possible order source options.

Identifier	Description
ORDER_REASON_CLIENT	Order placed manually from the desktop terminal
ORDER_REASON_EXPERT	Order placed from the desktop terminal by an Expert Adviser or a script
ORDER_REASON_MOBILE	Order placed from the mobile application
ORDER_REASON_WEB	Order placed from the web terminal (browser)
ORDER_REASON_SL	Order placed by the server as a result of Stop Loss triggering
ORDER_REASON_TP	Order placed by the server as a result of Take Profit triggering
ORDER_REASON_SO	Order placed by the server as a result of the Stop Out event

Real properties are collected in the ENUM_ORDER_PROPERTY_DOUBLE enumeration.

Identifier	Description
ORDER_VOLUME_INITIAL	Initial volume when placing an order
ORDER_VOLUME_CURRENT	Current volume (initial or remaining after partial execution)
ORDER_PRICE_OPEN	The price indicated in the order
ORDER_PRICE_CURRENT	The current symbol price of an order that has not yet been executed or the execution price
ORDER_SL	Stop Loss Level
ORDER_TP	Take Profit level
ORDER_PRICE_STOPLIMIT	The price for placing a Limit order when a StopLimit order is triggered

The ORDER_PRICE_CURRENT property contains the current *Ask* price for active buy pending orders or the *Bid* price for active sell pending orders. "Current" refers to the price known in the trading environment at the time the order is selected using *OrderSelect* or *OrderGetTicket*. For executed orders in the history, this property contains the execution price, which may differ from the one specified in the order due to slippage.

The ORDER_VOLUME_INITIAL and ORDER_VOLUME_CURRENT properties are not equal to each other only if the order status is ORDER_STATE_PARTIAL.

If the order was filled in parts, then its ORDER_VOLUME_INITIAL property in history will be equal to the size of the last filled part, and all other "fills" related to the original full volume will be executed as separate orders (and deals).

String properties are described in the ENUM_ORDER_PROPERTY_STRING enumeration.

Identifier	Description
ORDER_SYMBOL	The symbol on which the order is placed
ORDER_COMMENT	Comment
ORDER_EXTERNAL_ID	Order ID in the external trading system (on the exchange)

To read all the above properties, there are two different sets of functions: for active orders and for historical orders. First, we will consider the functions for active orders, and we will return to the historical ones after we get acquainted with the principles of selecting the required period in history.

6.4.24 Functions for reading properties of active orders

The sets of functions that can be used to get the values of all order properties differ for active and historical orders. This section describes the functions for reading the properties of active orders. For the functions for accessing the properties of orders in the history, see the relevant section.

Integer properties can be read using the *OrderGetInteger* function, which has two forms: the first one returns directly the value of the property, the second one returns a logical sign of success (*true*) or error (*false*), and the second parameter passed by reference is filled with the value of the property.

```
long OrderGetInteger(ENUM_ORDER_PROPERTY_INTEGER property)
bool OrderGetInteger(ENUM_ORDER_PROPERTY_INTEGER property, long &value)
```

Both functions allow you to get the requested order property of an integer-compatible type (*datetime*, *long/ulong* or listing). Although the prototype mentions *long*, from a technical point of view, the value is stored as an 8-byte cell, which can be cast to compatible types without any conversion of the internal representation, in particular, to *ulong*, which is used for all tickets.

A similar pair of functions is intended for properties of real type *double*.

```
double OrderGetDouble(ENUM_ORDER_PROPERTY_DOUBLE property)
bool OrderGetDouble(ENUM_ORDER_PROPERTY_DOUBLE property, double &value)
```

Finally, string properties are available through a pair of *OrderGetString* functions.

```
string OrderGetString(ENUM_ORDER_PROPERTY_STRING property)
bool OrderGetString(ENUM_ORDER_PROPERTY_STRING property, string &value)
```

As their first parameter, all functions take the identifier of the property we are interested in. This must be an element of one of the enumerations – ENUM_ORDER_PROPERTY_INTEGER, ENUM_ORDER_PROPERTY_DOUBLE, or ENUM_ORDER_PROPERTY_STRING – discussed in the previous section.

Please note before calling any of the previous functions, you should first select an order using *OrderSelect* or *OrderGetTicket*.

To read all the properties of a specific order, we will develop the *OrderMonitor* class (*OrderMonitor.mqh*) which operates on the same principle as the previously considered symbol (*SymbolMonitor.mqh*) and trading account (*AccountMonitor.mqh*) monitors.

These and other monitor classes discussed in the book offer a unified way to analyze properties through overloaded versions of virtual *get* methods.

Looking a little ahead, let's say that deals and positions have the same grouping of properties according to the three main types of values, and we also need to implement monitors for them. In this regard, it makes sense to separate the general algorithm into a base abstract class *MonitorInterface* (*TradeBaseMonitor.mqh*). This is a template class with three parameters intended to specify the types of specific enumerations, for integer (I), real (D), and string (S) property groups.

```
#include <MQL5Book/EnumToArray.mqh>

template<typename I,typename D,typename S>
class MonitorInterface
{
protected:
   bool ready;
public:
   MonitorInterface(): ready(false) { }

   bool isReady() const
   {
      return ready;
   }
   ...
```

Due to the fact that finding an order (deal or position) in the trading environment may fail for various reasons, the class has a reserved variable *ready* in which derived classes will have to write a sign of successful initialization, that is, the choice of an object to read its properties.

Several purely virtual methods declare access to properties of the corresponding types.

```
   virtual long get(const I property) const = 0;
   virtual double get(const D property) const = 0;
   virtual string get(const S property) const = 0;
   virtual long get(const int property, const long) const = 0;
   virtual double get(const int property, const double) const = 0;
   virtual string get(const int property, const string) const = 0;
   ...
```

In the first three methods, the property type is specified by one of the template parameters. In further three methods, the type is specified by the second parameter of the method itself: this is required because the last methods take not the constants of a particular enumeration but simply an integer as the first parameter. On the one hand, this is convenient for the continuous numbering of identifiers (the enumeration constants of the three types do not intersect). On the other hand, we need another source for determining the type of value since the type returned by the function/method does not participate in the process of choosing the appropriate overload.

This approach allows you to get properties based on various inputs available in the calling code. Next, we will create classes based on *OrderMonitor* (as well as future *DealMonitor* and *PositionMonitor*) to select objects according to a set of arbitrary conditions, and there all these methods will be in demand.

Quite often, programs need to get a string representation of any properties, for example, for logging. In the new monitors, this is implemented by the *stringify* methods. Obviously, they get the values of the requested properties through *get* method calls mentioned above.

```
virtual string stringify(const long v, const I property) const = 0;

virtual string stringify(const I property) const
{
   return stringify(get(property), property);
}

virtual string stringify(const D property, const string format = NULL) const
{
   if(format == NULL) return (string)get(property);
   return StringFormat(format, get(property));
}

virtual string stringify(const S property) const
{
   return get(property);
}
...
```

The only method that has not received implementation is the first version of *stringify* for type *long*. This is due to the fact that the group of integer properties, as we saw in the previous section, actually contain different application types, including date and time, enumerations, and integers. Therefore, only derived classes can provide their conversion to understandable strings. This situation is common for all trading entities, not only orders but also deals and positions the properties of which we will consider later.

When an integer property contains an enumeration element (for example, ENUM_ORDER_TYPE, ORDER_TYPE_FILLING, etc.), you should use the *EnumToString* function to convert it to a string. This task is fulfilled by a helper method *enumstr*. Soon we will see its widespread use in specific monitor classes, starting with *OrderMonitor* after a couple of paragraphs.

```
template<typename E>
static string enumstr(const long v)
{
   return EnumToString((E)v);
}
```

To log all properties of a particular type, we have created the *list2log* method which uses *stringify* in a loop.

```
template<typename E>
void list2log() const
{
   E e = (E)0; // suppress warning 'possible use of uninitialized variable'
   int array[];
   const int n = EnumToArray(e, array, 0, USHORT_MAX);
   Print(typename(E), " Count=", n);
   for(int i = 0; i < n; ++i)
   {
      e = (E)array[i];
      PrintFormat("% 3d %s=%s", i, EnumToString(e), stringify(e));
   }
}
```

Finally, to make it easier to log the properties of all three groups, there is a method *print* which calls *list2log* three times for each group of properties.

```
virtual void print() const
{
   if(!ready) return;

   Print(typename(this));
   list2log<I>();
   list2log<D>();
   list2log<S>();
}
```

Having at our disposal a base template class *MonitorInterface*, we describe *OrderMonitorInterface*, where we specify certain enumeration types for orders from the previous section and provide an implementation of *stringify* for integer properties of orders.

```
class OrderMonitorInterface:
   public MonitorInterface<ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,ENUM_ORDER_PROPERTY_STRING>
{
public:
   // description of properties according to subtypes
   virtual string stringify(const long v,
      const ENUM_ORDER_PROPERTY_INTEGER property) const override
   {
      switch(property)
      {
         case ORDER_TYPE:
            return enumstr<ENUM_ORDER_TYPE>(v);
         case ORDER_STATE:
            return enumstr<ENUM_ORDER_STATE>(v);
         case ORDER_TYPE_FILLING:
            return enumstr<ENUM_ORDER_TYPE_FILLING>(v);
         case ORDER_TYPE_TIME:
            return enumstr<ENUM_ORDER_TYPE_TIME>(v);
         case ORDER_REASON:
            return enumstr<ENUM_ORDER_REASON>(v);

         case ORDER_TIME_SETUP:
         case ORDER_TIME_EXPIRATION:
         case ORDER_TIME_DONE:
            return TimeToString(v, TIME_DATE | TIME_SECONDS);

         case ORDER_TIME_SETUP_MSC:
         case ORDER_TIME_DONE_MSC:
            return STR_TIME_MSC(v);
      }

      return (string)v;
   }
};
```

The STR_TIME_MSC macro for displaying time in milliseconds is defined as follows:

```
#define STR_TIME_MSC(T) (TimeToString((T) / 1000, TIME_DATE | TIME_SECONDS) \
    + StringFormat("'%03d", (T) % 1000))
```

Now we are ready to describe the final class for reading the properties of any order: *OrderMonitor* derived from *OrderMonitorInterface*. The order ticket is passed to the constructor, and it is selected in the trading environment using *OrderSelect*.

```
class OrderMonitor: public OrderMonitorInterface
{
public:
   const ulong ticket;
   OrderMonitor(const long t): ticket(t)
   {
      if(!OrderSelect(ticket))
      {
         PrintFormat("Error: OrderSelect(%lld) failed: %s",
            ticket, E2S(_LastError));
      }
      else
      {
         ready = true;
      }
   }
   ...
```

The main working part of the monitor consists of redefinitions of virtual functions for reading properties. Here we see the *OrderGetInteger*, *OrderGetDouble*, and *OrderGetString* function calls.

```
   virtual long get(const ENUM_ORDER_PROPERTY_INTEGER property) const override
   {
      return OrderGetInteger(property);
   }

   virtual double get(const ENUM_ORDER_PROPERTY_DOUBLE property) const override
   {
      return OrderGetDouble(property);
   }

   virtual string get(const ENUM_ORDER_PROPERTY_STRING property) const override
   {
      return OrderGetString(property);
   }

   virtual long get(const int property, const long) const override
   {
      return OrderGetInteger((ENUM_ORDER_PROPERTY_INTEGER)property);
   }

   virtual double get(const int property, const double) const override
   {
      return OrderGetDouble((ENUM_ORDER_PROPERTY_DOUBLE)property);
   }

   virtual string get(const int property, const string)  const override
   {
      return OrderGetString((ENUM_ORDER_PROPERTY_STRING)property);
   }
};
```

This code fragment is presented in a short form: operators for working with orders in the history have been removed from it. we will see the full code of *OrderMonitor* later when we explore this aspect in the following sections.

It is important to note that the monitor object does not store copies of its properties. Therefore, access to *get* methods must be carried out immediately after the creation of the object and, accordingly, the call *OrderSelect*. To read the properties at a later period, you will need to allocate the order again in the internal cache of the MQL program, for example, by calling the method *refresh*.

```
   void refresh()
   {
      ready = OrderSelect(ticket);
   }
```

Let's test the work of *OrderMonitor* by adding it to the Expert Advisor *MarketOrderSend.mq5*. A new version named *MarketOrderSendMonitor.mq5* connects the file *OrderMonitor.mqh* by the directive *#include*, and in the body of the function *OnTimer* (in the block of successful confirmation of opening a position on an order) creates a monitor object and calls its *print* method.

```
#include <MQL5Book/OrderMonitor.mqh>
...
void OnTimer()
{
   ...
   const ulong order = (wantToBuy ?
      request.buy(volume, Price) :
      request.sell(volume, Price));
   if(order != 0)
   {
      Print("OK Order: #=", order);
      if(request.completed())
      {
         Print("OK Position: P=", request.result.position);

         OrderMonitor m(order);
         m.print();
         ...
      }
   }
}
```

In the log, we should see new lines containing all the properties of the order.

```
OK Order: #=1287846602
Waiting for position for deal D=1270417032
OK Position: P=1287846602
MonitorInterface<ENUM_ORDER_PROPERTY_INTEGER, »
   » ENUM_ORDER_PROPERTY_DOUBLE,ENUM_ORDER_PROPERTY_STRING>

   » Request executed, Req=3
```

The fourth line starts the output from the *print* method which includes the full name of the monitor object *MonitorInterface* together with parameter types (in this case, the triple ENUM_ORDER_PROPERTY) and then all the properties of a particular order.

However, property printing is not the most interesting action a monitor can provide. The task of selecting orders by conditions (values of arbitrary properties) is much more in demand among Experts Advisors. Using the monitor as an auxiliary tool, we will create a mechanism for filtering orders similar to what we have done for symbols: *SymbolFilter.mqh*.

6.4.25 Selecting orders by properties

In one of the sections on symbol properties, we introduced the *SymbolFilter* class to select financial instruments with specified characteristics. Now we will apply the same approach for orders.

Since we have to analyze not only orders but also deals and positions in a similar way, we will separate the general part of the filtering algorithm into the base class *TradeFilter* (*TradeFilter.mqh*). It almost exactly repeats the source code of *SymbolFilter*. Therefore, we will not explain it here again.

Those who wish can perform a contextual file comparison of *SymbolFilter.mqh* and *TradeFilter.mqh* to see how similar they are and to localize minor edits.

The main difference is that the *TradeFilter* class is a template since it has to deal with the properties of different objects: orders, deals, and positions.

```
enum IS // supported comparison conditions in filters
{
   EQUAL,
   GREATER,
   NOT_EQUAL,
   LESS
};

enum ENUM_ANY // dummy enum to cast all enums to it
{
};

template<typename T,typename I,typename D,typename S>
class TradeFilter
{
protected:
   MapArray<ENUM_ANY,long> longs;
   MapArray<ENUM_ANY,double> doubles;
   MapArray<ENUM_ANY,string> strings;
   MapArray<ENUM_ANY,IS> conditions;
   ...

   template<typename V>
   static bool equal(const V v1, const V v2);

   template<typename V>
   static bool greater(const V v1, const V v2);

   template<typename V>
   bool match(const T &m, const MapArray<ENUM_ANY,V> &data) const;

public:
   // methods for adding conditions to the filter
   TradeFilter *let(const I property, const long value, const IS cmp = EQUAL);
   TradeFilter *let(const D property, const double value, const IS cmp = EQUAL);
   TradeFilter *let(const S property, const string value, const IS cmp = EQUAL);
   // methods for getting into arrays of records matching the filter
   template<typename E,typename V>
   bool select(const E property, ulong &tickets[], V &data[],
      const bool sort = false) const;
   template<typename E,typename V>
   bool select(const E &property[], ulong &tickets[], V &data[][],
      const bool sort = false) const
   bool select(ulong &tickets[]) const;
   ...
}
```

The template parameters I, D and S are enumerations for property groups of three main types (integer, real, and string): for orders, they were described in previous sections, so for clarity, you can imagine that I=ENUM_ORDER_PROPERTY_INTEGER, D=ENUM_ORDER_PROPERTY_DOUBLE, S=ENUM_ORDER_PROPERTY_STRING.

The T type is designed for specifying a monitor class. At the moment we have only one monitor ready, *OrderMonitor*. Later we will implement *DealMonitor* and *PositionMonitor*.

Earlier, in the *SymbolFilter* class, we did not use template parameters because for symbols, all types of property enumerations are invariably known, and there is a single class *SymbolMonitor*.

Recall the structure of the filter class. A group of *let* methods allows you to register a combination of "property=value" pairs in the filter, which will then be used to select objects in *select* methods. The ID property is specified in the *property* parameter, and the value is in the *value* parameter.

There are also several *select* methods. They allow the calling code to fill in an array with selected tickets, as well as, if necessary, additional arrays with the values of the requested object properties. The specific identifiers of the requested properties are set in the first parameter of the *select* method; it can be one property or several. Depending on this, the receiving array must be one-dimensional or two-dimensional.

The combination of property and value can be checked not only for equality (EQUAL) but also for greater/less operations (GREATER/LESS). For string properties, it is acceptable to specify a search pattern with the character "*" denoting any sequence of characters (for example, "*[tp]*" for the ORDER_COMMENT property will match all comments in which "[tp]" occurs anywhere, although this is only demonstration of the possibility – while to search for orders resulting from triggered *Take Profit* you should analyze ORDER_REASON).

Since the algorithm requires the implementation of a loop though all objects and objects can be of different types (so far these are orders, but then support for deals and positions will appear), we need to describe two abstract methods in the *TradeFilter* class: *total* and *get*:

```
virtual int total() const = 0;
virtual ulong get(const int i) const = 0;
```

The first one returns the number of objects and the second one returns the order ticket by its number. This should remind you of the pair of functions *OrdersTotal* and *OrderGetTicket*. Indeed, they are used in specific implementations of methods for filtering orders.

Below is the *OrderFilter* class (*OrderFilter.mqh*) in full.

```
#include <MQL5Book/OrderMonitor.mqh>
#include <MQL5Book/TradeFilter.mqh>

class OrderFilter: public TradeFilter<OrderMonitor,
   ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,
   ENUM_ORDER_PROPERTY_STRING>
{
protected:
   virtual int total() const override
   {
      return OrdersTotal();
   }
   virtual ulong get(const int i) const override
   {
      return OrderGetTicket(i);
   }
};
```

This simplicity is especially important given that similar filters will be created effortlessly for trades and positions.

With the help of the new class, we can much more easily check the presence of orders belonging to our Expert Advisor, i.e., replace any self-written versions of the *GetMyOrder* function used in the example *PendingOrderModify.mq5*.

```
OrderFilter filter;
ulong tickets[];

// set a condition for orders for the current symbol and our "magic" number
filter.let(ORDER_SYMBOL, _Symbol).let(ORDER_MAGIC, Magic);
// select suitable tickets in an array
if(filter.select(tickets))
{
   ArrayPrint(tickets);
}
```

By "any versions" here we mean that thanks to the filter class, we can create arbitrary conditions for selecting orders and changing them "on the go" (for example, at the direction of the user, not the programmer).

As an example of how to utilize the filter, let's use an Expert Advisor that creates a grid of pending orders for trading on a rebound from levels within a certain price range, that is, designed for a fluctuating market. Starting from this section and over the next few, we will modify the Expert Advisor in the context of the material being studied.

The first version of the Expert Advisor *PendingOrderGrid1.mq5* builds a grid of a given size from limit and stop-limit orders. The parameters will be the number of price levels and the step in points between them. The operation scheme is illustrated in the following chart.

Grid of pending orders on 4 levels with a step of 200 points

At a certain initial time, which can be determined by the intraday schedule and can correspond, for example, to the "night flat", the current price is rounded up to the size of the grid step, and a specified number of levels is laid up from this level up and down.

At each upper level, we place a limit sell order and a *stoplimit* buy order with the price of the future limit order one level lower. At each lower level, we place a limit buy order and a *stoplimit* sell order with the price of the future limit order one level higher.

When the price touches one of the levels, the limit order standing there turns into a buy or sell (position). At the same time, a stop-limit order of the same level is automatically converted by the system into a limit order of the opposite direction at the next level.

For example, if the price breaks through the level while moving up, we will get a short position, and a limit order to buy will be created at the step distance below it.

The Expert Advisor will monitor, that at each level there is a stop limit order paired with a limit order. Therefore, after a new limit buy order is detected, the program will add a stop-limit sell order to it at the same level, and the target price of the future limit order is the level next to the top, i.e., the one where the position is opened.

Let's say the price turns down and activates a limit order to the level below – we will get a long position. At the same time, the stop-limit order is converted into a limit order to sell at the next level above. Now the Expert Advisor will again detect a "bare" limit order and create a stop-limit order to buy as a pair to it, at the same level as the price of the future limit order one level lower.

If there are opposite positions, we will close them. We will also provide for the setting of an intraday period when the trading system is enabled, and for the rest of the time all orders and positions will be deleted. This, in particular, is useful for the "night flat", when the return fluctuations of the market are especially pronounced.

Of course, this is just one of many potential implementations of the grid strategy which lacks many of the customizations of grids, but we won't overcomplicate the example.

The Expert Advisor will analyze the situation on each bar (presumably H1 timeframe or less). In theory, this Expert Advisor's operation logic needs to be improved by promptly responding to trading events but we haven't explored them yet. Therefore, instead of constant tracking and instant "manual" restoration of limit orders at vacant grid levels, we entrusted this work to the server through the use of stop-limit orders. However, there is a nuance here.

The fact is that limit and stop-limit orders at each level are of opposite types (*buy/sell*) and therefore are activated by different types of prices.

It turns out that if the market moved up to the next level in the upper half of the grid, the *Ask* price may touch the level and activate a stop-limit buy order, but the *Bid* price will not reach the level, and the sell limit order will remain as it is (it will not turn into a position). In the lower half of the grid, when the market moves down, the situation is mirrored. Any level is first touched by the *Bid* price, and activates a stop-limit order to sell, and only with a further decrease the level is also reached by the *Ask* price. If there is no move, the buy limit order will remain as is.

This problem becomes critical as the spread increases. Therefore, the Expert Advisor will require additional control over "extra" limit orders. In other words, the Expert Advisor will not generate a stop-limit order that is missing at the level if there is already a limit order at its supposed target price (adjacent level).

The source code is included in the file *PendingOrderGrid1.mq5*. In the input parameters, you can set the *Volume* of each trade (by default, if left equal to 0, the minimum lot of the chart symbol is taken), the number of grid levels *GridSize* (must be even), and the step *GridStep* between levels in points. The start and end times of the intraday segment on which the strategy is allowed to work are specified in the parameters *StartTime* and *StopTime*: in both, only time is important.

```
#include <MQL5Book/MqlTradeSync.mqh>
#include <MQL5Book/OrderFilter.mqh>
#include <MQL5Book/MapArray.mqh>

input double Volume;                                    // Volume (0 = minimal lot
input uint GridSize = 6;                                // GridSize (even number o
input uint GridStep = 200;                              // GridStep (points)
input ENUM_ORDER_TYPE_TIME Expiration = ORDER_TIME_GTC;
input ENUM_ORDER_TYPE_FILLING Filling = ORDER_FILLING_FOK;
input datetime StartTime = D'1970.01.01 00:00:00';      // StartTime (hh:mm:ss)
input datetime StopTime = D'1970.01.01 09:00:00';       // StopTime (hh:mm:ss)
input ulong Magic = 1234567890;
```

The segment of working time can be either within a day (*StartTime* < *StopTime*) or cross the boundary of the day (*StartTime* > *StopTime*), for example, from 22:00 to 09:00. If the two times are equal, round-the-clock trading is assumed.

Before proceeding with the implementation of the trading idea, let's simplify the task of setting up queries and outputting diagnostic information to the log. To do this, we describe our own structure *MqlTradeRequestSyncLog*, the derivative of *MqlTradeRequestSync*.

```
const ulong DAYLONG = 60 * 60 * 24; // length of the day in seconds

struct MqlTradeRequestSyncLog: public MqlTradeRequestSync
{
   MqlTradeRequestSyncLog()
   {
      magic = Magic;
      type_filling = Filling;
      type_time = Expiration;
      if(Expiration == ORDER_TIME_SPECIFIED)
      {
         expiration = (datetime)(TimeCurrent() / DAYLONG * DAYLONG
            + StopTime % DAYLONG);
         if(StartTime > StopTime)
         {
            expiration = (datetime)(expiration + DAYLONG);
         }
      }
   }
   ~MqlTradeRequestSyncLog()
   {
      Print(TU::StringOf(this));
      Print(TU::StringOf(this.result));
   }
};
```

In the constructor, we fill in all fields with unchanged values. In the destructor, we log meaningful query and result fields. Obviously, the destructor of automatic objects will always be called at the moment of exit from the code block where the order was formed and sent, that is, the sent and received data will be printed.

In *OnInit* let's perform some checks for the correctness of the input variables, in particular, for an even grid size.

```
int OnInit()
{
   if(GridSize < 2 || !!(GridSize % 2))
   {
      Alert("GridSize should be 2, 4, 6+ (even number)");
      return INIT_FAILED;
   }
   return INIT_SUCCEEDED;
}
```

The main entry point of the algorithm is the *OnTick* handler. In it, for brevity, we will omit the same error handling mechanism based on TRADE_RETCODE_SEVERITY as in the example *PendingOrderModify.mq5*.

For bar-by-bar work, the function has a static variable *lastBar*, in which we store the time of the last successfully processed bar. All subsequent ticks on the same bar are skipped.

```
void OnTick()
{
   static datetime lastBar = 0;
   if(iTime(_Symbol, _Period, 0) == lastBar) return;
   uint retcode = 0;

   ... // main algorithm (see further)

   const TRADE_RETCODE_SEVERITY severity = TradeCodeSeverity(retcode);
   if(severity < SEVERITY_RETRY)
   {
      lastBar = iTime(_Symbol, _Period, 0);
   }
}
```

Instead of an ellipsis, the main algorithm will follow, divided into several auxiliary functions for systematization purposes. First of all, let's determine whether the working period of the day is set and, if so, whether the strategy is currently enabled. This attribute is stored in the *tradeScheduled* variable.

```
   ...
   bool tradeScheduled = true;

   if(StartTime != StopTime)
   {
      const ulong now = TimeCurrent() % DAYLONG;

      if(StartTime < StopTime)
      {
         tradeScheduled = now >= StartTime && now < StopTime;
      }
      else
      {
         tradeScheduled = now >= StartTime || now < StopTime;
      }
   }
   ...
```

With trading enabled, first, check if there is already a network of orders using the *CheckGrid* function. If there is no network, the function will return the GRID_EMPTY constant and we should create the network by calling *Setup Grid*. If the network has already been built, it makes sense to check if there are opposite positions to close: this is done by the *CompactPositions* function.

```
   if(tradeScheduled)
   {
      retcode = CheckGrid();

      if(retcode == GRID_EMPTY)
      {
         retcode = SetupGrid();
      }
      else
      {
         retcode = CompactPositions();
      }
   }
   ...
```

As soon as the trading period ends, it is necessary to delete orders and close all positions (if any). This is done, respectively, by the *RemoveOrders* and *CompactPositions function*, functions but with a boolean flag (*true*): this single, optional argument instructs to apply a simple close for the remaining positions after the opposite close.

```
   else
   {
      retcode = CompactPositions(true);
      if(!retcode) retcode = RemoveOrders();
   }
```

All functions return a server code, which is analyzed for success or failure with *TradeCodeSeverity*. The special application codes GRID_EMPTY and GRID_OK are also considered standard according to TRADE_RETCODE_SEVERITY.

```
#define GRID_OK    +1
#define GRID_EMPTY  0
```

Now let's take a look at the functions one by one.

The *CheckGrid* function uses the *OrderFilter* class presented at the beginning of this section. The filter requests all pending orders for the current symbol and with "our" identification number, and the tickets of found orders are stored in the array.

```
uint CheckGrid()
{
   OrderFilter filter;
   ulong tickets[];

   filter.let(ORDER_SYMBOL, _Symbol).let(ORDER_MAGIC, Magic)
      .let(ORDER_TYPE, ORDER_TYPE_SELL, IS::GREATER)
      .select(tickets);
   const int n = ArraySize(tickets);
   if(!n) return GRID_EMPTY;
   ...
```

The completeness of the grid is analyzed using the already familiar MapArray class that stores "key=value" pairs. In this case, the key is the level (price converted into points), and the value is the

bitmask (superposition) of order types at the given level. Also, limit and stop-limit orders are counted in the *limits* and *stops* variables, respectively.

```
// price levels => masks of types of orders existing there
MapArray<ulong,uint> levels;

const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);
int limits = 0;
int stops = 0;

for(int i = 0; i < n; ++i)
{
   if(OrderSelect(tickets[i]))
   {
      const ulong level = (ulong)MathRound(OrderGetDouble(ORDER_PRICE_OPEN) / poin
      const ulong type = OrderGetInteger(ORDER_TYPE);
      if(type == ORDER_TYPE_BUY_LIMIT || type == ORDER_TYPE_SELL_LIMIT)
      {
         ++limits;
         levels.put(level, levels[level] | (1 << type));
      }
      else if(type == ORDER_TYPE_BUY_STOP_LIMIT
         || type == ORDER_TYPE_SELL_STOP_LIMIT)
      {
         ++stops;
         levels.put(level, levels[level] | (1 << type));
      }
   }
}
...
```

If the number of orders of each type matches and is equal to the specified grid size, then everything is in order.

```
if(limits == stops)
{
   if(limits == GridSize) return GRID_OK; // complete grid

   Alert("Error: Order number does not match requested");
   return TRADE_RETCODE_ERROR;
}
...
```

The situation when the number of limit orders is greater than the stop limit ones is normal: it means that due to the price movement, one or more stop limit orders have turned into limit ones. The program should then add stop-limit orders to the levels where there are not enough of them. A separate order of a specific type for a specific level can be placed by the *RepairGridLevel* function.

```
      if(limits > stops)
      {
         const uint stopmask =
            (1 << ORDER_TYPE_BUY_STOP_LIMIT) | (1 << ORDER_TYPE_SELL_STOP_LIMIT);
         for(int i = 0; i < levels.getSize(); ++i)
         {
            if((levels[i] & stopmask) == 0) // there is no stop-limit order at this leve
            {
               // the direction of the limit is required to set the reverse stop limit
               const bool buyLimit = (levels[i] & (1 << ORDER_TYPE_BUY_LIMIT));
               // checks for "extra" orders due to the spread are omitted here (see the
               ...
               // create a stop-limit order in the desired direction
               const uint retcode = RepairGridLevel(levels.getKey(i), point, buyLimit);
               if(TradeCodeSeverity(retcode) > SEVERITY_NORMAL)
               {
                  return retcode;
               }
            }
         }
         return GRID_OK;
      }
      ...
```

The situation when the number of stop-limit orders is greater than the limit ones is treated as an error (probably the server skipped the price for some reason).

```
      Alert("Error: Orphaned Stop-Limit orders found");
      return TRADE_RETCODE_ERROR;
   }
```

The function *RepairGridLevel* performs the following actions.

```
uint RepairGridLevel(const ulong level, const double point, const bool buyLimit)
{
   const double price = level * point;
   const double volume = Volume == 0 ?
      SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volume;

   MqlTradeRequestSyncLog request;

   request.comment = "repair";

   // if there is an unpaired buy-limit, set the sell-stop-limit to it
   // if there is an unpaired sell-limit, set buy-stop-limit to it
   const ulong order = (buyLimit ?
      request.sellStopLimit(volume, price, price + GridStep * point) :
      request.buyStopLimit(volume, price, price - GridStep * point));
   const bool result = (order != 0) && request.completed();
   if(!result) Alert("RepairGridLevel failed");
   return request.result.retcode;
}
```

Please note that we do not need to actually fill in the structure (except for a comment that can be made more informative if necessary) since some of the fields are filled in automatically by the constructor, and we pass the volume and price directly to the *sellStopLimit* or *buyStopLimit* method.

A similar approach is used in the *SetupGrid* function, which creates a new full network of orders. At the beginning of the function, we prepare variables for calculations and describe the *MqlTradeRequestSyncLog* array of structures.

```
uint SetupGrid()
{
   const double current = SymbolInfoDouble(_Symbol, SYMBOL_BID);
   const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);
   const double volume = Volume == 0 ?
      SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volume;
   // central price of the range rounded to the nearest step,
   // from it up and down we identify the levels
   const double base = ((ulong)MathRound(current / point / GridStep) * GridStep)
      * point;
   const string comment = "G[" + DoubleToString(base,
      (int)SymbolInfoInteger(_Symbol, SYMBOL_DIGITS)) + "]";
   const static string message = "SetupGrid failed: ";
   MqlTradeRequestSyncLog request[][2]; // limit and stop-limit - one pair
   ArrayResize(request, GridSize);      // 2 pending orders per level
```

Next, we generate orders for the lower and upper half of the grid, diverging from the center to the sides.

```
   for(int i = 0; i < (int)GridSize / 2; ++i)
   {
      const int k = i + 1;

      // bottom half of the grid
      request[i][0].comment = comment;
      request[i][1].comment = comment;

      if(!(request[i][0].buyLimit(volume, base - k * GridStep * point)))
      {
         Alert(message + (string)i + "/BL");
         return request[i][0].result.retcode;
      }
      if(!(request[i][1].sellStopLimit(volume, base - k * GridStep * point,
         base - (k - 1) * GridStep * point)))
      {
         Alert(message + (string)i + "/SSL");
         return request[i][1].result.retcode;
      }

      // top half of the grid
      const int m = i + (int)GridSize / 2;

      request[m][0].comment = comment;
      request[m][1].comment = comment;

      if(!(request[m][0].sellLimit(volume, base + k * GridStep * point)))
      {
         Alert(message + (string)m + "/SL");
         return request[m][0].result.retcode;
      }
      if(!(request[m][1].buyStopLimit(volume, base + k * GridStep * point,
         base + (k - 1) * GridStep * point)))
      {
         Alert(message + (string)m + "/BSL");
         return request[m][1].result.retcode;
      }
   }
```

Then we check for readiness.

```
      for(int i = 0; i < (int)GridSize; ++i)
      {
         for(int j = 0; j < 2; ++j)
         {
            if(!request[i][j].completed())
            {
               Alert(message + (string)i + "/" + (string)j + " post-check");
               return request[i][j].result.retcode;
            }
         }
      }
      return GRID_OK;
   }
```

Although the check (call of *completed*) is spaced out with sending orders, our structure still uses the synchronous form *OrderSend* internally. In fact, to speed up sending a batch of orders (as in our grid Expert Advisor), it is better to use the asynchronous version *OrderSendAsync*. But then the order execution status should be initiated from the event handler *OnTradeTransaction*. We will study this one later.

An error when sending any order leads to an early exit from the loop and the return of the code from the server. This testing Expert Advisor will simply stop its further work in case of an error. For a real robot, it is desirable to provide an intellectual analysis of the meaning of the error and, if necessary, delete all orders and close positions.

Positions that will be generated by pending orders are closed by the function *CompactPositions*.

```
uint CompactPositions(const bool cleanup = false)
```

The *cleanup* parameter equal to *false* by default means regular "cleaning" of positions within the trading period, i.e., the closing of opposite positions (if any). Value *cleanup=true* is used to force close all positions at the end of the trading period.

The function fills the *ticketsLong* and *ticketsShort* arrays with tickets of long and short positions using a helper function *GetMyPositions*. We have already used the latter in the example *TradeCloseBy.mq5* in the section Closing opposite positions: full and partial. The *CloseByPosition* function from that example has undergone minimal changes in the new Expert Advisor: it returns a code from the server instead of a logical indicator of success or error.

```
uint CompactPositions(const bool cleanup = false)
{
   uint retcode = 0;
   ulong ticketsLong[], ticketsShort[];
   const int n = GetMyPositions(_Symbol, Magic, ticketsLong, ticketsShort);
   if(n > 0)
   {
      Print("CompactPositions, pairs: ", n);
      for(int i = 0; i < n; ++i)
      {
         retcode = CloseByPosition(ticketsShort[i], ticketsLong[i]);
         if(retcode) return retcode;
      }
   }
   ...
```

The second part of *CompactPositions* only works when *cleanup=true*. It is far from perfect and will be rewritten soon.

```
   if(cleanup)
   {
      if(ArraySize(ticketsLong) > ArraySize(ticketsShort))
      {
         retcode = CloseAllPositions(ticketsLong, ArraySize(ticketsShort));
      }
      else if(ArraySize(ticketsLong) < ArraySize(ticketsShort))
      {
         retcode = CloseAllPositions(ticketsShort, ArraySize(ticketsLong));
      }
   }

   return retcode;
}
```

For all found remaining positions, the usual closure is performed by calling *CloseAllPositions*.

```
uint CloseAllPositions(const ulong &tickets[], const int start = 0)
{
   const int n = ArraySize(tickets);
   Print("CloseAllPositions ", n);
   for(int i = start; i < n; ++i)
   {
      MqlTradeRequestSyncLog request;
      request.comment = "close down " + (string)(i + 1 - start)
         + " of " + (string)(n - start);
      if(!(request.close(tickets[i]) && request.completed()))
      {
         Print("Error: position is not closed ", tickets[i]);
         return request.result.retcode;
      }
   }
   return 0; // success
}
```

Now we only need to consider the *RemoveOrders* function. It also uses the order filter to get a list of them, and then calls the *remove* method in a loop.

```
uint RemoveOrders()
{
   OrderFilter filter;
   ulong tickets[];
   filter.let(ORDER_SYMBOL, _Symbol).let(ORDER_MAGIC, Magic)
      .select(tickets);
   const int n = ArraySize(tickets);
   for(int i = 0; i < n; ++i)
   {
      MqlTradeRequestSyncLog request;
      request.comment = "removal " + (string)(i + 1) + " of " + (string)n;
      if(!(request.remove(tickets[i]) && request.completed()))
      {
         Print("Error: order is not removed ", tickets[i]);
         return request.result.retcode;
      }
   }
   return 0;
}
```

Let's check how the Expert Advisor works in the tester with default settings (trading period from 00:00 to 09:00). Below is a screenshot for launching on EURUSD, H1.

Grid strategy PendingOrderGrid1.mq5 in the tester

In the log, in addition to periodic entries about the batch creation of several orders (at the beginning of the day) and their removal in the morning, we will regularly see the restoration of the network (adding orders instead of triggered ones) and closing positions.

```
buy stop limit 0.01 EURUSD at 1.14200 (1.14000) (1.13923 / 1.13923)

```

Now it's time to study the MQL5 functions for working with positions and improve their selection and analysis in our Expert Advisor. The following sections deal with this.

6.4.26 Getting the list of positions

In many examples of Expert Advisors, we have already used the MQL5 API functions designed to analyze open trading positions. This section presents their formal description.

It is important to note that the functions of this group are not able to create, modify, or delete positions. As we saw earlier, all such actions are performed indirectly through the sending of orders. If they are successfully executed, transactions are made, as a result of which positions are formed.

Another feature is that the functions are only applicable to online positions. To restore the history of positions, it is necessary to analyze the history of trades.

The *PositionsTotal* function allows you to find out the total number of open positions on the account (for all financial instruments).

```
int PositionsTotal()
```

With netting accounting of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), there can be only one position for each symbol at any time. This position can result from one or more deals.

With the independent representation of positions (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), several positions can be opened simultaneously for each symbol, including multidirectional ones. Each market entry trade creates a separate position, so a partial step-by-step execution of one order can generate several positions.

The *PositionGetSymbol* function returns the symbol of a position by its number.

```
string PositionGetSymbol(int index)
```

The index must be between 0 and N-1, where N is the value received by the pre-call of *PositionsTotal*. The order of positions is not regulated.

If the position is not found, then an empty string will be returned, and the error code will be available in *_LastError*.

Examples of using these two functions were provided in several test Experts Advisors (*TrailingStop.mq5*, *TradeCloseBy.mq5*, and others) in functions with names *GetMyPosition/GetMyPositions*.

An open position is characterized by a unique ticket which is the number that distinguishes it from other positions, but may change during its life in some cases, such as a position reversal in netting mode by one trade, or as a result of service operations on the server (reopening for swap accrual, clearing).

To get a position ticket by its number, we use the *PositionGetTicket* function.

```
ulong PositionGetTicket(int index)
```

Additionally, the function highlights a position in the trading environment of the terminal, which then allows you to read its properties using a group of special *PositionGet* functions. In other words, by analogy with orders, the terminal maintains an internal cache for each MQL program to store the properties of one position. To highlight a position, in addition to *PositionGetTicket*, there are two functions: *PositionSelect* and *PositionSelectByTicket* which we will discuss below.

In case of an error, the *PositionGetTicket* function will return 0.

> The ticket should not be confused with the identifier that is assigned to each position and never changes. It is the identifiers that are used to link positions with orders and deals. We will talk about this a little later.
>
> Tickets are needed to fulfill requests involving positions: the tickets are specified in the *position* and *position_by* fields of the *MqlTradeRequest* structure. Besides, by saving the ticket in a variable, the

program can subsequently select a specific position using the *PositionSelectByTicket* function (see below) and work with it without resorting to repeated enumeration of positions in the loop.

When a position is reversed on a netting account, POSITION_TICKET is changed to the ticket of the order that initiated this operation. However, such a position can still be tracked using an ID. Position reversal is not supported in hedging mode.

bool PositionSelect(const string symbol)

The function selects an open position by the name of the financial instrument.

With the independent representation of positions (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), there can be several open positions for each symbol at the same time. In this case, *PositionSelect* will select the position with the smallest ticket.

The returned result signals a successful (*true*) or unsuccessful (*false*) function execution.

The fact that the properties of the selected position are cached means that the position itself may no longer exist, or it may be changed if the program reads its properties after some time. It is recommended to call the *PositionSelect* function just before accessing the data.

bool PositionSelectByTicket(ulong ticket)

The function selects an open position for further work on the specified ticket.

We will look at examples of using functions later when studying properties and related *PositionGet* functions.

When constructing algorithms using the *PositionsTotal*, *OrdersTotal*, and similar functions, the asynchronous principles of the terminal operation should be taken into account. We have already touched on this topic when writing the *MqlTradeSync.mqh* classes and implementing waiting for the execution results from trade requests. However, this wait is not always possible on the client side. In particular, if we place a pending order, then its transformation into a market order and subsequent execution will take place on the server. At this moment, the order may cease to be listed among the active ones (*OrdersTotal* will return 0), but the position is not displayed yet (*PositionsTotal* also equals 0). Therefore, an MQL program that has a condition for placing an order in the absence of a position may erroneously initiate a new order, as a result of which the position will eventually double.

To solve this problem, an MQL program must analyze the trading environment more deeply than just checking the number of orders and positions at once. For example, you can keep a snapshot of the last correct state of the trading environment and not allow any entities to disappear without some kind of confirmation. Only then can a new cast be formed. Thus, an order can be deleted only together with a position change (creation, closing) or moved to history with a cancel status. One of the possible solutions is proposed in the form of the *TradeGuard* class in the *TradeGuard.mqh* file. The book also includes the demo script *TradeGuardExample.mq5* which you can study additionally.

6.4.27 Position properties

All position properties are divided into three groups according to the type of values: integer and compatible with them, real numbers, and strings. They are used to read *PositionGet* functions similar to *OrderGet* functions. We will describe the functions themselves in the next section, and here we will give the identifiers of all properties that are available for specifying in the first parameter of these functions.

Integer properties are provided in the ENUM_POSITION_PROPERTY_INTEGER enumeration.

Identifier	Description	Type
POSITION_TICKET	Position ticket	ulong
POSITION_TIME	Position opening time	datetime
POSITION_TIME_MSC	Position opening time in milliseconds	ulong
POSITION_TIME_UPDATE	Position change (volume) time	datetime
POSITION_TIME_UPDATE_MSC	Position change (volume) time in milliseconds	ulong
POSITION_TYPE	Position type	ENUM_POSITION_TYPE
POSITION_MAGIC	Position Magic number (based on ORDER_MAGIC)	ulong
POSITION_IDENTIFIER	Position identifier; a unique number that is assigned to each newly opened position and does not change during its entire life.	ulong
POSITION_REASON	Reason for opening a position	ENUM_POSITION_REASON

As a rule, POSITION_IDENTIFIER corresponds to the ticket of the order that opened the position. The position identifier is indicated in each order (ORDER_POSITION_ID) and deal (DEAL_POSITION_ID) that opened, changed, or closed it. Therefore, it is convenient to use it to search for orders and deals related to a position.

If the order is filled partially, then both the position and the active pending order for the remaining volume with matching tickets can exist simultaneously. Moreover, such a position can be closed in time, and at the next filling of the rest of the pending order, a position with the same ticket will appear again.

In netting mode, reversing a position with one trade is considered a position change, not a new one, so the POSITION_IDENTIFIER is preserved. A new position on a symbol is possible only after closing the previous one in zero volume.

The POSITION_TIME_UPDATE property only responds to volume changes (for example, as a result of partial closing or position increase), but not other parameters like *Stop Loss/Take Profit* levels or swap charges.

There are only two types of positions (ENUM_POSITION_TYPE).

Identifier	Description
POSITION_TYPE_BUY	Buy
POSITION_TYPE_SELL	Sell

Options for the origin of a position, that is, how the position was opened, are provided in the ENUM_POSITION_REASON enumeration.

Identifier	Description
POSITION_REASON_CLIENT	Triggering of an order placed from the desktop terminal
POSITION_REASON_MOBILE	Triggering of an order placed from a mobile application
POSITION_REASON_WEB	Triggering of an order placed from the web platform (browser)
POSITION_REASON_EXPERT	Triggering of an order placed by an Expert Advisor or a script

Real properties are collected in ENUM_POSITION_PROPERTY_DOUBLE.

Identifier	Description
POSITION_VOLUME	Position volume
POSITION_PRICE_OPEN	Position price
POSITION_SL	Stop Loss Price
POSITION_TP	Take profit price
POSITION_PRICE_CURRENT	Current symbol price
POSITION_SWAP	Accumulated swap
POSITION_PROFIT	Current profit

The current price type corresponds to the position closing operation. For example, a long position must be closed by selling, and therefore the *Bid* price for it is tracked in POSITION_PRICE_CURRENT.

Finally, the following string properties (ENUM_POSITION_PROPERTY_STRING) are supported for positions.

Identifier	Description
POSITION_SYMBOL	The symbol on which the position is opened
POSITION_COMMENT	Position comment
POSITION_EXTERNAL_ID	Position ID in the external system (on the exchange)

After reviewing the list of position properties, we are ready to look at the functions for reading these properties.

6.4.28 Functions for reading position properties

An MQL program can get position properties using several *PositionGet* functions depending on the type of properties. In all functions, the specific property being requested is defined in the first parameter, which takes the ID of one of the ENUM_POSITION_PROPERTY enumerations discussed in the previous section.

For each type of property, there is a short and long form of the function: the first returns the value of the property directly, and the second writes it into the second parameter, passed by reference.

Integer properties and properties of compatible types (*datetime*, enumerations) can be obtained by the *PositionGetInteger* function.

```
long PositionGetInteger(ENUM_POSITION_PROPERTY_INTEGER property)
bool PositionGetInteger(ENUM_POSITION_PROPERTY_INTEGER property, long &value)
```

If it fails, the function returns 0 or *false*.

The *PositionGetDouble* function is used to obtain real properties.

```
double PositionGetDouble(ENUM_POSITION_PROPERTY_DOUBLE property)
bool PositionGetDouble(ENUM_POSITION_PROPERTY_DOUBLE property, double &value)
```

Finally, the string properties are returned by the *PositionGetString* function.

```
string PositionGetString(ENUM_POSITION_PROPERTY_STRING property)
bool PositionGetString(ENUM_POSITION_PROPERTY_STRING property, string &value)
```

In case of failure, the first form of the function returns an empty string.

To read position properties, we already have a ready abstract interface *MonitorInterface* (*TradeBaseMonitor.mqh*) which we used to write an order monitor. Now it will be easy to implement a similar monitor for positions. The result is attached in the file *PositionMonitor.mqh*.

The *PositionMonitorInterface* class is inherited from *MonitorInterface* with assignment to the template types I, D, and S of the considered ENUM_POSITION_PROPERTY enumerations, and overrides a couple of *stringify* methods taking into account the specifics of position properties.

```
class PositionMonitorInterface:
   public MonitorInterface<ENUM_POSITION_PROPERTY_INTEGER,
   ENUM_POSITION_PROPERTY_DOUBLE,ENUM_POSITION_PROPERTY_STRING>
{
public:
   virtual string stringify(const long v,
      const ENUM_POSITION_PROPERTY_INTEGER property) const override
   {
      switch(property)
      {
         case POSITION_TYPE:
            return enumstr<ENUM_POSITION_TYPE>(v);
         case POSITION_REASON:
            return enumstr<ENUM_POSITION_REASON>(v);

         case POSITION_TIME:
         case POSITION_TIME_UPDATE:
            return TimeToString(v, TIME_DATE | TIME_SECONDS);

         case POSITION_TIME_MSC:
         case POSITION_TIME_UPDATE_MSC:
            return STR_TIME_MSC(v);
      }

      return (string)v;
   }

   virtual string stringify(const ENUM_POSITION_PROPERTY_DOUBLE property,
      const string format = NULL) const override
   {
      if(format == NULL &&
         (property == POSITION_PRICE_OPEN || property == POSITION_PRICE_CURRENT
         || property == POSITION_SL || property == POSITION_TP))
      {
         const int digits = (int)SymbolInfoInteger(PositionGetString(POSITION_SYMBOL)
            SYMBOL_DIGITS);
         return DoubleToString(PositionGetDouble(property), digits);
      }
      return MonitorInterface<ENUM_POSITION_PROPERTY_INTEGER,
         ENUM_POSITION_PROPERTY_DOUBLE,ENUM_POSITION_PROPERTY_STRING>
         ::stringify(property, format);
   }
```

The specific monitor class, ready to view positions, is next in the inheritance chain and is based on *PositionGet* functions. Selecting a position by ticket is done in the constructor.

```
class PositionMonitor: public PositionMonitorInterface
{
public:
   const ulong ticket;
   PositionMonitor(const ulong t): ticket(t)
   {
      if(!PositionSelectByTicket(ticket))
      {
         PrintFormat("Error: PositionSelectByTicket(%lld) failed: %s",
            ticket, E2S(_LastError));
      }
      else
      {
         ready = true;
      }
   }

   virtual long get(const ENUM_POSITION_PROPERTY_INTEGER property) const override
   {
      return PositionGetInteger(property);
   }

   virtual double get(const ENUM_POSITION_PROPERTY_DOUBLE property) const override
   {
      return PositionGetDouble(property);
   }

   virtual string get(const ENUM_POSITION_PROPERTY_STRING property) const override
   {
      return PositionGetString(property);
   }
   ...
};
```

A simple script will allow you to log all the characteristics of the first position (if at least one is available).

```
void OnStart()
{
   PositionMonitor pm(PositionGetTicket(0));
   pm.print();
}
```

In the log, we should get something like this.

```
MonitorInterface<ENUM_POSITION_PROPERTY_INTEGER, »
   » ENUM_POSITION_PROPERTY_DOUBLE,ENUM_POSITION_PROPERTY_STRING>
ENUM_POSITION_PROPERTY_INTEGER Count=9
  0 POSITION_TIME=2022.03.24 23:09:45
  1 POSITION_TYPE=POSITION_TYPE_BUY
  2 POSITION_MAGIC=0
  3 POSITION_IDENTIFIER=1291755067
  4 POSITION_TIME_MSC=2022.03.24 23:09:45'261
  5 POSITION_TIME_UPDATE=2022.03.24 23:09:45
  6 POSITION_TIME_UPDATE_MSC=2022.03.24 23:09:45'261
  7 POSITION_TICKET=1291755067
  8 POSITION_REASON=POSITION_REASON_EXPERT
ENUM_POSITION_PROPERTY_DOUBLE Count=8
  0 POSITION_VOLUME=0.01
  1 POSITION_PRICE_OPEN=1.09977
  2 POSITION_PRICE_CURRENT=1.09965
  3 POSITION_SL=0.00000
  4 POSITION_TP=1.10500
  5 POSITION_COMMISSION=0.0
  6 POSITION_SWAP=0.0
  7 POSITION_PROFIT=-0.12
ENUM_POSITION_PROPERTY_STRING Count=3
  0 POSITION_SYMBOL=EURUSD
  1 POSITION_COMMENT=
  2 POSITION_EXTERNAL_ID=
```

If there are no open positions at the moment, we will see an error message.

```
Error: PositionSelectByTicket(0) failed: TRADE_POSITION_NOT_FOUND
```

However, the monitor is useful not only and not so much by outputting properties to the log. Based on *PositionMonitor*, we create a class for selecting positions by conditions, similar to what we did for orders (*OrderFilter*). The ultimate goal is to improve our grid Expert Advisor.

Thanks to OOP, creating a new filter class is almost effortless. Below is the complete source code (file *PositionFilter.mqh*).

```
class PositionFilter: public TradeFilter<PositionMonitor,
   ENUM_POSITION_PROPERTY_INTEGER,
   ENUM_POSITION_PROPERTY_DOUBLE,
   ENUM_POSITION_PROPERTY_STRING>
{
protected:
   virtual int total() const override
   {
      return PositionsTotal();
   }
   virtual ulong get(const int i) const override
   {
      return PositionGetTicket(i);
   }
};
```

Now we can write such a script for receiving specific profit on positions with the given magic number, for example.

```
input ulong Magic;

void OnStart()
{
   PositionFilter filter;

   ENUM_POSITION_PROPERTY_DOUBLE properties[] =
      {POSITION_PROFIT, POSITION_VOLUME};

   double profits[][2];
   ulong tickets[];
   string symbols[];

   filter.let(POSITION_MAGIC, Magic).select(properties, tickets, profits);
   filter.select(POSITION_SYMBOL, tickets, symbols);

   for(int i = 0; i < ArraySize(symbols); ++i)
   {
      PrintFormat("%s[%lld]=%f",
         symbols[i], tickets[i], profits[i][0] / profits[i][1]);
   }
}
```

In this case, we had to call the *select* method twice, because the types of properties we are interested in are different: real profit and lot, but the string name of the instrument. In one of the sections at the beginning of the chapter, when we were developing the filter class for symbols, we described the concept of tuples. In MQL5, we can implement it as structure templates with fields of arbitrary types. Such tuples would come in very handy for finalizing the hierarchy of filter classes since then it would be possible to describe the *select* method that fills an array of tuples with fields of any type.

The tuples are described in the file *Tuples.mqh*. All structures in it have a name *TupleN<T1,...>*, where N is a number from 2 to 8, and it corresponds to the number of template parameters (Ti types). For example, *Tuple2*:

```
template<typename T1,typename T2>
struct Tuple2
{
   T1 _1;
   T2 _2;

   static int size() { return 2; };

   // M - order, position, deal monitor class, any MonitorInterface<>
   template<typename M>
   void assign(const int &properties[], M &m)
   {
      if(ArraySize(properties) != size()) return;
      _1 = m.get(properties[0], _1);
      _2 = m.get(properties[1], _2);
   }
};
```

In the class *TradeFilter* (*TradeFilter.mqh*) let's add a version of the function *select* with tuples.

```
template<typename T,typename I,typename D,typename S>
class TradeFilter
{
   ...
 template<typename U> // type U must be Tuple<>, e.g. Tuple3<T1,T2,T3>
   bool select(const int &property[], U &data[], const bool sort = false) const
   {
      const int q = ArraySize(property);
      static const U u;                 // PRB: U::size() does not compile
      if(q != u.size()) return false;   // required condition

      const int n = total();
      // cycle through orders/positions/deals
      for(int i = 0; i < n; ++i)
      {
         const ulong t = get(i);
         // access to properties via monitor T
         T m(t);
         // check all filter conditions for different types of properties
         if(match(m, longs)
         && match(m, doubles)
         && match(m, strings))
         {
            // for a suitable object, store the properties in an array of tuples
            const int k = EXPAND(data);
            data[k].assign(property, m);
         }
      }

      if(sort)
      {
         sortTuple(data, u._1);
      }

      return true;
   }
```

An array of tuples can optionally be sorted by the first field _1, so you can additionally study the *sortTuple* helper method.

With tuples, you can query a filter object for properties of three different types in one *select* call.

Below there are positions with some *Magic* number displayed, sorted by profit; for each a symbol and a ticket are additionally obtained.

```
input ulong Magic;

  void OnStart()
  {
     int props[] = {POSITION_PROFIT, POSITION_SYMBOL, POSITION_TICKET};
     Tuple3<double,string,ulong> tuples[];
     PositionFilter filter;
     filter.let(POSITION_MAGIC, Magic).select(props, tuples, true);
     ArrayPrint(tuples);
  }
```

Of course, the parameter types in the description of the array of tuples (in this case, *Tuple3<double,string,ulong>*) must match the requested property enumeration types (POSITION_PROFIT, POSITION_SYMBOL, POSITION_TICKET).

Now we can slightly simplify the grid Expert Advisor (meaning not just a shorter, but also a more understandable code). The new version is called *PendingOrderGrid2.mq5*. The changes will affect all functions related to position management.

The *GetMyPositions* function populates the *types4tickets* array of tuples passed by reference. In each *Tuple2* tuple, it is supposed to store the type and ticket of the position. In this particular case, we could manage just with a two-dimensional array *ulong* instead of tuples because both properties are of the same base type. However, we use tuples to demonstrate how to work with them in the calling code.

```
#include <MQL5Book/Tuples.mqh>
#include <MQL5Book/PositionFilter.mqh>

int GetMyPositions(const string s, const ulong m,
   Tuple2<ulong,ulong> &types4tickets[])
{
   int props[] = {POSITION_TYPE, POSITION_TICKET};
   PositionFilter filter;
   filter.let(POSITION_SYMBOL, s).let(POSITION_MAGIC, m)
      .select(props, types4tickets, true);
   return ArraySize(types4tickets);
}
```

Note that the last, third parameter of the *select* method equals *true*, which instructs to sort the array by the first field, i.e., the type of positions. Thus, we will have purchases at the beginning, and sales at the end. This will be required for the counter closure.

The reincarnation of the *CompactPositions* method is as follows.

```
uint CompactPositions(const bool cleanup = false)
{
   uint retcode = 0;
   Tuple2<ulong,ulong> types4tickets[];
   int i = 0, j = 0;
   int n = GetMyPositions(_Symbol, Magic, types4tickets);
   if(n > 0)
   {
      Print("CompactPositions: ", n);
      for(i = 0, j = n - 1; i < j; ++i, --j)
      {
         if(types4tickets[i]._1 != types4tickets[j]._1) // as long as the types are d
         {
            retcode = CloseByPosition(types4tickets[i]._2, types4tickets[j]._2);
            if(retcode) return retcode; // error
         }
         else
         {
            break;
         }
      }
   }

   if(cleanup && j < n)
   {
      retcode = CloseAllPositions(types4tickets, i, j + 1);
   }

   return retcode;
}
```

The *CloseAllPositions* function is almost the same:

```
uint CloseAllPositions(const Tuple2<ulong,ulong> &types4tickets[],
   const int start = 0, const int end = 0)
{
   const int n = end == 0 ? ArraySize(types4tickets) : end;
   Print("CloseAllPositions ", n - start);
   for(int i = start; i < n; ++i)
   {
      MqlTradeRequestSyncLog request;
      request.comment = "close down " + (string)(i + 1 - start)
         + " of " + (string)(n - start);
      const ulong ticket = types4tickets[i]._2;
      if(!(request.close(ticket) && request.completed()))
      {
         Print("Error: position is not closed ", ticket);
         return request.result.retcode; // error
      }
   }
   return 0; // success
}
```

You can compare the work of Expert Advisors *PendingOrderGrid1.mq5* and *PendingOrderGrid2.mq5* in the tester.

The reports will be slightly different, because if there are several positions, they are closed in opposite combinations, due to which the closing of other, unpaired positions takes place with respect to their individual spreads.

6.4.29 Deal properties

A deal is a reflection of the fact that a trading operation was performed on the basis of an order. One order can generate several deals due to the execution in parts or the opposite closing of positions.

Deals are characterized by properties of three basic types: integer (and compatible with them), real, and string. Each property is described by its own constant in one of the enumerations: ENUM_DEAL_PROPERTY_INTEGER, ENUM_DEAL_PROPERTY_DOUBLE, ENUM_DEAL_PROPERTY_STRING.

To read deal properties, use the *HistoryDealGet* functions. All of them assume that the necessary section of history was previously requested using special functions for the selection of orders and deals from history.

Integer properties are described in the ENUM_DEAL_PROPERTY_INTEGER enumeration.

Identifier	Description	Type
DEAL_TICKET	Deal ticket; a unique number that is assigned to each transaction	ulong
DEAL_ORDER	The ticket of the order on the basis of which the deal was executed	ulong
DEAL_TIME	Deal time	datetime
DEAL_TIME_MSC	Deal time in milliseconds	ulong
DEAL_TYPE	Deal type	ENUM_DEAL_TYPE (see below)
DEAL_ENTRY	Deal direction; market entry, market exit, or reversal	ENUM_DEAL_ENTRY (see below)
DEAL_MAGIC	Magic number for the deal (based on ORDER_MAGIC)	ulong
DEAL_REASON	Deal reason or source	ENUM_DEAL_REASON (see below)
DEAL_POSITION_ID	Identifier of the position that was opened, modified or closed by the deal	ulong

Possible deal types are represented by the ENUM_DEAL_TYPE enumeration.

Identifier	Description
DEAL_TYPE_BUY	Buy
DEAL_TYPE_SELL	Sell
DEAL_TYPE_BALANCE	Balance accrued
DEAL_TYPE_CREDIT	Credit accrual
DEAL_TYPE_CHARGE	Additional charges
DEAL_TYPE_CORRECTION	Correction
DEAL_TYPE_BONUS	Bonuses
DEAL_TYPE_COMMISSION	Additional commission
DEAL_TYPE_COMMISSION_DAILY	Commission charged at the end of the trading day
DEAL_TYPE_COMMISSION_MONTHLY	Commission charged at the end of the month
DEAL_TYPE_COMMISSION_AGENT_DAILY	Agent commission charged at the end of the trading day
DEAL_TYPE_COMMISSION_AGENT_MONTHLY	Agent commission charged at the end of the month

Identifier	Description
DEAL_TYPE_INTEREST	Interest accrual on free funds
DEAL_TYPE_BUY_CANCELED	Canceled buy deal
DEAL_TYPE_SELL_CANCELED	Canceled sell deal
DEAL_DIVIDEND	Dividend accrual
DEAL_DIVIDEND_FRANKED	Accrual of a franked dividend (tax exempt)
DEAL_TAX	Tax accrual

The DEAL_TYPE_BUY_CANCELED and DEAL_TYPE_SELL_CANCELED options reflect the situation when an earlier deal is canceled. In this case, the type of the previously executed deal (DEAL_TYPE_BUY or DEAL_TYPE_SELL) is changed to DEAL_TYPE_BUY_CANCELED or DEAL_TYPE_SELL_CANCELED, and its profit/loss is reset to zero. Previously received profit/loss is credited/debited from the account as a separate balance operation.

Deals differ in the way the position is changed. This can be a simple opening of a position (entry to the market), increasing the volume of a previously opened position, closing a position with a deal in the opposite direction or position reversal when the opposite deal covers the volume of a previously opened position. The latter operation is only supported on netting accounts.

All these situations are described by the elements of the ENUM_DEAL_ENTRY enumeration.

Identifier	Description
DEAL_ENTRY_IN	Market entry
DEAL_ENTRY_OUT	Market exit
DEAL_ENTRY_INOUT	Reversal
DEAL_ENTRY_OUT_BY	Closing by an opposite position

The reasons for the deal are summarized in the ENUM_DEAL_REASON enumeration.

Identifier	Description
DEAL_REASON_CLIENT	Triggering of an order placed from the desktop terminal
DEAL_REASON_MOBILE	Triggering of an order placed from a mobile application
DEAL_REASON_WEB	Triggering of an order placed from the web platform
DEAL_REASON_EXPERT	Triggering of an order placed by an Expert Advisor or a script
DEAL_REASON_SL	Stop Loss order triggered
DEAL_REASON_TP	Take Profit order triggering
DEAL_REASON_SO	Stop Out event
DEAL_REASON_ROLLOVER	Position transfer to a new day
DEAL_REASON_VMARGIN	Add/deduct variation margin
DEAL_REASON_SPLIT	Split (lower price) the instrument on which there was a position

Real type properties are represented by the ENUM_DEAL_PROPERTY_DOUBLE enumeration.

Identifier	Description
DEAL_VOLUME	Deal volume
DEAL_PRICE	Deal price
DEAL_COMMISSION	Deal commission
DEAL_SWAP	Accumulated swap at close
DEAL_PROFIT	Financial result of the deal
DEAL_FEE	Fee for the deal which is charged immediately after the deal
DEAL_SL	Stop Loss Level
DEAL_TP	Take Profit level

The two last properties are filled as follows: for an entry or reversal deal, the *Stop Loss/Take Profit* value is taken from the order by which the position was opened or expanded. For the exit deal, the *Stop Loss/Take Profit* value is taken from the position at the time of its closing.

String deal properties are available via ENUM_DEAL_PROPERTY_STRING enumeration constants.

Identifier	Description
DEAL_SYMBOL	The name of the symbol for which the deal was made
DEAL_COMMENT	Deal comment
DEAL_EXTERNAL_ID	Deal identifier in the external trading system (on the exchange)

We will test how to read the properties in the section on *HistoryDealGet* functions through the *DealMonitor* and *DealFilter* classes.

6.4.30 Selecting orders and deals from history

MetaTrader 5 allows you to create a snapshot of history for a specific time period for an Expert Advisor or a script. The snapshot is a list of orders and deals which can be further accessed through the appropriate functions. In addition, history can be requested in relation to specific orders, deals or positions.

Selecting the required period explicitly (by dates) is performed by the *HistorySelect* function. After that, the size of the list of deals and the list of orders can be found using the *HistoryDealsTotal* and *HistoryOrdersTotal* functions, respectively. The elements of the orders list can be checked using the *HistoryOrderGetTicket* function; for elements of the deals list use *HistoryDealGetTicket*.

> It is necessary to distinguish between active (working) orders and orders in history, i.e., those executed, canceled or rejected. To analyze active orders, use the functions discussed in the sections related to getting a list of active orders and reading their properties.

bool HistorySelect(datetime from, datetime to)

The function requests the history of deals and orders for the specified period of server time (*from* and *to* inclusive, *to* >= *from*) and returns *true* in case of success.

Even if there are no orders and transactions in the requested period, the function will return *true* in the absence of errors. An error can be, for example, a lack of memory for building a list of orders or deals.

> Please note that orders have two times: set (ORDER_TIME_SETUP) and execution (ORDER_TIME_DONE). The function *HistorySelect* selects orders by execution time.

To extract the entire account history, you can use the syntax *HistorySelect(0, LONG_MAX)*.

Another way to access a part of the history is by position ID.

bool HistorySelectByPosition(ulong positionID)

The function requests the history of deals and orders with the specified position ID in the ORDER_POSITION_ID, DEAL_POSITION_ID properties.

> Attention! The function does not select orders by the ID of the opposite position for Close By operations. In other words, the ORDER_POSITION_BY_ID property is ignored, despite the fact that the order data was involved in the formation of the position.
>
> For example, an Expert Advisor could complete a buy (order #1) and sell (order #2) on a hedging-enabled account. This will then lead to the formation of positions #1 and #2. Opposite closing of

positions requires the ORDER_TYPE_CLOSE_BY (#3) order. As a result, the *HistorySelectByPosition(#1)* call will select orders #1 and #3, which is expected. However, the call of *HistorySelectByPosition(#2)* will select only order #2 (despite the fact that order #3 has #2 in the ORDER_POSITION_BY_ID property, and strictly speaking, order #3 participated in closing position #2).

Upon successful execution of either of the two functions, *HistorySelect* or *HistorySelectByPosition*, the terminal generates an internal list of orders and deals for the MQL program. You can also change the historical context with the functions *HistoryOrderSelect* and *HistoryDealSelect*, for which you need to know the ticket of the corresponding object in advance (for example, save it from the request result).

It is important to note that *HistoryOrderSelect* affects only the list of orders, and *HistoryDealSelect* is only used for the list of deals.

All context selection functions return a *bool* value for success (*true*) or error (*false*). The error code can be read in the built-in *_LastError* variable.

bool HistoryOrderSelect(ulong ticket)

The *HistoryOrderSelect* function selects an order in the history by its ticket. The order is then used for further operations with the deal (reading properties).

During the application of the *HistoryOrderSelect* function, if the search for an order by ticket was successful, the new list of orders selected in the history will consist of the only order just found. In other words, the previous list of selected orders (if any) is reset. However, the function does not reset the previously selected transaction history, i.e., it does not select the transaction(s) associated with the order.

bool HistoryDealSelect(ulong ticket)

The function *HistoryDealSelect* selects a deal in the history for further access to it through the appropriate functions. The function does not reset the order history, i.e., it does not select the order associated with the selected deal.

After a certain context is selected in the history by calling one of the above functions, the MQL program can call the functions to iterate over the orders and deals that fall into this context and read their properties.

int HistoryOrdersTotal()

The *HistoryOrdersTotal* function returns the number of orders in history (in the selection).

ulong HistoryOrderGetTicket(int index)

The *HistoryOrderGetTicket* function allows you to get an order ticket by its serial number in the selected history context. The index must be between 0 and N-1, where N is obtained from the *HistoryOrdersTotal* function.

Knowing the order ticket, it is easy to get all the necessary properties of it using *HistoryOrderGet* functions. The properties of historical orders are exactly the same as those of existing orders.

There is a similar pair of functions for working with deals.

int HistoryDealsTotal()

The *HistoryDealsTotal* function returns the number of deals in history (in the selection).

```
ulong HistoryDealGetTicket(int index)
```

The *HistoryDealGetTicket* function allows you to get a deal ticket by its serial number in the selected history context. This is necessary for further processing of the deal using *HistoryDealGet* functions. The list of deal properties accessible through these functions was described in the previous section.

We will consider an example of using functions after studying *HistoryOrderGet* and *HistoryDealGet* functions.

6.4.31 Functions for reading order properties from history

The functions for reading properties of historical orders are divided into 3 groups according to the basic type of property values, in accordance with the division of identifiers of available properties into three enumerations: ENUM_ORDER_PROPERTY_INTEGER, ENUM_ORDER_PROPERTY_DOUBLE and ENUM_ORDER_PROPERTY_STRING discussed earlier in a separate section when exploring active orders.

Before calling these functions, you need to somehow select the appropriate set of tickets in the history.

If you try to read the properties of an order or a deal having tickets outside the selected history context, the environment may generate a WRONG_INTERNAL_PARAMETER (4002) error, which can be analyzed via *_LastError*.

For each base property type, there are two function forms: one directly returns the value of the requested property, the second one writes it into a parameter passed by reference and returns a success indicator (*true*) or errors (*false*).

For integer and compatible types (*datetime*, enums) of properties there is a dedicated function *HistoryOrderGetInteger*.

```
long HistoryOrderGetInteger(ulong ticket, ENUM_ORDER_PROPERTY_INTEGER property)
bool HistoryOrderGetInteger(ulong ticket, ENUM_ORDER_PROPERTY_INTEGER property,
   long &value)
```

The function allows you to find out the order *property* from the selected history by its ticket number.

For real properties, the *HistoryOrderGetDouble* function is assigned.

```
double HistoryOrderGetDouble(ulong ticket, ENUM_ORDER_PROPERTY_DOUBLE property)
bool HistoryOrderGetDouble(ulong ticket, ENUM_ORDER_PROPERTY_DOUBLE property,
   double &value)
```

Finally, string properties can be read with *HistoryOrderGetString*.

```
string HistoryOrderGetString(ulong ticket, ENUM_ORDER_PROPERTY_STRING property)
bool HistoryOrderGetString(ulong ticket, ENUM_ORDER_PROPERTY_STRING property,
   string &value)
```

Now we can supplement the *OrderMonitor* class (*OrderMonitor.mqh*) for working with historical orders. First, let's add a boolean variable to the *history* class, which we will fill in the constructor based on the segment in which the order with the passed ticket was selected: among the active ones (*OrderSelect*) or in history (*HistoryOrderSelect*).

```
class OrderMonitor: public OrderMonitorInterface
{
   bool history;

public:
   const ulong ticket;
   OrderMonitor(const long t): ticket(t), history(!OrderSelect(t))
   {
      if(history && !HistoryOrderSelect(ticket))
      {
         PrintFormat("Error: OrderSelect(%lld) failed: %s", ticket, E2S(_LastError));
      }
      else
      {
         ResetLastError();
         ready = true;
      }
   }
   ...
```

We need to call the *ResetLastError* function in a successful *if* branch in order to reset the possible error that could be set by the *OrderSelect* function (if the order is in history).

In fact, this version of the constructor contains a serious logical error, and we will return to it after a few paragraphs.

To read properties in get methods, we now call different built-in functions, depending on the value of the *history* variable.

```
   virtual long get(const ENUM_ORDER_PROPERTY_INTEGER property) const override
   {
      return history ? HistoryOrderGetInteger(ticket, property) : OrderGetInteger(pro
   }

   virtual double get(const ENUM_ORDER_PROPERTY_DOUBLE property) const override
   {
      return history ? HistoryOrderGetDouble(ticket, property) : OrderGetDouble(prope
   }

   virtual string get(const ENUM_ORDER_PROPERTY_STRING property) const override
   {
      return history ? HistoryOrderGetString(ticket, property) : OrderGetString(prope
   }
   ...
```

The main purpose of the *OrderMonitor* class is to supply data to other analytical classes. The *OrderMonitor* objects are used to filter active orders in the *OrderFilter* class, and we need a similar class for selecting orders by arbitrary conditions on the history: *HistoryOrderFilter*.

Let's write this class in the same file *OrderFilter.mqh*. It uses two new functions for working with history: *HistoryOrdersTotal* and *HistoryOrderGetTicket*.

```
class HistoryOrderFilter: public TradeFilter<OrderMonitor,
   ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,
   ENUM_ORDER_PROPERTY_STRING>
{
protected:
   virtual int total() const override
   {
      return HistoryOrdersTotal();
   }
   virtual ulong get(const int i) const override
   {
      return HistoryOrderGetTicket(i);
   }
};
```

This simple code inherits from the template class *TradeFilter*, where the class is passed as the first parameter of the template *OrderMonitor* to read the properties of the corresponding objects (we saw an analog for positions, and will soon create one for deals).

Here lies the problem with the *OrderMonitor* constructor. As we learned in the section Selecting orders and deals from history, to analyze the account we must first set up the context with one of the functions such as *HistorySelect*. So here in the source code *HistoryOrderFilter* it is assumed that the MQL program has already selected the required history fragment. However, the new, intermediate version of the *OrderMonitor* constructor uses the *HistoryOrderSelect* call to check the existence of a ticket in history. Meanwhile, this function resets the previous context of historical orders and selects a single order.

So we need a helper method *historyOrderSelectWeak* to validate the ticket in a "soft" way without breaking the existing context. To do this, we can simply check if the ORDER_TICKET property is equal to the passed ticket *t*: *(HistoryOrderGetInteger(t, ORDER_TICKET) == t)*. If such a ticket has already been selected (available), the check will succeed, and the monitor does not need to manipulate the history.

```
class OrderMonitor: public OrderMonitorInterface
{
   bool historyOrderSelectWeak(const ulong t) const
   {
      return (((HistoryOrderGetInteger(t, ORDER_TICKET) == t) ||
         (HistorySelect(0, LONG_MAX) && (HistoryOrderGetInteger(t, ORDER_TICKET) == t
   }
   bool history;

public:
   const ulong ticket;
   OrderMonitor(const long t): ticket(t), history(!OrderSelect(t))
   {
      if(history && !historyOrderSelectWeak(ticket))
      {
         PrintFormat("Error: OrderSelect(%lld) failed: %s", ticket, E2S(_LastError));
      }
      else
      {
         ResetLastError();
         ready = true;
      }
   }
```

An example of applying order filtering on history will be considered in the next section after we prepare a similar functionality for deals.

6.4.32 Functions for reading deal properties from history

To read deal properties, there are groups of functions organized by property type: integer, real and string. Before calling functions, you need to select the desired period of history and thus ensure the availability of deals with tickets that are passed in the first parameter (*ticket*) of all functions.

There are two forms for each type of property: returning a value directly and writing to a variable by reference. The second form returns *true* to indicate success. The first form will simply return 0 on error. The error code is in the *_LastError* variable.

Integer and compatible property types (*datetime*, enumerations) can be obtained using the *HistoryDealGetInteger* function.

```
long HistoryDealGetInteger(ulong ticket, ENUM_DEAL_PROPERTY_INTEGER property)
bool HistoryDealGetInteger(ulong ticket, ENUM_DEAL_PROPERTY_INTEGER property,
  long &value)
```

Real properties are read by the *HistoryDealGetDouble* function.

```
double HistoryDealGetDouble(ulong ticket, ENUM_DEAL_PROPERTY_DOUBLE property)
bool HistoryDealGetDouble(ulong ticket, ENUM_DEAL_PROPERTY_DOUBLE property,
  double &value)
```

For string properties there is the *HistoryDealGetString* function.

string HistoryDealGetString(ulong ticket, ENUM_DEAL_PROPERTY_STRING property)
bool HistoryDealGetString(ulong ticket, ENUM_DEAL_PROPERTY_STRING property,
string &value)

A unified reading of deal properties will be provided by the *DealMonitor* class (*DealMonitor.mqh*), organized in exactly the same way as *OrderMonitor* and *PositionMonitor*. The base class is *DealMonitorInterface*, inherited from the template *MonitorInterface* (we described it in the section Functions for reading the properties of active orders). It is at this level that the specific types of ENUM_DEAL_PROPERTY enumerations are specified as template parameters and the specific implementation of the *stringify* method.

```
#include <MQL5Book/TradeBaseMonitor.mqh>

class DealMonitorInterface:
   public MonitorInterface<ENUM_DEAL_PROPERTY_INTEGER,
   ENUM_DEAL_PROPERTY_DOUBLE,ENUM_DEAL_PROPERTY_STRING>
{
public:
   // property descriptions taking into account integer subtypes
   virtual string stringify(const long v,
      const ENUM_DEAL_PROPERTY_INTEGER property) const override
   {
      switch(property)
      {
         case DEAL_TYPE:
            return enumstr<ENUM_DEAL_TYPE>(v);
         case DEAL_ENTRY:
            return enumstr<ENUM_DEAL_ENTRY>(v);
         case DEAL_REASON:
            return enumstr<ENUM_DEAL_REASON>(v);

         case DEAL_TIME:
            return TimeToString(v, TIME_DATE | TIME_SECONDS);

         case DEAL_TIME_MSC:
            return STR_TIME_MSC(v);
      }

      return (string)v;
   }
};
```

The *DealMonitor* class below is somewhat similar to a class recently modified to work with history *OrderMonitor*. In addition to the application of *HistoryDeal* functions instead of *HistoryOrder* functions, it should be noted that for deals there is no need to check the ticket in the online environment because deals exist only in history.

```
class DealMonitor: public DealMonitorInterface
{
   bool historyDealSelectWeak(const ulong t) const
   {
      return ((HistoryDealGetInteger(t, DEAL_TICKET) == t) ||
         (HistorySelect(0, LONG_MAX) && (HistoryDealGetInteger(t, DEAL_TICKET) == t))
   }
public:
   const ulong ticket;
   DealMonitor(const long t): ticket(t)
   {
      if(!historyDealSelectWeak(ticket))
      {
         PrintFormat("Error: HistoryDealSelect(%lld) failed", ticket);
      }
      else
      {
         ready = true;
      }
   }

   virtual long get(const ENUM_DEAL_PROPERTY_INTEGER property) const override
   {
      return HistoryDealGetInteger(ticket, property);
   }

   virtual double get(const ENUM_DEAL_PROPERTY_DOUBLE property) const override
   {
      return HistoryDealGetDouble(ticket, property);
   }

   virtual string get(const ENUM_DEAL_PROPERTY_STRING property) const override
   {
      return HistoryDealGetString(ticket, property);
   }
   ...
};
```

Based on *DealMonitor* and *TradeFilter* it is easy to create a deal filter (*DealFilter.mqh*). Recall that *TradeFilter*, as the base class for many entities, was described in the section Selecting orders by properties.

```
#include <MQL5Book/DealMonitor.mqh>
#include <MQL5Book/TradeFilter.mqh>

class DealFilter: public TradeFilter<DealMonitor,
   ENUM_DEAL_PROPERTY_INTEGER,
   ENUM_DEAL_PROPERTY_DOUBLE,
   ENUM_DEAL_PROPERTY_STRING>
{
protected:
   virtual int total() const override
   {
      return HistoryDealsTotal();
   }
   virtual ulong get(const int i) const override
   {
      return HistoryDealGetTicket(i);
   }
};
```

As a generalized example of working with histories, consider the position history recovery script *TradeHistoryPrint.mq5*.

TradeHistoryPrint

The script will build a history for the current chart symbol.

We first need filters for deals and orders.

```
#include <MQL5Book/OrderFilter.mqh>
#include <MQL5Book/DealFilter.mqh>
```

From the deals, we will extract the position IDs and, based on them, we will request details about the orders.

The history can be viewed in its entirety or for a specific position, for which we will provide a mode selection and an input field for the identifier in the input variables.

```
enum SELECTOR_TYPE
{
   TOTAL,    // Whole history
   POSITION, // Position ID
};

input SELECTOR_TYPE Type = TOTAL;
input ulong PositionID = 0; // Position ID
```

It should be remembered that sampling a long account history can be an overhead, so it is desirable to provide for caching of the obtained results of history processing in working Expert Advisors, along with the last processing timestamp. With each subsequent analysis of history, you can start the process not from the very beginning, but from a remembered moment.

To display information about history records with column alignment in a visually attractive way, it makes sense to represent it as an array of structures. However, our filters already support querying data stored in special structures - tuples. Therefore, we will apply a trick: we will describe our application structures, observing the rules of tuples:

- The first field must have the name _1; it is optionally used in the sorting algorithm.
- The *size* function returning the number of fields must be described in the structure.
- The structure should have a template method *assign* to populate fields from the properties of the passed monitor object derived from *MonitorInterface*.

In standard tuples, the method *assign* is described like this:

```
template<typename M>
void assign(const int &properties[], M &m);
```

As the first parameter, it receives an array with the property IDs corresponding to the fields we are interested in. In fact, this is the array that is passed by the calling code to the *select* method of the filter (*TradeFilter::select*), and then by reference it gets to *assign*. But since we will now create not some standard tuples but our own structures that "know" about the applied nature of their fields, we can leave the array with property identifiers inside the structure itself and not "drive" it into the filter and back to the *assign* method of the same structure.

In particular, to request deals, we describe the *DealTuple* structure with 8 fields. Their identifiers will be specified in the *fields* static array.

```
struct DealTuple
{
   datetime _1;   // deal time
   ulong deal;    // deal ticket
   ulong order;   // order ticket
   string type;   // ENUM_DEAL_TYPE as string
   string in_out; // ENUM_DEAL_ENTRY as string
   double volume;
   double price;
   double profit;

   static int size() { return 8; }; // number of properties
   static const int fields[]; // identifiers of the requested deal properties
   ...
};

static const int DealTuple::fields[] =
{
   DEAL_TIME, DEAL_TICKET, DEAL_ORDER, DEAL_TYPE,
   DEAL_ENTRY, DEAL_VOLUME, DEAL_PRICE, DEAL_PROFIT
};
```

This approach brings together identifiers and fields to store the corresponding values in a single place, which makes it easier to understand and maintain the source code.

Filling fields with property values will require a slightly modified (simplified) version of the *assign* method which takes the IDs from the *fields* array and not from the input parameter.

```
struct DealTuple
{
   ...
   template<typename M> // M is derived from MonitorInterface<>
   void assign(M &m)
   {
      static const int DEAL_TYPE_ = StringLen("DEAL_TYPE_");
      static const int DEAL_ENTRY_ = StringLen("DEAL_ENTRY_");
      static const ulong L = 0; // default type declaration (dummy)

      _1 = (datetime)m.get(fields[0], L);
      deal = m.get(fields[1], deal);
      order = m.get(fields[2], order);
      const ENUM_DEAL_TYPE t = (ENUM_DEAL_TYPE)m.get(fields[3], L);
      type = StringSubstr(EnumToString(t), DEAL_TYPE_);
      const ENUM_DEAL_ENTRY e = (ENUM_DEAL_ENTRY)m.get(fields[4], L);
      in_out = StringSubstr(EnumToString(e), DEAL_ENTRY_);
      volume = m.get(fields[5], volume);
      price = m.get(fields[6], price);
      profit = m.get(fields[7], profit);
   }
};
```

At the same time, we convert the numeric elements of the ENUM_DEAL_TYPE and ENUM_DEAL_ENTRY enumerations into user-friendly strings. Of course, this is only needed for logging. For programmatic analysis, the types should be left as they are.

Since we have invented a new version of the *assign* method in their tuples, you need to add a new version of the *select* method for it in the *TradeFilter* class. The innovation will certainly be useful for other programs, and therefore we will introduce it directly into *TradeFilter*, not into some new derived class.

```
template<typename T,typename I,typename D,typename S>
class TradeFilter
{
   ...
   template<typename U> // U must have first field _1 and method assign(T)
   bool select(U &data[], const bool sort = false) const
   {
      const int n = total();
      // loop through the elements
      for(int i = 0; i < n; ++i)
      {
         const ulong t = get(i);
         // read properties through the monitor object
         T m(t);
         // check all filtering conditions
         if(match(m, longs)
         && match(m, doubles)
         && match(m, strings))
         {
            // for a suitable object, add its properties to an array
            const int k = EXPAND(data);
            data[k].assign(m);
         }
      }

      if(sort)
      {
         static const U u;
         sortTuple(data, u._1);
      }

      return true;
   }
```

Recall that all template methods are not implemented by the compiler until they are called in code with a specific type. Therefore, the presence of such patterns in *TradeFilter* does not oblige you to include any tuple header files or describe similar structures if you don't use them.

So, if earlier, to select transactions using a standard tuple, we would have to write like this:

```
#include <MQL5Book/Tuples.mqh>
...
DealFilter filter;
int properties[] =
{
   DEAL_TIME, DEAL_TICKET, DEAL_ORDER, DEAL_TYPE,
   DEAL_ENTRY, DEAL_VOLUME, DEAL_PRICE, DEAL_PROFIT
};
Tuple8<ulong,ulong,ulong,ulong,ulong,double,double,double> tuples[];
filter.let(DEAL_SYMBOL, _Symbol).select(properties, tuples);
```

Then with a customized structure, everything is much simpler:

```
DealFilter filter;
DealTuple tuples[];
filter.let(DEAL_SYMBOL, _Symbol).select(tuples);
```

Similar to the *DealTuple* structure, let's describe the 10-field structure for orders *OrderTuple*.

```
struct OrderTuple
{
   ulong _1;       // ticket (also used as 'ulong' prototype)
   datetime setup;
   datetime done;
   string type;
   double volume;
   double open;
   double current;
   double sl;
   double tp;
   string comment;

   static int size() { return 10; }; // number of properties
   static const int fields[]; // identifiers of requested order properties

   template<typename M> // M is derived from MonitorInterface<>
   void assign(M &m)
   {
      static const int ORDER_TYPE_ = StringLen("ORDER_TYPE_");

      _1 = m.get(fields[0], _1);
      setup = (datetime)m.get(fields[1], _1);
      done = (datetime)m.get(fields[2], _1);
      const ENUM_ORDER_TYPE t = (ENUM_ORDER_TYPE)m.get(fields[3], _1);
      type = StringSubstr(EnumToString(t), ORDER_TYPE_);
      volume = m.get(fields[4], volume);
      open = m.get(fields[5], open);
      current = m.get(fields[6], current);
      sl = m.get(fields[7], sl);
      tp = m.get(fields[8], tp);
      comment = m.get(fields[9], comment);
   }
};

static const int OrderTuple::fields[] =
{
   ORDER_TICKET, ORDER_TIME_SETUP, ORDER_TIME_DONE, ORDER_TYPE, ORDER_VOLUME_INITIAL,
   ORDER_PRICE_OPEN, ORDER_PRICE_CURRENT, ORDER_SL, ORDER_TP, ORDER_COMMENT
};
```

Now everything is ready to implement the main function of the script – *OnStart*. At the very beginning, we will describe the objects of filters for deals and orders.

```
void OnStart()
{
   DealFilter filter;
   HistoryOrderFilter subfilter;
   ...
```

Depending on the input variables, we choose either the entire history or a specific position.

```
   if(PositionID == 0 || Type == TOTAL)
   {
      HistorySelect(0, LONG_MAX);
   }
   else if(Type == POSITION)
   {
      HistorySelectByPosition(PositionID);
   }
   ...
```

Next, we will collect all position identifiers in an array, or leave one specified by the user.

```
   ulong positions[];
   if(PositionID == 0)
   {
      ulong tickets[];
      filter.let(DEAL_SYMBOL, _Symbol)
         .select(DEAL_POSITION_ID, tickets, positions, true); // true - sorting
      ArrayUnique(positions);
   }
   else
   {
      PUSH(positions, PositionID);
   }

   const int n = ArraySize(positions);
   Print("Positions total: ", n);
   if(n == 0) return;
   ...
```

The helper function *ArrayUnique* leaves non-repeating elements in the array. It requires the source array to be sorted for it to work.

Further, in a loop through positions, we request deals and orders related to each of them. Deals are sorted by the first field of the *DealTuple* structure, i.e., by time. Perhaps the most interesting is the calculation of profit/loss on a position. To do this, we sum the values of the *profit* field of all deals.

```
      for(int i = 0; i < n; ++i)
      {
         DealTuple deals[];
         filter.let(DEAL_POSITION_ID, positions[i]).select(deals, true);
         const int m = ArraySize(deals);
         if(m == 0)
         {
            Print("Wrong position ID: ", positions[i]);
            break; // invalid id set by user
         }
         double profit = 0; // TODO: need to take into account commissions, swaps and fe
         for(int j = 0; j < m; ++j) profit += deals[j].profit;
         PrintFormat("Position: % 8d %16lld Profit:%f", i + 1, positions[i], (profit));
         ArrayPrint(deals);

         Print("Order details:");
         OrderTuple orders[];
         subfilter.let(ORDER_POSITION_ID, positions[i], IS::OR_EQUAL)
            .let(ORDER_POSITION_BY_ID, positions[i], IS::OR_EQUAL)
            .select(orders);
         ArrayPrint(orders);
      }
   }
```

This code does not analyze commissions (DEAL_COMMISSION), swaps (DEAL_SWAP), and fees (DEAL_FEE) in deal properties. In real Expert Advisors, this should probably be done (depending on the requirements of the strategy). We will look at another example of trading history analysis in the section on testing multicurrency Expert Advisors, and there we will take into account this moment.

You can compare the results of the script with the table on the History tab in the terminal: its Profit column shows the net profit for each position (swaps, commissions, and fees are in adjacent columns, but they need to be included).

It is important to note that an order of the ORDER_TYPE_CLOSE_BY type will be displayed in both positions only if the entire history is selected in the settings. If a specific position was selected, the system will include such an order only in one of them (the one that was specified in the trade request first, in the *position* field) but not the second one (which was specified in *position_by*).

Below is an example of the result of the script for a symbol with a small history.

```
Positions total: 3
Position:        1       1253500309 Profit:238.150000

```

We will consider a partial history using the example of specific positions for the case of an opposite closure on a hedging account. First, you can view the first position separately: PositionID=1276109280. It will be shown in full regardless of the input parameter *Type*.

```
Positions total: 1
Position:        1       1276109280 Profit:-0.040000
                   [_1]     [deal]    [order] [type] [in_out] [volume] [price] [profi
[0] 2022.03.07 12:20:53 1258725455 1276109280 "BUY"  "IN"      0.01000 1.08344  0.000
[1] 2022.03.07 12:20:58 1258725503 1276109328 "SELL" "OUT_BY"  0.01000 1.08340 -0.040
Order details:
          [_1]             [setup]              [done]     [type] [volume]  [open] [c
   » [sl] [tp]                    [comment]
[0] 1276109280 2022.03.07 12:20:53 2022.03.07 12:20:53 "BUY"       0.01000 1.08344
   » 0.00 0.00 ""
[1] 1276109328 2022.03.07 12:20:58 2022.03.07 12:20:58 "CLOSE_BY"  0.01000 1.08340
   » 0.00 0.00 "#1276109280 by #1276109283"
```

You can also see the second one: PositionID=1276109283. However, if *Type* equals "*position*", to select a fragment of history, the function *HistorySelectByPosition* is used, and as a result there will be only one exit order (despite the fact that there are two deals).

```
Positions total: 1
Position:        1       1276109283 Profit:0.000000
                   [_1]     [deal]    [order] [type] [in_out] [volume] [price] [profi
[0] 2022.03.07 12:20:53 1258725458 1276109283 "SELL" "IN"      0.01000 1.08340  0.000
[1] 2022.03.07 12:20:58 1258725504 1276109328 "BUY"  "OUT_BY"  0.01000 1.08344  0.000
Order details:
          [_1]             [setup]              [done] [type] [volume]  [open] [curre
   » [sl] [tp] [comment]
[0] 1276109283 2022.03.07 12:20:53 2022.03.07 12:20:53 "SELL"  0.01000 1.08340   1.08
   » 0.00 0.00 ""
```

If we set *Type* to the "whole history", a "CLOSE_BY" order will appear.

```
Positions total: 1
Position:        1       1276109283 Profit:0.000000
                   [_1]     [deal]    [order] [type] [in_out] [volume] [price] [profi
[0] 2022.03.07 12:20:53 1258725458 1276109283 "SELL" "IN"      0.01000 1.08340  0.000

   » 0.00 0.00 ""
[1] 1276109328 2022.03.07 12:20:58 2022.03.07 12:20:58 "CLOSE_BY"  0.01000 1.08340
   » 0.00 0.00 "#1276109280 by #1276109283"
```

With such settings, the history is selected completely, but the filter leaves only those orders, in which the identifier of the specified position is found in the ORDER_POSITION_ID or ORDER_POSITION_BY_ID properties. For composing conditions with a logical OR, the IS::OR_EQUAL element has been added to the *TradeFilter* class. You can additionally study it.

6.4.33 Types of trading transactions

In addition to performing trading operations, MQL programs can respond to trading events. It is important to note that such events occur not only as a result of the actions of programs, but also for other reasons, for example, when manually managed by the user or performing automatic actions on the server (activation of a pending order, *Stop Loss*, *Take Profit*, *Stop Out*, position transfer to a new day, depositing or withdrawing funds from the account, and much more).

Regardless of the initiator of the actions, they result in the execution of trading transactions on the account. Trading transactions are indivisible steps that include:

- Processing a trade request
- Changing the list of active orders (including adding a new order, executing and deleting a triggered order)
- Changing the history of orders
- Changing the history of deals
- Changing positions

Depending on the nature of the operation, some steps may be optional. For example, modifying the protective levels of a position will miss three middle points. And when a buy order is sent, the market will go through a full cycle: the request is processed, a corresponding order is created for the account, the order is executed, it is removed from the active list, added to the order history, then the corresponding deal is added to the history and a new position is created. All these actions are trading transactions.

To receive notifications about such events, the special *OnTradeTransaction* handler function should be described in an Expert Advisor or an indicator. We will look at it in detail in the next section. The fact is that one of its parameters, the first and most important, has the type of a predefined structure *MqlTradeTransaction*. So let's first talk about transactions as such.

```
struct MqlTradeTransaction
{
   ulong                     deal;             // Deal ticket
   ulong                     order;            // Order ticket
   string                    symbol;           // Name of the trading instrument
   ENUM_TRADE_TRANSACTION_TYPE type;           // Trade transaction type
   ENUM_ORDER_TYPE           order_type;       // Order type
   ENUM_ORDER_STATE          order_state;      // Order state
   ENUM_DEAL_TYPE            deal_type;        // Deal type
   ENUM_ORDER_TYPE_TIME      time_type;        // Order type by duration
   datetime                  time_expiration;  // Order expiration date
   double                    price;            // Price
   double                    price_trigger;    // Stop limit order trigger price
   double                    price_sl;         // Stop Loss Level
   double                    price_tp;         // Take Profit Level
   double                    volume;           // Volume in lots
   ulong                     position;         // Position ticket
   ulong                     position_by;      // Opposite position ticket
};
```

The following table describes each structure field.

Field	Description
deal	Deal ticket
order	Order ticket
symbol	The name of the trading instrument on which the transaction was made
type	Trade transaction type ENUM_TRADE_TRANSACTION_TYPE (see below)
order_type	Order type ENUM_ORDER_TYPE
order_state	Order status ENUM_ORDER_STATE
deal_type	Deal type ENUM_DEAL_TYPE
time_type	Order type by expiration ENUM_ORDER_TYPE_TIME
time_expiration	Pending order expiration date
price	The price of an order, deal or position, depending on the transaction
price_trigger	Stop price (trigger price) of a stop limit order
price_sl	*Stop Loss* price; it may refer to an order, deal, or position, depending on the transaction
price_tp	*Take Profit* price; it may refer to an order, deal, or position, depending on the transaction
volume	Volume in lots; it may indicate the current volume of the order, deal, or position, depending on the transaction

Field	Description
position	Ticket of the position affected by the transaction
position_by	Opposite position ticket

Some fields only make sense in certain cases. In particular, the *time_expiration* field is filled for orders with *time_type* equal to the ORDER_TIME_SPECIFIED or ORDER_TIME_SPECIFIED_DAY expiration type. The *price_trigger* field is reserved for stop-limit orders only (ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT).

It is also obvious that position modifications operate on the position ticket (field *position*), but do not use order or deal tickets. In addition, the *position_by* field is reserved exclusively for closing a counter position, that is, the one opened for the same instrument but in the opposite direction.

The defining characteristic for the analysis of a transaction is its type (field *type*). To describe it, the MQL5 API introduces a special enumeration ENUM_TRADE_TRANSACTION_TYPE, which contains all possible types of transactions.

Identifier	Description
TRADE_TRANSACTION_ORDER_ADD	Adding a new order
TRADE_TRANSACTION_ORDER_UPDATE	Changing an active order
TRADE_TRANSACTION_ORDER_DELETE	Deleting an active order
TRADE_TRANSACTION_DEAL_ADD	Adding a deal to history
TRADE_TRANSACTION_DEAL_UPDATE	Changing a deal in history
TRADE_TRANSACTION_DEAL_DELETE	Deleting a deal from history
TRADE_TRANSACTION_HISTORY_ADD	Adding an order to history as a result of execution or cancellation
TRADE_TRANSACTION_HISTORY_UPDATE	Changing an order in history
TRADE_TRANSACTION_HISTORY_DELETE	Deleting an order from history
TRADE_TRANSACTION_POSITION	Change a position
TRADE_TRANSACTION_REQUEST	Notification that a trade request has been processed by the server and the result of its processing has been received

Let's provide some explanations.

In a transaction of the TRADE_TRANSACTION_ORDER_UPDATE type, order changes include not only explicit changes on the part of the client terminal or trade server but also changes in its state (for example, transition from the ORDER_STATE_STARTED state to ORDER_STATE_PLACED or from ORDER_STATE_PLACED to ORDER_STATE_PARTIAL, etc.).

During the TRADE_TRANSACTION_ORDER_DELETE transaction, an order can be deleted as a result of a corresponding explicit request or execution (fill) on the server. In both cases, it will be transferred to history and the transaction TRADE_TRANSACTION_HISTORY_ADD must also occur.

The TRADE_TRANSACTION_DEAL_ADD transaction is carried out not only as a result of order execution but also as a result of transactions with the account balance.

Some transactions, such as TRADE_TRANSACTION_DEAL_UPDATE, TRADE_TRANSACTION_DEAL_DELETE, TRADE_TRANSACTION_HISTORY_DELETE are quite rare because they describe situations when a deal or order in the history is changed or deleted on the server retroactively. This, as a rule, is a consequence of synchronization with an external trading system (exchange).

It is important to note that adding or liquidating a position does not entail the appearance of the TRADE_TRANSACTION_POSITION transaction. This type of transaction informs that the position has been changed on the side of the trade server, programmatically or manually by the user. In particular, a position can experience changes of the volume (partial opposite closing, reversal), opening price, as well as *Stop Loss* and *Take Profit* levels. Some actions, such as refills, do not trigger this event.

All trade requests issued by MQL programs are reflected in TRADE_TRANSACTION_REQUEST transactions, which allows analyzing their execution in a deferred way. This is especially important when using the function *OrderSendAsync*, which immediately returns control to the calling code, so the result is not known. At the same time, transactions are generated in the same way when using the synchronous *OrderSend* function.

In addition, using the TRADE_TRANSACTION_REQUEST transactions, you can analyze the user's trading actions from the terminal interface.

6.4.34 OnTradeTransaction event

Expert Advisors and indicators can receive notifications about trading events if their code contains a special processing function *OnTradeTransaction*.

```
void OnTradeTransaction(const MqlTradeTransaction &trans,
  const MqlTradeRequest &request, const MqlTradeResult &result)
```

The first parameter is the *MqlTradeTransaction* structure described in the previous section. The second and third parameters are structures *MqlTradeRequest* and *MqlTradeResult*, which were presented earlier in the relevant sections.

The *MqlTradeTransaction* structure that describes the trade transaction is filled in differently depending on the type of transaction specified in the *type* field. For example, for transactions of the TRADE_TRANSACTION_REQUEST type, all other fields are not important, and to obtain additional information, it is necessary to analyze the second and third parameters of the function (*request* and *result*). Conversely, for all other types of transactions, the last two parameters of the function should be ignored.

In case of TRADE_TRANSACTION_REQUEST, the *request_id* field in the *result* variable contains an identifier (through serial number), under which the trade *request* is registered in the terminal. This number has nothing to do with order and deal tickets, as well as position identifiers. During each session with the terminal, the numbering starts from the beginning (1). The presence of a request identifier allows you to associate the performed action (calling *OrderSend* or *OrderSendAsync* functions) with the result of this action passed to *OnTradeTransaction*. We'll look at examples later.

For trading transactions related to active orders (TRADE_TRANSACTION_ORDER_ADD, TRADE_TRANSACTION_ORDER_UPDATE and TRADE_TRANSACTION_ORDER_DELETE) and order history (TRADE_TRANSACTION_HISTORY_ADD, TRADE_TRANSACTION_HISTORY_UPDATE, TRADE_TRANSACTION_HISTORY_DELETE), the following fields are filled in the *MqlTradeTransaction* structure:

- order — order ticket
- symbol — name of the financial instrument in the order
- type — trade transaction type
- order_type — order type
- orders_state — current order state
- time_type — order expiration type
- time_expiration — order expiration time (for orders with ORDER_TIME_SPECIFIED and ORDER_TIME_SPECIFIED_DAY expiration types)
- price — order price specified by the client/program
- price_trigger — stop price for triggering a stop-limit order (only for ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT)
- price_sl — *Stop Loss* order price (filled if specified in the order)
- price_tp — *Take Profit* order price (filled if specified in the order)
- volume — current order volume (not executed), the initial order volume can be found from the order history
- position — ticket of an open, modified, or closed position
- position_by — opposite position ticket (only for orders to close with opposite position)

For trading transactions related to deals (TRADE_TRANSACTION_DEAL_ADD, TRADE_TRANSACTION_DEAL_UPDATE and TRADE_TRANSACTION_DEAL_DELETE), the following fields are filled in the *MqlTradeTransaction* structure:

- deal — deal ticket
- order — order ticket on the basis of which the deal was made
- symbol — name of the financial instrument in the deal
- type — trade transaction type
- deal_type — deal type
- price — deal price
- price_sl — *Stop Loss* price (filled if specified in the order on the basis of which the deal was made)
- price_tp — *Take Profit* price (filled if specified in the order on the basis of which the deal was made)
- volume — deal volume
- position — ticket of an open, modified, or closed position
- position_by — opposite position ticket (for deals to close with opposite position)

For trading transactions related to position changes (TRADE_TRANSACTION_POSITION), the following fields are filled in the *MqlTradeTransaction* structure:

- symbol — name of the financial instrument of the position
- type — trade transaction type

- deal_type — position type (DEAL_TYPE_BUY or DEAL_TYPE_SELL)
- price — weighted average position opening price
- price_sl — *Stop Loss* price
- price_tp — *Take Profit* price
- volume — position volume in lots
- position — position ticket

Not all available information on orders, deals and positions (for example, a comment) is transmitted in the description of a trading transaction. For more information use the relevant functions: *OrderGet*, *HistoryOrderGet*, *HistoryDealGet* and *PositionGet*.

One trade request sent from the terminal manually or through the trading functions *OrderSend/OrderSendAsync* can generate several consecutive trade transactions on the trade server. At the same time, the order in which notifications about these transactions arrive at the terminal is not guaranteed, so you cannot build your trading algorithm on waiting for some trading transactions after others.

Trading events are processed asynchronously, that is, delayed (in time) relative to the moment of generation. Each trade event is sent to the queue of the MQL program, and the program sequentially picks them up in the order of the queue.

When an Expert Advisor is processing trade transactions inside the *OnTradeTransaction* processor, the terminal continues to accept incoming trade transactions. Thus, the state of the trading account may change while *OnTradeTransaction* is running. In the future, the program will be notified of all these events in the order the appear.

The length of the transaction queue is 1024 elements. If *OnTradeTransaction* processes the next transaction for too long, old transactions in the queue may be ousted by newer ones.

Due to parallel multi-threaded operation of the terminal with trading objects, by the time the *OnTradeTransaction* handler is called, all the entities mentioned in it, including orders, deals, and positions, may already be in a different state than that specified in the transaction properties. To get their current state, you should select them in the current environment or in the history and request their properties using the appropriate MQL5 functions.

Let's start with a simple Expert Advisor example *TradeTransactions.mq5*, which logs all *OnTradeTransaction* trading events. Its only parameter *DetailedLog* allows you to optionally use classes *OrderMonitor*, *DealMonitor*, *PositionMonitor* to display all properties. By default, the Expert Advisor displays only the contents of the filled fields of the *MqlTradeTransaction*, *MqlTradeRequest* and *MqlTradeResult* structures, coming to the handler in the form of parameters; at the same time *request* and *result* are processed only for TRADE_TRANSACTION_REQUEST transactions.

```
input bool DetailedLog = false; // DetailedLog ('true' shows order/deal/position deta

void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &request,
   const MqlTradeResult &result)
{
   static ulong count = 0;
   PrintFormat(">>>% 6d", ++count);
   Print(TU::StringOf(transaction));

   if(transaction.type == TRADE_TRANSACTION_REQUEST)
   {
      Print(TU::StringOf(request));
      Print(TU::StringOf(result));
   }

   if(DetailedLog)
   {
      if(transaction.order != 0)
      {
         OrderMonitor m(transaction.order);
         m.print();
      }
      if(transaction.deal != 0)
      {
         DealMonitor m(transaction.deal);
         m.print();
      }
      if(transaction.position != 0)
      {
         PositionMonitor m(transaction.position);
         m.print();
      }
   }
}
```

Let's run it on the EURUSD chart and perform several actions manually, and the corresponding entries will appear in the log (for the purity of the experiment, it is assumed that no one and nothing else performs operations on the trading account, in particular, no other Expert Advisors are running).

Let's open a long position with a minimum lot.

```
>>>      1
TRADE_TRANSACTION_ORDER_ADD, #=1296991463(ORDER_TYPE_BUY/ORDER_STATE_STARTED), EURUSD
   » @ 1.10947, V=0.01
>>>      2

```

If you wish, you can enable the *DetailedLog* option to log all properties of trading objects at the moment of event processing. In a detailed log, you can notice discrepancies between the state of objects stored in the transaction structure (at the time of its initiation) and the current state. For example, when adding an order to close a position (opposite or normal), a ticket is specified in the transaction, according to which the monitor object will no longer be able to read anything, since the position has been deleted. As a result, we will see lines like this in the log:

```
TRADE_TRANSACTION_ORDER_ADD, #=1297777749(ORDER_TYPE_CLOSE_BY/ORDER_STATE_STARTED), E
   » @ 1.10953, V=0.01, P=1297774881, b=1297776850
...
Error: PositionSelectByTicket(1297774881) failed: TRADE_POSITION_NOT_FOUND
```

Let's restart the Expert Advisor *TradeTransaction.mq5* to reset the logged events for the next test. This time we will use default settings (no details).

Now let's try to perform trading actions programmatically in the new Expert Advisor *OrderSendTransaction1.mq5*, and at the same time describe our *OnTradeTransaction* handler in it (same as in the previous example).

This Expert Advisor allows you to select the trade direction and volume: if you leave it at zero, the minimum lot of the current symbol is used by default. Also in the parameters there is a distance to the protective levels in points. The market is entered with the specified parameters, there is a 5 second pause between the setting of *Stop Loss* and *Take Profit*, and then closing the position, so that the user can intervene (for example, edit the stop loss manually), although this is not necessary, since we have already made sure that manual operations are intercepted by the program.

```
enum ENUM_ORDER_TYPE_MARKET
{
   MARKET_BUY = ORDER_TYPE_BUY,     // ORDER_TYPE_BUY
   MARKET_SELL = ORDER_TYPE_SELL    // ORDER_TYPE_SELL
};

input ENUM_ORDER_TYPE_MARKET Type;
input double Volume;                // Volume (0 - minimal lot)
input uint Distance2SLTP = 1000;
```

The strategy is launched once, for which a 1-second timer is used, which is turned off in its own handler.

```
int OnInit()
{
   EventSetTimer(1);
   return INIT_SUCCEEDED;
}

void OnTimer()
{
   EventKillTimer();
   ...
```

All actions are performed through an already familiar *MqlTradeRequestSync* structure with advanced features (*MqlTradeSync.mqh*): implicit initialization of fields with correct values, *buy/sell* methods for market orders, *adjust* for protective levels, and *close* for closing the position.

Step 1:

```
      MqlTradeRequestSync request;

      const double volume = Volume == 0 ?
         SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volume;

      Print("Start trade");
      const ulong order = (Type == MARKET_BUY ? request.buy(volume) : request.sell(volum
      if(order == 0 || !request.completed())
      {
         Print("Failed Open");
         return;
      }

      Print("OK Open");
```

Step 2:

```
      Sleep(5000); // wait 5 seconds (user can edit position)
      Print("SL/TP modification");
      const double price = PositionGetDouble(POSITION_PRICE_OPEN);
      const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);
      TU::TradeDirection dir((ENUM_ORDER_TYPE)Type);
      const double SL = dir.negative(price, Distance2SLTP * point);
      const double TP = dir.positive(price, Distance2SLTP * point);
      if(request.adjust(SL, TP) && request.completed())
      {
         Print("OK Adjust");
      }
      else
      {
         Print("Failed Adjust");
      }
```

Step 3:

```
      Sleep(5000); // wait another 5 seconds
      Print("Close down");
      if(request.close(request.result.position) && request.completed())
      {
         Print("Finish");
      }
      else
      {
         Print("Failed Close");
      }
   }
```

Intermediate waits not only make it possible to have time to consider the process, but also demonstrate an important aspect of MQL5 programming, which is single-threading. While our trading Expert Advisor is inside *OnTimer*, trading events generated by the terminal are accumulated in its queue and will be forwarded to the internal *OnTradeTransaction* handler in a deferred style, only after the exit from *OnTimer*.

At the same time, the *TradeTransactions* Expert Advisor running in parallel is not busy with any calculations and will receive trading events as quickly as possible.

The result of the execution of two Expert Advisors is presented in the following log with timing (for brevity *OrderSendTransaction1* tagged as *OS1*, and *Trade Transactions* tagged as *TTs*).

```

                   D=10, #=1298022443, P=1298021794, M=1234567890
19:09:18.218  OS1  DONE, D=1280661967, #=1298022443, V=0.01, @ 1.10901, Bid=1.10901,
                   Req=11
```

The numbering of events in the programs is the same (provided that they are started cleanly, as recommended). Note that the same event is printed first from *TTs* immediately after the request is executed, and the second time only at the end of the test, where, in fact, all events are output from the queue to the *OS1*.

If we remove artificial delays, the script will, of course, run faster, but still the *OnTradeTransaction* handler will receive notifications (multiple times) after all three steps, not after each respective request. How critical it is?

Now the examples use our modification of the structure *MqlTradeRequestSync*, purposefully using the synchronous option *OrderSend*, which also implements a universal *completed* method which checks if the request completed successfully. With this control, we can set protective levels for a position, because we know how to wait for its ticket to appear. Within the framework of such a synchronous concept (adopted for the sake of convenience), we do not need to analyze query results in *OnTradeTransaction*. However, this is not always the case.

When an Expert Advisor needs to send many requests at once, as in the case of the example with setting a grid of orders *PendingOrderGrid2.mq5* discussed in the section on position properties, waiting for each position or order to be "ready" may reduce the overall performance of the Expert Advisor. In such cases, it is recommended to use the *OrderSendAsync* function. But if successful, it fills only the *request_id* field in the *MqlTradeResult*, with which you then need to track the appearance of orders, deals and positions in *OnTradeTransaction*.

One of the most obvious but not particularly elegant tricks for implementing this scheme is to store the identifiers of requests or entire structures of the requests being sent in an array, in the global context. These identifiers can then be looked up in incoming transactions in *OnTradeTransaction*, the tickets can be found in the *MqlTradeResult* parameter and further actions can be taken. As a result, the trading logic is separated into different functions. For example, in the context of the last Expert Advisor *OrderSendTransaction1.mq5* this "diversification" lies in the fact that after sending the first order, the code fragments must be transferred to *OnTradeTransaction* and checked for the following:

- transaction type in *MqlTradeTransaction* (*transaction type*);
- request type in *MqlTradeRequest* (*request action*);
- request id in *MqlTradeResult* (*result.request_id*);

All this should be supplemented with specific applied logic (for example, checking for the existence of a position), which provides branching by trading strategy states. A little later we will make a similar modification of the *OrderSendTransaction* Expert Advisor under a different number to visually show the amount of additional source code. And then we will offer a way to organize the program more linearly, but without abandoning transactional events.

For now, we only note that the developer should choose whether to build an algorithm around *OnTradeTransaction* or without it. In many cases, when bulk sending of orders is not needed, it is possible to stay in the synchronous programming paradigm. However, *OnTradeTransaction* is the most practical way to control the triggering of pending orders and protective levels, as well as other events generated by the server. After a little preparation, we will present two relevant examples: the final modification of the grid Expert Advvisor and the implementation of the popular setup of two OCO (One Cancels Other) orders (see the section *On Trade*).

An alternative to application of *OnTradeTransaction* consists in periodic analysis of the trading environment, that is, in fact, in remembering the number of orders and positions and looking for changes among them. This approach is suitable for strategies based on schedules or allowing certain time delays.

We emphasize again that the use of *OnTradeTransaction* does not mean that the program must necessarily switch from *OrderSend* on *OrderSendAsync*: You can use either variety or both. Recall that the *OrderSend* function is also not quite synchronous, as it returns, at best, the ticket of the order and the deal but not the position. Soon we will be able to measure the execution time of a batch of orders within the same grid strategy using both variants of the function: *OrderSend* and *OrderSendAsync*.

To unify the development of synchronous and asynchronous programs, it would be great to support *OrderSendAsync* in our structure *MqlTradeRequestSync* (despite its name). This can be done with just a

couple of corrections. First, you need to replace all currently existing calls *OrderSend* to your own method *orderSend*, and in it switch the call to *OrderSend* or *OrderSendAsync* depending on a flag.

```
struct MqlTradeRequestSync: public MqlTradeRequest
{
   ...
   static bool AsyncEnabled;
   ...
private:
   bool orderSend(const MqlTradeRequest &req, MqlTradeResult &res)
   {
      return AsyncEnabled ? ::OrderSendAsync(req, res) : ::OrderSend(req, res);
   }
};
```

By setting the *AsyncEnabled* public variable to *true* or *false*, you can switch from one mode to another, for example, in the code fragment where mass orders are sent.

Second, those methods of the structure that returned a ticket (for example, for entering the market) you should return the *request_id* field instead of *order*. For example, inside the methods *_pending* and *_market* we had the following operator:

```
if(OrderSend(this, result)) return result.order;
```

Now it is replaced by:

```
if(orderSend(this, result)) return result.order ? result.order :
   (result.retcode == TRADE_RETCODE_PLACED ? result.request_id : 0);
```

Of course, when asynchronous mode is enabled, we can no longer use the *completed* method to wait for the query results to be ready immediately after it is sent. But this method is, basically, optional: you can just drop it even when working through *OrderSend*.

So, taking into account the new modification of the *MqlTradeSync.mqh* file, let's create *OrderSendTransaction2.mq5*.

This Expert Advisor will send the initial request as before from *OnTimer*, while setting protective levels and closing a position in *OnTradeTransaction* step by step. Although we will not have an artificial delay between the stages this time, the sequence of states itself is standard for many Expert Advisors: opened a position, modified, closed (if certain market conditions are met, which are left behind the scenes here).

Two global variables will allow you to track the state: *RequestID* with the id of the last request sent (the result of which we expect) and *Position Ticket* with an open position ticket. When there the position did not appear yet, or no longer exists, the ticket is equal to 0.

```
uint RequestID = 0;
ulong PositionTicket = 0;
```

Asynchronous mode is enabled in the *OnInit* handler.

```
int OnInit()
{
   ...
   MqlTradeRequestSync::AsyncEnabled = true;
   ...
}
```

The *OnTimer* function is now much shorter.

```
void OnTimer()
{
   ...
   // send a request TRADE_ACTION_DEAL (asynchronously!)
   const ulong order = (Type == MARKET_BUY ? request.buy(volume) : request.sell(volum
   if(order) // in asynchronous mode this is now request_id
   {
      Print("OK Open?");
      RequestID = request.result.request_id; // same as order
   }
   else
   {
      Print("Failed Open");
   }
}
```

On successful completion of the request, we get only *request_id* and store it in the *RequestID* variable. The status print now contains a question mark, like "OK Open?", because the actual result is not yet known.

OnTradeTransaction became significantly more complicated due to the verification of the results and the execution of subsequent trading orders according to the conditions. Let's consider it gradually.

In this case, the entire trading logic has moved into the branch for transactions of the TRADE_TRANSACTION_REQUEST type. Of course, the developer can use other types if desired, but we use this one because it contains information in the form of a familiar structure *MqlTradeResult*, i.e., this sort of represents a delayed ending of an asynchronous call *OrderSendAsync*.

```
void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &request,
   const MqlTradeResult &result)
{
   static ulong count = 0;
   PrintFormat(">>>% 6d", ++count);
   Print(TU::StringOf(transaction));

   if(transaction.type == TRADE_TRANSACTION_REQUEST)
   {
      Print(TU::StringOf(request));
      Print(TU::StringOf(result));

      ...
      // here is the whole algorithm
   }
}
```

We should only be interested in requests with the ID we expect. So the next statement will be nested *if*. In its block, we describe the *MqlTradeRequestSync* object in advance, because it will be necessary to send regular trade requests according to the plan.

```
      if(result.request_id == RequestID)
      {
         MqlTradeRequestSync next;
         next.magic = Magic;
         next.deviation = Deviation;
         ...
      }
```

We have only two working request types, so we add one more nested *if* one for them.

```
         if(request.action == TRADE_ACTION_DEAL)
         {
            ... // here is the reaction to opening and closing a position
         }
         else if(request.action == TRADE_ACTION_SLTP)
         {
            ... // here is the reaction to setting SLTP for an open position
         }
```

Please note that TRADE_ACTION_DEAL is used for both opening and closing a position, and therefore one more *if* is required, in which we will distinguish between these two states depending on the value of the *PositionTicket* variable.

```
if(PositionTicket == 0)
{
   ... // there is no position, so this is an opening notification
}
else
{
   ... // there is a position, so this is a closure
}
```

There are no position increases (for netting) or multiple positions (for hedging) in the trading strategy under consideration, which is why this part is logically simple. Real Expert Advisors will require much more different estimates of intermediate states.

In the case of a position opening notification, the block of code looks like this:

```
if(PositionTicket == 0)
{
   // trying to get results from the transaction: select an order by tick
   if(!HistoryOrderSelect(result.order))
   {
      Print("Can't select order in history");
      RequestID = 0;
      return;
   }
   // get position ID and ticket
   const ulong posid = HistoryOrderGetInteger(result.order, ORDER_POSITIC
   PositionTicket = TU::PositionSelectById(posid);
   ...
```

For simplicity, we have omitted error and requote checking here. You can see an example of their handling in the attached source code. Recall that all these checks have already been implemented in the methods of the *MqlTradeRequestSync* structure, but they only work in synchronous mode, and therefore we have to repeat them explicitly.

The next code fragment for setting protective levels has not changed much.

```
if(PositionTicket == 0)
{
   ...
   const double price = PositionGetDouble(POSITION_PRICE_OPEN);
   const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);
   TU::TradeDirection dir((ENUM_ORDER_TYPE)Type);
   const double SL = dir.negative(price, Distance2SLTP * point);
   const double TP = dir.positive(price, Distance2SLTP * point);
   // sending TRADE_ACTION_SLTP request (asynchronously!)
   if(next.adjust(PositionTicket, SL, TP))
   {
      Print("OK Adjust?");
      RequestID = next.result.request_id;
   }
   else
   {
      Print("Failed Adjust");
      RequestID = 0;
   }
}
```

The only difference here is: we fill the *RequestID* variable with ID of the new TRADE_ACTION_SLTP request.

Receiving a notification about a deal with a non-zero *PositionTicket* implies that the position has been closed.

```
if(PositionTicket == 0)
{
   ... // see above
}
else
{
   if(!PositionSelectByTicket(PositionTicket))
   {
      Print("Finish");
      RequestID = 0;
      PositionTicket = 0;
   }
}
```

In case of successful deletion, the position cannot be selected using *PositionSelectByTicket*, so we reset *RequestID* and *PositionTicket*. The Expert Advisor then returns to its initial state and is ready to make the next buy/sell-modify-close cycle.

It remains for us to consider sending a request to close the position. In our simplified to a minimum strategy, this happens immediately after the successful modification of the protective levels.

```
   if(request.action == TRADE_ACTION_DEAL)
   {
      ... // see above
   }
   else if(request.action == TRADE_ACTION_SLTP)
   {
      // send a TRADE_ACTION_DEAL request to close (asynchronously!)
      if(next.close(PositionTicket))
      {
         Print("OK Close?");
         RequestID = next.result.request_id;
      }
      else
      {
         PrintFormat("Failed Close %lld", PositionTicket);
      }
   }
```

That's the whole function *OnTradeTransaction*. The Expert Advisor is ready.

Let's run *OrderSendTransaction2.mq5* with default settings on EURUSD. Below is an example log.

```
Start trade

Finish
```

The trading logic is working as expected, and transaction events arrive strictly after each next order is sent. If we now run our new Expert Advisor and the transactions interceptor *TradeTransactions.mq5* in parallel, log messages from two Expert Advisors will appear synchronously.

However, a remake from the first straight version *OrderSendTransaction1.mq5* to an asynchronous second version *OrderSendTransaction2.mq5* required significantly more sophisticated code. The

question arises: is it possible to somehow combine the principles of sequential description of trading logic (code transparency) and parallel processing (speed)?

In theory, this is possible, but it will require at some point to spend time to work on creating some kind of auxiliary mechanism.

6.4.35 Synchronous and asynchronous requests

Before going into details, let's remind you that each MQL program is executed in its own thread, and therefore parallel asynchronous processing of transactions (and other events) is only possible due to the fact that another MQL program would be doing it. At the same time, it is necessary to ensure information exchange between programs. We already know a couple of ways to do this: global variables of the terminal and files. In Part 7 of the book, we will explore other features such as graphical resources and databases.

Indeed, imagine that an Expert Advisor similar to *TradeTransactions.mq5* runs in parallel with the trading Expert Advisor and saves the received transactions (not necessarily all fields, but only selective ones that affect decision-making) in global variables. Then the Expert Advisor could check the global variables immediately after sending the next request and read the results from them without leaving the current function. Moreover, it does not need its own *OnTradeTransaction* handler.

However, it is not easy to organize the running of a third-party Expert Advisor. From the technical point of view, this could be done by creating a chart object and applying a template with a predefined transaction monitor Expert Advisor. But there is an easier way. The point is that events of *OnTradeTransaction* are translated not only into Expert Advisor but also into indicators. In turn, an indicator is the most easily launched type of MQL program: it is enough to call *iCustom*.

In addition, the use of the indicator gives one more nice bonus: it can describe the indicator buffer available from external programs via *CopyBuffer*, and arrange a *ring buffer* in it for storing transactions coming from the terminal (request results). Thus, there is no need to mess with global variables.

> Attention! The *OnTradeTransaction* event is not generated for indicators in the tester, so you can only check the operation of the Expert Advisor-indicator pair online.

Let's call this indicator *TradeTransactionRelay.mq5* and describe one buffer in it. It could be made invisible because it will write data that cannot be rendered, but we left it visible to prove the concept.

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1

double Buffer[];

void OnInit()
{
   SetIndexBuffer(0, Buffer, INDICATOR_DATA);
}
```

The *OnCalculate* handler is empty.

```
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   return rates_total;
}
```

In the code, we need a ready converter from *double* to *ulong* and vice versa, since buffer cells can corrupt large *ulong* values if they are written there using a simple typecast (see Real numbers).

```
#include <MQL5Book/ConverterT.mqh>
Converter<ulong,double> cnv;
```

Here is the *OnTradeTransaction* function.

```
#defineFIELD_NUM6// the most important fields in MqlTradeResult

void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &request,
   const MqlTradeResult &result)
{
   if(transaction.type == TRADE_TRANSACTION_REQUEST)
   {
      ArraySetAsSeries(Buffer, true);

      // store FIELD_NUM result fields into consecutive buffer cells
      const int offset = (int)((result.request_id * FIELD_NUM)
         % (Bars(_Symbol, _Period) / FIELD_NUM * FIELD_NUM));
      Buffer[offset + 1] = result.retcode;
      Buffer[offset + 2] = cnv[result.deal];
      Buffer[offset + 3] = cnv[result.order];
      Buffer[offset + 4] = result.volume;
      Buffer[offset + 5] = result.price;
      // this assignment must come last,
      // because it is the result ready flag
      Buffer[offset + 0] = result.request_id;
   }
}
```

We decided to keep only the six most important fields of the *MqlTradeResult* structure. If desired, you can extend the mechanism to the entire structure, but to transfer the string field *comment* you will need an array of characters for which you will have to reserve quite a lot of elements.

Thus, each result now occupies six consecutive buffer cells. The index of the first cell of these six is determined based on the request ID: this number is simply multiplied by 6. Since there can be many requests, the entry works on the principle of a ring buffer, i.e., the resulting index is normalized by dividing with remainder ('%') by the size of the indicator buffer, which is the number of bars rounded up to 6. When the request numbers exceed the size, the record will go in a circle from the initial elements.

Since the numbering of bars is affected by the formation of new bars, it is recommended to put the indicator on large timeframes, such as D1. Then only at the beginning of the day is it likely (yet rather unlikely) the situation when the numbering of bars in the indicator will shift directly during the

processing of the next transaction, and then the results recorded by the indicator will not be read by the Expert Advisor (one transaction may be missed).

The indicator is ready. Now let's start implementing a new modification of the test Expert Advisor *OrderSendTransaction3.mq5* (hooray, this is its latest version). Let's describe the *handle* variable for the indicator handle and create the indicator in *OnInit*.

```
int handle = 0;

int OnInit()
{
   ...
   const static string indicator = "MQL5Book/p6/TradeTransactionRelay";
   handle = iCustom(_Symbol, PERIOD_D1, indicator);
   if(handle == INVALID_HANDLE)
   {
      Alert("Can't start indicator ", indicator);
      return INIT_FAILED;
   }
   return INIT_SUCCEEDED;
}
```

To read query results from the indicator buffer, let's prepare a helper function *AwaitAsync*. As its first parameter, it receives a reference to the *MqlTradeRequestSync* structure. If successful, the results obtained from the indicator buffer with *handle* will be written to this structure. The identifier of the request we are interested in should already be in the nested structure, in the *result.request_id* field. Of course, here we must read the data according to the same principle, that is, in six bars.

```
#define FIELD_NUM   6  // the most important fields in MqlTradeResult
#define TIMEOUT  1000  // 1 second

bool AwaitAsync(MqlTradeRequestSync &r, const int _handle)
{
   Converter<ulong,double> cnv;
   const int offset = (int)((r.result.request_id * FIELD_NUM)
      % (Bars(_Symbol, _Period) / FIELD_NUM * FIELD_NUM));
   const uint start = GetTickCount();
   // wait for results or timeout
   while(!IsStopped() && GetTickCount() - start < TIMEOUT)
   {
      double array[];
      if((CopyBuffer(_handle, 0, offset, FIELD_NUM, array)) == FIELD_NUM)
      {
         ArraySetAsSeries(array, true);
         // when request_id is found, fill other fields with results
         if((uint)MathRound(array[0]) == r.result.request_id)
         {
            r.result.retcode = (uint)MathRound(array[1]);
            r.result.deal = cnv[array[2]];
            r.result.order = cnv[array[3]];
            r.result.volume = array[4];
            r.result.price = array[5];
            PrintFormat("Got Req=%d at %d ms",
               r.result.request_id, GetTickCount() - start);
            Print(TU::StringOf(r.result));
            return true;
         }
      }
   }
   Print("Timeout for: ");
   Print(TU::StringOf(r));
   return false;
}
```

Now that we have this function, let's write a trading algorithm in an asynchronous-synchronous style: as a direct sequence of steps, each of which waits for the previous one to be ready due to notifications from the parallel indicator program while remaining inside one function.

```
void OnTimer()
{
   EventKillTimer();

   MqlTradeRequestSync::AsyncEnabled = true;

   MqlTradeRequestSync request;
   request.magic = Magic;
   request.deviation = Deviation;

   const double volume = Volume == 0 ?
      SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volume;
   ...
```

Step 1.

```
   Print("Start trade");
   ResetLastError();
   if((bool)(Type == MARKET_BUY ? request.buy(volume) : request.sell(volume)))
   {
      Print("OK Open?");
   }

   if(!(AwaitAsync(request, handle) && request.completed()))
   {
      Print("Failed Open");
      return;
   }
   ...
```

Step 2.

```
   Print("SL/TP modification");
   ...
   if(request.adjust(SL, TP))
   {
      Print("OK Adjust?");
   }

   if(!(AwaitAsync(request, handle) && request.completed()))
   {
      Print("Failed Adjust");
   }
```

Step 3.

```
      Print("Close down");
      if(request.close(request.result.position))
      {
         Print("OK Close?");
      }

      if(!(AwaitAsync(request, handle) && request.completed()))
      {
         Print("Failed Close");
      }

      Print("Finish");
   }
```

Please note that the *completed* method calls are now done not after sending the request but after the result is received by the *AwaitAsync* function.

Otherwise, everything is very similar to the first version of this algorithm, but now it is built on asynchronous function calls and reacts to asynchronous events.

It probably doesn't seem significant in this particular example of a chain of manipulations on a single position. However, we can use the same technique to send and control a batch of orders. And then the benefits will become obvious. After a moment, we will demonstrate this with the help of a grid Expert Advisor and at the same time compare the performance of two functions: *OrderSend* and *OrderSendAsync*.

But right now, as we complete the series of *OrderSendTransaction* Expert Advisors, let's run the latest version and see in the log the regular, linear execution of all steps.

```
Start trade
OK Open?
Got Req=1 at 62 ms
DONE, D=1282677007, #=1300045365, V=0.01, @ 1.10564, Bid=1.10564, Ask=1.10564, Order
Waiting for position for deal D=1282677007
SL/TP modification
OK Adjust?
Got Req=2 at 63 ms
DONE, Order placed, Req=2
Close down
OK Close?
Got Req=3 at 78 ms
DONE, D=1282677008, #=1300045366, V=0.01, @ 1.10564, Bid=1.10564, Ask=1.10564, Order
Finish
```

Timing with response delays can significantly depend on the server, time of day, and symbol. Of course, part of the time here is spent not on a trade request with confirmation but on the execution of the *CopyBuffer* function. According to our observations, it takes no more than 16 ms (within one cycle of a standard system timer, those who wish can profile programs using high-precision timers *GetMicrosecondCount*).

Ignore the difference between the status (DONE) and the string description ("Order placed"). The fact is that the comment (as well as the *ask/bid* fields) remains in the structure from the moment it is sent by the *OrderSendAsync* function, and the final status in the *retcode* field is written by our *AwaitAsync*

function. It is important for us that in the structure with the results, the ticket numbers (*deal* and *order*), exercise price (*price*) and volume (*volume*) are up-to-date.

Based on the earlier considered example of *OrderSendTransaction3.mq5*, let's create a new version of the grid Expert Advisor *PendingOrderGrid3.mq5* (the previous version is provided in the section Functions for reading position properties). It will be able to set a complete grid of orders in synchronous or asynchronous mode, at the user's choice. We will also detect the times of setting the full grid for comparison.

The mode is controlled by the input variable *EnableAsyncSetup*. The *handle* variable is allocated for the indicator handle.

```
input bool EnableAsyncSetup = false;

int handle;
```

During initialization, in the case of asynchronous mode, we create an instance of the *TradeTransactionRelay* indicator.

```
int OnInit()
{
   ...
   if(EnableAsyncSetup)
   {
      const uint start = GetTickCount();
      const static string indicator = "MQL5Book/p6/TradeTransactionRelay";
      handle = iCustom(_Symbol, PERIOD_D1, indicator);
      if(handle == INVALID_HANDLE)
      {
         Alert("Can't start indicator ", indicator);
         return INIT_FAILED;
      }
      PrintFormat("Started in %d ms", GetTickCount() - start);
   }
   ...
}
```

In order to simplify coding, we have replaced the two-dimensional *request* array with a one-dimensional one in the *SetupGrid* function.

```
uint SetupGrid()
{
   ...                                  // prev:
   MqlTradeRequestSyncLog request[];    // MqlTradeRequestSyncLog request[][2];
   ArrayResize(request, GridSize * 2);  // ArrayResize(request, GridSize);
   ...
}
```

Further in the loop through the array, instead *request[i][1]* type calls we use the addressing *request[i * 2 + 1]*.

This small transformation was required for the following reasons. Since we use this array of structures for queries when creating the grid, and we need to wait for all the results, the *AwaitAsync* function

should now take as its first parameter a reference to an array. A one-dimensional array is easier to handle.

For each request, its offset in the indicator buffer is calculated in accordance with its *request_id*: all offsets are placed into the *offset* array. As request confirmations are received, the corresponding elements of the array are marked as processed by writing the value of -1 there. The number of executed requests is counted in the *done* variable. When it equals the size of the array, the entire grid is ready.

```
bool AwaitAsync(MqlTradeRequestSyncLog &r[], const int _handle)
{
   Converter<ulong,double> cnv;
   int offset[];
   const int n = ArraySize(r);
   int done = 0;
   ArrayResize(offset, n);

   for(int i = 0; i < n; ++i)
   {
      offset[i] = (int)((r[i].result.request_id * FIELD_NUM)
         % (Bars(_Symbol, _Period) / FIELD_NUM * FIELD_NUM));
   }

   const uint start = GetTickCount();
   while(!IsStopped() && done < n && GetTickCount() - start < TIMEOUT)
   for(int i = 0; i < n; ++i)
   {
      if(offset[i] == -1) continue; // skip empty elements
      double array[];
      if((CopyBuffer(_handle, 0, offset[i], FIELD_NUM, array)) == FIELD_NUM)
      {
         ArraySetAsSeries(array, true);
         if((uint)MathRound(array[0]) == r[i].result.request_id)
         {
            r[i].result.retcode = (uint)MathRound(array[1]);
            r[i].result.deal = cnv[array[2]];
            r[i].result.order = cnv[array[3]];
            r[i].result.volume = array[4];
            r[i].result.price = array[5];
            PrintFormat("Got Req=%d at %d ms", r[i].result.request_id,
               GetTickCount() - start);
            Print(TU::StringOf(r[i].result));
            offset[i] = -1; // mark processed
            done++;
         }
      }
   }
   return done == n;
}
```

Returning to the *SetupGrid* function, let's show how *AwaitAsync* is called after the request sending loop.

```
uint SetupGrid()
{
   ...
   const uint start = GetTickCount();
   for(int i = 0; i < (int)GridSize / 2; ++i)
   {
      // calls of buyLimit/sellStopLimit/sellLimit/buyStopLimit
   }

   if(EnableAsyncSetup)
   {
      if(!AwaitAsync(request, handle))
      {
         Print("Timeout");
         return TRADE_RETCODE_ERROR;
      }
   }

   PrintFormat("Done %d requests in %d ms (%d ms/request)",
      GridSize * 2, GetTickCount() - start,
      (GetTickCount() - start) / (GridSize * 2));
   ...
}
```

If a timeout occurs when setting the grid (not all requests will receive confirmation within the allotted time), we will return the TRADE_RETCODE_ERROR code, and the Expert Advisor will try to "roll back" what it managed to create.

It's important to note that asynchronous mode is only intended to set up a full grid when we need to send a batch of requests. Otherwise, the synchronous mode will still be used. Therefore, we must set the *MqlTradeRequestSync::AsyncEnabled* flag to *true* before the send loop and set it back to *false* after that. However, please pay attention to the following. Errors can occur inside the loop, due to which it is terminated prematurely, returning the last code from the server. Thus, if we place an asynchronous reset after the loop, there is no guarantee that it will be reset.

To solve this problem, a small *AsyncSwitcher* class is added to the *MqlTradeSync.mqh* file. The class controls the enabling and disabling of asynchronous mode from its constructor and destructor. This aligns with the RAII resource management concept discussed in section File descriptor management.

```
class AsyncSwitcher
{
public:
   AsyncSwitcher(const bool enabled = true)
   {
      MqlTradeRequestSync::AsyncEnabled = enabled;
   }
   ~AsyncSwitcher()
   {
      MqlTradeRequestSync::AsyncEnabled = false;
   }
};
```

Now, for the safe temporary activation of the asynchronous mode, we can simply describe the local *AsyncSwitcher* object in the *SetupGrid* function. The code will automatically return to the synchronous mode on any exit from the function.

```
uint SetupGrid()
{
   ...
   AsyncSwitcher sync(EnableAsyncSetup);
   ...
   for(int i = 0; i < (int)GridSize / 2; ++i)
   {
      ...
   }
   ...
}
```

The Expert Advisor is ready. Let's try to run it twice: in synchronous and asynchronous modes for a large enough grid (10 levels, grid step 200).

For a grid of 10 levels, we will get 20 queries, so below are some of the logs. First, a synchronous mode was used. Let's clarify that the inscription about the readiness of requests is displayed before messages about the requests because the latter are generated by the structure destructors when the function exits. The processing speed is 51ms per request.

```
Start setup at 1.10379
Done 20 requests in 1030 ms (51 ms/request)

```

The middle of the grid matched the price of 1.10400. The system assigns numbers to requests in the order in which they are received, and their numbering in the array corresponds to the order in which we place orders: from the central base level, we gradually diverge to the sides. Therefore, do not be surprised that after a pair of 1 and 2 (for the level 1.10200) comes 5 and 6 (1.10000), since 3 and 4 (1.10600) were sent earlier.

In asynchronous mode, destructors are preceded by messages about the readiness of specific requests received in *AwaitAsync* in real time, and not necessarily in the order in which the requests were sent (for example, the 49th and 50th requests "overtook" the 47th and 48th).

Done 20 requests in 234 ms (11 ms/request)
...
```

Due to the fact that all requests were executed in parallel, the total send time (234ms) is only slightly more than the time of a single request (here around 100ms, but you will have your own timing). As a result, we got a speed of 11ms per request, which is 5 times faster than with the synchronous method. Since the requests were sent almost simultaneously, we cannot know the execution time of each, and milliseconds indicate the arrival of the result of a particular request from the moment the general start of the group sending.

Further logs, as in the previous case, contain all query and result fields which are printed from structure destructors. The "Order placed" line remained unchanged after *OrderSendAsync*, since our auxiliary indicator *TradeTransactionRelay.mq5* does not publish the *MqlTradeResult* structure from the TRADE_TRANSACTION_REQUEST message in full.

```

Until now, our grid Expert Advisor had a pair of pending orders at each level: limit and stop-limit. To avoid such duplication, we leave only limit orders. This will be the final version of *PendingOrderGrid4.mq5*, which can also be run in synchronous and asynchronous mode. We will not go into the source code in detail but will only note the main differences from the previous version.

In the *SetupGrid* function, we need an array of structures of size equal to *GridSize* and not doubled. The number of requests will also decrease by 2 times: the only methods used for them are *buyLimit* and *sellLimit*.

The *CheckGrid* function checks the integrity of the grid in a different way. Previously, the absence of a paired stop-limit order at the level where there is a limit was considered a mistake. This could happen when a stop-limit order was triggered on the server from a neighboring level. However, this scheme is not capable of restoring the grid if a strong two-way price movement (spike) occurs on one bar: it will knock out not only the original limit orders but also new ones generated from stop-limit ones. Now the algorithm honestly checks the vacant levels on both sides of the current price and creates limit orders there using *RepairGridLevel*. This helper function previously placed stop-limit orders.

Finally, the *OnTradeTransaction* handler appeared in *PendingOrderGrid4.mq5*. The triggering of a pending order will lead to the execution of a deal (and a change in the grid configuration that needs to be corrected), so we control deals by a given symbol and magic. When a transaction is detected, the function *CheckGrid* is called instantly, in addition to the fact that it is still executed at the beginning of each bar.

```
void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &,
   const MqlTradeResult &)
{
   if(transaction.type == TRADE_TRANSACTION_DEAL_ADD)
   {
      if(transaction.symbol == _Symbol)
      {
         DealMonitor dm(transaction.deal); // select the deal
         if(dm.get(DEAL_MAGIC) == Magic)
         {
            CheckGrid();
         }
      }
   }
}
```

It should be noted that the presence of *OnTradeTransaction* is not enough to write Expert Advisors that are resistant to unforeseen external influences. Of course, events allow you to quickly respond to the situation, but we have no guarantee that the Expert Advisor will not be turned off (or go offline) for one reason or another for some time and skip this or that transaction. Therefore the *OnTradeTransaction* handler should only help speed up the processes that the program can perform without it. In particular, to restore its state correctly after the start.

However, in addition to the *OnTradeTransaction* event, MQL5 provides another, simpler event: *OnTrade*.

6.4.36 OnTrade event

The *OnTrade* event occurs when changing the list of placed orders and open positions, the history of orders, and the history of deals. Any trading action (placing/activating/deleting a pending order, opening/closing a position, setting protective levels, etc.) changes the history of orders and deals and/or the list of positions and current orders accordingly. The initiator of an action can be a user, a program, or a server.

To receive the event in a program, you should describe the corresponding handler.

void OnTrade(void)

In the case of sending trade requests using *OrderSend/OrderSendAsync*, one request will trigger multiple *OnTrade* events since processing usually takes place in several stages and each operation can change the state of orders, positions, and trading history.

In general, there is no exact ratio in the number of *OnTrade* and *OnTradeTransaction* calls. *OnTrade* is called after the corresponding calls *OnTradeTransaction*.

Since the *OnTrade* event is of a generalized nature and does not specify the essence of the operation, it is less popular with developers of MQL programs. It is usually necessary to check all aspects of the trading account state in the code and compare it with some saved state, that is, with the applied cache of trading entities used in the trading strategy. In the simplest case, you can, for example, remember the ticket of the created order in the *OnTrade* handler to interrogate all its properties. However, this may imply the "unnecessary" analysis of a large number of incidental events that are not related to a specific order.

We will talk about the possibility of applied caching of the trading environment and history in the section on multicurrency Expert Advisors.

To further explore *OnTrade*, let's deal with an Expert Advisor implementing a strategy on two OCO ("One Cancels Other") pending orders. It will place a pair of breakout stop orders and wait for one of them to trigger, after which the second one will be removed. For clarity, we will provide support for both types of trading events, *OnTrade* and *OnTradeTransaction*, so that the working logic will run either from one handler or another, as chosen by the user.

The source code is available in the *OCO2.mq5* file. Its input parameters include the lot size *Volume* (default is 0 which means minimum), the *Distance2SLTP* distance in points to place each of the orders and it also determines the protective levels, the expiration date *Expiration* in seconds from the setup time, and the event switcher *ActivationBy* (default, *OnTradeTransaction*). Since *Distance2SLTP* sets both the offset from the current price and the distance to the stop loss, the stop losses of the two orders are the same and equal to the price at the time of setting.

```
enum EVENT_TYPE
{
   ON_TRANSACTION, // OnTradeTransaction
   ON_TRADE        // OnTrade
};

input double Volume;            // Volume (0 - minimal lot)
input uint Distance2SLTP = 500; // Distance Indent/SL/TP (points)
input ulong Magic = 1234567890;
input ulong Deviation = 10;
input ulong Expiration = 0;     // Expiration (seconds in future, 3600 - 1 hour, etc)
input EVENT_TYPE ActivationBy = ON_TRANSACTION;
```

To simplify the initialization of request structures, we will describe our own *MqlTradeRequestSyncOCO* structure derived from *MqlTradeRequestSync*.

```
struct MqlTradeRequestSyncOCO: public MqlTradeRequestSync
{
   MqlTradeRequestSyncOCO()
   {
      symbol = _Symbol;
      magic = Magic;
      deviation = Deviation;
      if(Expiration > 0)
      {
         type_time = ORDER_TIME_SPECIFIED;
         expiration = (datetime)(TimeCurrent() + Expiration);
      }
   }
};
```

At the global level, let's introduce several objects and variables.

```
OrderFilter orders;        // object for selecting orders
PositionFilter trades;     // object for selecting positions
bool FirstTick = false;    // or single processing of OnTick at start
ulong ExecutionCount = 0;  // counter of trading strategy calls RunStrategy()
```

All trading logic, except for the start moment, will be triggered by trading events. In the *OnInit* handler, we set up filter objects and wait for the first tick (set *FirstTick* to *true*).

```
int OnInit()
{
   FirstTick = true;

   orders.let(ORDER_MAGIC, Magic).let(ORDER_SYMBOL, _Symbol)
      .let(ORDER_TYPE, (1 << ORDER_TYPE_BUY_STOP) | (1 << ORDER_TYPE_SELL_STOP),
      IS::OR_BITWISE);
   trades.let(POSITION_MAGIC, Magic).let(POSITION_SYMBOL, _Symbol);

   return INIT_SUCCEEDED;
}
```

We are only interested in stop orders (buy/sell) and positions with a specific magic number and the current symbol.

In the *OnTick* function, we once call the main part of the algorithm designed as *RunStrategy* (we will describe it below). Further, this function will be called only from *OnTrade* or *OnTradeTransaction*.

```
void OnTick()
{
   if(FirstTick)
   {
      RunStrategy();
      FirstTick = false;
   }
}
```

For example, when the *OnTrade* mode is enabled, this fragment works.

```
void OnTrade()
{
   static ulong count = 0;
   PrintFormat("OnTrade(%d)", ++count);
   if(ActivationBy == ON_TRADE)
   {
      RunStrategy();
   }
}
```

Note that the *OnTrade* handler calls are counted regardless of whether the strategy is activated here or not. Similarly, the relevant events are counted in the *OnTradeTransaction* handler (even if they occur in vain). This is done in order to be able to see both events and their counters in the log at the same time.

When the *OnTradeTransaction* mode is on, obviously, *RunStrategy* starts from there.

```
void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &request,
   const MqlTradeResult &result)
{
   static ulong count = 0;
   PrintFormat("OnTradeTransaction(%d)", ++count);
   Print(TU::StringOf(transaction));

   if(ActivationBy != ON_TRANSACTION) return;

   if(transaction.type == TRADE_TRANSACTION_ORDER_DELETE)
   {
      // why not here? for answer, see the text
      /* // this won't work online: m.isReady() == false because order temporarily lo
      OrderMonitor m(transaction.order);
      if(m.isReady() && m.get(ORDER_MAGIC) == Magic && m.get(ORDER_SYMBOL) == _Symbol
      {
         RunStrategy();
      }
      */
   }
   else if(transaction.type == TRADE_TRANSACTION_HISTORY_ADD)
   {
      OrderMonitor m(transaction.order);
      if(m.isReady() && m.get(ORDER_MAGIC) == Magic && m.get(ORDER_SYMBOL) == _Symbol
      {
         // the ORDER_STATE property does not matter - in any case, you need to remov
         // if(transaction.order_state == ORDER_STATE_FILLED
         // || transaction.order_state == ORDER_STATE_CANCELED ...)
         RunStrategy();
      }
   }
}
```

It should be noted that when trading online, a triggered pending order may disappear from the trading environment for some time due to being transferred from the existing ones to history. When we receive the TRADE_TRANSACTION_ORDER_DELETE event, the order has already been removed from the active

list but has not yet appeared in history. It only gets there when we receive the TRADE_TRANSACTION_HISTORY_ADD event. This behavior is not observed in the tester, that is, a deleted order is immediately added to history and is available there for selecting and reading properties already in the TRADE_TRANSACTION_ORDER_DELETE phase.

In both trade event handlers, we count and log the number of calls. For the case with *OnTrade*, it must match *ExecutionCount* which we will soon see inside *RunStrategy*. But for *OnTradeTransaction*, the counter and *ExecutionCount* will differ significantly because the strategy here is called very selectively, for one type of event. Based on this, we can conclude that *OnTradeTransaction* allows for a more efficient use of resources by calling the algorithm only when appropriate.

The *ExecutionCount* counter is output to the log when the Expert Advisor is unloaded.

```
void OnDeinit(const int r)
{
   Print("ExecutionCount = ", ExecutionCount);
}
```

Now, finally, let's introduce the *RunStrategy* function. The promised counter is incremented at the very beginning.

```
void RunStrategy()
{
   ExecutionCount++;
   ...
```

Next, two arrays are described for receiving order tickets and their statuses from the *orders* filter object.

```
   ulong tickets[];
   ulong states[];
```

To begin with, we will request orders that fall under our conditions. If there are two of them, everything is fine, and nothing needs to be done.

```
   orders.select(ORDER_STATE, tickets, states);
   const int n = ArraySize(tickets);
   if(n == 2) return; // OK - standard state
   ...
```

If one order remains, then the other one was triggered and the remaining one must be deleted.

```
      if(n > 0)          // 1 or 2+ orders is an error, you need to delete everything
      {
         // delete all matching orders, except for partially filled ones
         MqlTradeRequestSyncOCO r;
         for(int i = 0; i < n; ++i)
         {
            if(states[i] != ORDER_STATE_PARTIAL)
            {
               r.remove(tickets[i]) && r.completed();
            }
         }
      }
      ...
```

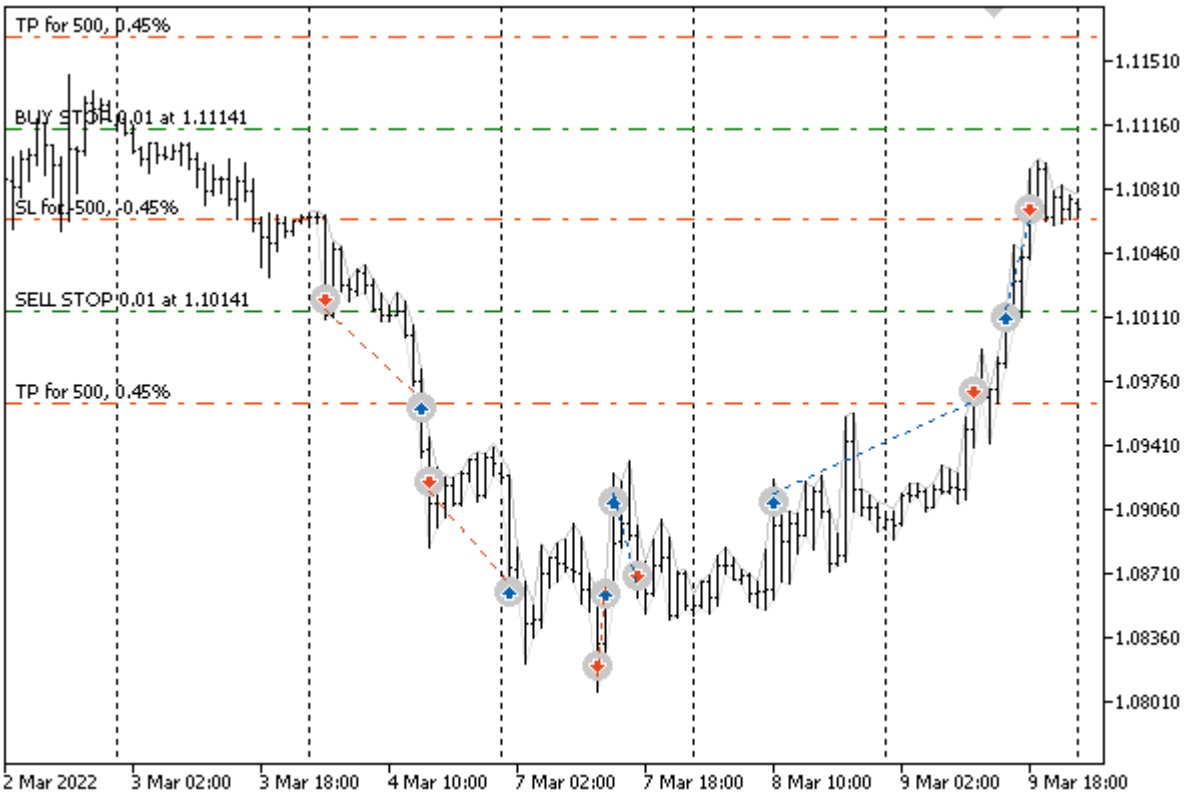
Otherwise, there are no orders. Therefore, you need to check if there is an open position: for this, we use another *trades* filter object but the results are added to the same receiving array *tickets*. If there is no position, we place a new pair of orders.

```
      else // n == 0
      {
         // if there are no open positions, place 2 orders
         if(!trades.select(tickets))
         {
            MqlTradeRequestSyncOCO r;
            SymbolMonitor sm(_Symbol);

            const double point = sm.get(SYMBOL_POINT);
            const double lot = Volume == 0 ? sm.get(SYMBOL_VOLUME_MIN) : Volume;
            const double buy = sm.get(SYMBOL_BID) + point * Distance2SLTP;
            const double sell = sm.get(SYMBOL_BID) - point * Distance2SLTP;

            r.buyStop(lot, buy, buy - Distance2SLTP * point,
               buy + Distance2SLTP * point) && r.completed();
            r.sellStop(lot, sell, sell + Distance2SLTP * point,
               sell - Distance2SLTP * point) && r.completed();
         }
      }
   }
```

Let's run the Expert Advisor in the tester with default settings, on the EURUSD pair. The following image shows the testing process.



Expert Advisor with a pair of pending stop orders based on the OCO strategy in the tester

At the stage of placing a pair of orders, we will see the following entries in the log.

```
buy stop 0.01 EURUSD at 1.11151 sl: 1.10651 tp: 1.11651 (1.10646 / 1.10683)
sell stop 0.01 EURUSD at 1.10151 sl: 1.10651 tp: 1.09651 (1.10646 / 1.10683)
OnTradeTransaction(1)
TRADE_TRANSACTION_ORDER_ADD, #=2(ORDER_TYPE_BUY_STOP/ORDER_STATE_PLACED), ORDER_TIME_
   » @ 1.11151, SL=1.10651, TP=1.11651, V=0.01
OnTrade(1)
OnTradeTransaction(2)
TRADE_TRANSACTION_REQUEST
OnTradeTransaction(3)
TRADE_TRANSACTION_ORDER_ADD, #=3(ORDER_TYPE_SELL_STOP/ORDER_STATE_PLACED), ORDER_TIME

OnTrade(7)
OnTradeTransaction(10)
TRADE_TRANSACTION_REQUEST
```

Order #3 was deleted by itself, and order #2 was deleted (canceled) by our Expert Advisor.

If we run the Expert Advisor with only the mode of operation through the *OnTrade* event changed in settings, we should get completely similar financial results (ceteris paribus, that is, for example, if random delays in tick generation are not included). The only thing that will be different is the number of *RunStrategy* function calls. For example, for 4 months of 2022 on EURUSD, H1 with 88 trades, we will get the following approximate metrics of *ExecutionCount* (what matters is the ratio, not the absolute values associated with your broker's ticks):

- OnTradeTransaction – 132
- OnTrade – 438

This is a practical proof of the possibility of building more selective algorithms based on *OnTradeTransaction* compared with *OnTrade*.

This *OCO2.mq5* Expert Advisor version reacts to actions with orders and positions quite straightforwardly. In particular, as soon as the previous position is closed by stop loss or take profit, it will place two new orders. If you delete one of the orders manually, the Expert Advisor will immediately delete the second one and then recreate a new pair with an offset from the current price. You can improve the behavior by embedding a schedule similar to what is done in the grid Expert Advisor and not reacting to canceled orders in the history (although, please note that MQL5 does not provide means for finding out whether an order was canceled manually or programmatically). We will present a different direction for improving this Expert Advisor when exploring the economic calendar API.

In addition, an interesting mode is already available in the current version, related to setting the expiration date for pending orders in the input variable *Expiration*. If a pair of orders does not trigger,

then, immediately after their expiration, a new pair is placed relative to the changed new current price. As an independent exercise, you can try to optimize the Expert Advisor in the tester by changing *Expiration* and *Distance2SLTP*. Programmatic work with the tester, including in the optimization mode, will be covered in the next chapter.

Below is one of the setting options (*Distance2SLTP=250*, *Expiration=5000*) found over a period of 16 months from the beginning of 2021 for the EURUSD pair.

6.4.37 Monitoring trading environment changes

In the previous section related to the *OnTrade* event, we mentioned that some trading strategy programming approaches may require you to take snapshots of the environment and compare them with each other over time. This is a common practice when using *OnTrade* but it can also be activated on a schedule, on every bar, or even tick. Our monitor classes that can read the properties of orders, deals, and positions lacked the ability to save the state. In this section, we will present one of the trading environment caching options.

The properties of all trading objects are divided by types into three groups: integer, real, and string. Each object class has its own groups (for example, for orders, integer properties are described in the ENUM_ORDER_PROPERTY_INTEGER enumeration, and for positions they are described in ENUM_POSITION_PROPERTY_INTEGER), but the essence of division is the same. Therefore, we will introduce the PROP_TYPE enumeration, with the help of which it will be possible to describe to which type an object property belongs. This generalization comes up naturally since the mechanisms for storing and processing properties of the same type should be the same, regardless of whether the property belongs to an order, position, or deal.

```
enum PROP_TYPE
{
   PROP_TYPE_INTEGER,
   PROP_TYPE_DOUBLE,
   PROP_TYPE_STRING,
};
```

Arrays are the simplest way to store property values. Obviously, due to the presence of three base types, we will need three different arrays. Let's describe them inside a new class *TradeState* nested in *MonitorInterface* (*TradeBaseMonitor.mqh*).

The basic template *MonitorInterface<I,D,S>* forms the basis of all applied monitor classes (*OrderMonitor*, *DealMonitor*, *PositionMonitor*). Types I, D, and S here correspond to concrete enumerations of integer, real, and string properties.

It is quite logical to include the storage mechanism in the base monitor, especially since the created property cache will be filled with data by reading properties from the monitor object.

```
template<typename I,typename D,typename S>
class MonitorInterface
{
   ...
   class TradeState
   {
   public:
      ...
      long ulongs[];
      double doubles[];
      string strings[];
      const MonitorInterface *owner;

      TradeState(const MonitorInterface *ptr) : owner(ptr)
      {
         ...
      }
   };
```

The entire *TradeState* class has been made public because its fields would need to be accessed from the parent monitor object (which is passed as a pointer to the constructor), and besides *TradeState* will be used only in the protected part of the monitor (they cannot be reached from the outside).

In order to fill three arrays with property values of three different types, you must first find out the distribution of properties by type and indexes in each particular array.

For each trading object type (orders, deals, and positions), the identifiers of the 3 corresponding enumerations with properties of different types do not intersect and form a continuous numbering. Let's demonstrate this.

In the Enumerations chapter, we considered the script *ConversionEnum.mq5* which implements the *process* function to log all elements of a particular enumeration. That script examined the ENUM_APPLIED_PRICE enum. Now we can create a copy of the script and analyze the other three enumerations. For example, like this:

```
void OnStart()
{
   process((ENUM_POSITION_PROPERTY_INTEGER)0);
   process((ENUM_POSITION_PROPERTY_DOUBLE)0);
   process((ENUM_POSITION_PROPERTY_STRING)0);
}
```

As a result of its execution, we get the following log. The left column contains the numbering inside the enumerations, and the values on the right (after the '=' sign) are the built-in constants (identifiers) of the elements.

```
ENUM_POSITION_PROPERTY_INTEGER Count=9
0 POSITION_TIME=1
1 POSITION_TYPE=2
2 POSITION_MAGIC=12
3 POSITION_IDENTIFIER=13
4 POSITION_TIME_MSC=14
5 POSITION_TIME_UPDATE=15
6 POSITION_TIME_UPDATE_MSC=16
7 POSITION_TICKET=17
8 POSITION_REASON=18
ENUM_POSITION_PROPERTY_DOUBLE Count=8
0 POSITION_VOLUME=3
1 POSITION_PRICE_OPEN=4
2 POSITION_PRICE_CURRENT=5
3 POSITION_SL=6
4 POSITION_TP=7
5 POSITION_COMMISSION=8
6 POSITION_SWAP=9
7 POSITION_PROFIT=10
ENUM_POSITION_PROPERTY_STRING Count=3
0 POSITION_SYMBOL=0
1 POSITION_COMMENT=11
2 POSITION_EXTERNAL_ID=19
```

For example, the property with a constant of 0 is a string POSITION_SYMBOL, the properties with constants 1 and 2 are integers POSITION_TIME and POSITION_TYPE, the property with a constant of 3 is a real POSITION_VOLUME, and so on.

Thus, constants are a system of end-to-end indexes on properties of all types, and we can use the same algorithm (based on *EnumToArray.mqh*) to get them.

For each property, you need to remember its type (which determines which of the three arrays will store the value) and the serial number among the properties of the same type (this will be the index of the element in the corresponding array). For example, we see that positions have only 3 string properties, so the *strings* array in the snapshot of one position will have to have the same size, and POSITION_SYMBOL (0), POSITION_COMMENT (11), and POSITION_EXTERNAL_ID (19) will be written to its indexes 0, 1, and 2.

The conversion of end-to-end indexes of properties into their type (one of PROP_TYPE) and into an ordinal number in an array of the corresponding type can be done once at the start of the program since enumerations with properties are constant (built into the system). We write the resulting indirect addressing table into a static two-dimensional *indices* array. Its size in the first dimension will be

dynamically determined as the total number of properties (of all 3 types). We will write the size into the *limit* static variable. A couple of cells are allocated for the second dimension: *indices[i][0]* – type PROP_TYPE, *indices[i][1]* – index in one of the arrays *ulongs*, *doubles*, or *strings* (depending on *indices[i][0]*).

```
class TradeState
{
   ...
   static int indices[][2];
   static int j, d, s;
public:
   const static int limit;

   static PROP_TYPE type(const int i)
   {
      return (PROP_TYPE)indices[i][0];
   }

   static int offset(const int i)
   {
      return indices[i][1];
   }
   ...
```

Variables *j*, *d*, and *s* will be used to sequentially index properties within each of the 3 different types. Here's how it's done in the static method *calcIndices*.

```
static int calcIndices()
{
   const int size = fmax(boundary<I>(),
      fmax(boundary<D>(), boundary<S>())) + 1;
   ArrayResize(indices, size);
   j = d = s = 0;
   for(int i = 0; i < size; ++i)
   {
      if(detect<I>(i))
      {
         indices[i][0] = PROP_TYPE_INTEGER;
         indices[i][1] = j++;
      }
      else if(detect<D>(i))
      {
         indices[i][0] = PROP_TYPE_DOUBLE;
         indices[i][1] = d++;
      }
      else if(detect<S>(i))
      {
         indices[i][0] = PROP_TYPE_STRING;
         indices[i][1] = s++;
      }
      else
      {
         Print("Unresolved int value as enum: ", i, " ", typename(TradeState));
      }
   }
   return size;
}
```

The *boundary* method returns the maximum constant among all elements of the given enumeration E.

```
template<typename E>
static int boundary(const E dummy = (E)NULL)
{
   int values[];
   const int n = EnumToArray(dummy, values, 0, 1000);
   ArraySort(values);
   return values[n - 1];
}
```

The largest value of all three types of enumerations determines the range of integers that should be sorted in accordance with the property type to which they belong.

Here we use the *detect* method which returns *true* if the integer is an element of an enumeration.

```
   template<typename E>
   static bool detect(const int v)
   {
      ResetLastError();
      const string s = EnumToString((E)v); // result is not used
      if(_LastError == 0) // only the absence of an error is important
      {
         return true;
      }
      return false;
   }
```

The last question is how to run this calculation when the program starts. This is achieved by utilizing the static nature of the variables and the method.

```
template<typename I,typename D,typename S>
static int MonitorInterface::TradeState::indices[][2];
template<typename I,typename D,typename S>
static int MonitorInterface::TradeState::j,
   MonitorInterface::TradeState::d,
   MonitorInterface::TradeState::s;
template<typename I,typename D,typename S>
const static int MonitorInterface::TradeState::limit =
   MonitorInterface::TradeState::calcIndices();
```

Note that *limit* is initialized by the result of calling our *calcIndices* function.

Having a table with indexes, we implement the filling of arrays with property values in the *cache* method.

```
class TradeState
{
   ...
   TradeState(const MonitorInterface *ptr) : owner(ptr)
   {
      cache(); // when creating an object, immediately cache the properties
   }

   template<typename T>
   void _get(const int e, T &value) const // overload with record by reference
   {
      value = owner.get(e, value);
   }

   void cache()
   {
      ArrayResize(ulongs, j);
      ArrayResize(doubles, d);
      ArrayResize(strings, s);
      for(int i = 0; i < limit; ++i)
      {
         switch(indices[i][0])
         {
         case PROP_TYPE_INTEGER: _get(i, ulongs[indices[i][1]]); break;
         case PROP_TYPE_DOUBLE: _get(i, doubles[indices[i][1]]); break;
         case PROP_TYPE_STRING: _get(i, strings[indices[i][1]]); break;
         }
      }
   }
};
```

We loop through the entire range of properties from 0 to *limit* and, depending on the property type in *indices[i][0]*, write its value to the element of the *ulongs*, *doubles*, or *strings* array under the number *indices[i][1]* (the corresponding element of the array is passed by reference to the *_get* method).

A call of *owner.get(e, value)* refers to one of the standard methods of the monitor class (here it is visible as an abstract pointer *MonitorInterface*). In particular, for positions in the *PositionMonitor* class, this will lead to *PositionGetInteger*, *PositionGetDouble,* or *PositionGetString* calls. The compiler will choose the correct type. Order and deal monitors have their own similar implementations, which are automatically included by this base code.

It is logical to inherit the description of a snapshot of one trading object from the monitor class. Since we have to cache orders, deals, and positions, it makes sense to make the new class a template and collect all common algorithms suitable for all objects in it. Let's call it *TradeBaseState* (file*TradeState.mqh*).

```
template<typename M,typename I,typename D,typename S>
class TradeBaseState: public M
{
   M::TradeState state;
   bool cached;

public:
   TradeBaseState(const ulong t) : M(t), state(&this), cached(ready)
   {
   }

   void passthrough(const bool b)   // enable/disable cache as desired
   {
      cached = b;
   }
   ...
```

One of the specific monitor classes described earlier is hidden under the letter M (*OrderMonitor.mqh*, *PositionMonitor.mqh*, *DealMonitor.mqh*). The basis is the *state* caching object of the newly introduced *M::TradeState* class. Depending on M, a specific index table will be formed inside (one for class M) and arrays of properties will be distributed (own for each instance of M, that is, for each order, deal, position).

The *cached* variable contains a sign of whether the arrays in the *state* are filled with property values, and whether to query properties on an object to return values from the cache. This will be required later to compare the saved and current states.

In other words, when *cached* is set to *false*, the object will behave like a regular monitor, reading properties from the trading environment. When *cached* equals *true*, the object will return previously stored values from internal arrays.

```
   virtual long get(const I property) const override
   {
      return cached ? state.ulongs[M::TradeState::offset(property)] : M::get(property
   }

   virtual double get(const D property) const override
   {
      return cached ? state.doubles[M::TradeState::offset(property)] : M::get(propert
   }

   virtual string get(const S property) const override
   {
      return cached ? state.strings[M::TradeState::offset(property)] : M::get(propert
   }
   ...
```

By default, caching is, of course, enabled.

We must also provide a method that directly performs caching (filling arrays). To do this, just call the *cache* method for the *state* object.

```
bool update()
{
   if(refresh())
   {
      cached = false; // disable reading from the cache
      state.cache();  // read real properties and write to cache
      cached = true;  // enable external cache access back
      return true;
   }
   return false;
}
```

What is the *refresh* method?

So far, we have been using monitor objects in simple mode: creating, reading properties, and deleting them. At the same time, property reading assumes that the corresponding order, deal, or position was selected in the trading context (inside the constructor). Since we are now improving monitors to support the internal state, it is necessary to ensure that the desired element is re-allocated in order to read the properties even after an indefinite time (of course, with a check that the element still exists). To implement this, we have added the *refresh* virtual method to the template *MonitorInterface* class.

```
// TradeBaseMonitor.mqh
template<typename I,typename D,typename S>
class MonitorInterface
{
   ...
   virtual bool refresh() = 0;
```

It must return *true* upon successful allocation of an order, deal, or position. If the result is *false*, one of the following errors should be contained in the built-in *_LastError* variable:

- 4753 ERR_TRADE_POSITION_NOT_FOUND;
- 4754 ERR_TRADE_ORDER_NOT_FOUND;
- 4755 ERR_TRADE_DEAL_NOT_FOUND;

In this case, the *ready* member variable, which signals the availability of the object, must be reset to *false* in implementations of this method in derived classes.

For example, in the *PositionMonitor* constructor, we had and still have such an initialization. The situation is similar to order and deal monitors.

```
// PositionMonitor.mqh
   const ulong ticket;
   PositionMonitor(const ulong t): ticket(t)
   {
      if(!PositionSelectByTicket(ticket))
      {
         PrintFormat("Error: PositionSelectByTicket(%lld) failed: %s", ticket,
            E2S(_LastError));
      }
      else
      {
         ready = true;
      }
   }
   ...
```

Now we will add the *refresh* method to all specific classes of this kind (see example *PositionMonitor*):

```
// PositionMonitor.mqh
   virtual bool refresh() override
   {
      ready = PositionSelectByTicket(ticket);
      return ready;
   }
```

But populating cache arrays with property values is only half the battle. The second half is to compare these values with the actual state of the order, deal, or position.

To identify differences and write indexes of changed properties to the *changes* array, the generated *TradeBaseState* class provides the *getChanges* method. The method returns *true* when changes are detected.

```
template<typename M,typename I,typename D,typename S>
class TradeBaseState: public M
{
   ...
   bool getChanges(int &changes[])
   {
      const bool previous = ready;
      if(refresh())
      {
         // element is selected in the trading environment = properties can be read a
         cached = false;    // read directly
         const bool result = M::diff(state, changes);
         cached = true;     // turn cache back on by default
         return result;
      }
      // no longer "ready" = most likely deleted
      return previous != ready; // if just deleted, this is also a change
   }
```

As you can see, the main work is entrusted to a certain method *diff* in class M. This is a new method: we need to write it. Fortunately, thanks to OOP, you can do this once in the base template *MonitorInterface*, and the method will appear immediately for orders, deals, and positions.

```
// TradeBaseMonitor.mqh
template<typename I,typename D,typename S>
class MonitorInterface
{
   ...
   bool diff(const TradeState &that, int &changes[])
   {
      ArrayResize(changes, 0);
      for(int i = 0; i < TradeState::limit; ++i)
      {
         switch(TradeState::indices[i][0])
         {
         case PROP_TYPE_INTEGER:
            if(this.get((I)i) != that.ulongs[TradeState::offset(i)])
            {
               PUSH(changes, i);
            }
            break;
         case PROP_TYPE_DOUBLE:
            if(!TU::Equal(this.get((D)i), that.doubles[TradeState::offset(i)]))
            {
               PUSH(changes, i);
            }
            break;
         case PROP_TYPE_STRING:
            if(this.get((S)i) != that.strings[TradeState::offset(i)])
            {
               PUSH(changes, i);
            }
            break;
         }
      }
      return ArraySize(changes) > 0;
   }
```

So, everything is ready to form specific caching classes for orders, deals, and positions. For example, positions will be stored in the extended monitor *PositionState* on the base of *PositionMonitor*.

```
class PositionState: public TradeBaseState<PositionMonitor,
   ENUM_POSITION_PROPERTY_INTEGER,
   ENUM_POSITION_PROPERTY_DOUBLE,
   ENUM_POSITION_PROPERTY_STRING>
{
public:
   PositionState(const long t): TradeBaseState(t) { }
};
```

Similarly, a caching class for deals is defined in the file *TradeState.mqh*.

```
class DealState: public TradeBaseState<DealMonitor,
   ENUM_DEAL_PROPERTY_INTEGER,
   ENUM_DEAL_PROPERTY_DOUBLE,
   ENUM_DEAL_PROPERTY_STRING>
{
public:
   DealState(const long t): TradeBaseState(t) { }
};
```

With orders, things are a little more complicated, because they can be active and historical. So far we have had one generic monitor class for orders, *OrderMonitor*. It tries to find the submitted order ticket both among the active orders and in the history. This approach is not suitable for caching, because Expert Advisors need to track the transition of an order from one state to another.

For this reason, we add 2 more specific classes to the *OrderMonitor.mqh* file: *ActiveOrderMonitor* and *HistoryOrderMonitor*.

```
// OrderMonitor.mqh
class ActiveOrderMonitor: public OrderMonitor
{
public:
   ActiveOrderMonitor(const ulong t): OrderMonitor(t)
   {
      if(history) // if the order is in history, then it is already inactive
      {
         ready = false;   // reset ready flag
         history = false; // this object is only for active orders by definition
      }
   }

   virtual bool refresh() override
   {
      ready = OrderSelect(ticket);
      return ready;
   }
};

class HistoryOrderMonitor: public OrderMonitor
{
public:
   HistoryOrderMonitor(const ulong t): OrderMonitor(t) { }

   virtual bool refresh() override
   {
      history = true; // work only with history
      ready = historyOrderSelectWeak(ticket);
      return ready; // readiness is determined by the presence of a ticket in the his
   }
};
```

Each of them searches for a ticket only in their area. Based on these monitors, you can already create caching classes.

```
                                                                    // TradeState.mqh
class OrderState: public TradeBaseState<ActiveOrderMonitor,
   ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,
   ENUM_ORDER_PROPERTY_STRING>
{
public:
   OrderState(const long t): TradeBaseState(t) { }
};

class HistoryOrderState: public TradeBaseState<HistoryOrderMonitor,
   ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,
   ENUM_ORDER_PROPERTY_STRING>
{
public:
   HistoryOrderState(const long t): TradeBaseState(t) { }
};
```

The final touch that we will add to the *TradeBaseState* class for convenience is a special method for converting a property value to a string. Although there are several versions of the *stringify* methods in the monitor, they will all "print" either values from the cache (if the member variable *cached* equals *true*) or values from the original object of the trading environment (if *cached* equals *false*). To visualize the differences between the cache and the changed object (when these differences are found), we need to simultaneously read the value from the cache and bypass the cache. In this regard, we add the *stringifyRaw* method which always works with the property directly (due to the fact that the *cached* variable is temporarily reset and reinstalled).

```
   // get the string representation of the property 'i' bypassing the cache
   string stringifyRaw(const int i)
   {
      const bool previous = cached;
      cached = false;
      const string s = stringify(i);
      cached = previous;
   }
```

Let's check the performance of the caching monitor using a simple example of an Expert Advisor that monitors the status of an active order (*OrderSnapshot.mq5*). Later we will develop this idea for caching any set of orders, deals, or positions, that is, we will create a full-fledged cache.

The Expert Advisor will try to find the last one in the list of active orders and create the *OrderState* object for it. If there are no orders, the user will be prompted to create an order or open a position (the latter is associated with placing and executing an order on the market). As soon as an order is found, we check if the order state has changed. This check is performed in the *OnTrade* handler. The Expert Advisor will continue to monitor this order until it is unloaded.

```
int OnInit()
{
   if(OrdersTotal() == 0)
   {
      Alert("Please, create a pending order or open/close a position");
   }
   else
   {
      OnTrade(); // self-invocation
   }
   return INIT_SUCCEEDED;
}

void OnTrade()
{
   static int count = 0;
   // object pointer is stored in static AutoPtr
   static AutoPtr<OrderState> auto;
   // get a "clean" pointer (so as not to dereference auto[] everywhere)
   OrderState *state = auto[];

   PrintFormat(">>> OnTrade(%d)", count++);

   if(OrdersTotal() > 0 && state == NULL)
   {
      const ulong ticket = OrderGetTicket(OrdersTotal() - 1);
      auto = new OrderState(ticket);
      PrintFormat("Order picked up: %lld %s", ticket,
         auto[].isReady() ? "true" : "false");
      auto[].print(); // initial state at the time of "capturing" the order
   }
   else if(state)
   {
      int changes[];
      if(state.getChanges(changes))
      {
         Print("Order properties changed:");
         ArrayPrint(changes);
         ...
      }
      if(_LastError != 0) Print(E2S(_LastError));
   }
}
```

In addition to displaying an array of changed properties, it would be nice to display the changes themselves. Therefore, instead of an ellipsis, we will add such a fragment (it will be useful to us in future classes of full-fledged caches).

```
for(int k = 0; k < ArraySize(changes); ++k)
{
   switch(OrderState::TradeState::type(changes[k]))
   {
   case PROP_TYPE_INTEGER:
      Print(EnumToString((ENUM_ORDER_PROPERTY_INTEGER)changes[k]), ": ",
         state.stringify(changes[k]), " -> ",
         state.stringifyRaw(changes[k]));
         break;
   case PROP_TYPE_DOUBLE:
      Print(EnumToString((ENUM_ORDER_PROPERTY_DOUBLE)changes[k]), ": ",
         state.stringify(changes[k]), " -> ",
         state.stringifyRaw(changes[k]));
         break;
   case PROP_TYPE_STRING:
      Print(EnumToString((ENUM_ORDER_PROPERTY_STRING)changes[k]), ": ",
         state.stringify(changes[k]), " -> ",
         state.stringifyRaw(changes[k]));
         break;
   }
}
```

Here we use the new *stringifyRaw* method. After displaying the changes, do not forget to update the cache state.

```
state.update();
```

If you run the Expert Advisor on an account with no active orders and place a new one, you will see the following entries in the log (here *buy limit* for EURUSD is created below the current market price).

```
Alert: Please, create a pending order or open/close a position
>>> OnTrade(0)
Order picked up: 1311736135 true
MonitorInterface<ENUM_ORDER_PROPERTY_INTEGER,ENUM_ORDER_PROPERTY_DOUBLE,ENUM_ORDER_PR
ENUM_ORDER_PROPERTY_INTEGER Count=14

  2 ORDER_PRICE_OPEN=1.087
  3 ORDER_PRICE_CURRENT=1.087
  4 ORDER_PRICE_STOPLIMIT=0.0
  5 ORDER_SL=0.0
  6 ORDER_TP=0.0
ENUM_ORDER_PROPERTY_STRING Count=3
  0 ORDER_SYMBOL=EURUSD
  1 ORDER_COMMENT=
  2 ORDER_EXTERNAL_ID=
>>> OnTrade(1)
Order properties changed:
10 14
ORDER_PRICE_CURRENT: 1.087 -> 1.09073
ORDER_STATE: ORDER_STATE_STARTED -> ORDER_STATE_PLACED
>>> OnTrade(2)
>>> OnTrade(3)
>>> OnTrade(4)
```

Here you can see how the status of the order changed from STARTED to PLACED. If, instead of a pending order, we opened on the market with a small volume, we might not have time to receive these changes, because such orders, as a rule, are set very quickly, and their observed status changes from STARTED immediately to FILLED. And the latter already means that the order has been moved to history. Therefore, parallel history monitoring is required to track them. We will show this in the next example.

Please note that there may be many *OnTrade* events but not all of them are related to our order.

Let's try to set the *Take Profit* level and check the log.

```
>>> OnTrade(5)
Order properties changed:
10 13
ORDER_PRICE_CURRENT: 1.09073 -> 1.09079
ORDER_TP: 0.0 -> 1.097
>>> OnTrade(6)
>>> OnTrade(7)
```

Next, change the expiration date: from GTC to one day.

```
>>> OnTrade(8)
Order properties changed:
10
ORDER_PRICE_CURRENT: 1.09079 -> 1.09082
>>> OnTrade(9)
>>> OnTrade(10)
Order properties changed:
2 6
ORDER_TIME_EXPIRATION: 1970.01.01 00:00:00 -> 2022.04.11 00:00:00
ORDER_TYPE_TIME: ORDER_TIME_GTC -> ORDER_TIME_DAY
>>> OnTrade(11)
```

Here, in the process of changing our order, the price had enough time to change, and therefore we "hooked" an intermediate notification about the new value in ORDER_PRICE_CURRENT. And only after that, the expected changes in ORDER_TYPE_TIME and ORDER_TIME_EXPIRATION got into the log.

Next, we removed the order.

```
>>> OnTrade(12)
TRADE_ORDER_NOT_FOUND
```

Now for any actions with the account that lead to *OnTrade* events, our Expert Advisor will output TRADE_ORDER_NOT_FOUND, because it is designed to track a single order. If the Expert Advisor is restarted, it will "catch" another order if there is one. But we will stop the Expert Advisor and start preparing for a more urgent task.

As a rule, caching and controlling changes is required not for a single order or position, but for all or a set of them, selected according to certain conditions. For these purposes, we will develop a base template class *TradeCache* (*TradeCache.mqh*) and, based on it, we will create applied classes for lists of orders, deals, and positions.

```
template<typename T,typename F,typename E>
class TradeCache
{
   AutoPtr<T> data[];
   const E property;
   const int NOT_FOUND_ERROR;

public:
   TradeCache(const E id, const int error): property(id), NOT_FOUND_ERROR(error) { }

   virtual string rtti() const
   {
      return typename(this); // will be redefined in derived classes for visual outpu
   }
   ...
```

In this template, the letter T denotes one of the classes of the *TradeState* family. As you can see, an array of such objects in the form of auto-pointers is reserved under the name *data*.

The letter F describes the type of one of the filter classes (*OrderFilter.mqh*, including *HistoryOrderFilter*, *DealFilter.mqh*, *PositionFilter.mqh*) used to select cached items. In the simplest case, when the filter does not contain *let* conditions, all elements will be cached (with respect to sampling history for objects from history).

The letter E corresponds to the enumeration in which the *property* identifying the objects is located. Since this property is usually SOME_TICKET, the enumeration is assumed to be an integer ENUM_SOMETHING_PROPERTY_INTEGER.

The NOT_FOUND_ERROR variable is intended for the error code that occurs when trying to allocate a non-existent object for reading, for example, ERR_TRADE_POSITION_NOT_FOUND for positions.

In parameters, the main class method *scan* receives a reference to the configured filter (it should be configured by the calling code).

```
   void scan(F &f)
   {
      const int existedBefore = ArraySize(data);

      ulong tickets[];
      ArrayResize(tickets, existedBefore);
      for(int i = 0; i < existedBefore; ++i)
      {
         tickets[i] = data[i][].get(property);
      }
      ...
```

At the beginning of the method, we collect the identifiers of already cached objects into the *tickets* array. Obviously, on the first run, it will be empty.

Next, we fill the *objects* array with tickets of relevant objects using a filter. For each new ticket, we create a caching monitor object T and add it to the *data* array. For old objects, we analyze the presence of changes by calling *data[j][].getChanges(changes)* and then update the cache by calling *data[j][].update()*.

```
      ulong objects[];
      f.select(objects);
      for(int i = 0, j; i < ArraySize(objects); ++i)
      {
         const ulong ticket = objects[i];
         for(j = 0; j < existedBefore; ++j)
         {
            if(tickets[j] == ticket)
            {
               tickets[j] = 0; // mark as found
               break;
            }
         }

         if(j == existedBefore) // this is not in the cache, you need to add
         {
            const T *ptr = new T(ticket);
            PUSH(data, ptr);
            onAdded(*ptr);
         }
         else
         {
            ResetLastError();
            int changes[];
            if(data[j][].getChanges(changes))
            {
               onUpdated(data[j][], changes);
               data[j][].update();
            }
            if(_LastError) PrintFormat("%s: %lld (%s)", rtti(), ticket, E2S(_LastErro
         }
      }
      ...
```

As you can see, in each phase of the change, that is, when an object is added or after it is changed, the *onAdded* and *onUpdated* methods are called. These are virtual stub methods that the scan can use to notify the program of the appropriate events. Application code is expected to implement a derived class with overridden versions of these methods. We will touch on this issue a little later, but for now, we will continue to consider the method *scan*.

In the above loop, all found tickets in the *tickets* array are set to zero, and therefore the remaining elements correspond to the missing objects of the trading environment. Next, they are checked by calling *getChanges* and comparing the error code with NOT_FOUND_ERROR. If this is true, the *onRemoved* virtual method is called. It returns a boolean flag (provided by your application code) saying whether the item should be removed from the cache.

```
      for(int j = 0; j < existedBefore; ++j)
      {
         if(tickets[j] == 0) continue; // skip processed elements

         // this ticket was not found, most likely deleted
         int changes[];
         ResetLastError();
         if(data[j][].getChanges(changes))
         {
            if(_LastError == NOT_FOUND_ERROR) // for example, ERR_TRADE_POSITION_NOT_FOUND
            {
               if(onRemoved(data[j][]))
               {
                  data[j] = NULL;              // release the object and array element
               }
               continue;
            }

            // NB! Usually we shouldn't fall here
            PrintFormat("Unexpected ticket: %lld (%s) %s", tickets[j],
               E2S(_LastError), rtti());
            onUpdated(data[j][], changes, true);
            data[j][].update();
         }
         else
         {
            PrintFormat("Orphaned element: %lld (%s) %s", tickets[j],
               E2S(_LastError), rtti());
         }
      }
   }
```

At the very end of the *scan* method, the *data* array is cleared of null elements but this fragment is omitted here for brevity.

The base class provides standard implementations of the *onAdded*, *onRemoved*, and *onUpdated* methods which display the essence of events in the log. By defining the PRINT_DETAILS macro in your code before including the header file *TradeCache.mqh*, you can order a printout of all the properties of each new object.

```
virtual void onAdded(const T &state)
{
   Print(rtti(), " added: ", state.get(property));
   #ifdef PRINT_DETAILS
   state.print();
   #endif
}

virtual bool onRemoved(const T &state)
{
   Print(rtti(), " removed: ", state.get(property));
   return true; // allow the object to be removed from the cache (false to save)
}

virtual void onUpdated(T &state, const int &changes[],
   const bool unexpected = false)
{
   ...
}
```

We will not present the *onUpdated* method, because it practically repeats the code for outputting changes from the Expert Advisor *OrderSnapshot.mq5* shown above.

Of course, the base class has facilities for getting the size of the cache and accessing a specific object by number.

```
int size() const
{
   return ArraySize(data);
}

T *operator[](int i) const
{
   return data[i][]; // return pointer (T*) from AutoPtr object
}
```

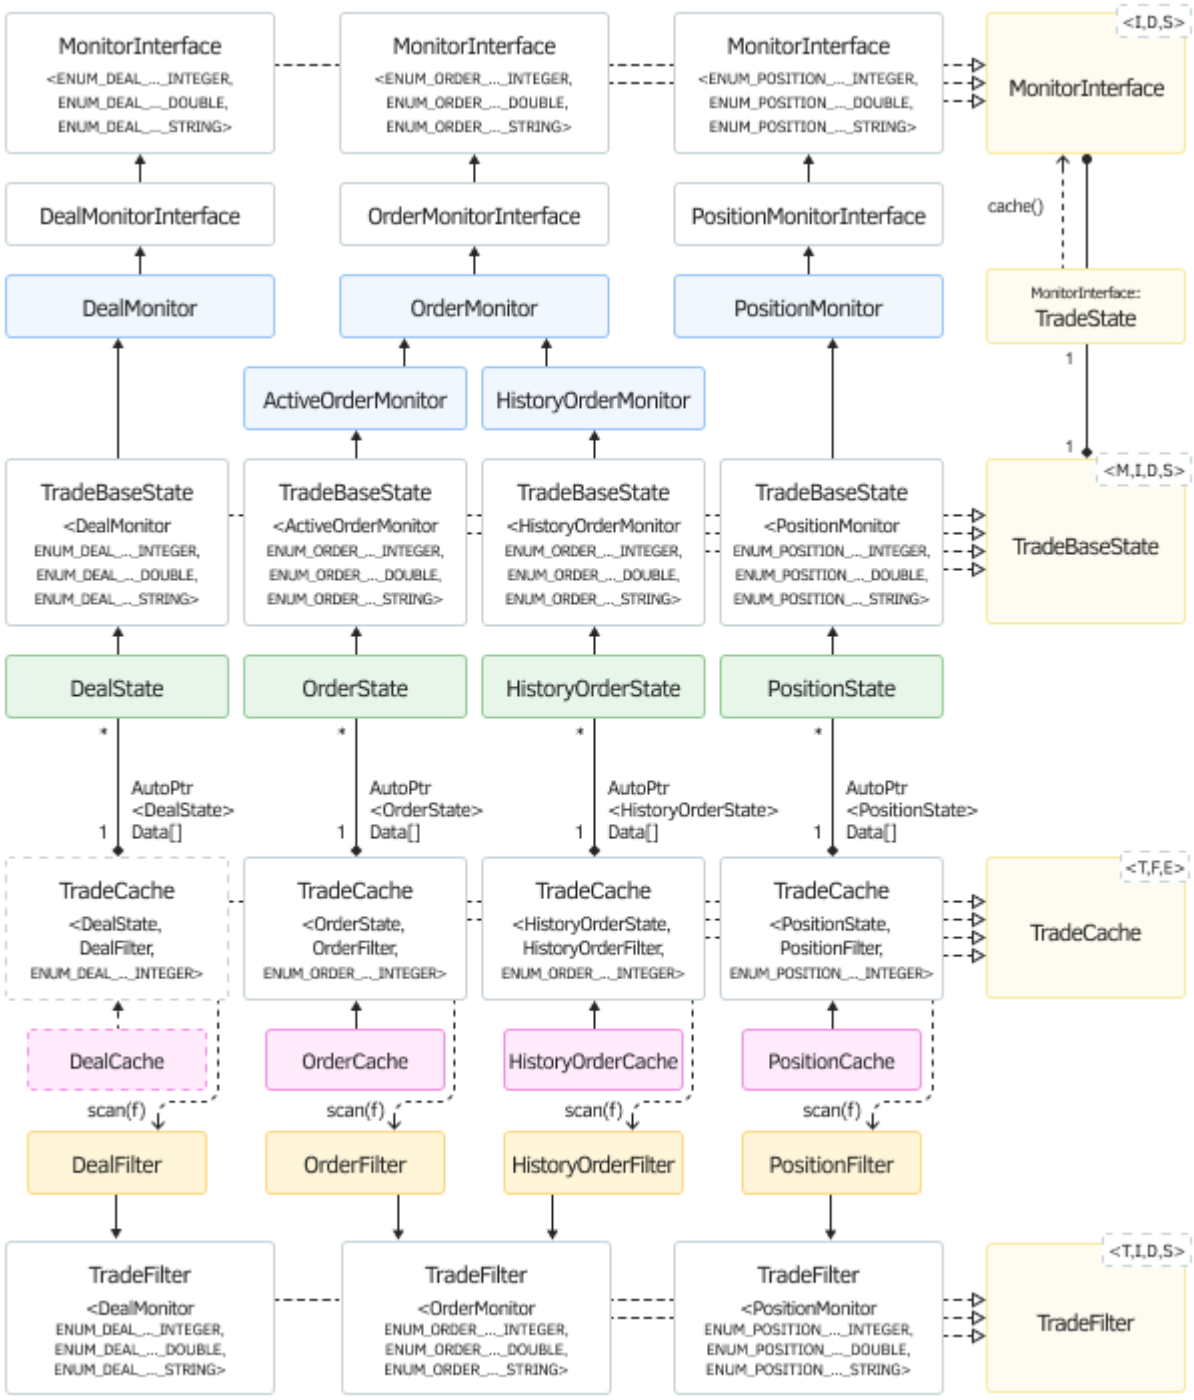
Based on the base *TradeCache* class, we can easily create certain classes for caching lists of positions, active orders, and orders from history. Deal caching is left as an independent task.

```
class PositionCache: public TradeCache<PositionState,PositionFilter,
   ENUM_POSITION_PROPERTY_INTEGER>
{
public:
   PositionCache(const ENUM_POSITION_PROPERTY_INTEGER selector = POSITION_TICKET,
      const int error = ERR_TRADE_POSITION_NOT_FOUND): TradeCache(selector, error) {
};

class OrderCache: public TradeCache<OrderState,OrderFilter,
   ENUM_ORDER_PROPERTY_INTEGER>
{
public:
   OrderCache(const ENUM_ORDER_PROPERTY_INTEGER selector = ORDER_TICKET,
      const int error = ERR_TRADE_ORDER_NOT_FOUND): TradeCache(selector, error) { }
};

class HistoryOrderCache: public TradeCache<HistoryOrderState,HistoryOrderFilter,
   ENUM_ORDER_PROPERTY_INTEGER>
{
public:
   HistoryOrderCache(const ENUM_ORDER_PROPERTY_INTEGER selector = ORDER_TICKET,
      const int error = ERR_TRADE_ORDER_NOT_FOUND): TradeCache(selector, error) { }
};
```

To summarize the process of developing the presented functionality, we present a diagram of the main classes. This is a simplified version of UML diagrams which can be useful when designing complex programs in MQL5.



Class diagram of monitors, filters, and caches of trading objects

Templates are marked in yellow, abstract classes are left in white, and certain implementations are shown in color. Solid arrows with filled tips indicate inheritance, and dotted arrows with hollow tips indicate template typing. Dotted arrows with open tips indicate the use of the specified methods of each other by classes. Connections with diamonds are a composition (inclusion of some objects into others).

As an example of using the cache, let's create an Expert Advisor *TradeSnapshot.mq5*, which will respond to any changes in the trading environment from the *OnTrade* handler. For filtering and caching, the code describes 6 objects, 2 (filter and cache) for each type of element: positions, active orders, and historical orders.

```
PositionFilter filter0;
PositionCache positions;

OrderFilter filter1;
OrderCache orders;

HistoryOrderFilter filter2;
HistoryOrderCache history;
```

No conditions are set for filters through the *let* method calls so that all discovered online objects will get into the cache. There is an additional setting for orders from the history.

Optionally, at startup, you can load past orders to the cache at a given history depth. This can be done via the *HistoryLookup* input variable. In this variable, you can select the last day, last week (by duration, not calendar), month (30 days), or year (360 days). By default, the past history is not loaded (more precisely, it is loaded only in 1 second). Since the macro PRINT_DETAILS is defined in the Expert Advisor, be careful with accounts with a large history: they can generate a large log if the period is not limited.

```
enum ENUM_HISTORY_LOOKUP
{
   LOOKUP_NONE = 1,
   LOOKUP_DAY = 86400,
   LOOKUP_WEEK = 604800,
   LOOKUP_MONTH = 2419200,
   LOOKUP_YEAR = 29030400,
   LOOKUP_ALL = 0,
};

input ENUM_HISTORY_LOOKUP HistoryLookup = LOOKUP_NONE;

datetime origin;
```

In the *OnInit* handler, we reset the caches (in case the Expert Advisor is restarted with new parameters), calculate the start date of the history in the *origin* variable, and call *OnTrade* for the first time.

```
int OnInit()
{
   positions.reset();
   orders.reset();
   history.reset();
   origin = HistoryLookup ? TimeCurrent() - HistoryLookup : 0;

   OnTrade(); // self start
   return INIT_SUCCEEDED;
}
```

The *OnTrade* handler is minimalistic as all the complexities are now hidden inside the classes.

```
void OnTrade()
{
   static int count = 0;

   PrintFormat(">>> OnTrade(%d)", count++);
   positions.scan(filter0);
   orders.scan(filter1);
   // make a history selection just before using the filter
   // inside the 'scan' method
   HistorySelect(origin, LONG_MAX);
   history.scan(filter2);
   PrintFormat(">>> positions: %d, orders: %d, history: %d",
      positions.size(), orders.size(), history.size());
}
```

Immediately after launching the Expert Advisor on a clean account, we will see the following message:

```
>>> OnTrade(0)
>>> positions: 0, orders: 0, history: 0
```

Let's try to execute the simplest test case: let's buy or sell on an "empty" account which has no open positions and pending orders. The log will record the following events (occurring almost instantly).

First, an active order will be detected.

```
>>> OnTrade(1)

```

Note that these modifications happened within the same call of *OnTrade*. In other words, while our program was analyzing the properties of the new order (by calling *orders.scan*), the order was processed by the terminal in parallel, and by the time the history was checked (by calling *history.scan*), it has already gone down in history. That is why it is listed both here and there according to the last line of this log fragment. This behavior is normal for multithreaded programs and should be taken into account when designing them. But it doesn't always have to be. Here we are simply drawing attention to it. When executing an MQL program quickly, this situation usually does not occur.

If we were to check the history first, and then the online orders, then at the first stage we could find that the order is not yet in the history, and at the second stage that the order is no longer online. That is, it could theoretically get lost for a moment. A more realistic situation is to skip an order in its active phase due to history synchronization, i.e., right away fix it for the first time in history.

Recall that MQL5 does not allow you to synchronize the trading environment as a whole, but only in parts:

- Among active orders, information is relevant for the order for which the *OrderSelect* or *OrderGetTicket* function has just been called
- Among the positions, the information is relevant for the position for which the function *PositionSelect*, *PositionSelectByTicket*, or *PositionGetTicket* has just been called
- For orders and transactions in the history, information is available in the context of the last call of *HistorySelect*, *HistorySelectByPosition*, *HistoryOrderSelect*, *HistoryDealSelect*

In addition, let's remind you that trade events (like any MQL5 events) are messages about changes that have occurred, placed in the queue, and retrieved from the queue in a delayed way, and not immediately at the time of the changes. Moreover, the *OnTrade* event occurs after the relevant *OnTradeTransaction* events.

Try different program configurations, debug, and generate detailed logs to choose the most reliable algorithm for your trading system.

Let's return to our log. On the next triggering of *OnTrade*, the situation has already been fixed: the cache of active orders has detected the deletion of the order. Along the way, the position cache saw an open position.

```
>>> OnTrade(2)

```

```
ENUM_ORDER_PROPERTY_STRING Count=3
  0 ORDER_SYMBOL=EURUSD
  1 ORDER_COMMENT=
  2 ORDER_EXTERNAL_ID=
>>> positions: 1, orders: 1, history: 2
```

There are already 2 orders in the history cache, but the position and active order caches that were analyzed before the history cache have not yet applied these changes.

But in the next *OnTrade* event, we see that the position is closed, and the market order has disappeared.

```
>>> OnTrade(9)
PositionCache removed: 1311792104
OrderCache removed: 1311796883
>>> positions: 0, orders: 0, history: 2
```

If we monitor caches on every tick (or once per second, but not only for OnTrade events), we will see changes in the ORDER_PRICE_CURRENT and POSITION_PRICE_CURRENT properties on the go. POSITION_PROFIT will also change.

Our classes do not have *persistence*, that is, they live only in RAM and do not know how to save and restore their state in any long-term storage, such as files. This means that the program may miss a change that happened between terminal sessions. If you need such functionality, you should implement it yourself. In the future, in Part 7 of the book, we will look at the built-in SQLite database support in MQL5, which provides the most efficient and convenient way to store the trading environment cache and similar tabular data.

6.4.38 Creating multi-symbol Expert Advisors

Until now, within the framework of the book, we have mainly analyzed examples of Expert Advisors trading on the current working symbol of the chart. However, MQL5 allows you to generate trade orders for any symbols of *Market Watch*, regardless of the working symbol of the chart.

In fact, many of the examples in the previous sections had an input parameter *symbol*, in which you can specify an arbitrary symbol. By default, there is an empty string, which is treated as the current symbol of the chart. So, we have already considered the following examples:

- *CustomOrderSend.mq5* in Sending a trade request
- *MarketOrderSend.mq5* in Buying and selling operations
- *MarketOrderSendMonitor.mq5* in Functions for reading the properties of active orders
- *PendingOrderSend.mq5* in Setting a pending order
- *PendingOrderModify.mq5* in Modifying a pending order
- *PendingOrderDelete.mq5* in Deleting a pending order

You can try to run these examples with a different symbol and make sure that trading operations are performed exactly the same as with the native one.

Moreover, as we saw in the description of *OnBookEven* and *OnTradeTransaction* events, they are universal and inform about changes in the trading environment concerning arbitrary symbols. But this is not true for the *OnTick* event which is only generated when there is a change in the new prices of the current symbol. Usually, this is not a problem, but high-frequency multicurrency trading requires some

additional technical steps to be taken, such as subscribing to *OnBookEvent* events for other symbols or setting a high-frequency timer. Another option to bypass this limitation in the form of a spy indicator *EventTickSpy.mq5* was presented in the section Generating custom events.

In the context of talking about the support of multi-symbol trading, it should be noted that a similar concept of multi-timeframe Expert Advisors is not entirely correct. Trading at new bar opening times is only a special case of grouping ticks by arbitrary periods, not necessarily standard ones. Of course, the analysis of the emergence of a new bar on a specific timeframe is simplified by the system core due to functions like *iTime(_Symbol, PERIOD_XX, 0)*, but this analysis is based on ticks anyway.

You can build virtual bars inside your Expert Advisor by the number of ticks (equivolume), by the range of prices (renko, range) and so on. In some cases, including for clarity, it makes sense to generate such "timeframes" explicitly outside the Expert Advisor, in the form of custom symbols. But this approach has its limitations: we will talk about them in the next part of the book.

However, if the trading system still requires analysis of quotes based on the opening of bars or uses a multi-currency indicator, one should somehow wait for the synchronization of bars on all involved instruments. We provided an example of a class that performs this task in the section Tracking bar formation.

When developing a multi-symbol Expert Advisor, the imperative task involves segregating a universal trading algorithm into distinct blocks. These blocks can subsequently be applied to various symbols with differing settings. The most logical approach to achieve this is to articulate one or more classes within the framework of the Object-Oriented Programming (OOP) concept.

Let's illustrate this methodology using an example of an Expert Advisor employing the well-known martingale strategy. As is commonly understood, the martingale strategy is inherently risky, given its practice of doubling lots after each losing trade in anticipation of recovering previous losses. Mitigating this risk is essential, and one effective approach is to simultaneously trade multiple symbols, preferably those with weak correlations. This way, temporary drawdowns on one instrument can potentially be offset by gains on others.

The incorporation of a variety of instruments (or diverse settings within a single trading system, or even distinct trading systems) within the Expert Advisor serves to diminish the overall impact of individual component failures. In essence, the greater the diversity in instruments or systems, the less the final result is contingent on the isolated setbacks of its constituent parts.

Let's call a new Expert Advisor *MultiMartingale.mq5*. Trading algorithm settings include:

- *UseTime* – logical flag for enabling/disabling scheduled trading
- *HourStart* and *Hour End* – the range of hours within which trading is allowed, if *UseTime* equals *true*
- *Lots* – the volume of the first deal in the series
- *Factor* – coefficient of increase in volume for subsequent transactions after a loss
- *Limit* – the maximum number of trades in a losing series with multiplication of volumes (after it, return to the initial lot)
- *Stop Loss* and *Take Profit* – distance to protective levels in points
- *StartType* – type of the first deal (purchase or sale)
- *Trailing* – indication of a stop loss trailing

In the source code, they are described in this way.

```
input bool UseTime = true;       // UseTime (hourStart and hourEnd)
input uint HourStart = 2;        // HourStart (0...23)
input uint HourEnd = 22;         // HourEnd (0...23)
input double Lots = 0.01;        // Lots (initial)
input double Factor = 2.0;       // Factor (lot multiplication)
input uint Limit = 5;            // Limit (max number of multiplications)
input uint StopLoss = 500;       // StopLoss (points)
input uint TakeProfit = 500;     // TakeProfit (points)
input ENUM_POSITION_TYPE StartType = 0; // StartType (first order type: BUY or SELL)
input bool Trailing = true;      // Trailing
```

In theory, it is logical to establish protective levels not in points but in terms of shares of the Average True Range indicator (ATR). However, at present, this is not a primary task.

Additionally, the Expert Advisor incorporates a mechanism to temporarily halt trading operations for a user-specified duration (controlled by the parameter *SkipTimeOnError*) in case of errors. We will omit a detailed discussion of this aspect here, as it can be referenced in the source codes.

To consolidate the entire set of configurations into a unified entity, a structure named *Settings* is defined. This structure has fields that mirror input variables. Furthermore, the structure includes the *symbol* field, addressing the strategy's multicurrency nature. In other words, the symbol can be arbitrary and differs from the working symbol on the chart.

```
struct Settings
{
   bool useTime;
   uint hourStart;
   uint hourEnd;
   double lots;
   double factor;
   uint limit;
   uint stopLoss;
   uint takeProfit;
   ENUM_POSITION_TYPE startType;
   ulong magic;
   bool trailing;
   string symbol;
   ...
};
```

In the initial development phase, we populate the structure with input variables. Nevertheless, this is only sufficient for trading on a single symbol. Subsequently, as we expand the algorithm to encompass multiple symbols, we'll be required to read various sets of settings (using a different approach) and append them to an array of structures.

The structure also encompasses several beneficial methods. Specifically, the *validate* method verifies the correctness of the settings, confirming the existence of the specified symbol, and returns a success indicator (*true*).

```
struct Settings
{
   ...
   bool validate()
   {
 ...// checking the lot size and protective levels (see the source code)

      double rates[1];
      const bool success = CopyClose(symbol, PERIOD_CURRENT, 0, 1, rates) > -1;
      if(!success)
      {
         Print("Unknown symbol: ", symbol);
      }
      return success;
   }
   ...
};
```

Calling *CopyClose* not only checks if the symbol is online in the *Market Watch* but also initiates the loading of its quotes (of the desired timeframe) and ticks in the tester. If this is not done, only quotes and ticks (in real ticks mode) of the currently selected instrument and timeframe are available in the tester by default. Since we are writing a multi-currency Expert Advisor, we will need third-party quotes and ticks.

```
struct Settings
{
   ...
   void print() const
   {
      Print(symbol, (startType == POSITION_TYPE_BUY ? "+" : "-"), (float)lots,
        "*", (float)factor,
        "^", limit,
        "(", stopLoss, ",", takeProfit, ")",
        useTime ? "[" + (string)hourStart + "," + (string)hourEnd + "]": "");
   }
};
```

The *print* method outputs all fields to the log in abbreviated form in one line. For example,

```
EURUSD+0.01*2.0^5(500,1000)[2,22]
|      | |   |   |  |    |   |  |
|      | |   |   |  |    |   |  `until this hour trading is allowed
|      | |   |   |  |    |   `from this hour trading is allowed
|      | |   |   |  |    `take profit in points
|      | |   |   |  `stop loss in points
|      | |   |   `maximum size of a series of losing trades (after '^')
|      | |   `lot multiplication factor (after '*')
|      | `initial lot in series
|      `+ start with Buy
|      `- start with Sell
`instrument
```

We will need other methods in the *Settings* structure when we move to multicurrency. For now, let's imagine a simplified version of what the handler *OnInit* of the Expert Advisor trading on one symbol might look like.

```
int OnInit()
{
   Settings settings =
   {
      UseTime, HourStart, HourEnd,
      Lots, Factor, Limit,
      StopLoss, TakeProfit,
      StartType, Magic, SkipTimeOnError, Trailing, _Symbol
   };

   if(settings.validate())
   {
      settings.print();
      ...
      // here you will need to initialize the trading algorithm with these settings
   }
   ...
}
```

Adhering to the OOP, the trading system in a generalized form should be described as a software interface. Again, in order to simplify the example, we will only use one method in this interface: *trade*.

```
interface TradingStrategy
{
   virtual bool trade(void);
};
```

Well, the main task of the algorithm is to trade, and it doesn't even matter where we decide to call this method from: on each tick from *OnTick*, at the bar opening, or possibly on timer.

Your working Expert Advisors will most likely need additional interface methods to set up and support various modes. But they are not needed in this example.

Let's start creating a class of a specific trading system based on the interface. In our case, all instances will be of the class *SimpleMartingale*. However, it is also possible to implement many different classes that inherit the interface within one Expert Advisor and then use them in a uniform way in an

arbitrary combination. A portfolio of strategies (preferably very different in nature) is usually characterized by increased stability of financial performance.

```
class SimpleMartingale: public TradingStrategy
{
protected:
   Settings settings;
   SymbolMonitor symbol;
   AutoPtr<PositionState> position;
   AutoPtr<TrailingStop> trailing;
   ...
};
```

Inside the class, we see a familiar *Settings* structure and the working symbol monitor *SymbolMonitor*. In addition, we will need to control the presence of positions and follow the stop-loss level for them, for which we have introduced variables with auto-pointers to objects *PositionState* and *TrailingStop*. Auto-pointers allow us in our code not to worry about the explicit deletion of objects as this will be done automatically when the control exits the scope, or when a new pointer is assigned to the auto-pointer.

> The class *TrailingStop* is a base class, with the simplest implementation of price tracking, from which you can inherit a lot of more complex algorithms, an example of which we considered as a derivative *TrailingStopByMA*. Therefore, in order to give the program flexibility in the future, it is desirable to ensure that the calling code can pass its own specific, customized trailing object, derived from *TrailingStop*. This can be done, for example, by passing a pointer to the constructor or by turning *SimpleMartingale* into a template class (then the trail class will be set by the template parameter).
>
> This principle of OOP is called *dependency injection* and is widely used along with many others that we briefly mentioned in the section Theoretical foundations of OOP: composition.

The settings are passed to the strategy class as a constructor parameter. Based on them, we assign all internal variables.

```
class SimpleMartingale: public TradingStrategy
{
   ...
   double lotsStep;
   double lotsLimit;
   double takeProfit, stopLoss;
public:
   SimpleMartingale(const Settings &state) : symbol(state.symbol)
   {
      settings = state;
      const double point = symbol.get(SYMBOL_POINT);
      takeProfit = settings.takeProfit * point;
      stopLoss = settings.stopLoss * point;
      lotsLimit = settings.lots;
      lotsStep = symbol.get(SYMBOL_VOLUME_STEP);

      // calculate the maximum lot in the series (after a given number of multiplicat
      for(int pos = 0; pos < (int)settings.limit; pos++)
      {
         lotsLimit = MathFloor((lotsLimit * settings.factor) / lotsStep) * lotsStep;
      }

      double maxLot = symbol.get(SYMBOL_VOLUME_MAX);
      if(lotsLimit > maxLot)
      {
         lotsLimit = maxLot;
      }
      ...
```

Next, we use the object *PositionFilter* to search for existing "own" positions (by the magic number and symbol). If such a position is found, we create the *PositionState* object and, if necessary, the *TrailingStop* object for it.

```
      PositionFilter positions;
      ulong tickets[];
      positions.let(POSITION_MAGIC, settings.magic).let(POSITION_SYMBOL, settings.sym
         .select(tickets);
      const int n = ArraySize(tickets);
      if(n > 1)
      {
         Alert(StringFormat("Too many positions: %d", n));
      }
      else if(n > 0)
      {
         position = new PositionState(tickets[0]);
         if(settings.stopLoss && settings.trailing)
         {
           trailing = new TrailingStop(tickets[0], settings.stopLoss,
              ((int)symbol.get(SYMBOL_SPREAD) + 1) * 2);
         }
      }
   }
```

Schedule operations will be left "behind the scene" in the *trade* method for now (*useTime*, *hourStart*, and *hourEnd* parameter fields). Let's proceed directly to the trading algorithm.

If there are no and have not been any positions yet, the *PositionState* pointer will be zero, and we need to open a long or short position in accordance with the selected direction *startType*.

```
   virtual bool trade() override
   {
      ...
      ulong ticket = 0;

      if(position[] == NULL)
      {
         if(settings.startType == POSITION_TYPE_BUY)
         {
            ticket = openBuy(settings.lots);
         }
         else
         {
            ticket = openSell(settings.lots);
         }
      }
      ...
```

Helper methods *openBuy* and *openSell* are used here. We'll get to them in a couple of paragraphs. For now, we only need to know that they return the ticket number on success or 0 on failure.

If the *position* object already contains information about the tracked position, we check whether it is live by calling *refresh*. In case of success (*true*), update position information by calling *update* and also trail the stop loss, if it was requested by the settings.

```
else // position[] != NULL
{
   if(position[].refresh()) // does position still exists?
   {
      position[].update();
      if(trailing[]) trailing[].trail();
   }
   ...
```

If the position is closed, *refresh* will return *false*, and we will be in another *if* branch to open a new position: either in the same direction, if a profit was fixed, or in the opposite direction, if a loss occurred. Please note that we still have a snapshot of the previous position in the cache.

```
   else // the position is closed - you need to open a new one
   {
      if(position[].get(POSITION_PROFIT) >= 0.0)
      {
        // keep the same direction:
        // BUY in case of profitable previous BUY
        // SELL in case of profitable previous SELL
         if(position[].get(POSITION_TYPE) == POSITION_TYPE_BUY)
            ticket = openBuy(settings.lots);
         else
            ticket = openSell(settings.lots);
      }
      else
      {
         // increase the lot within the specified limits
         double lots = MathFloor((position[].get(POSITION_VOLUME) * settings.fa

         if(lotsLimit < lots)
         {
            lots = settings.lots;
         }

         // change the trade direction:
         // SELL in case of previous unprofitable BUY
         // BUY in case of previous unprofitable SELL
         if(position[].get(POSITION_TYPE) == POSITION_TYPE_BUY)
            ticket = openSell(lots);
         else
            ticket = openBuy(lots);
      }
   }
}
...
```

The presence of a non-zero ticket at this final stage means that we must start controlling it with new objects *PositionState* and *TrailingStop*.

```
      if(ticket > 0)
      {
         position = new PositionState(ticket);
         if(settings.stopLoss && settings.trailing)
         {
            trailing = new TrailingStop(ticket, settings.stopLoss,
               ((int)symbol.get(SYMBOL_SPREAD) + 1) * 2);
         }
      }

      return true;
   }
```

We now present, with some abbreviations, the *openBuy* method (*openSell* is all the same). It has three steps:

- Preparing the *MqlTradeRequestSync* structure using the *prepare* method (not shown here, it fills *deviation* and *magic*)
- Sending an order using a *request.buy* method call
- Checking the result with the *postprocess* method (not shown here, it calls *request.completed* and in case of an error, the period of suspension of trading begins in anticipation of better conditions);

```
ulong openBuy(double lots)
{
   const double price = symbol.get(SYMBOL_ASK);

   MqlTradeRequestSync request;
   prepare(request);
   if(request.buy(settings.symbol, lots, price,
      stopLoss ? price - stopLoss : 0,
      takeProfit ? price + takeProfit : 0))
   {
      return postprocess(request);
   }
   return 0;
}
```

Usually, positions will be closed by stop loss or take profit. However, we support scheduled operations that may result in closures. Let's go back to the beginning of the *trade* method for scheduling work.

```
virtual bool trade() override
{
   if(settings.useTime && !scheduled(TimeCurrent())) // time out of schedule?
   {
      // if there is an open position, close it
      if(position[] && position[].isReady())
      {
         if(close(position[].get(POSITION_TICKET)))
         {
                              // at the request of the designer:
            position = NULL; // clear the cache or we could...
            // do not do this zeroing, that is, save the position in the cache,
            // to transfer the direction and lot of the next trade to a new series
         }
         else
         {
            position[].refresh(); // guaranteeing reset of the 'ready' flag
         }
      }
      return false;
   }
   ...// opening positions (given above)
}
```

Working method *close* is largely similar to *openBuy* so we will not consider it here. Another method, *scheduled*, just returns *true* or *false*, depending on whether the current time falls within the specified working hours range (*hourStart*, *hourEnd*).

So, the trading class is ready. But for multi-currency work, you will need to create several copies of it. The *TradingStrategyPool* class will manage them, in which we describe an array of pointers to *TradingStrategy* and methods for replenishing it: parametric constructor and *push*.

```
class TradingStrategyPool: public TradingStrategy
{
private:
   AutoPtr<TradingStrategy> pool[];
public:
   TradingStrategyPool(const int reserve = 0)
   {
      ArrayResize(pool, 0, reserve);
   }

   TradingStrategyPool(TradingStrategy *instance)
   {
      push(instance);
   }

   void push(TradingStrategy *instance)
   {
      int n = ArraySize(pool);
      ArrayResize(pool, n + 1);
      pool[n] = instance;
   }

   virtual bool trade() override
   {
      for(int i = 0; i < ArraySize(pool); i++)
      {
         pool[i][].trade();
      }
      return true;
   }
};
```

It is not necessary to make the pool derived from the interface *TradingStrategy* interface, but if we do so, this allows future packing of strategy pools into other larger strategy pools, and so on. The *trade* method simply calls the same method on all array objects.

In the global context, let's add an autopointer to the trading pool, and in the *OnInit* handler we will ensure its filling. We can start with one single strategy (we will deal with multicurrency a bit later).

```
AutoPtr<TradingStrategyPool> pool;

int OnInit()
{
   ... // settings initialization was given earlier
   if(settings.validate())
   {
      settings.print();
      pool = new TradingStrategyPool(new SimpleMartingale(settings));
      return INIT_SUCCEEDED;
   }
   else
   {
      return INIT_FAILED;
   }
   ...
}
```

To start trading, we just need to write the following small handler *OnTick*.

```
void OnTick()
{
   if(pool[] != NULL)
   {
      pool[].trade();
   }
}
```

But what about multicurrency support?

The current set of input parameters is designed for only one instrument. We can use this to test and optimize the Expert Advisor on a single symbol, but after the optimal settings are found for all symbols, they need to be somehow combined and passed to the algorithm.

In this case, we apply the simplest solution. The code above contained a line with the settings formed by the *print* method generated by the *Settings* structures. We implement the method in the *parse* structure which does the reverse operation: restores the state of the fields by the line description. Also, since we need to concatenate several settings for different characters, we will agree that they can be concatenated into a single long string through a special delimiter character, for example ';'. Then it is easy to write the *parseAll* static method to read the merged set of settings, which will call *parse* to fill the array of *Settings* structures passed by reference. The full source code of the methods can be found in the attached file.

```
struct Settings
{
   ...
   bool parse(const string &line);
   void static parseAll(const string &line, Settings &settings[])
   ...
};
```

For example, the following concatenated string contains settings for three symbols.

```
EURUSD+0.01*2.0^7(500,500)[2,22];AUDJPY+0.01*2.0^8(300,500)[2,22];GBPCHF+0.01*1.7^8(1
```

It is lines of this kind that the method *parseAll* can parse. To enter such a string into the Expert Advisor, we describe the input *WorkSymbols* variable.

```
input string WorkSymbols = ""; // WorkSymbols (name±lots*factor^limit(sl,tp)[start,stop];...)
```

If it is empty, the Expert Advisor will work with the settings from the individual input variables presented earlier. If the string is specified, the *OnInit* handler will fill the pool of trading systems based on the results of parsing this line.

```
int OnInit()
{
   if(WorkSymbols == "")
   {
      ...// work with the current single character, as before
   }
   else
   {
      Print("Parsed settings:");
      Settings settings[];
      Settings::parseAll(WorkSymbols, settings);
      const int n = ArraySize(settings);
      pool = new TradingStrategyPool(n);
      for(int i = 0; i < n; i++)
      {
         settings[i].trailing = Trailing;
         // support multiple systems on one symbol for hedging accounts
         settings[i].magic = Magic + i;  // different magic numbers for each subsyste
         pool[].push(new SimpleMartingale(settings[i]));
      }
   }
   return INIT_SUCCEEDED;
}
```

It's important to note that in MQL5, the length of the input string is restricted to 250 characters. Additionally, during optimization in the tester, strings are further truncated to a maximum of 63 characters. Consequently, to optimize concurrent trading across numerous symbols, it becomes imperative to devise an alternative method for loading settings, such as retrieving them from a text file. This can be easily accomplished by utilizing the same input variable, provided it is designated with a file name rather than a string containing settings.

This approach is implemented in the mentioned *Settings::parseAll* method. The name of the text file in which an input string will be passed to the Expert Advisor without length limitation is set according to the universal principle suitable for all similar cases: the file name begins with the name of the Expert Advisor, and then, after the hyphen, there must be the name of the variable whose data the file contains. For example, in our case, in the *WorkSymbols* input variable, you can optionally specify the file name "MultiMartingale-WorkSymbols.txt". Then the *parseAll* method will try to read the text from the file (it should be in the standard *MQL5/Files* sandbox).

> Passing file names in input parameters requires additional steps to be taken for further testing and optimization of such an Expert Advisor: the *#property tester_file "MultiMartingale-WorkSymbols.txt"* directive should be added to the source code. This will be discussed in detail in the section Tester

preprocessor directives. When this directive is added, the Expert Advisor will require the presence of the file and will not start without it in the tester!

The Expert Advisor is ready. We can test it on different symbols separately, choose the best settings for each and build a trading portfolio. In the next chapter, we will study the tester API, including optimization, and this Expert Advisor will come in handy. In the meantime, let's check its multi-currency operation.

```
WorkSymbols=EURUSD+0.01*1.2^4(300,600)[9,11];GBPCHF+0.01*2.0^7(300,400)[14,16];AUDJPY
```

In the first quarter of 2022, we will receive the following report (MetaTrader 5 reports do not provide statistics broken down by symbols, so it is possible to distinguish a single-currency report from a multi-currency one only by the table of deals/orders/positions).

History Quality	100%				
Bars	1534	Ticks	6281503	Symbols	3

Tester's report for a multi-currency Martingale strategy Expert Advisor

It should be noted that due to the fact that the strategy is launched from the *OnTick* handler, the runs on different main symbols (that is, those selected in the tester's settings drop-down list) will give slightly different results. In our test, we simply used EURUSD as the most liquid and most frequently ticked instrument, which is sufficient for most applications. However, if you want to react to ticks of all instruments, you can use an indicator like *EventTickSpy.mq5*. Optionally, you can run the trading logic on a timer without being tied to the ticks of a specific instrument.

And here is what the trading strategy looks like for a single symbol, in this case AUDJPY.

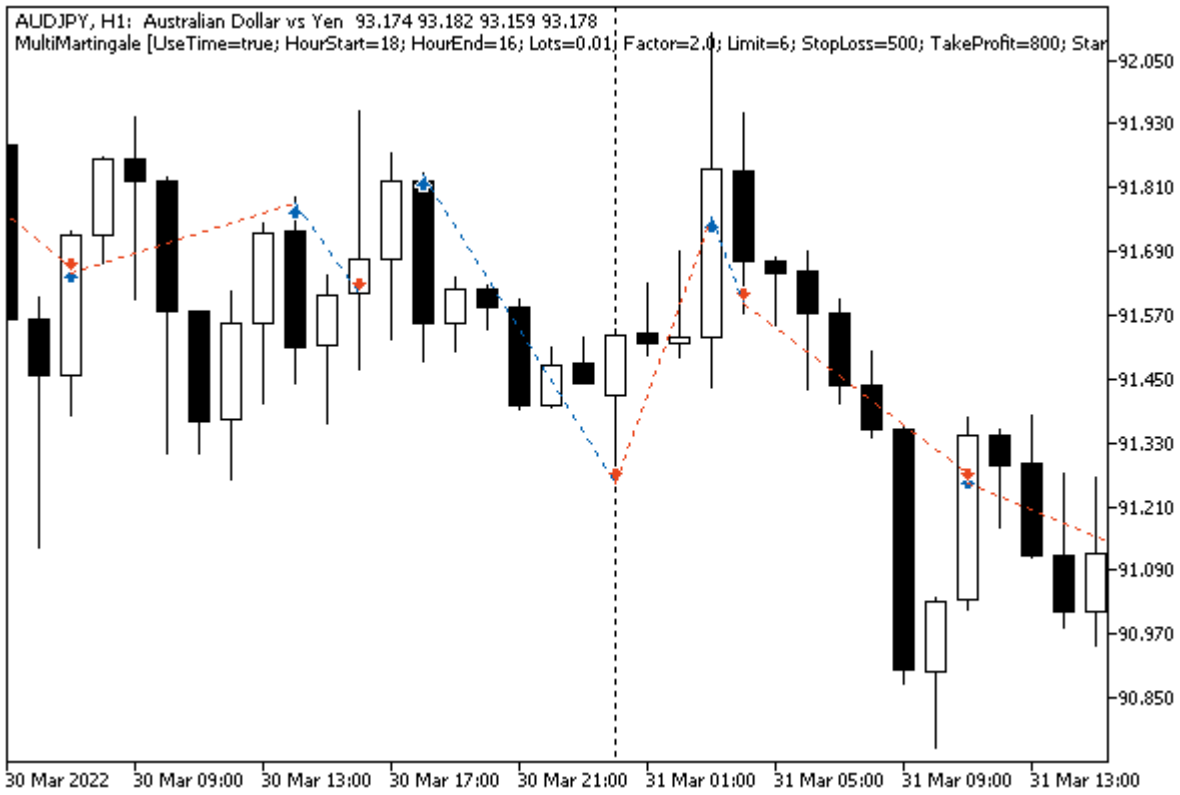

Chart with a test of a multi-currency Martingale strategy Expert Advisor

By the way, for all multicurrency Expert Advisors, there is another important issue that is left unattended here. We are talking about the method of selecting the lot size, for example, based on the loading of the deposit or risk. Earlier, we showed examples of such calculations in a non-trading Expert Advisor *LotMarginExposureTable.mq5*. In *MultiMartingale.mq5*, we have simplified the task by choosing a fixed lot and displaying it in the settings for each symbol. However, in operational multicurrency Expert Advisors, it makes sense to choose lots in proportion to the value of the instruments (by margin or volatility).

In conclusion, I would like to note that multi-currency strategies may require different optimization principles. The considered strategy makes it possible to separately find parameters for symbols and then combine them. However, some arbitrage and cluster strategies (for example, pair trading) are based on the simultaneous analysis of all tools for making trading decisions. In this case, the settings associated with all symbols should be separately included in the input parameters.

6.4.39 Limitations and benefits of Expert Advisors

Due to their specific operation, Expert Advisors have some limitations, as well as advantages over other types of MQL programs. In particular, all functions intended for indicators are banned in Expert Advisors:

- *SetIndexBuffer*
- *IndicatorSetDouble*
- *IndicatorSetInteger*
- *IndicatorSetString*
- *PlotIndexSetDouble*
- *PlotIndexSetInteger*

- *PlotIndexSetString*
- *PlotIndexGetInteger*

Also, Expert Advisors should not describe event handlers that are typical for other types of programs: *OnStart* (scripts and services) and *OnCalculate* (indicators).

Unlike indicators, only one Expert Advisor can be placed on each chart.

At the same time, Expert Advisors are the only type of MQL programs that in addition to testing (which we have already done for both indicators and Expert Advisors), can also be optimized. The optimizer allows finding the best input parameters according to various criteria, both trading and abstract mathematical ones. For these purposes, the API includes additional functions and several specific event handlers. We will study this material in the next chapter.

In addition, groups of built-in MQL5 functions for working with the network at the socket level and various Internet protocols (HTTP, FTP, SMTP) are available in Expert Advisors (as well as in scripts and services, that is, in all types of programs except indicators). We will consider them in the seventh part of the book.

6.4.40 Creating Expert Advisors in the MQL Wizard

So, we are completing the study of trading APIs for developing Expert Advisors. Throughout this chapter, we have considered various examples, which you can use as a starting point for your own project. However, if you want to start an Expert Advisor from scratch, you don't have to do it literally "from scratch". The MetaEditor provides the built-in MQL Wizard which, among other things, allows the creation of Expert Advisor templates. Moreover, in the case of Expert Advisor, this Wizard offers two different ways to generate source code.

We already got acquainted with the first step of the Wizard in the section MQL Wizard and program draft. Obviously, in the first step, we select the type of project to be created. In the previously mentioned chapter, we created a script template. Later, in the chapter on indicators, we took a tour of creating an indicator template. Now we will consider the following two options:

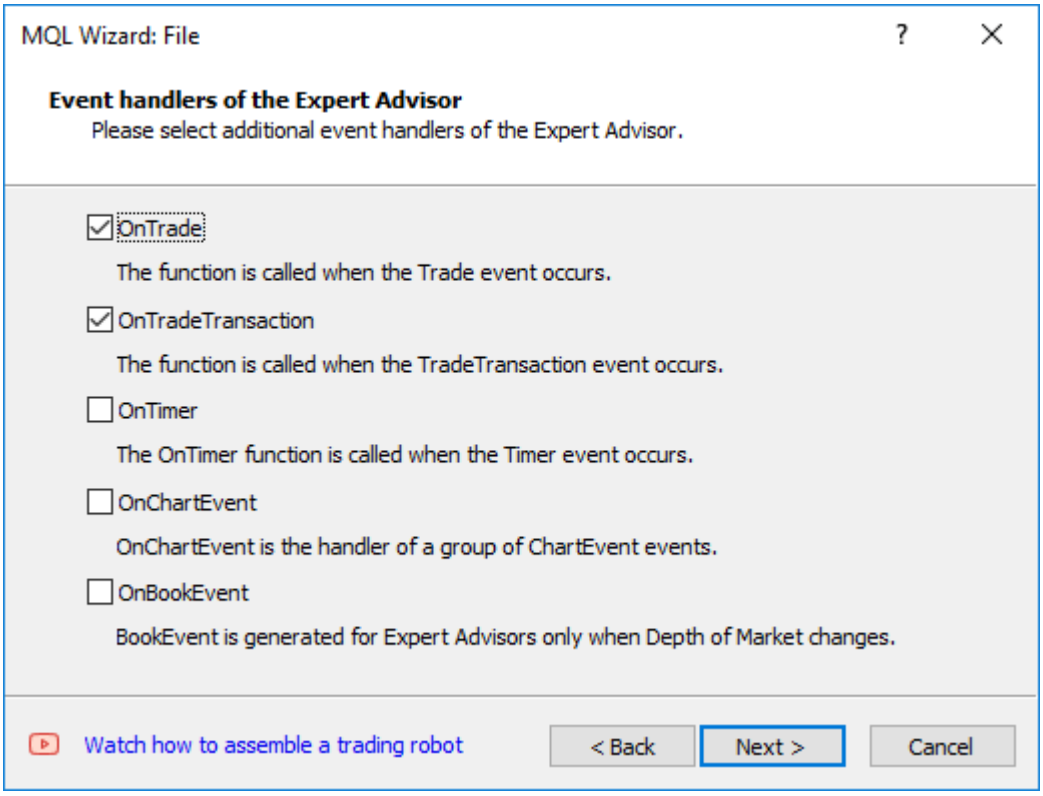
- Expert Advisor (template)
- Expert Advisor (generate)

The first one is more simple. You can select a name, input parameters, and required event handlers, as shown in screenshots below, but there will be no trading logic and ready-made algorithms in the resulting source file.

The second option is more complicated. It will result in a ready-made Expert Advisor based on the standard library that provides a set of classes in header files available in the standard MetaTrader 5 package. Files are located in folders *MQL5/Include/Expert/*, *MQL5/Include/Trade*, *MQL5/Include/Indicators*, and several others. The library classes implement the most popular indicator signals, mechanisms for performing trading operations based on combinations of signals, as well as money management and trailing stop algorithms. The detailed study of the standard library is beyond the scope of this book.

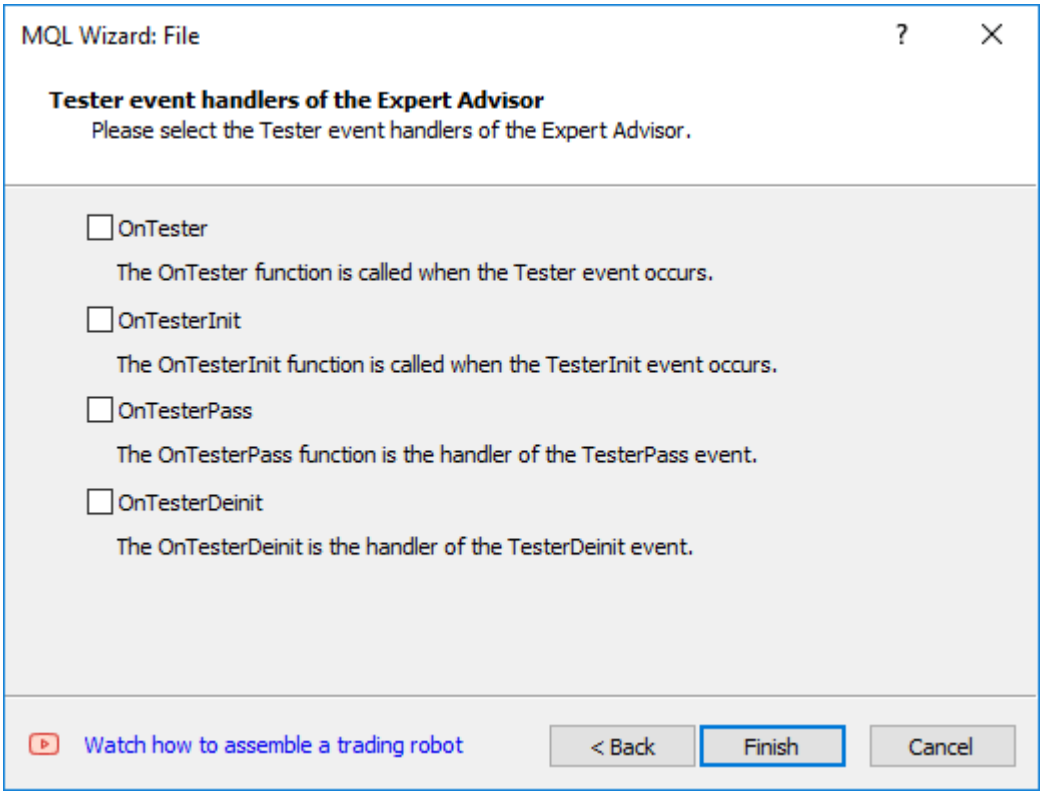
Regardless of which options you select, at the second step of the Wizard, you need to enter the Expert Advisor name and input parameters. The appearance of this step is similar to what was also already shown in the section MQL Wizard and program draft. The only caveat is that Expert Advisors based on the standard library must have two mandatory (non-removable) parameters: *Symbol* and *TimeFrame*.

For a simple template, at the 3rd step, it is proposed to select additional event handlers that will be added to the source code, in addition to *OnTick* (*OnTick* always inserted).



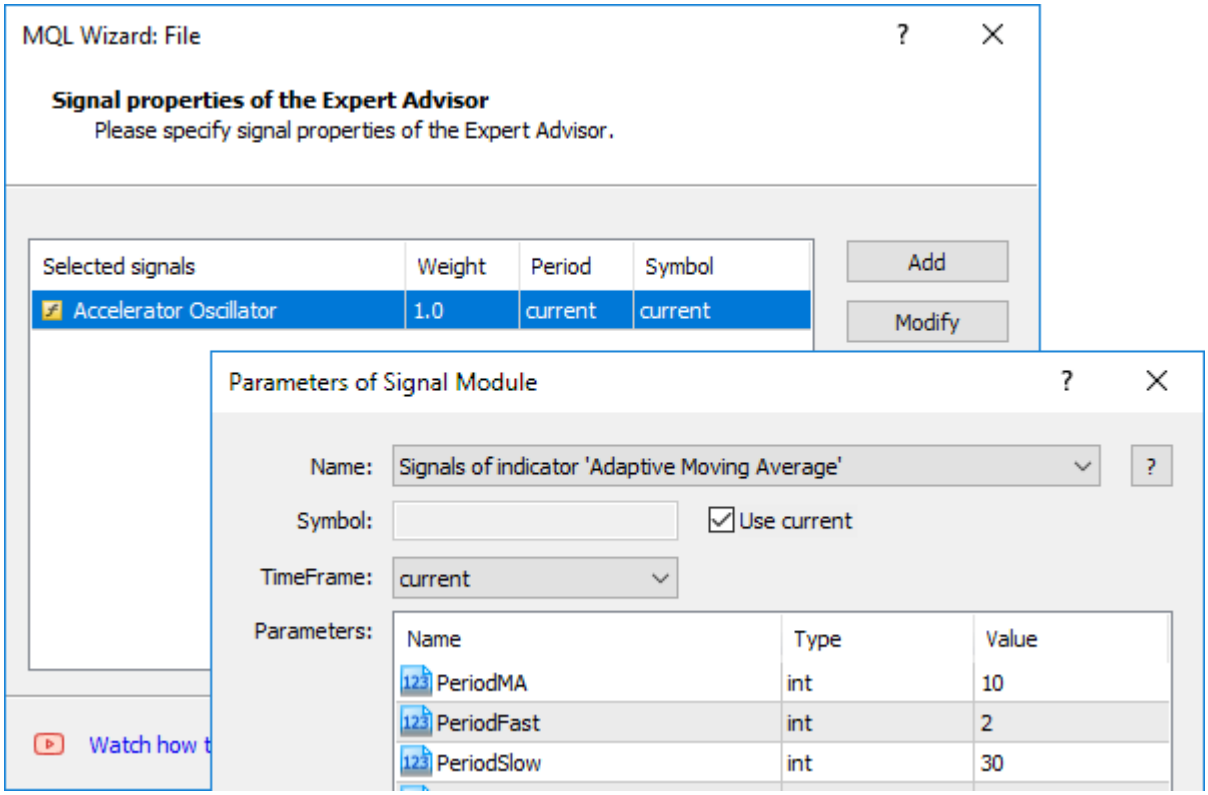
Creation of an Expert Advisor template. Step 3. Additional event handlers

The final fourth step allows you to specify one or more optional event handlers for the tester. Those will be discussed in the next chapter.



Creation of an Expert Advisor template. Step 4. Tester event handlers

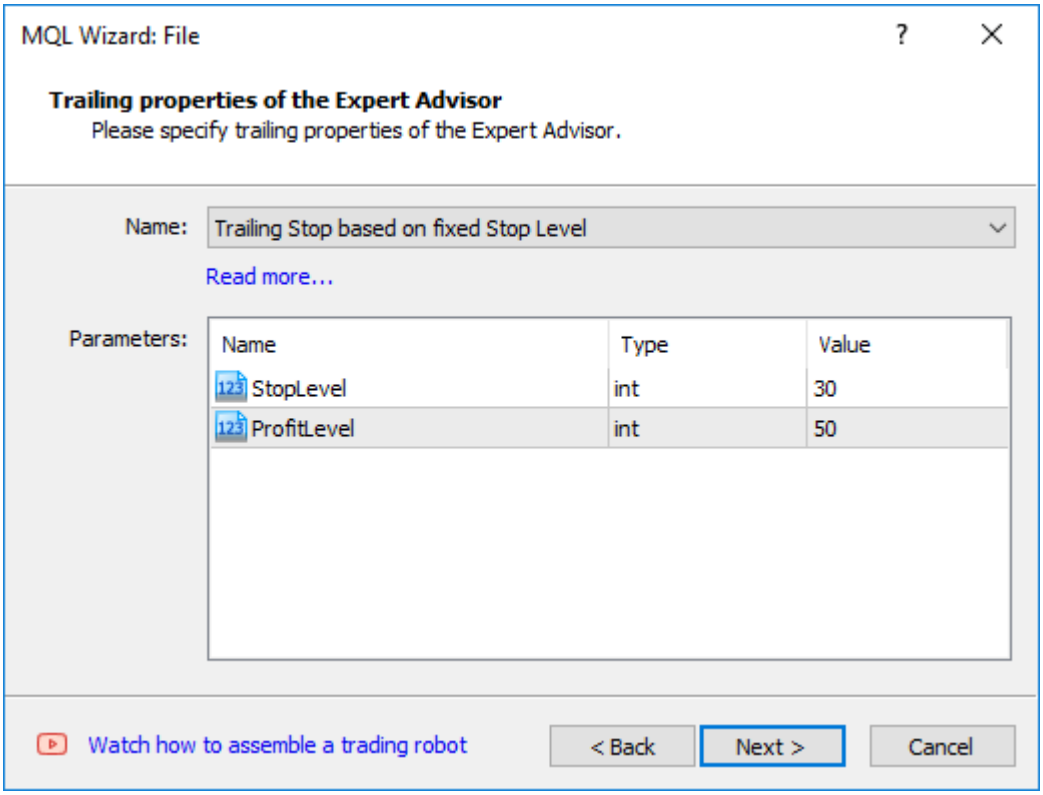
If the user chooses to generate a program based on the standard library at the first step of the Wizard, then the 3rd step is to set up trading signals.



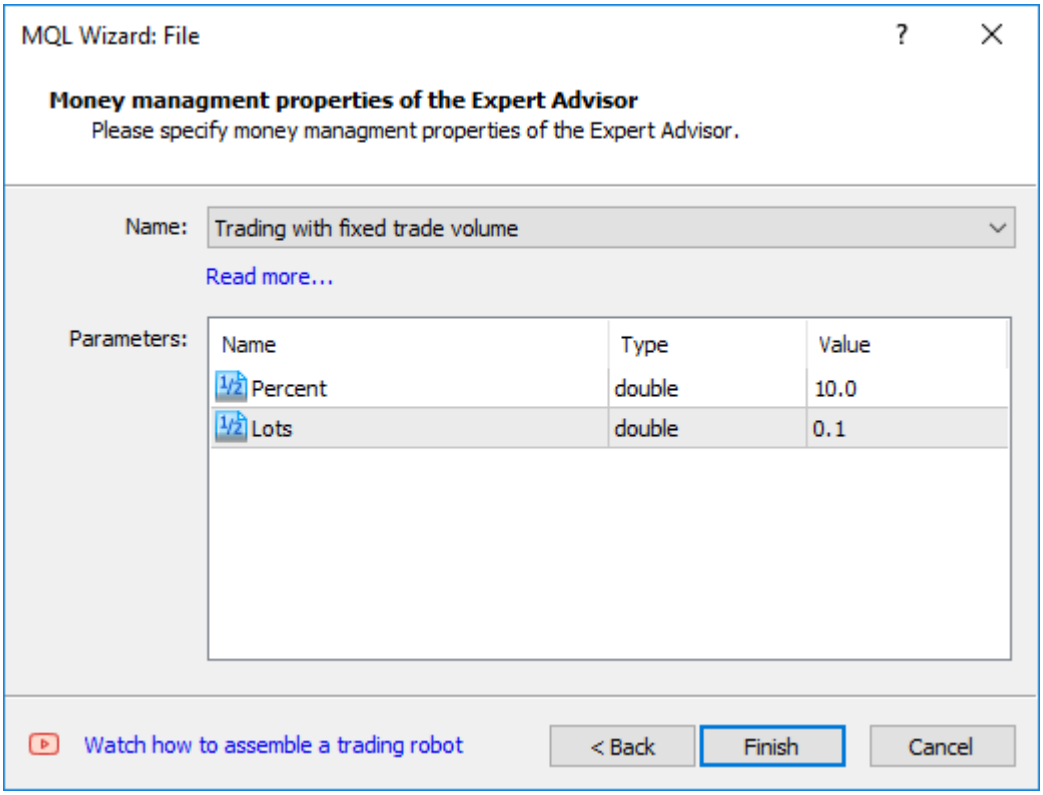
Generation of a ready Expert Advisor. Step 3. Setting up trading signals

You can read more about it in the documentation.

Steps 4 and 5 are designed to include trailing in the Expert Advisor and automatically select lots according to one of the predefined methods.



Generation of a ready Expert Advisor. Step 4. Choosing a trailing stop method



Generation of a ready Expert Advisor. Step 5. Selection of lots

The Wizard, of course, is not a universal tool, and the resulting program prototype, as a rule, needs to be improved. However, the knowledge gained in this chapter will give you more confidence in the generated source codes and extend them as needed.

6.5 Testing and optimization of Expert Advisors

Development of Expert Advisors implies not only and not so much the implementation of a trading strategy in MQL5 but to a greater extent testing its financial performance, finding optimal settings, and debugging (searching for and correcting errors) in various situations. All this can be done in the integrated MetaTrader 5 tester.

The tester works for various currencies and supports several tick generation modes: based on opening prices of the selected timeframe, on OHLC prices of the M1 timeframe, on artificially generated ticks, and on the real tick history. This way you can choose the optimal ratio of speed and accuracy of trading simulation.

The tester settings allow you to set the testing time interval in the past, the size of the deposit, and the leverage; they are used to emulate requotes and specific account features (including the size of commissions, margins, session schedules, limiting the number of lots). All the details of working with the tester from the user's point of view can be found in terminal documentation.

Earlier, we already briefly discussed working with the tester, in particular, in the section Testing indicators. Let's recall that the tester control functions and their optimization are not available for indicators, unlike for Expert Advisors. However, personally, I would like to see an option of adaptive self-tuning of indicators: all that is needed is to support the *OnTester* handler in them, which we will present in a separate section.

As you know, various modes are available for optimization, such as direct enumeration of combinations of Expert Advisor input parameters, accelerated genetic algorithm, mathematical calculations, or sequential runs through symbols in *Market Watch*. As an optimization criterion, you can use both well-known metrics such as profitability, Sharpe ratio, recovery factor, and expected payoff, as well as "custom" variables embedded in the source code by the developer of the Expert Advisor. In the context of this book, it is assumed that the reader is already familiar with the principles of setting up, running, and interpreting optimization results because in this chapter we will begin to study the tester control API. Those interested can refresh their knowledge with the help of the relevant section of documentation.

A particularly important function of the tester is multi-threaded optimization, which can be performed using local and distributed (network) agent programs, including those in the MQL5 Cloud Network. A single testing run (with specific input parameters) launched manually by the user, or one of the many runs called during optimization (when we implement enumeration of parameter values in given ranges) is performed in a separate program – the agent. Technically, this is a metatester64.exe file, and the copies of its processes can be seen in the Windows Task Manager during testing and optimization. It is due to this that the tester is multi-threaded.

The terminal is a dispatcher that distributes tasks to local and remote agents. It launches local agents if necessary. When optimizing, by default, several agents are launched; their quantity corresponds to the number of processor cores. After executing the next task for testing an Expert Advisor with the specified parameters, the agent returns the results to the terminal.

Each agent creates its own trading and software environment. All agents are isolated from each other and from the client terminal.

In particular, the agent has its own global variables and its own file sandbox, including the folder where detailed agent logs are written: *Tester/Agent-IPaddress-Port/Logs*. Here *Tester* is the tester installation directory (during a standard installation together with MetaTrader 5, this is the subfolder where the terminal is installed). The name of the directory *Agent-IPaddress-Port*, instead of *IPaddress* and *Port*, will contain the specific network address and port values that are used to communicate with the terminal. For local agents, this is the address 127.0.0.1 and the range of ports, by default, starting from 3000 (for example, on a computer with 4 cores, we will see agents on ports 3000, 3001, 3002, 3003).

When testing an Expert Advisor, all file operations are performed in the *Tester/Agent-IPaddress-Port/MQL5/Files* folder. However, it is possible to implement interaction between local agents and the client terminal (as well as between different copies of the terminal on the same computer) via a shared folder. For this, when opening a file with the *FileOpen* function, the FILE_COMMON flag must be specified. Another way to transfer data from agents to the terminal is provided by the frames mechanism.

The agent's local sandbox is automatically cleared before each test due to security reasons (to prevent different Expert Advisors from reading each other's data).

A folder with the quotes history is created next to the file sandbox for each agent: *Tester/Agent-IPaddress-Port/bases/ServerName/Symbol/*. In the next section, we briefly remind you how it is formed.

The results of individual test runs and optimizations are stored by the terminal in a special cache which can be found in the installation directory, in the subfolder *Tester/cache/*. Test results are stored in files with the extension *tst*, and the optimization results are stored in *opt* files. Both formats are open-sourced by MetaQuotes developers, so you can implement your own batch analytical data processing, or use ready-made source codes from the codebase on the mql5.com website.

In this chapter, first, we will consider the basic principles of how MQL programs work in the tester, and then we will learn how to interact with it in practice.

6.5.1 Generating ticks in tester

The presence of the *OnTick* handler in the Expert Advisor is not mandatory for it to be tested in the tester. The Expert Advisor can use one or more of the other familiar functions:

- *OnTick* – event handler for the arrival of a new tick
- *OnTrade* – trade event handler
- *OnTradeTransaction* – trade transaction handler
- *OnTimer* – timer signal handler
- *OnChartEvent* – event handler on the chart, including custom charts

At the same time, inside the tester, the main equivalent of the time course is a thread of ticks, which contain not only price changes but also time accurate to milliseconds. Therefore, to test Expert Advisors, it is necessary to generate tick sequences. The MetaTrader 5 tester has 4 tick generation modes:

- Real ticks (if their history is provided by the broker)
- Every tick (emulation based on available M1 timeframe quotes)
- OHLC prices from minute bars (1 Minute OHLC)

- Open prices only (1 tick per bar)

Another mode of operation – mathematical calculations – we will analyze later since it is not related to quotes and ticks.

Whichever of the 4 modes the user chooses, the terminal loads the available historical data for testing. If the mode of real ticks was selected, and the broker does not have them for this instrument, then the "All ticks" mode is used. The tester indicates the nature of tick generation in its report graphically and as a percentage (where 100% means all ticks are real).

The history of the instrument selected in the tester settings is synchronized and downloaded by the terminal from the trading server before starting the testing process. At the same time, for the first time, the terminal downloads the history from the trading server to the required depth (with a certain margin, depending on the timeframe, at least 1 year before the start of the test), so as not to apply for it later. In the future, only the download of new data will occur. All this is accompanied by corresponding messages in the tester's log.

The testing agent receives the history of the tested instrument from the client terminal immediately after testing is started. If the testing process uses data on other instruments (for example, this is a multicurrency Expert Advisor), then in this case the testing agent requests the required history from the client terminal at the first call. If historical data is available on the terminal, they are immediately transferred to testing agents. If the data is missing, the terminal will request and download it from the server, and then transfer it to the testing agents.

Additional instruments are also used when the cross-rate price is calculated during trading operations. For example, when testing a strategy on EURCHF with a deposit currency in US dollars, before processing the first trading operation, the testing agent will request the history of EURUSD and USDCHF from the client terminal, although the strategy does not directly refer to these instruments.

In this regard, before testing a multicurrency strategy, it is recommended that you first download all the necessary historical data into the client terminal. This will assist in avoiding testing/optimization delays associated with resuming data. You can download the history, for example, by opening the corresponding charts and scrolling them to the beginning of the history.

Now let's look at tick generation modes in more detail.

Real ticks from history

Testing and optimization on real ticks are as close to real conditions as possible. These are ticks from exchanges and liquidity providers.

> If there is a minute bar in the symbol's history, but no tick data for that minute, the tester will generate ticks in the "Every tick" mode (see further). This allows you to build the correct chart in the tester in case of incomplete tick data from the broker. Moreover, tick data may not match minute bars for various reasons. For example, due to disconnections or other failures in the transmission of data from the source to the client terminal. When testing, minute data is considered more reliable.

Ticks are stored in the symbol cache in the strategy tester. The cache size is no more than 128,000 ticks. When new ticks arrive, the oldest data is pushed out of it. However, using the *CopyTicks* function, you can get ticks outside the cache (only when testing using real ticks). In this case, the data will be requested from the tester's tick database, which fully corresponds to the similar database of the client terminal. No adjustments by minute bars are made to this base. Therefore, the ticks in it may differ from the ticks in the cache.

Every tick (emulation)

If the real tick history is not available or if you need to minimize network traffic (because the archive of real ticks can consume significant resources), you can choose to artificially generate ticks based on the available quotes of the M1 timeframe.

The history of quotes for financial instruments is transmitted from the trading server to the MetaTrader 5 client terminal in the form of tightly packed blocks of minute bars. The history query procedure and the constructions of the required timeframes were considered in detail in the section Technical features of organization and storage of timeseries.

The minimum element of the price history is a minute bar, from which you can get information about four OHLC price values: Open, High, Low, and Close.

A new minute bar opens not at the moment when a new minute begins (the number of seconds becomes 0) but when a tick – a price change of at least one point – occurs. Similarly, we cannot determine from the bar with accuracy of a second when the tick corresponding to the closing price of this minute bar arrived: we only know the last price of the one-minute bar, which was recorded as the Close price.

Thus, for each minute bar, we know 4 control points, which we can say for sure that the price has been there. If the bar has only 4 ticks, then this information is enough for testing, but usually, the tick volume is more than 4. This means that it is necessary to generate additional checkpoints for ticks that came between prices *Open*, *High*, *Low*, and *Close*. The basics of generating ticks in the "Every tick" mode are described in the documentation.

When testing in the "Every tick" mode, the *OnTick* function of the Expert Advisor will be called on every generated tick. The Expert Advisor will receive time and *Ask/Bid/Last* prices the same way as when working online.

The "Every tick" testing mode is the most accurate (after the real ticks mode), but also the most time-consuming. For the primary evaluation of most trading strategies, it is usually sufficient to use one of two simplified testing modes: at OHLC M1 prices or at the opening of bars of the selected timeframe.

1 minute OHLC

In the "1 minute OHLC" mode, the tick sequence is built only by OHLC prices of minute bars, the number of the *OnTick* function calls is significantly reduced; hence, the testing time is also reduced. This is a very efficient, useful mode that offers a compromise between testing accuracy and speed. However, you need to be careful with it when it comes to someone else's Expert Advisor.

Refusal to generate additional intermediate ticks between prices *Open*, *High*, *Low*, and *Close* leads to the appearance of rigid determinism in the development of prices from the moment the *Open* price is defined. This makes it possible to create a "Testing Grail" that shows a nice upward trending balance chart when testing.

> For a minute bar, 4 prices are known, of which the first one is *Open*, and the last one is *Close*. Prices registered between them are *High* and *Low*, and information about the order of their occurrence is lost, but we know that the *High* price is greater than or equal to *Open*, and *Low* is less than or equal to *Open*.
>
> After receiving the *Open* price, we need to analyze only the next tick to determine whether it is *High* or *Low*. If the price is below *Open*, this is *Low* – buy on this tick, as the next tick will correspond to the *High* price, on which we close the buy trade and open a sell one. The next tick is the last on the bar, *Close*, on which we close sell.

If a tick with a price higher than the opening price comes after our price, then the sequence of transactions is reversed. Seemingly, one could trade on every bar in this mode. When testing such an Expert Advisor on history, everything goes perfectly, but online it will fail.

A similar effect can happen unintentionally, due to a combination of features of the calculation algorithm (for example, statistics calculation) and tick generation.

Thus, it is always important to test it in the "Every tick" mode or, better, based on real ticks after finding the optimal Expert Advisor settings on rough testing modes ("1 minute OHLC" and "Only Open Prices").

Open prices only

In this mode, ticks are generated using the OHLC prices of the timeframe selected for testing. In this case, the *OnTick* function runs only once, at the beginning of each bar. Because of this feature, stop levels and pending orders may be triggered at a price different from the requested one (especially when testing on higher timeframes). In exchange for this, we get the opportunity to quickly conduct evaluation testing of the Expert Advisor.

For example, the Expert Advisor is tested on EURUSD H1 in the "Open price only" mode. In this case, the total number of ticks (control points) will be 4 times more than the number of hourly bars that fall within the tested interval. But in this case, the *OnTick* handler will only be called at the opening of hourly bars. For the rest ticks ("hidden" from the Expert Advisor), the following checks required for correct testing are performed:

- calculation of margin requirements
- triggering of *Stop Loss* and *Take Profit*
- triggering pending orders
- deleting pending orders upon expiration

If there are no open positions or pending orders, then there is no need for these checks on hidden ticks, and the speed increase can be significant.

An exception when generating ticks in the "Open prices only" mode are the W1 and MN1 periods: for these timeframes, ticks are generated for the OHLC prices of each day, not weekly or monthly, respectively.

This "Open prices only" mode is well suited for testing strategies that perform trades only at the opening of the bar and do not use pending orders, and do not use *Stop Loss* and *Take Profit* levels. For the class of such strategies, all the necessary testing accuracy is preserved.

The MQL5 API does not allow the program to find out in which mode it is running in the tester. At the same time, this may be important for Expert Advisors or the indicators they use, which are not designed, for example, to work correctly at opening prices or OHLC. In this regard, we implement a simple mode detection mechanism. The source code is attached in the file *TickModel.mqh*.

Let's declare our enumeration with the existing modes.

```
enum TICK_MODEL
{
   TICK_MODEL_UNKNOWN = -1,     /*Unknown (any)*/     // unknown/not yet defined
   TICK_MODEL_REAL = 0,         /*Real ticks*/        // best quality
   TICK_MODEL_GENERATED = 1,    /*Generated ticks*/   // good quality
   TICK_MODEL_OHLC_M1 = 2,      /*OHLC M1*/           // acceptable quality and fast
   TICK_MODEL_OPEN_PRICES = 3, /*Open prices*/       // worse quality, but very fast
   TICK_MODEL_MATH_CALC = 4,    /*Math calculations*/// no ticks (not defined)
};
```

Except the first element, which is reserved for the case when the mode has not yet been determined or cannot be determined for some reason, all other elements are arranged in descending order of simulation quality, starting from real and ending with opening prices (for them, the developer must check the compatibility strategy with the fact that its trading is carried out only at the opening of a new bar). The last mode TICK_MODEL_MATH_CALC operates without ticks altogether; we will consider it separately.

The mode detection principle is based on the check of the availability of ticks and their times on the first two ticks when starting the test. The check itself is wrapped in the *getTickModel* function, which the Expert Advisor should call from the *OnTick* handler. Since the check is done once, the static variable model is described inside the function initially set to TICK_MODEL_UNKNOWN. It will store and switch the current state of the check, which will be required to distinguish between OHLC modes and opening prices.

```
TICK_MODEL getTickModel()
{
   static TICK_MODEL model = TICK_MODEL_UNKNOWN;
   ...
```

On the first analyzed tick, the model is equal to TICK_MODEL_UNKNOWN, and an attempt is made to get real ticks by calling *CopyTicks*.

```
   if(model == TICK_MODEL_UNKNOWN)
   {
      MqlTick ticks[];
      const int n = CopyTicks(_Symbol, ticks, COPY_TICKS_ALL, 0, 10);
      if(n == -1)
      {
         switch(_LastError)
         {
         case ERR_NOT_ENOUGH_MEMORY:    // emulate ticks
            model = TICK_MODEL_GENERATED;
            break;

         case ERR_FUNCTION_NOT_ALLOWED: // prices of opening and OHLC
            if(TimeCurrent() != iTime(_Symbol, _Period, 0))
            {
               model = TICK_MODEL_OHLC_M1;
            }
            else if(model == TICK_MODEL_UNKNOWN)
            {
               model = TICK_MODEL_OPEN_PRICES;
            }
            break;
         }

         Print(E2S(_LastError));
      }
      else
      {
         model = TICK_MODEL_REAL;
      }
   }
   ...
```

If it succeeds, the detection immediately ends with setting the model to TICK_MODEL_REAL. If real ticks are not available, the system will return a certain error code, according to which we can draw the following conclusions. The error code ERR_NOT_ENOUGH_MEMORY corresponds to the tick emulation mode. Why the code is this way is not entirely clear, but this is a characteristic feature, and we use it here. In the other two tick generation modes, we will get the ERR_FUNCTION_NOT_ALLOWED error.

You can distinguish one mode from the other by the tick time. If it turns out to be a non-multiple of the timeframe for a tick, then we are talking about the OHLC mode. However, the problem here is that the first tick in both modes can be aligned with the bar opening time. Thus, we will get the value TICK_MODEL_OPEN_PRICES, but it needs to be specified. Therefore, for the final conclusion, one more tick should be analyzed (call the function on it again if TICK_MODEL_OPEN_PRICES was received earlier). For this case, the following *if* branch is provided inside the function.

```
      else if(model == TICK_MODEL_OPEN_PRICES)
      {
         if(TimeCurrent() != iTime(_Symbol, _Period, 0))
         {
            model = TICK_MODEL_OHLC_M1;
         }
      }
      return model;
   }
```

Let's check the operation of the detector in a simple Expert Advisor *TickModel.mq5*. In the *TickCount* input parameter, we specify the maximum number of analyzed ticks, that is, how many times the *getTickModel* function will be called. We know that two is enough, but in order to make sure that the model does not change afterward, 5 ticks are suggested by default. We also provide the *RequireTickModel* parameter which instructs the Expert Advisor to terminate operation if the simulation level is lower than the requested one. By default, its value is TICK_MODEL_UNKNOWN, which means no mode restriction.

```
input int TickCount = 5;
input TICK_MODEL RequireTickModel = TICK_MODEL_UNKNOWN;
```

In the *OnTick* handler, we run our code only if it works in the tester.

```
void OnTick()
{
   if(MQLInfoInteger(MQL_TESTER))
   {
      static int count = 0;
      if(count++ < TickCount)
      {
         // output tick information for reference
         static MqlTick tick[1];
         SymbolInfoTick(_Symbol, tick[0]);
         ArrayPrint(tick);
         // define and display the model (preliminarily)
         const TICK_MODEL model = getTickModel();
         PrintFormat("%d %s", count, EnumToString(model));
         // if the tick counter is 2+, the conclusion is final and we act based on it
         if(count >= 2)
         {
            if(RequireTickModel != TICK_MODEL_UNKNOWN
            && RequireTickModel < model) // quality less than requested
            {
               PrintFormat("Tick model is incorrect (%s %sis required), terminating",
                  EnumToString(RequireTickModel),
                  (RequireTickModel != TICK_MODEL_REAL ? "or better " : ""));
               ExpertRemove(); // end operation
            }
         }
      }
   }
}
```

Let's try to run the Expert Advisor in the tester with different tick generation modes by choosing a common combination of EURUSD H1.

The *RequireTickModel* parameter in the Expert Advisor is set to OHLC M1. If the tester mode is "Every tick", we will receive a corresponding message in the log, and the Expert Advisor will continue working.

```
                  [time]   [bid]   [ask]  [last] [volume]    [time_msc] [flags] [volum
[0] 2022.04.01 00:00:30 1.10656 1.10679 1.10656        0 1648771230000      14
NOT_ENOUGH_MEMORY
1 TICK_MODEL_GENERATED
                  [time]   [bid]   [ask]  [last] [volume]    [time_msc] [flags] [volum
[0] 2022.04.01 00:01:00 1.10656 1.10680 1.10656        0 1648771260000      12
2 TICK_MODEL_GENERATED
                  [time]   [bid]   [ask]  [last] [volume]    [time_msc] [flags] [volum
[0] 2022.04.01 00:01:30 1.10608 1.10632 1.10608        0 1648771290000      14
3 TICK_MODEL_GENERATED
```

The OHLC M1 and real ticks modes are also suitable, and in the latter case, there will be no error code.

```
                  [time]   [bid]   [ask] [last] [volume]    [time_msc] [flags] [volume
[0] 2022.04.01 00:00:00 1.10656 1.10687 0.0000        0 1648771200122     134       0
1 TICK_MODEL_REAL
                  [time]   [bid]   [ask] [last] [volume]    [time_msc] [flags] [volume
[0] 2022.04.01 00:00:00 1.10656 1.10694 0.0000        0 1648771200417       4       0
2 TICK_MODEL_REAL
                  [time]   [bid]   [ask] [last] [volume]    [time_msc] [flags] [volume
[0] 2022.04.01 00:00:00 1.10656 1.10691 0.0000        0 1648771200816       4       0
3 TICK_MODEL_REAL
```

However, if you change the mode in the tester to "Open prices only", the Expert Advisor will stop after the second tick.

```
                  [time]   [bid]   [ask]  [last] [volume]    [time_msc] [flags] [volum
[0] 2022.04.01 00:00:00 1.10656 1.10679 1.10656        0 1648771200000      14
FUNCTION_NOT_ALLOWED
1 TICK_MODEL_OPEN_PRICES
                  [time]   [bid]   [ask]  [last] [volume]    [time_msc] [flags] [volum
[0] 2022.04.01 01:00:00 1.10660 1.10679 1.10660        0 1648774800000      14
2 TICK_MODEL_OPEN_PRICES
Tick model is incorrect (TICK_MODEL_OHLC_M1 or better is required), terminating
ExpertRemove() function called
```

This method requires running a test and waiting for a couple of ticks in order to determine the mode. In other words, we cannot stop the test early by returning an error from *OnInit*. Even more, when starting an optimization with the wrong type of tick generation, we will not be able to stop the optimization, which can only be done from the *OnTesterInit* function. Thus, the tester will try to complete all passes during the optimization, although they will be stopped at the very beginning. This is the current platform limitation.

6.5.2 Time management in the tester: timer, Sleep, GMT

When developing Expert Advisors, it should be taken into account that the tester has some specifics of simulating the passage of time based on generated ticks and operation of time-related functions.

When testing, the local time returned by the *TimeLocal* function is always equal to the server time according to *TimeTradeServer*. In turn, server time is always equal to GMT *TimeGMT*. Thus, all these functions, when tested, give the same time. This is a technical feature of the platform, which occurs because it was decided not to store information about the server time locally, but always take it from the server, with which there may be no connection at a particular moment.

This feature creates difficulties in the implementation of strategies related to global time, in particular, with reference to news releases. In such cases, it is necessary to specify the time zone of quotes in the settings of the Expert Advisor being tested or to invent methods for auto-detection of the time zone (see section Daylight saving time).

Let's turn now to other functions for working with time.

As we know, it is possible to process timer events in MQL5. The *OnTimer* handler is called regardless of the testing mode. This means that if testing is launched in the "Open prices only" mode on the H4 period, and a timer is set inside the Expert Advisor with a call coming every second, then the *OnTick* handler will be called once at the opening of each H4 bar and then, within the bar, the *OnTimer* handler will be called 14400 times (3600 seconds * 4 hours). The extent to which the Expert Advisor testing time will increase in this case depends on its algorithm.

Another function that influences the course of time within a program is the *Sleep* function. It allows you to suspend the execution of an Expert Advisor for some time. This may be necessary when requesting any data that is not yet ready at the time of the request, and it is necessary to wait until it is ready.

It is important to understand that *Sleep* affects only the program that calls it and does not delay the testing process. In fact, when calling *Sleep*, the generated ticks are "played" within the specified delay, as a result of which pending orders, stop levels, etc. can be triggered. After calling *Sleep*, the time simulated in the tester is increased by the interval specified in the function parameter.

Later, in the section on testing multi-currency Expert Advisors, we will show how you can use the timer and the *Sleep* function to synchronize bars.

6.5.3 Testing visualization: chart, objects, indicators

The tester allows testing in two different ways: with and without visualization. The method is selected by choosing a corresponding option on the main settings tab of the tester.

When visualization is enabled, the tester opens a separate window in which it reproduces trading operations and displays indicators and objects. Though it is visual, we don't need to see it for every case, but only for programs with a user interface (for example, trading panels or controlled markup made by graphical objects). For other Expert Advisors, only the execution of the algorithm according to the established strategy is important. This can be checked without visualization, which can significantly speed up the process. By the way, it is in this mode that test runs are made during optimization.

During such "background" testing and optimization, no graphical objects are built. Therefore, when accessing the properties of objects, the Expert Advisor will receive zero values. Thus, you can check the work with objects and the chart only when testing in the visual mode.

Previously, in the Testing indicators section, we have seen the specific behavior of indicators in the tester. To increase the efficiency of non-visual testing and optimization of Expert Advisors (using indicators), indicators can be calculated not on every tick, but only when we request data from them. Recalculation on each tick occurs only if there are *EventChartCustom*, *OnChartEvent*, *OnTimer* functions or *tester_everytick_calculate* directives in the indicator (see Preprocessor directives for the tester). In the visual tester window online indicators always receive *OnCalculate* events on every tick.

If testing is carried out in a non-visual mode, after its completion, the symbol chart automatically opens in the terminal, which displays completed deals and indicators that were used in the Expert Advisor. This helps to correlate the market entry and exit moments with indicator values. However, here we mean only indicators that work on the symbol and timeframe of testing. If the Expert Advisor created indicators on other symbols or timeframes, they will not be shown.

> It is important to note that the indicators displayed on the chart automatically opened after testing is completed are recalculated after the end of testing. This happens even if these indicators were used in the tested Expert Advisor and were previously calculated "on the go", as the bars were forming.

In some cases, the programmer may need to hide information about which indicators are used in the trading algorithm, and therefore their visualization on the chart is undesirable. The *IndicatorRelease* function can be used for this.

The *IndicatorRelease* function is originally intended to release the calculated part of the indicator if it is no longer needed. This saves memory and processor resources. Its second purpose is to prohibit the display of the indicator on the testing chart after completing a single run.

To disable the display of the indicator on the chart at the end of testing, just call *IndicatorRelease* with the indicator handle in the *OnDeinit* handler. The *OnDeinit* function is always called in Expert Advisors after completion and before displaying the test chart. Neither OnDeinit nor the destructors of global and static objects are called in the indicators themselves in the tester – this is what the developers of MetaTrader 5 agreed on.

In addition, the MQL5 API includes a special function *TesterHideIndicators* with a similar purpose, which we will consider later.

At the same time, it should be taken into account that tpl templates (if they are created) can additionally influence the external representation of the testing graph.

So if there is a *tester.tpl* template in the *MQL5/Profiles/Templates* directory, it will be applied to the opened chart. If the Expert Advisor used other indicators in its work and did not prohibit their display, then the indicators from the template and from the Expert Advisor will be combined on the chart.

When *tester.tpl* is absent, the default template (*default.tpl*) is applied.

If the *MQL5/Profiles/Templates* folder contains a tpl template with the same name as the Expert Advisor (for example, *ExpertMACD.tpl*), then during visual testing or on the chart opened after testing, only indicators from this template will be shown. In this case, no indicators used in the tested Expert Advisor will be shown.

6.5.4 Multicurrency testing

As you know, the MetaTrader 5 tester allows you to test strategies that trade multiple financial instruments. Purely technically, subject to the computer hardware resources, it is possible to simulate simultaneous trading for all available instruments.

Testing such strategies imposes several additional technical requirements on the tester:

- Generation of tick sequences for all instruments
- Calculation of indicators for all instruments
- Calculation of margin requirements and emulation of other trading conditions for all instruments

The tester automatically downloads the history of required instruments from the terminal when accessing the history for the first time. If the terminal does not contain the required history, it will in turn request it from the trade server. Therefore, before testing a multicurrency Expert Advisor, it is recommended to select the required instruments in the terminal's *Market Watch* and download the desired amount of data.

The agent uploads the missing history with a small margin to provide the necessary data for calculating indicators or copying by the Expert Advisor at the time of testing. The minimum amount of history downloaded from the trading server depends on the timeframe. For example, for D1 timeframes and less, it is one year. In other words, the preliminary history is downloaded from the beginning of the previous year relative to the tester start date. This gives at least 1 year of history if testing is requested from January 1st and a maximum of almost two years if testing is ordered from December. For a weekly timeframe, a history of 100 bars is requested, that is, approximately two years (there are 52 weeks in a year). For testing on a monthly timeframe, the agent will request 100 months (equal to the history of about 8 years: 12 months * 8 years = 96). In any case, on timeframes lower than the working one, a proportionally larger number of bars will be available. If the existing data is not enough for the predefined depth of the preliminary history, this fact will be recorded in the test log.

You cannot configure (change) this behavior. Therefore, if you need to provide a specified number of historical bars of the current timeframe from the very beginning, you should set an earlier start date for the test and then "wait" in the Expert Advisor code for the required trading start date or a sufficient number of bars. Before that, you should skip all events.

The tester also emulates its own *Market Watch*, from which the program can obtain information on instruments. By default, at the beginning of testing, the tester *Market Watch* contains only one symbol: the symbol on which testing is started. All additional symbols are added to the tester *Market Watch* automatically when accessing them through the API functions. At the first access to a "third-party" symbol from an MQL program, the testing agent will synchronize the symbol data with the terminal.

The data of additional symbols can be accessed in the following cases:

- Using technical indicators, *iCustom*, or *IndicatorCreate* for the symbol/timeframe pair
- Querying another symbol's *Market Watch*:
  - SeriesInfoInteger
  - Bars
  - SymbolSelect
  - SymbolIsSynchronized
  - SymbolInfoDouble
  - SymbolInfoInteger
  - SymbolInfoString
  - SymbolInfoTick
  - SymbolInfoSessionQuote
  - SymbolInfoSessionTrade
  - MarketBookAdd
  - MarketBookGet
- Querying the symbol/timeframe pair timeseries using the following functions:
  - CopyBuffer
  - CopyRates
  - CopyTime
  - CopyOpen
  - CopyHigh
  - CopyLow
  - CopyClose
  - CopyTickVolume
  - CopyRealVolume
  - CopySpread

In addition, you can explicitly request the history for the desired symbols by calling the *SymbolSelect* function in the *OnInit* handler. The history will be loaded in advance before the Expert Advisor testing starts.

At the moment when another symbol is accessed for the first time, the testing process stops and the symbol/period pair history is downloaded from the terminal into the testing agent. The tick sequence generation is also enabled at this moment.

Each instrument generates its own tick sequence according to the set tick generation mode.

Synchronization of bars of different symbols is of particular importance when implementing multicurrency Expert Advisors since the correctness of calculations depends on this. A state is considered synchronized when the last bars of all used symbols have the same opening time.

The tester generates and plays its tick sequence for each instrument. At the same time, a new bar on each instrument is opened regardless of how bars are opened on other instruments. This means that when testing a multicurrency Expert Advisor, a situation is possible (and most often it happens) when a new bar has already opened on one instrument, but not yet on another.

For example, if we are testing an Expert Advisor using EURUSD symbol data and a new hourly candlestick has opened for this symbol, we will receive the *OnTick* event. But at the same time, there is no guarantee that a new candlestick has opened on GBPUSD, which we might also be using.

Thus, the synchronization algorithm implies that you need to check the quotes of all instruments and wait for the equality of the opening times of the last bars.

This does not raise any questions for as long as the real tick, emulation of all ticks, or OHLC M1 testing modes are used. With these modes, a sufficient number of ticks are generated within one candlestick to wait for the moment of synchronization of bars from different symbols. Just complete the *OnTick* function and check the appearance of a new bar on GBPUSD on the next tick. But when testing in the "Open prices only" mode, there will be no other tick, since the Expert Advisor is called only once per bar, and it may seem that this mode is not suitable for testing multicurrency Expert Advisors. In fact, the tester allows you to detect the moment when a new bar opens on another symbol using the *Sleep* function (in a loop) or a timer.

First, let's consider an example of an Expert Advisor *SyncBarsBySleep.mq5*, which demonstrates the synchronization of bars through *Sleep*.

A pair of input parameters allows you to set the *Pause* size in seconds to wait for other symbol's bars, as well as the name of that other symbol (*OtherSymbol*), which must be different from the chart symbol.

```
input uint Pause = 1;                    // Pause (seconds)
input string OtherSymbol = "USDJPY";
```

To identify patterns in the delay of bar opening times, we describe a simple class *BarTimeStatistics*. It contains a field for counting the total number of bars (*total*) and the number of bars on which there was no synchronization initially (*late*), that is, the other symbol was late.

```
class BarTimeStatistics
{
public:
   int total;
   int late;

   BarTimeStatistics(): total(0), late(0) { }

   ~BarTimeStatistics()
   {
      PrintFormat("%d bars on %s was late among %d total bars on %s (%2.1f%%)",
         late, OtherSymbol, total, _Symbol, late * 100.0 / total);
   }
};
```

The object of this class prints the received statistics in its destructor. Since we are going to make this object static, the report will be printed at the very end of the test.

If the tick generation mode selected in the tester differs from the opening prices, we will detect this using the previously considered *getTickModel* function and will return a warning.

```
void OnTick()
{
   const TICK_MODEL model = getTickModel();
   if(model != TICK_MODEL_OPEN_PRICES)
   {
      static bool shownOnce = false;
      if(!shownOnce)
      {
         Print("This Expert Advisor is intended to run in \"Open Prices\" mode");
         shownOnce = true;
      }
   }
```

Next, *OnTick* provides the working synchronization algorithm.

```
   // time of the last known bar for _Symbol
   static datetime lastBarTime = 0;
   // attribute of synchronization
   static bool synchronized = false;
   // bar counters
   static BarTimeStatistics stats;

   const datetime currentTime = iTime(_Symbol, _Period, 0);

   // if it is executed for the first time or the bar has changed, save the bar
   if(lastBarTime != currentTime)
   {
      stats.total++;
      lastBarTime = currentTime;
      PrintFormat("Last bar on %s is %s", _Symbol, TimeToString(lastBarTime));
      synchronized = false;
   }

   // time of the last known bar for another symbol
   datetime otherTime;
   bool late = false;

   // wait until the times of two bars become the same
   while(currentTime != (otherTime = iTime(OtherSymbol, _Period, 0)))
   {
      late = true;
      PrintFormat("Wait %d seconds...", Pause);
      Sleep(Pause * 1000);
   }
   if(late) stats.late++;

   // here we are after synchronization, save the new status
   if(!synchronized)
   {
      // use TimeTradeServer() because TimeCurrent() does not change in the absence o
      Print("Bars are in sync at ", TimeToString(TimeTradeServer(),
         TIME_DATE | TIME_SECONDS));
      // no longer print a message until the next out of sync
      synchronized = true;
   }
   // here is your synchronous algorithm
   // ...
}
```

Let's set up the tester to run the Expert Advisor on EURUSD, H1, which is the most liquid instrument. Let's use the default Expert Advisor parameters, that is, USDJPY will be the "other" symbol.

As a result of the test, the log will contain the following entries (we intentionally show the logs related to the downloading of the USDJPY history, which occurred during the first *iTime* call).

```
2022.04.15 00:00:00   Last bar on EURUSD is 2022.04.15 00:00
USDJPY: load 27 bytes of history data to synchronize in 0:00:00.001
USDJPY: history synchronized from 2020.01.02 to 2022.04.20
USDJPY,H1: history cache allocated for 8109 bars and contains 8006 bars from 2021.01.
USDJPY,H1: 1 bar from 2022.04.15 00:00 added
USDJPY,H1: history begins from 2021.01.04 00:00
2022.04.15 00:00:00   Bars are in sync at 2022.04.15 00:00:00
2022.04.15 01:00:00   Last bar on EURUSD is 2022.04.15 01:00
2022.04.15 01:00:00   Wait 1 seconds...
2022.04.15 01:00:01   Bars are in sync at 2022.04.15 01:00:01
2022.04.15 02:00:00   Last bar on EURUSD is 2022.04.15 02:00
2022.04.15 02:00:00   Wait 1 seconds...
2022.04.15 02:00:01   Bars are in sync at 2022.04.15 02:00:01
...
2022.04.20 23:59:59   95 bars on USDJPY was late among 96 total bars on EURUSD (99.0%
```

You can see that the USDJPY bars are delayed regularly. If you select USDJPY, H1 in the tester settings and EURUSD in the Expert Advisor parameters, you will get the opposite picture.

```
2022.04.15 00:00:00   Last bar on USDJPY is 2022.04.15 00:00
EURUSD: load 27 bytes of history data to synchronize in 0:00:00.002
EURUSD: history synchronized from 2018.01.02 to 2022.04.20
EURUSD,H1: history cache allocated for 8109 bars and contains 8006 bars from 2021.01.
EURUSD,H1: 1 bar from 2022.04.15 00:00 added
EURUSD,H1: history begins from 2021.01.04 00:00
2022.04.15 00:00:00   Bars are in sync at 2022.04.15 00:00:00
2022.04.15 01:00:00   Last bar on USDJPY is 2022.04.15 01:00
2022.04.15 01:00:00   Wait 1 seconds...
2022.04.15 01:00:01   Bars are in sync at 2022.04.15 01:00:01
2022.04.15 02:00:00   Last bar on USDJPY is 2022.04.15 02:00
2022.04.15 02:00:00   Wait 1 seconds...
2022.04.15 02:00:01   Bars are in sync at 2022.04.15 02:00:01
...
2022.04.20 23:59:59   23 bars on EURUSD was late among 96 total bars on USDJPY (24.0%
```

Here, in most cases, there was no need to wait: the EURUSD bars already existed at the time the USDJPY bar was formed.

There is another way to synchronize bars: using a timer. An example of such an Expert Advisor, *SyncBarsByTimer.mq5*, is included in the book. Please note that the timer events, as a rule, occur inside the bar (because the probability of hitting exactly the beginning is very low). Because of this, the bars are almost always synchronized.

We could also remind you about the possibility of synchronizing bars using the spy indicator *EventTickSpy.mq5*, but it's based on custom events that only work when testing visually. In addition, for such indicators that require a response to each tick, it is important to use the *#property tester_everytick_calculate* directive. We have already talked about it in the Testing indicators section, and we will remind you about it once again in the section on specific tester directives.

6.5.5 Optimization criteria

An optimization criterion is a certain metric that defines the quality of the tested set of input parameters. The greater the value of the optimization criterion, the better the test result with a given

set of parameters is estimated. The parameter is selected on the "Settings" tab to the right of the "Optimization" field.

The criterion is important not only for the user to be able to compare the results. Without an optimization criterion, it is impossible to use a genetic algorithm, since on the basis of the criterion it "decides" how to select candidates for new generations. The criterion is not used during full optimization with a complete iteration of all possible variants.

The following built-in optimization criteria are available in the tester:

- Maximum balance
- Maximum profitability
- Maximum expected win (average profit/loss per trade)
- Minimum drawdown as a percentage of equity
- Maximum recovery factor
- Maximum Sharpe ratio
- Custom optimization criterion

When choosing the latter option, the value of the *OnTester* function implemented in the Expert Advisor will be taken into account as an optimization criterion – we will consider it later. This parameter allows the programmer to use any custom index for optimization.

A special "complex criterion" is also available in MetaTrader 5. This is an integral metric of the quality of the testing pass, which takes into account several parameters at once:

- Number of deals
- Drawdown
- Recovery factor
- Mathematical expectation of winning
- Sharpe ratio

The formula is not disclosed by the developers, but it is known that possible values range from 0 to 100. It is important that the values of the complex parameter affect the color of the cells of the *Result* column in the optimization table regardless of the criterion, i.e., highlighting following this scheme works even when another criterion is chosen for display in the *Result* column. Weak combinations with values below 20 are highlighted in red, strong combinations above 80 are highlighted in dark green.

The search for a universal criterion of the trading system quality factor is an urgent and difficult task for most traders, since the choice of settings based on the maximum value of one criterion (for example, profit) is, as a rule, far from the best option in terms of stable and predictable behavior of the Expert Advisor in the foreseeable future.

The presence of a complex indicator allows you to level the weaknesses of each individual metric (and they are necessarily available and widely known) and provides a guideline when developing your own custom variables for calculation in *OnTester*. We will deal with this soon.

6.5.6 Getting testing financial statistics: TesterStatistics

We usually evaluate the quality of an Expert Advisor based on a trading report, which is similar to a testing report when dealing with a tester. It contains a large number of variables that characterize the trading style, stability and, of course, profitability. All these metrics, with some exceptions, are

available to the MQL program through a special function *TesterStatistics*. Thus, the Expert Advisor developer has the ability to analyze individual variables in the code and construct their own combined optimization quality criteria from them.

double TesterStatistics(ENUM_STATISTICS statistic)

The *TesterStatistics* function returns the value of the specified statistical variable, calculated based on the results of a separate run of the Expert Advisor in the tester. A function can be called in the *OnDeinit* or *OnTester* handler, which is yet to be discussed.

All available statistical variables are summarized in the ENUM_STATISTICS enumeration. Some of them serve as qualitative characteristics, that is, real numbers (usually total profits, drawdowns, ratios, and so on), and the other part is quantitative, that is, integers (for example, the number of transactions). However, both groups are controlled by the same function with the *double* result.

The following table shows real indicators (monetary amounts and coefficients). All monetary amounts are expressed in the deposit currency.

Identifier	Description
STAT_INITIAL_DEPOSIT	Initial deposit
STAT_WITHDRAWAL	The amount of funds withdrawn from the account
STAT_PROFIT	Net profit or loss at the end of testing, the sum of STAT_GROSS_PROFIT and STAT_GROSS_LOSS
STAT_GROSS_PROFIT	Total profit, the sum of all profitable trades (greater than or equal to zero)
STAT_GROSS_LOSS	Total loss, the sum of all losing trades (less than or equal to zero)
STAT_MAX_PROFITTRADE	Maximum profit: the largest value among all profitable trades (greater than or equal to zero)
STAT_MAX_LOSSTRADE	Maximum loss: the smallest value among all losing trades (less than or equal to zero)
STAT_CONPROFITMAX	Total maximum profit in a series of profitable trades (greater than or equal to zero)
STAT_MAX_CONWINS	Total profit in the longest series of profitable trades
STAT_CONLOSSMAX	Total maximum loss in a series of losing trades (less than or equal to zero)
STAT_MAX_CONLOSSES	Total loss in the longest series of losing trades
STAT_BALANCEMIN	Minimum balance value
STAT_BALANCE_DD	Maximum balance drawdown in money
STAT_BALANCEDD_PERCENT	Balance drawdown in percent, which was recorded at the time of the maximum balance drawdown in money (STAT_BALANCE_DD)
STAT_BALANCE_DDREL_PERCENT	Maximum balance drawdown in percent

Identifier	Description
STAT_BALANCE_DD_RELATIVE	Balance drawdown in money equivalent, which was recorded at the moment of the maximum balance drawdown in percent (STAT_BALANCE_DDREL_PERCENT)
STAT_EQUITYMIN	Minimum equity value
STAT_EQUITY_DD	Maximum drawdown in money
STAT_EQUITYDD_PERCENT	Drawdown in percent, which was recorded at the time of the maximum drawdown of funds in the money (STAT_EQUITY_DD)
STAT_EQUITY_DDREL_PERCENT	Maximum drawdown in percent
STAT_EQUITY_DD_RELATIVE	Drawdown in money that was recorded at the time of the maximum drawdown in percent (STAT_EQUITY_DDREL_PERCENT)
STAT_EXPECTED_PAYOFF	Mathematical expectation of winnings (arithmetic mean of the total profit and the number of transactions)
STAT_PROFIT_FACTOR	Profitability, which is the ratio STAT_GROSS_PROFIT/STAT_GROSS_LOSS (if STAT_GROSS_LOSS = 0; profitability takes the value DBL_MAX)
STAT_RECOVERY_FACTOR	Recovery factor: the ratio of STAT_PROFIT/STAT_BALANCE_DD
STAT_SHARPE_RATIO	Sharpe ratio
STAT_MIN_MARGINLEVEL	Minimum margin level reached
STAT_CUSTOM_ONTESTER	The value of the custom optimization criterion returned by the OnTester function

The following table shows integer indicators (amounts).

Identifier	Description
STAT_DEALS	Total number of completed transactions
STAT_TRADES	Number of trades (deals to exit the market)
STAT_PROFIT_TRADES	Profitable trades
STAT_LOSS_TRADES	Losing trades
STAT_SHORT_TRADES	Short trades
STAT_LONG_TRADES	Long trades
STAT_PROFIT_SHORTTRADES	Short profitable trades
STAT_PROFIT_LONGTRADES	Long profitable trades
STAT_PROFITTRADES_AVGCON	Average length of a profitable series of trades

Identifier	Description
STAT_LOSSTRADES_AVGCON	Average length of a losing series of trades
STAT_CONPROFITMAX_TRADES	Number of trades that formed STAT_CONPROFITMAX (maximum profit in the sequence of profitable trades)
STAT_MAX_CONPROFIT_TRADES	Number of trades in the longest series of profitable trades STAT_MAX_CONWINS
STAT_CONLOSSMAX_TRADES	Number of trades that formed STAT_CONLOSSMAX (maximum loss in the sequence of losing trades)
STAT_MAX_CONLOSS_TRADES	Number of trades in the longest series of losing trades STAT_MAX_CONLOSSES

Let's try to use the presented metrics to create our own complex Expert Advisor quality criterion. To do this, we need some kind of "experimental" example of an MQL program. Let's take the Expert Advisor *MultiMartingale.mq5* as a starting point, but we will simplify it: we will remove multicurrency, built-in error handling, and scheduling. Moreover, we will choose a signal trading strategy for it with a single calculation on the bar, i.e., at the opening prices. This will speed up optimization and expand the field for experiments.

The strategy will be based on the overbought and oversold conditions determined by the OsMA indicator. The Bollinger Bands indicator superimposed on OsMA will help you dynamically find the boundaries of excess volatility, which means trading signals.

When OsMA returns inside the corridor, crossing the lower border from the bottom up, we will open a buy trade. When OsMA crosses the upper boundary in the same way from top to bottom, we will sell. To exit positions, we use the moving average, also applied to OsMA. If OsMA shows a reverse movement (down for a long position or up for a short position) and touches the MA, the position will be closed. This strategy is illustrated in the following screenshot.

Trading strategy based on OsMA, BBands and MA indicators

The blue vertical line corresponds to the bar where the buy is opened, since on the two previous bars the lower Bollinger band was crossed by the OsMA histogram from the bottom up (this place is marked with a hollow blue arrow in the subwindow). The red vertical line is the location of the reverse signal, so the buy was closed and the sell was opened. In the subwindow, in this place (or rather, on the two previous bars, where the hollow red arrow is located), the OsMA histogram crosses the upper Bollinger band from top to bottom. Finally, the green line indicates the closing of the sale, due to the fact that the histogram began to rise above the red MA.

Let's name the Expert Advisor *BandOsMA.mq5*. The general settings will include a magic number, a fixed lot, and a stop loss distance in points. For the stop loss, we will use *TrailingStop* from the previous example. Take profit is not used here.

```
input group "C O M M O N   S E T T I N G S"
sinput ulong Magic = 1234567890;
input double Lots = 0.01;
input int StopLoss = 1000;
```

Three groups of settings are intended for indicators.

```
input group "O S M A   S E T T I N G S"
input int FastOsMA = 12;
input int SlowOsMA = 26;
input int SignalOsMA = 9;
input ENUM_APPLIED_PRICE PriceOsMA = PRICE_TYPICAL;

input group "B B A N D S   S E T T I N G S"
input int BandsMA = 26;
input int BandsShift = 0;
input double BandsDeviation = 2.0;

input group "M A   S E T T I N G S"
input int PeriodMA = 10;
input int ShiftMA = 0;
input ENUM_MA_METHOD MethodMA = MODE_SMA;
```

In the *MultiMartingale.mq5* Expert Advisor, we had no trading signals, while the opening direction was set by the user. Here we have trading signals, and it makes sense to arrange them as a separate class. First, let's describe the abstract interface *TradingSignal*.

```
interface TradingSignal
{
   virtual int signal(void);
};
```

It is as simple as our other interface *TradingStrategy*. And this is good. The simpler the interfaces and objects, the more likely they are to do one single thing, which is a good programming style because it minimizes bugs and makes large software projects more understandable. Due to abstraction in any program that uses *TradingSignal*, it will be possible to replace one signal with another. We can also replace the strategy. Our strategies are now responsible for preparing and sending orders, and signals initiate them based on market analysis.

In our case, let's pack the specific implementation of *TradingSignal* into the *BandOsMaSignal* class. Of course, we need variables to store the descriptors of the 3 indicators. Indicator instances are created and deleted in the constructor and destructor, respectively. All parameters will be passed from input variables. Note that *iBands* and *iMA* are built based on the *hOsMA* handler.

```
class BandOsMaSignal: public TradingSignal
{
   int hOsMA, hBands, hMA;
   int direction;
public:
   BandOsMaSignal(const int fast, const int slow, const int signal,
      const ENUM_APPLIED_PRICE price,
      const int bands, const int shift, const double deviation,
      const int period, const int x, ENUM_MA_METHOD method)
   {
      hOsMA = iOsMA(_Symbol, _Period, fast, slow, signal, price);
      hBands = iBands(_Symbol, _Period, bands, shift, deviation, hOsMA);
      hMA = iMA(_Symbol, _Period, period, x, method, hOsMA);
      direction = 0;
   }

   ~BandOsMaSignal()
   {
      IndicatorRelease(hMA);
      IndicatorRelease(hBands);
      IndicatorRelease(hOsMA);
   }
   ...
```

The direction of the current trading signal is placed in the variable *direction*: 0 – no signals (undefined situation), +1 – buy, -1 – sell. We will fill in this variable in the *signal* method. Its code repeats the above verbal description of signals in MQL5.

```
   virtual int signal(void) override
   {
      double osma[2], upper[2], lower[2], ma[2];
      // get two values of each indicator on bars 1 and 2
      if(CopyBuffer(hOsMA, 0, 1, 2, osma) != 2) return 0;
      if(CopyBuffer(hBands, UPPER_BAND, 1, 2, upper) != 2) return 0;
      if(CopyBuffer(hBands, LOWER_BAND, 1, 2, lower) != 2) return 0;
      if(CopyBuffer(hMA, 0, 1, 2, ma) != 2) return 0;

      // if there was a signal already, check if it has ended
      if(direction != 0)
      {
         if(direction > 0)
         {
            if(osma[0] >= ma[0] && osma[1] < ma[1])
            {
               direction = 0;
            }
         }
         else
         {
            if(osma[0] <= ma[0] && osma[1] > ma[1])
            {
               direction = 0;
            }
         }
      }

      // in any case, check if there is a new signal
      if(osma[0] <= lower[0] && osma[1] > lower[1])
      {
         direction = +1;
      }
      else if(osma[0] >= upper[0] && osma[1] < upper[1])
      {
         direction = -1;
      }

      return direction;
   }
};
```

As you can see, the indicator values are read for bars 1 and 2, since we will work on opening a bar, and the 0th bar has just opened by the time we we call the *signal* method.

The new class that implements the *TradingStrategy* interface will be called *SimpleStrategy*.

The class provides some new features while also using some previously existing parts. In particular, it retained autopointers for *PositionState* and *TrailingStop* and has a new autopointer to the *TradingSignal* signal. Also, since we are going to trade only on the opening of bars, we needed the *lastBar* variable, which will store the time of the last processed bar.

```
class SimpleStrategy: public TradingStrategy
{
protected:
   AutoPtr<PositionState> position;
   AutoPtr<TrailingStop> trailing;
   AutoPtr<TradingSignal> command;

   const int stopLoss;
   const ulong magic;
   const double lots;

   datetime lastBar;
   ...
```

The global parameters are passed to the *SimpleStrategy* constructor. We also pass a pointer to the *TradingSignal* object: in this case, it will be *BandOsMaSignal* which will have to be created by the calling code. Next, the constructor tries to find among the existing positions those that have the required *magic* number and symbol, and if successful, adds a trailing stop. This will be useful if the Expert Advisor has a break for one reason or another, and the position has already been opened.

```
public:
   SimpleStrategy(TradingSignal *signal, const ulong m, const int sl, const double v)
      command(signal), magic(m), stopLoss(sl), lots(v), lastBar(0)
   {
 // select "our" position among the existing ones (if there is a suitable one)
      PositionFilter positions;
      ulong tickets[];
      positions.let(POSITION_MAGIC, magic).let(POSITION_SYMBOL, _Symbol).select(ticke
      const int n = ArraySize(tickets);
      if(n > 1)
      {
         Alert(StringFormat("Too many positions: %d", n));
 // TODO: close extra positions - this is not allowed by the strategy
      }
      else if(n > 0)
      {
         position = new PositionState(tickets[0]);
         if(stopLoss)
         {
           trailing = new TrailingStop(tickets[0], stopLoss, stopLoss / 50);
         }
      }
   }
```

The implementation of the *trade* method is similar to the martingale example. However, we have removed lot multiplications and added the *signal* method call.

```
virtual bool trade() override
{
   // we work only once when a new bar appears
   if(lastBar == iTime(_Symbol, _Period, 0)) return false;

   int s = command[].signal(); // getting a signal

   ulong ticket = 0;

   if(position[] != NULL)
   {
      if(position[].refresh()) // position exists
      {
         // the signal has changed to the opposite or disappeared
         if((position[].get(POSITION_TYPE) == POSITION_TYPE_BUY && s != +1)
         || (position[].get(POSITION_TYPE) == POSITION_TYPE_SELL && s != -1))
         {
            PrintFormat("Signal lost: %d for position %d %lld",
               s, position[].get(POSITION_TYPE), position[].get(POSITION_TICKET));
            if(close(position[].get(POSITION_TICKET)))
            {
               position = NULL;
            }
            else
            {
              // update internal flag 'ready'
              // according to whether or not there was a closure
               position[].refresh();
            }
         }
         else
         {
            position[].update();
            if(trailing[]) trailing[].trail();
         }
      }
      else // position is closed
      {
         position = NULL;
      }
   }

   if(position[] == NULL && s != 0)
   {
      ticket = (s == +1) ? openBuy() : openSell();
   }

   if(ticket > 0) // new position just opened
   {
      position = new PositionState(ticket);
      if(stopLoss)
```

```
         {
            trailing = new TrailingStop(ticket, stopLoss, stopLoss / 50);
         }
      }
      // store the current bar
      lastBar = iTime(_Symbol, _Period, 0);

      return true;
   }
```

Auxiliary methods *openBuy*, *openSell*, and others have undergone minimal changes, so we will not list them (the full source code is attached).

Since we always have only one strategy in this Expert Advisor, in contrast to the multi-currency martingale in which each symbol required its own settings, let's exclude the strategy pool and manage the strategy object directly.

```
AutoPtr<TradingStrategy> strategy;

int OnInit()
{
   if(FastOsMA >= SlowOsMA) return INIT_PARAMETERS_INCORRECT;
   strategy = new SimpleStrategy(
      new BandOsMaSignal(FastOsMA, SlowOsMA, SignalOsMA, PriceOsMA,
         BandsMA, BandsShift, BandsDeviation,
         PeriodMA, ShiftMA, MethodMA),
         Magic, StopLoss, Lots);
   return INIT_SUCCEEDED;
}

void OnTick()
{
   if(strategy[] != NULL)
   {
      strategy[].trade();
   }
}
```

We now have a ready Expert Advisor which we can use as a tool for studying the tester. First, let's create an auxiliary structure *TesterRecord* for querying and storing all statistical data.

```
struct TesterRecord
{
   string feature;
   double value;

   static void fill(TesterRecord &stats[])
   {
      ResetLastError();
      for(int i = 0; ; ++i)
      {
         const double v = TesterStatistics((ENUM_STATISTICS)i);
         if(_LastError) return;
         TesterRecord t = {EnumToString((ENUM_STATISTICS)i), v};
         PUSH(stats, t);
      }
   }
};
```

In this case, the *feature* string field is needed only for informative log output. To save all indicators (for example, to be able to generate your own report form later), a simple array of type *double* of appropriate length is enough.

Using the structure in the *OnDeinit* handler, we make sure that the MQL5 API returns the same values as the tester's report.

```
void OnDeinit(const int)
{
   TesterRecord stats[];
   TesterRecord::fill(stats);
   ArrayPrint(stats, 2);
}
```

For example, when running the Expert Advisor on EURUSD, H1 with a deposit of 10000 and without any optimizations (with default settings), we will get approximately the following values for 2021 (fragment):

```
                          [feature]  [value]
[ 0] "STAT_INITIAL_DEPOSIT"       10000.00
[ 1] "STAT_WITHDRAWAL"                0.00
[ 2] "STAT_PROFIT"                    6.01
[ 3] "STAT_GROSS_PROFIT"            303.63
[ 4] "STAT_GROSS_LOSS"             -297.62
[ 5] "STAT_MAX_PROFITTRADE"          15.15
[ 6] "STAT_MAX_LOSSTRADE"           -10.00
...
[27] "STAT_DEALS"                   476.00
[28] "STAT_TRADES"                  238.00
...
[37] "STAT_CONLOSSMAX_TRADES"         8.00
[38] "STAT_MAX_CONLOSS_TRADES"        8.00
[39] "STAT_PROFITTRADES_AVGCON"       2.00
[40] "STAT_LOSSTRADES_AVGCON"         2.00
```

Knowing all these values, we can invent our own formula for the combined metric of the Expert Advisor quality and, at the same time, the objective optimization function. But the value of this indicator in any case will need to be reported to the tester. And that's what the *OnTester* function does.

6.5.7 OnTester event

The *OnTester* event is generated upon the completion of Expert Advisor testing on historical data (both a separate tester run initiated by the user and one of the multiple runs automatically launched by the tester during optimization). To handle the *OnTester* event, an MQL program must have a corresponding function in its source code, but this is not necessary. Even without the *OnTester* function, Expert Advisors can be successfully optimized based on standard criteria.

The function can only be used in Expert Advisors.

double OnTester()

The function is designed to calculate some value of type *double*, used as a custom optimization criterion (*Custom max*). Criterion selection is important primarily for successful genetic optimization, while it also allows the user to evaluate and compare the effects of different settings.

In genetic optimization, the results are sorted within one generation in the criterion descending order. That is, the results with the highest value are considered the best in terms of the optimization criterion. The worst values in this sorting are subsequently discarded and do not take part in the formation of the next generation.

> Please note that the values returned by the *OnTester* function are taken into account only when a custom criterion is selected in the tester settings. The availability of the *OnTester* function does not automatically mean its use by the genetic algorithm.
>
> The MQL5 API does not provide the means to programmatically find out which optimization criterion the user has selected in the tester settings. Sometimes it is very important to know this in order to implement your own analytical algorithms to post-process optimization results.

The function is called by the kernel only in the tester, just before the call of the *OnDeinit* function.

To calculate the return value, we can use both the standard statistics available through the *TesterStatistics* function and their arbitrary calculations.

In the *BandOsMA.mq5* Expert Advisor, we create the *OnTester* handler which takes into account several metrics: profit, profitability, the number of trades, and the Sharpe ratio. Next, we multiply all the metrics after taking the square root of each. Of course, each developer may have their own preferences and ideas for constructing such generalized quality criteria.

```
double sign(const double x)
{
   return x > 0 ? +1 : (x < 0 ? -1 : 0);
}

double OnTester()
{
   const double profit = TesterStatistics(STAT_PROFIT);
   return sign(profit) * sqrt(fabs(profit))
      * sqrt(TesterStatistics(STAT_PROFIT_FACTOR))
      * sqrt(TesterStatistics(STAT_TRADES))
      * sqrt(fabs(TesterStatistics(STAT_SHARPE_RATIO)));
}
```

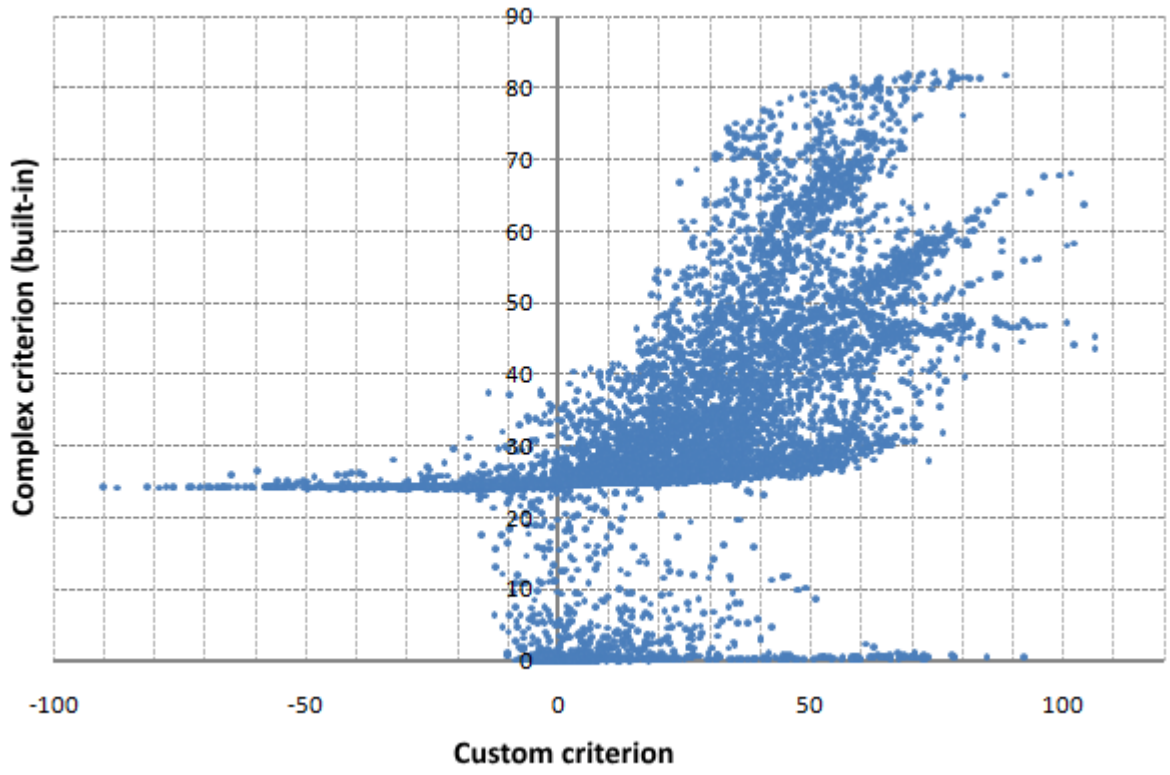
The unit test log displays a line with the value of the *OnTester* function.

Let's launch the genetic optimization of the Expert Advisor for 2021 on EURUSD, H1 with the selection of indicator parameters and stop loss size (the file *MQL5/Presets/MQL5Book/BandOsMA.set* is provided with the book). To check the quality of optimization, we will also include forward tests from the beginning of 2022 (5 months).

First, let's optimize according to our criterion.

As you know, MetaTrader 5 saves all standard criteria in the optimization results in addition to the current one used during optimization. This allows, upon completion of the optimization, to analyze the results from different points by selecting certain criteria from the drop-down list in the upper right corner of the panel with the table. Thus, although we did optimization according to our own criterion, the most interesting built-in complex criterion is also available to us.

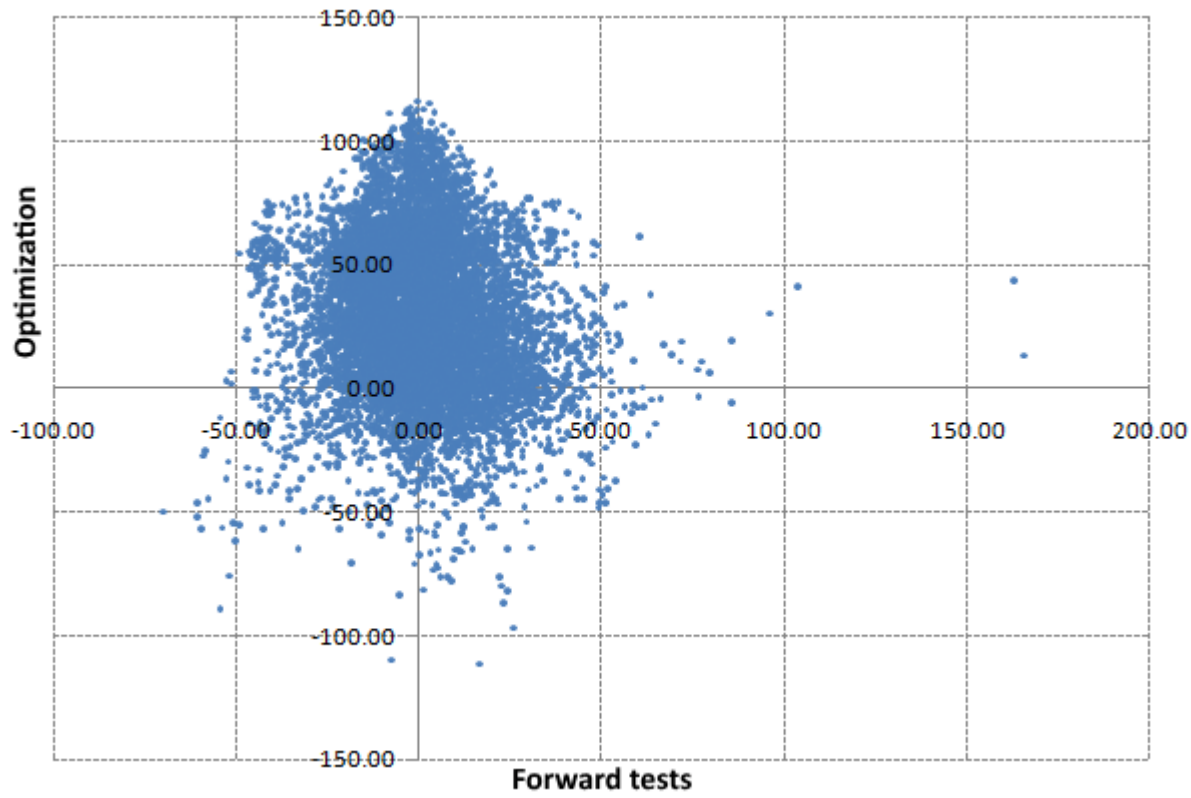
We can export the optimization table to an XML file, first with our criteria selected, and then with a complex criterion giving the file a new name (unfortunately, only one criterion is written to the export file; it is important not to change the sorting between two exports). This makes it possible to combine two tables in an external program and build a diagram on which two criteria are plotted along the axes; each point there indicates a combination of criteria in one run.



Comparison of custom and complex optimization criteria

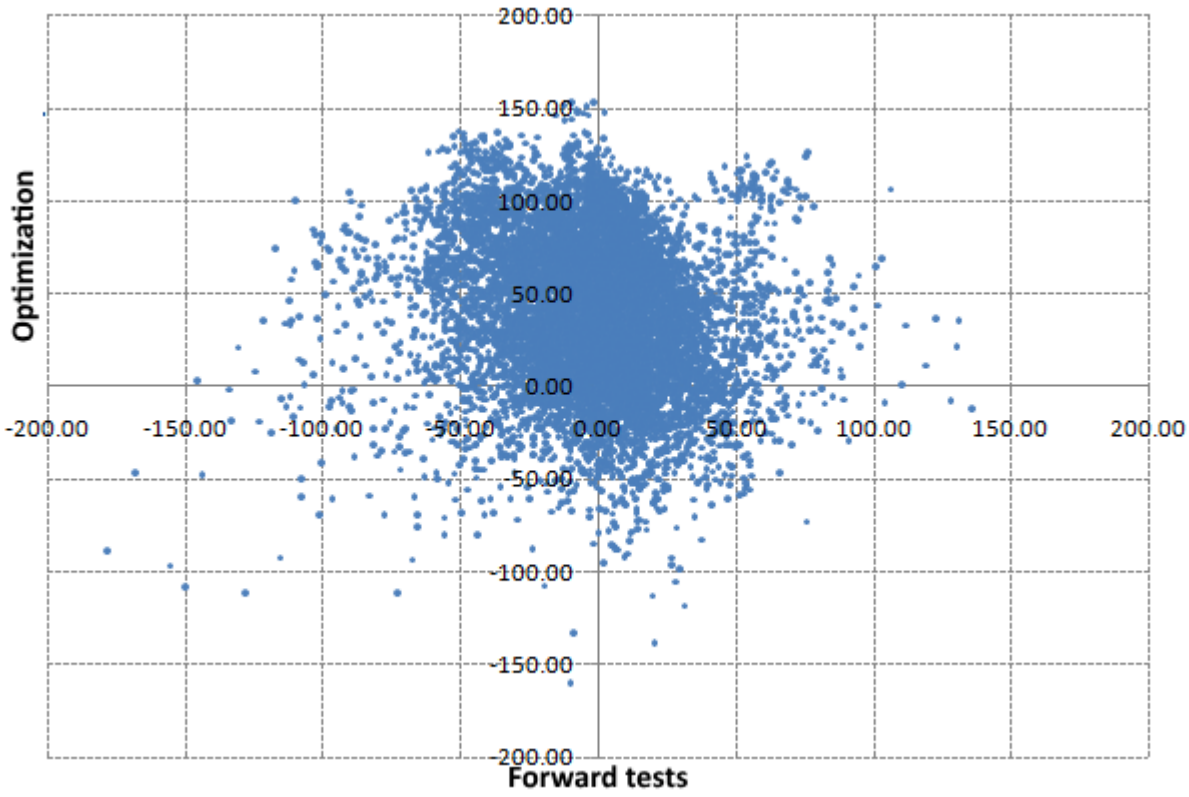
In a complex criterion, we observe a multi-level structure, since it is calculated according to a formula with conditions: somewhere one branch works, and somewhere else another one operates. Our custom criteria are always calculated using the same formula. We also note the presence of negative values in our criterion (this is expected) and the declared range of 0-100 for the complex criterion.

Let's check how good our criterion is by analyzing its values for the forward period.



Values of the custom criterion on periods of optimization and forward tests

As expected, only a part of the good optimization indicators remained on the forward. But we are more interested not in the criterion, but in profit. Let's look at its distribution in the optimization-forward link.



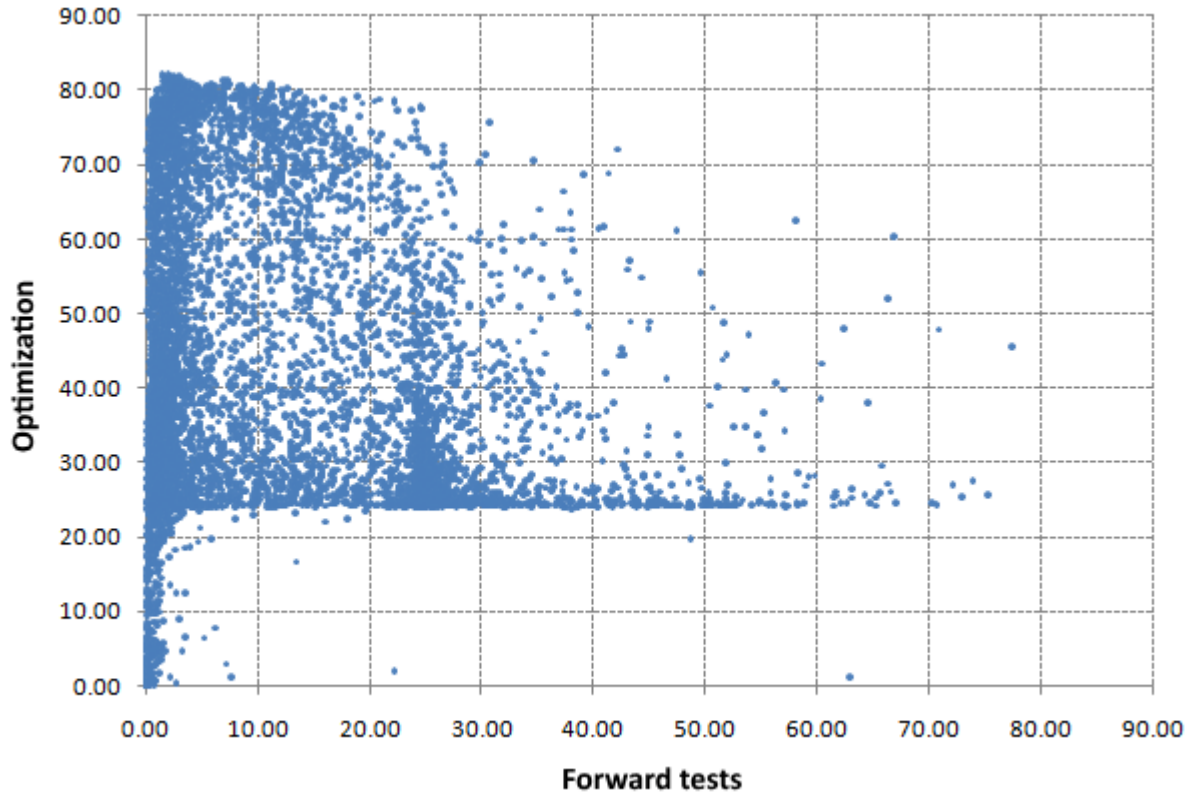
Profit on periods of optimization and forward tests

The picture here is similar. Of the 6850 passes with a profit in the optimization period, 3123 turned out to be profitable in the forward as well (45%). And out of the first 1000 best, only 323 were profitable, which is not good enough. Therefore, this Expert Advisor will need a lot of work to identify stable profitable settings. But maybe it's the optimization criteria problem?

Let's repeat the optimization, this time using the built-in complex criterion.

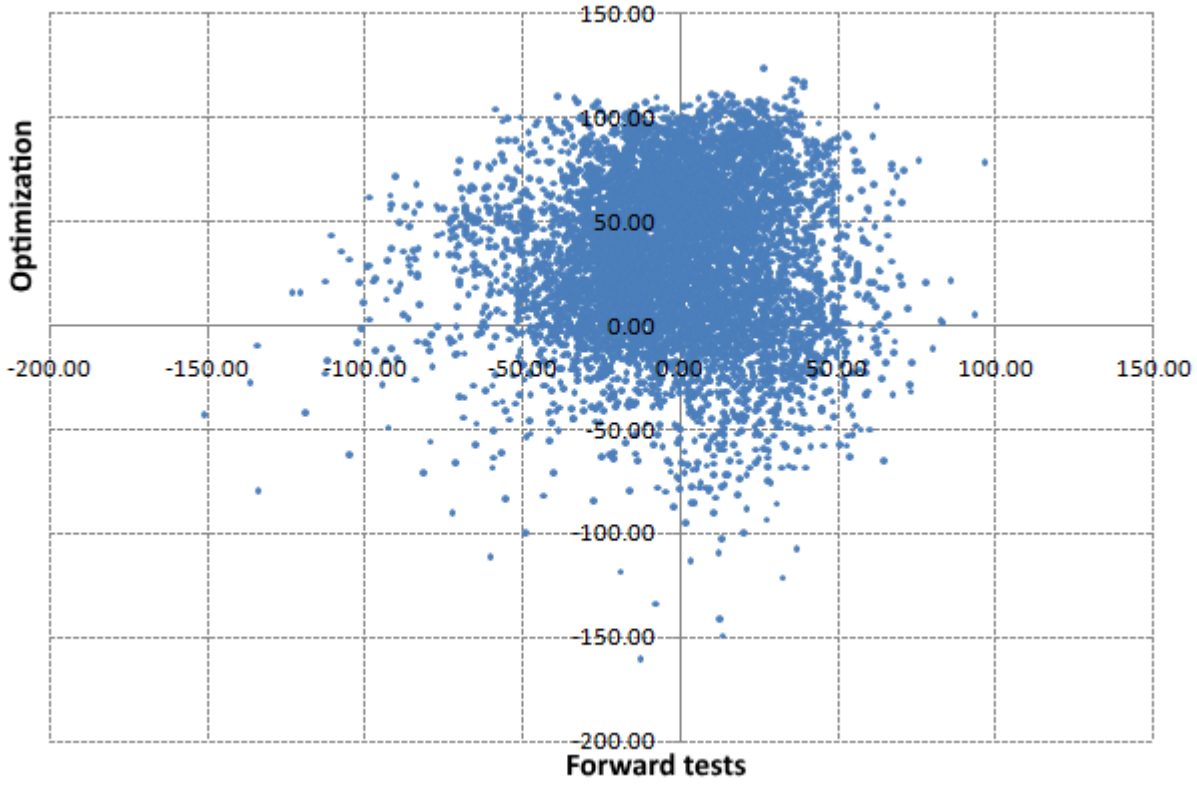
> Attention! MetaTrader 5 generates optimization caches during optimizations: opt files at *Tester/cache*. When starting the next optimization, it looks for suitable caches to continue the optimization. If there is a cache file with the previous settings, the process does not start from the very beginning, but it takes into account previous results. This allows you to build genetic optimizations in chains, assuming that you find the best results (after all, each genetic optimization is a random process).
>
> MetaTrader 5 does not take into account the optimization criterion as a distinguishing factor in the settings. This may be useful in some cases, based on the foregoing, but it will interfere with our current task. To conduct a pure experiment, we need optimization from scratch. Therefore, immediately after the first optimization using our criterion, we cannot launch the second one using the complex criterion.
>
> There is no way to disable the current behavior from the terminal interface. Therefore, you should either delete or rename (change the extension) the previous opt-file manually in any file manager. A little later we will get acquainted with the preprocessor directive for the tester *tester_no_cache*, which can be specified in the source code of a particular Expert Advisor, allowing you to disable the cache reading.

Comparison of the values of the complex criterion on the periods of optimization and the forward period takes the following form.



Complex criterion for periods of optimization and forward tests

Here's the stability of profits on forwards.



Profit on periods of optimization and forward tests

Of the 5952 positive results in history, only 2655 (also about 45%) remained in the black. But out of the first 1000, 581 turned out to be successful on the forward.

So, we have seen that it is quite simple to use *OnTester* from the technical point of view, but our criterion works worse than the built-in one (ceteris paribus), although it is far from ideal. Thus, from the point of view of the search for the formula of the criterion itself, and the subsequent reasonable choice of parameters without looking into the future, there are more questions about the content of *OnTester*, than there are answers.

Here, programming smoothly flows into research and scientific activity, and is beyond the scope of this book. But we will give one example of a criterion calculated on our own metric, and not on ready-made metrics: *TesterStatistics*. We will talk about the criterion R2, also known as the coefficient of determination (*RSquared.mqh*).

Let's create a function to calculate R2 from the balance curve. It is known that when trading with a permanent lot, an ideal trading system should show the balance in the form of a straight line. We are now using a permanent lot, and therefore it will suit us. As for R2 in the case of variable lots, we will deal with it a little later.

In the end, R2 is an inverse measure of the variance of the data relative to the linear regression built on them. The range of R2 values lies from minus infinity to +1 (although large negative values are very unlikely in our case). It is obvious that the found line is simultaneously characterized by a slope, therefore, in order to universalize the code, we will save both R2 and the tangent of the angle in the R2A structure as an intermediate result.

```
struct R2A
{
   double r2;    // square of correlation coefficient
   double angle; // tangent of the slope
   R2A(): r2(0), angle(0) { }
};
```

Calculation of indicators is performed in the *RSquared* function which takes an array of data as input and returns an R2A structure.

```
R2A RSquared(const double &data[])
{
   int size = ArraySize(data);
   if(size <= 2) return R2A();
   double x, y, div;
   int k = 0;
   double Sx = 0, Sy = 0, Sxy = 0, Sx2 = 0, Sy2 = 0;
   for(int i = 0; i < size; ++i)
   {
      if(data[i] == EMPTY_VALUE
      || !MathIsValidNumber(data[i])) continue;
      x = i + 1;
      y = data[i];
      Sx  += x;
      Sy  += y;
      Sxy += x * y;
      Sx2 += x * x;
      Sy2 += y * y;
      ++k;
   }
   size = k;
   const double Sx22 = Sx * Sx / size;
   const double Sy22 = Sy * Sy / size;
   const double SxSy = Sx * Sy / size;
   div = (Sx2 - Sx22) * (Sy2 - Sy22);
   if(fabs(div) < DBL_EPSILON) return R2A();
   R2A result;
   result.r2 = (Sxy - SxSy) * (Sxy - SxSy) / div;
   result.angle = (Sxy - SxSy) / (Sx2 - Sx22);
   return result;
}
```

For optimization, we need one criterion value, and here the angle is important because a smooth falling balance curve with a negative slope can also get a good R2 estimate. Therefore, we will write one more function that will "add minus" to any estimates of R2 with a negative angle. We take the value of R2 modulo because it can itself be negative in the case of very bad (scattered) data that do not fit into our linear model. Thus, we must prevent a situation where a minus times minus gives a plus.

```
double RSquaredTest(const double &data[])
{
   const R2A result = RSquared(data);
   const double weight = 1.0 - 1.0 / sqrt(ArraySize(data) + 1);
   if(result.angle < 0) return -fabs(result.r2) * weight;
   return result.r2 * weight;
}
```

Additionally, our criterion takes into account the size of the series, which corresponds to the number of trades. Due to this, an increase in the number of transactions will increase the indicator.

Having this tool at our disposal, we will implement the function of calculating the balance line in the Expert Advisor and find R2 for it. At the end, we multiply the value by 100, thereby converting the scale to the range of the built-in complex criterion.

```
#define STAT_PROPS 4

double GetR2onBalanceCurve()
{
   HistorySelect(0, LONG_MAX);

   const ENUM_DEAL_PROPERTY_DOUBLE props[STAT_PROPS] =
   {
      DEAL_PROFIT, DEAL_SWAP, DEAL_COMMISSION, DEAL_FEE
   };
   double expenses[][STAT_PROPS];
   ulong tickets[]; // only needed because of the 'select' prototype, but useful for

   DealFilter filter;
   filter.let(DEAL_TYPE, (1 << DEAL_TYPE_BUY) | (1 << DEAL_TYPE_SELL), IS::OR_BITWISE
      .let(DEAL_ENTRY,
      (1 << DEAL_ENTRY_OUT) | (1 << DEAL_ENTRY_INOUT) | (1 << DEAL_ENTRY_OUT_BY),
      IS::OR_BITWISE)
      .select(props, tickets, expenses);

   const int n = ArraySize(tickets);

   double balance[];

   ArrayResize(balance, n + 1);
   balance[0] = TesterStatistics(STAT_INITIAL_DEPOSIT);

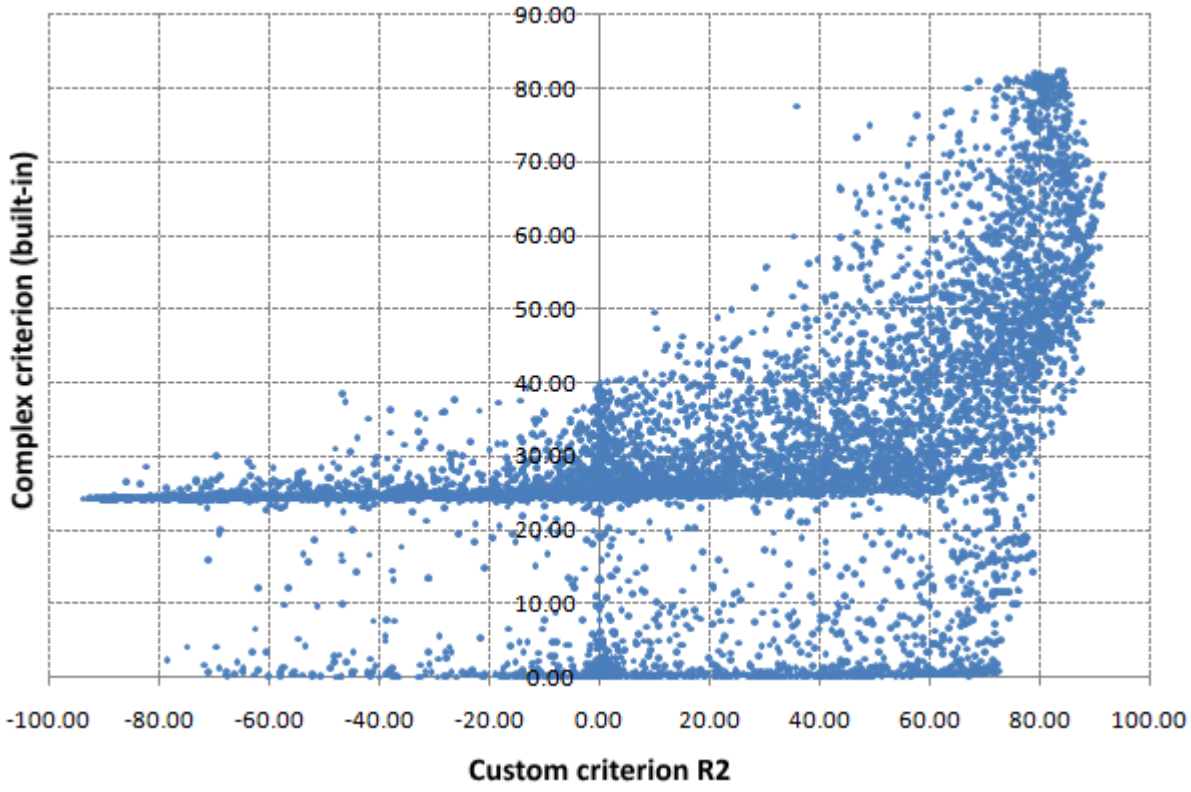
   for(int i = 0; i < n; ++i)
   {
      double result = 0;
      for(int j = 0; j < STAT_PROPS; ++j)
      {
         result += expenses[i][j];
      }
      balance[i + 1] = result + balance[i];
   }
   const double r2 = RSquaredTest(balance);
   return r2 * 100;
}
```

In the *OnTester* handler, we will use the new criterion under the conditional compilation directive, so we need to uncomment the directive *#define USE_R2_CRITERION* at the beginning of the source code.

```
double OnTester()
{
#ifdef USE_R2_CRITERION
   return GetR2onBalanceCurve();
#else
   const double profit = TesterStatistics(STAT_PROFIT);
   return sign(profit) * sqrt(fabs(profit))
      * sqrt(TesterStatistics(STAT_PROFIT_FACTOR))
      * sqrt(TesterStatistics(STAT_TRADES))
      * sqrt(fabs(TesterStatistics(STAT_SHARPE_RATIO)));
#endif
}
```

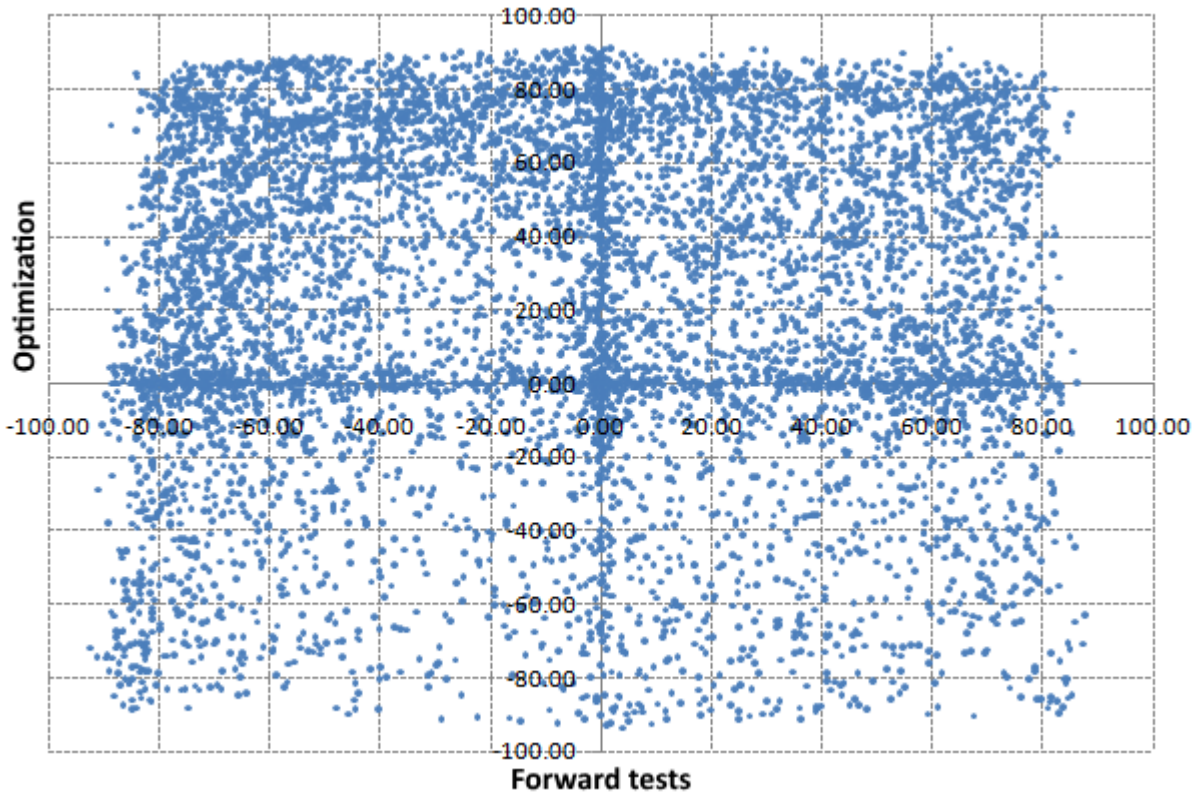
Let's delete the previous results of optimizations (opt-files with cache) and launch a new optimization of the Expert Advisor: by the R2 criterion.

When comparing the values of the R2 criterion with the complex criterion, we can say that the "convergence" between them has increased.



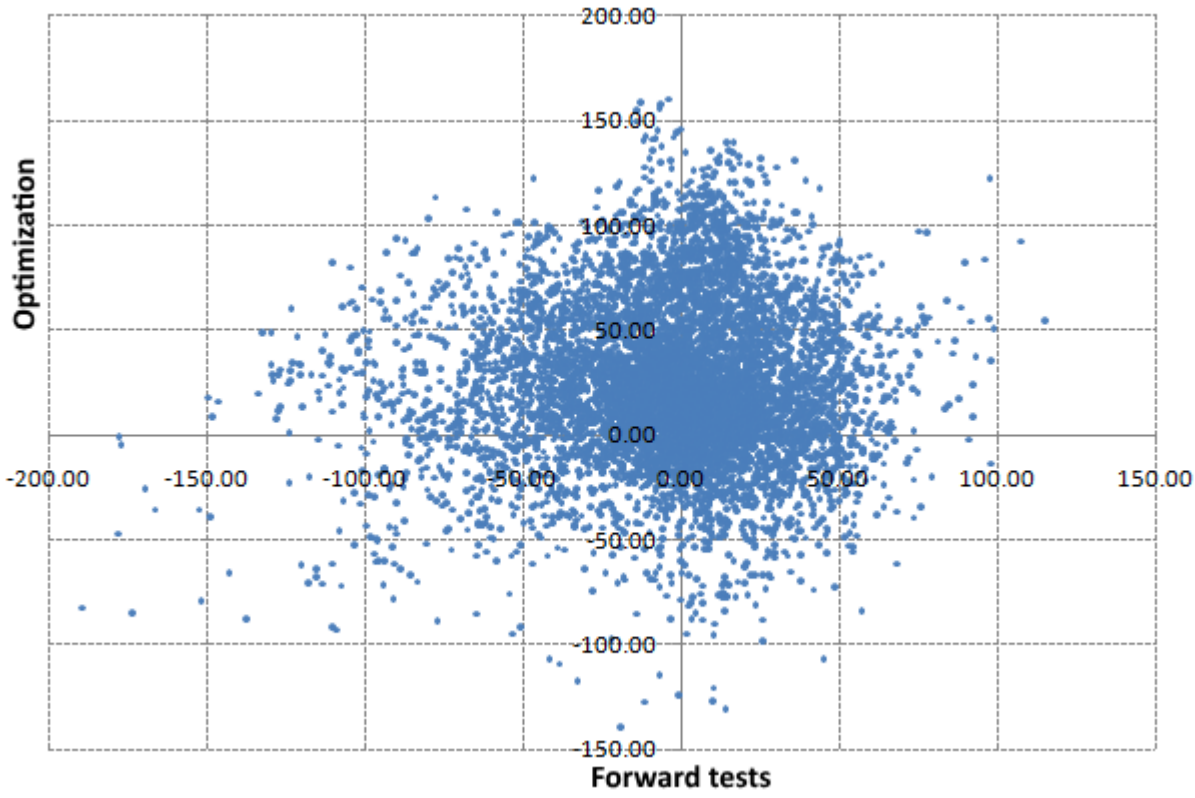
Comparison of custom criterion R2 and complex built-in criterion

The values of the R2 criterion in the optimization window and on the forward period for the corresponding sets of parameters look as follows.



Criterion R2 on periods of optimization and forward tests

And here is how the profits in the past and in the future are combined.



Profit on periods of optimization and forward tests for R2

The statistics are as follows: out of the last 5582 profitable passes, 2638 (47%) remained profitable, and out of the first 1000 most profitable passes there are 566 that remained profitable, which is comparable to the built-in complex criterion.

As mentioned above, the statistics provide raw source material for the next, more intelligent optimization stages, which is more than just a programming task. We will concentrate on other, purely programmatic aspects of optimization.

6.5.8 Auto-tuning: ParameterGetRange and ParameterSetRange

In the previous section, we learned how to pass an optimization criterion to the tester. However, we missed one important point. If you look into our optimization logs, you can see a lot of error messages there, like the ones below.

```
...
Best result 90.61004580175876 produced at generation 25. Next generation 26
genetic pass (26, 388) tested with error "incorrect input parameters" in 0:00:00.021
genetic pass (26, 436) tested with error "incorrect input parameters" in 0:00:00.007
genetic pass (26, 439) tested with error "incorrect input parameters" in 0:00:00.007
genetic pass (26, 363) tested with error "incorrect input parameters" in 0:00:00.008
genetic pass (26, 365) tested with error "incorrect input parameters" in 0:00:00.008
...
```

In other words, every few test passes, something is wrong with the input parameters, and such a pass is not performed. The *OnInit* handler contains the following check:

```
if(FastOsMA >= SlowOsMA) return INIT_PARAMETERS_INCORRECT;
```

On our part, it is quite logical to impose such a restriction that the period of the slow MA should be greater than the period of the fast one. However, the tester does not know such things about our algorithm therefore tries to sort through a variety of combinations of periods, including incorrect ones. This might be a common situation for optimization which, however, has a negative consequence.

Since we apply genetic optimization, there are several rejected samples in each generation that do not participate in further mutations. The MetaTrader 5 optimizer does not make up for these losses, i.e., it does not generate a replacement for them. Then, a smaller population size can negatively affect quality. Thus, it is necessary to come up with a way to ensure that the input settings are enumerated only in the correct combinations. And here two MQL5 API functions come to our aid: *ParameterGetRange* and *ParameterSetRange*.

Both functions have two overloaded prototypes that differ in parameter types: *long* and *double*. This is how the two variants of the *ParameterGetRange* function are described.

bool ParameterGetRange(const string name, bool &enable, long &value, long &start, long &step, long &stop)
bool ParameterGetRange(const string name, bool &enable, double &value, double &start, double &step, double &stop)

For the input variable specified by name, the function receives information about its current value (*value*), range of values (*start*, *stop*), and change step (*step*) during optimization. In addition, an attribute is written to the *enable* variable of whether the optimization is enabled for the input variable named 'name'.

The function returns an indication of success (*true*) or error (*false*).

The function can only be called from three special optimization-related handlers: *OnTesterInit*, *OnTesterPass*, and *OnTesterDeinit*. We will talk about them in the next section. As you can guess from the names, *OnTesterInit* is called before optimization starts, *OnTesterDeinit* – after completion of optimization, and *OnTesterPass* – after each pass in the optimization process. For now, we are only interested in *OnTesterInit*. Just like the other two functions, it has no parameters and can be declared with the type *void*, i.e., it returns nothing.

Two versions of the *ParameterSetRange* function have similar prototypes and perform the opposite action: they set the optimization properties of the Expert Advisor's input parameter.

bool ParameterSetRange(const string name, bool enable, long value, long start, long step, long stop)
bool ParameterSetRange(const string name, bool enable, double value, double start, double step, double stop)

The function sets the modification rules of the *input* variable with the *name* name when optimizing: value, change step, start and end values.

This function can only be called from the *OnTesterInit* handler when starting optimization in the strategy tester.

Thus, using the *ParameterGetRange* and *ParameterSetRange* functions, you can analyze and set new range and step values, as well as completely exclude, or, vice versa, include certain parameters from optimization, despite the settings in the strategy tester. This allows you to create your own scripts to manage the space of input parameters during optimization.

The function allows you to use in optimization even those variables that are declared with the *sinput* modifier (they are not available for inclusion in the optimization by the user).

> Attention! After the call of *ParameterSetRange* with a change in the settings of a specific input variable, subsequent calls of *ParameterGetRange* will not "see" these changes and will still return to the original settings. This makes it impossible to use functions together in complex software products, where settings can be handled by different classes and libraries from independent developers.

Let's improve the *BandOsMA* Expert Advisor using the new functions. The updated version is named *BandOsMApro.mq5* ("pro" can be conditionally decoded as "parameter range optimization").

So, we have the *OnTesterInit* handler, in which we read the settings for the *FastOsMA* and *SlowOsMA* parameters, and check if they are included in the optimization. If so, you need to turn them off and offer something in return.

```
void OnTesterInit()
{
   bool enabled1, enabled2;
   long value1, start1, step1, stop1;
   long value2, start2, step2, stop2;
   if(ParameterGetRange("FastOsMA", enabled1, value1, start1, step1, stop1)
   && ParameterGetRange("SlowOsMA", enabled2, value2, start2, step2, stop2))
   {
      if(enabled1 && enabled2)
      {
         if(!ParameterSetRange("FastOsMA", false, value1, start1, step1, stop1)
         || !ParameterSetRange("SlowOsMA", false, value2, start2, step2, stop2))
         {
            Print("Can't disable optimization by FastOsMA and SlowOsMA: ",
               E2S(_LastError));
            return;
         }
         ...
      }
   }
   else
   {
      Print("Can't adjust optimization by FastOsMA and SlowOsMA: ", E2S(_LastError));
   }
}
```

Unfortunately, due to the addition of *OnTesterInit*, the compiler also requires you to add *OnTesterDeinit*, although we do not need this function. But we are forced to agree and add an empty handler.

```
void OnTesterDeinit()
{
}
```

The presence of the *OnTesterInit/OnTesterDeinit* functions in the code will lead to the fact that when the optimization is started, an additional chart will open in the terminal with a copy of our Expert Advisor running on it. It works in a special mode that allows you to receive additional data (the so-called *frames*) from tested copies on agents, but we will explore this possibility later. For now, it is important for us to note that all operations with files, logs, charts, and objects work in this auxiliary copy of the Expert Advisor directly in the terminal, as usual (and not on the agent). In particular, all error messages and *Print* calls will be displayed in the log on the *Experts* tab of the terminal.

We have information about the change ranges and steps of these parameters, we can literally recalculate all the correct combinations. This task is assigned to a separate *Iterate* function because a similar operation will have to be reproduced by copies of the Expert Advisor on agents, in the *OnInit* handler.

In the *Iterate* function, we have two nested loops over the periods of fast and slow MA in which we count the number of valid combinations, i.e. when the *i* period is less than *j*. We need the optional *find* parameter when calling *Iterate* from *OnInit* to return the pair by the sequence number of the combination *i* and *j*. Since it is required to return 2 numbers, we declared the *PairOfPeriods* structure for them.

```
struct PairOfPeriods
{
   int fast;
   int slow;
};

PairOfPeriods Iterate(const long start1, const long stop1, const long step1,
   const long start2, const long stop2, const long step2,
   const long find = -1)
{
   int count = 0;
   for(int i = (int)start1; i <= (int)stop1; i += (int)step1)
   {
      for(int j = (int)start2; j <= (int)stop2; j += (int)step2)
      {
         if(i < j)
         {
            if(count == find)
            {
               PairOfPeriods p = {i, j};
               return p;
            }
            ++count;
         }
      }
   }
   PairOfPeriods p = {count, 0};
   return p;
}
```

When calling *Iterate* from *OnTesterInit*, we don't use the *find* parameter and keep counting until the very end, and return the resulting amount in the first field of the structure. This will be the range of values of some new shadow parameter, for which we must enable optimization. Let's call it *FastSlowCombo4Optimization* and add to the new group of auxiliary input parameters. More will be added here soon.

```
input group "A U X I L I A R Y"
sinput int FastSlowCombo4Optimization = 0;   // (reserved for optimization)
...
```

Let's go back to *OnTesterInit* and organize an MQL5 optimization by the *FastSlowCombo4Optimization* parameter in the desired range using *ParameterSetRange*.

```
void OnTesterInit()
{
   ...
         PairOfPeriods p = Iterate(start1, stop1, step1, start2, stop2, step2);
         const int count = p.fast;
         ParameterSetRange("FastSlowCombo4Optimization", true, 0, 0, 1, count);
         PrintFormat("Parameter FastSlowCombo4Optimization is enabled with maximum: %
            count);
   ...
}
```

Please note that the resulting number of iterations for the new parameter should be displayed in the terminal log.

When testing on the agent, use the number in *FastSlowCombo4Optimization* to get a couple of periods by calling *Iterate* again, this time with the filled *find* parameter. But the problem is that for this operation, it is required to know the initial ranges and the *FastOsMA* and *SlowOsMA* parameter change step. This information is present only in the terminal. So, we need to somehow transfer it to the agent.

Now we will apply the only solution we know so far: we will add 3 more shadow optimization parameters and set some values for them. In the future, we will get acquainted with the technology of transferring files to agents (see Preprocessor directives for the tester). Then we will be able to write to the file the entire array of indexes calculated by the *Iterate* function and send it to agents. This will avoid three extra shadow optimization parameters.

So, let's add three input parameters:

```
sinput ulong FastShadow4Optimization = 0;    // (reserved for optimization)
sinput ulong SlowShadow4Optimization = 0;    // (reserved for optimization)
sinput ulong StepsShadow4Optimization = 0;   // (reserved for optimization)
```

We use the *ulong* type to be more economical: to pack 2 *int* numbers into each value. This is how they are filled in *OnTesterInit*.

```
void OnTesterInit()
{
   ...
         const ulong fast = start1 | (stop1 << 16);
         const ulong slow = start2 | (stop2 << 16);
         const ulong step = step1 | (step2 << 16);
         ParameterSetRange("FastShadow4Optimization", false, fast, fast, 1, fast);
         ParameterSetRange("SlowShadow4Optimization", false, slow, slow, 1, slow);
         ParameterSetRange("StepsShadow4Optimization", false, step, step, 1, step);
   ...
}
```

All 3 parameters are non-optimizable (*false* in the second argument).

This concludes our operations with the *OnTesterInit* function. Let's move to the receiving side: the *OnInit* handler.

```
int OnInit()
{
   // keep the check for single tests
   if(FastOsMA >= SlowOsMA) return INIT_PARAMETERS_INCORRECT;

   // when optimizing, we require the presence of shadow parameters
   if(MQLInfoInteger(MQL_OPTIMIZATION) && StepsShadow4Optimization == 0)
   {
      return INIT_PARAMETERS_INCORRECT;
   }

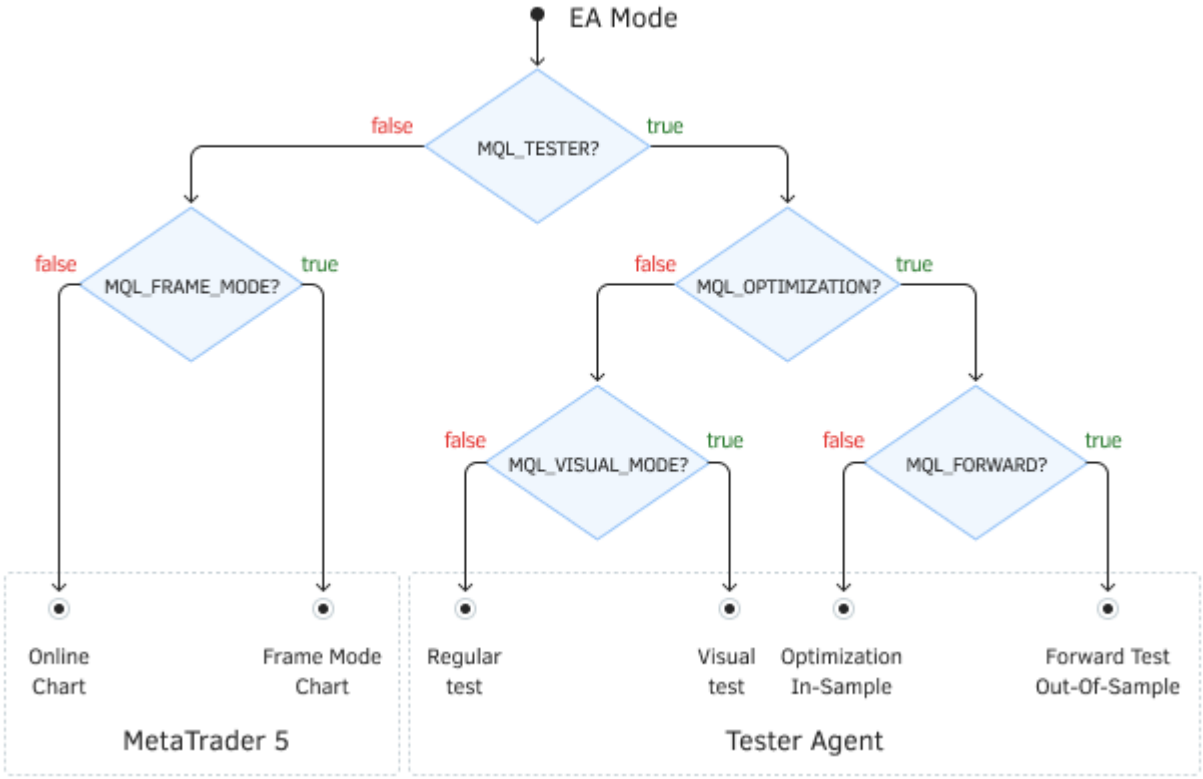
   PairOfPeriods p = {FastOsMA, SlowOsMA}; // by default we work with normal paramete
   if(FastShadow4Optimization && SlowShadow4Optimization && StepsShadow4Optimization)
   {
      // if the shadow parameters are full, decode them into periods
      int FastStart = (int)(FastShadow4Optimization & 0xFFFF);
      int FastStop = (int)((FastShadow4Optimization >> 16) & 0xFFFF);
      int SlowStart = (int)(SlowShadow4Optimization & 0xFFFF);
      int SlowStop = (int)((SlowShadow4Optimization >> 16) & 0xFFFF);
      int FastStep = (int)(StepsShadow4Optimization & 0xFFFF);
      int SlowStep = (int)((StepsShadow4Optimization >> 16) & 0xFFFF);

      p = Iterate(FastStart, FastStop, FastStep,
         SlowStart, SlowStop, SlowStep, FastSlowCombo4Optimization);
      PrintFormat("MA periods are restored from shadow: FastOsMA=%d SlowOsMA=%d",
         p.fast, p.slow);
   }

   strategy = new SimpleStrategy(
      new BandOsMaSignal(p.fast, p.slow, SignalOsMA, PriceOsMA,
         BandsMA, BandsShift, BandsDeviation,
         PeriodMA, ShiftMA, MethodMA),
         Magic, StopLoss, Lots);
   return INIT_SUCCEEDED;
}
```

Using the *MQLInfoInteger* function, we can determine all Expert Advisor modes, including those related to the tester and optimization. Having specified one of the elements of the ENUM_MQL_INFO_INTEGER enumeration as a parameter, we will get a logical sign as a result (*true/false*):

- MQL_TESTER – the program works in the tester
- MQL_VISUAL_MODE – the tester is running in the visual mode
- MQL_OPTIMIZATION – the test pass is performed during optimization (not separately)
- MQL_FORWARD – the test pass is performed on the forward period after optimization (if specified by optimization settings)
- MQL_FRAME_MODE – the Expert Advisor is running in a special service mode on the terminal chart (and not on the agent) to control optimization (more on this in the next section)



Tester modes of MQL programs

Everything is ready to start optimization. As soon as it starts, with the mentioned settings *Presets/MQL5Book/BandOsMA.set*, we will see a message in the *Experts* log in the terminal:

```
Parameter FastSlowCombo4Optimization is enabled with maximum: 698
```

This time there should be no errors in the optimization log and all generations are generated without crashing.

```
...
Best result 91.02452934181422 produced at generation 39. Next generation 42
Best result 91.56338892567393 produced at generation 42. Next generation 43
Best result 91.71026391877101 produced at generation 43. Next generation 44
Best result 91.71026391877101 produced at generation 43. Next generation 45
Best result 92.48460871443507 produced at generation 45. Next generation 46
...
```

This can be determined even by the increased overall optimization time: earlier, some passes were rejected at an early stage, and now they are all processed in full.

But our solution has one drawback. Now the working settings of the Expert Advisor include not just a couple of periods in the *FastOsMA* and *SlowOsMA* parameters, but also the ordinal number of their combination among all possible (*FastSlowCombo4Optimization*). The only thing we can do is output the periods decoded in the *OnInit* function, which was demonstrated above.

Thus, having found good settings with the help of optimization, the user, as usual, will perform a single run to refine the behavior of the trading system. At the beginning of the test log, an inscription of the following form should appear:

```
MA periods are restored from shadow: FastOsMA=27 SlowOsMA=175
```

Then you can enter the specified periods in the parameters of the same name, and reset all shadow parameters.

6.5.9 Group of OnTester events for optimization control

There are three special events in MQL5 to manage the optimization process and transfer arbitrary applied results (in addition to trading indicators) from agents to the terminal: *OnTesterInit*, *OnTesterDeinit*, and *OnTesterPass*. Having described the handlers for them in the code, the programmer will be able to perform the actions they need before starting the optimization, after the optimization is completed, and at the end of each of the individual optimization passes (if application data has been received from the agent, more on that below).

All handlers are optional. As we have seen, optimization works without them. It should also be understood that all three events work only during optimization, but not in a single test.

The Expert Advisor with these handlers is automatically loaded on a separate chart of the terminal with the symbol and period specified in the tester. This Expert instance Advisor does not trade, but only performs service actions. All other event handlers, such as *OnInit*, *OnDeinit*, and *OnTick* do not work in it.

To find out whether an Expert Advisor is executed in the regular trading mode on the agent or in the service mode in the terminal, call the function *MQLInfoInteger(MQL_FRAME_MODE)* in its code and get *true* or *false*. This service mode is also referred to as the "frames" mode which applies to data packets that can be sent to the terminal from Expert Advisor instances on agents. We will see a little later how it is done.

During optimization, only one Expert Advisor instance works in the terminal and, if necessary, receives incoming frames. Don't forget that such an instance is launched only if the Expert Advisor code contains one of the three described event handlers.

The *OnTesterInit* event is generated when optimization is launched in the strategy tester before the very first pass. The handler has two versions: with return type *int* and *void*.

```
int OnTesterInit(void)
void OnTesterInit(void)
```

In the *int* return version, a zero value (INIT_SUCCEEDED) means successful initialization of the Expert Advisor launched on the chart in the terminal, which allows starting optimization. Any other value means an error code, and optimization will not start.

The second version of the function always implies successful preparation of the Expert Advisor for optimization.

A limited time is provided for the execution of *OnTesterInit*, after which the Expert Advisor will be forced to terminate, and the optimization itself will be canceled. In this case, a corresponding message will be displayed in the tester's log.

In the previous section, we saw an example of how the *OnTesterInit* handler was used to modify the optimization parameters using the *ParameterGetRange/ParameterSetRange* functions.

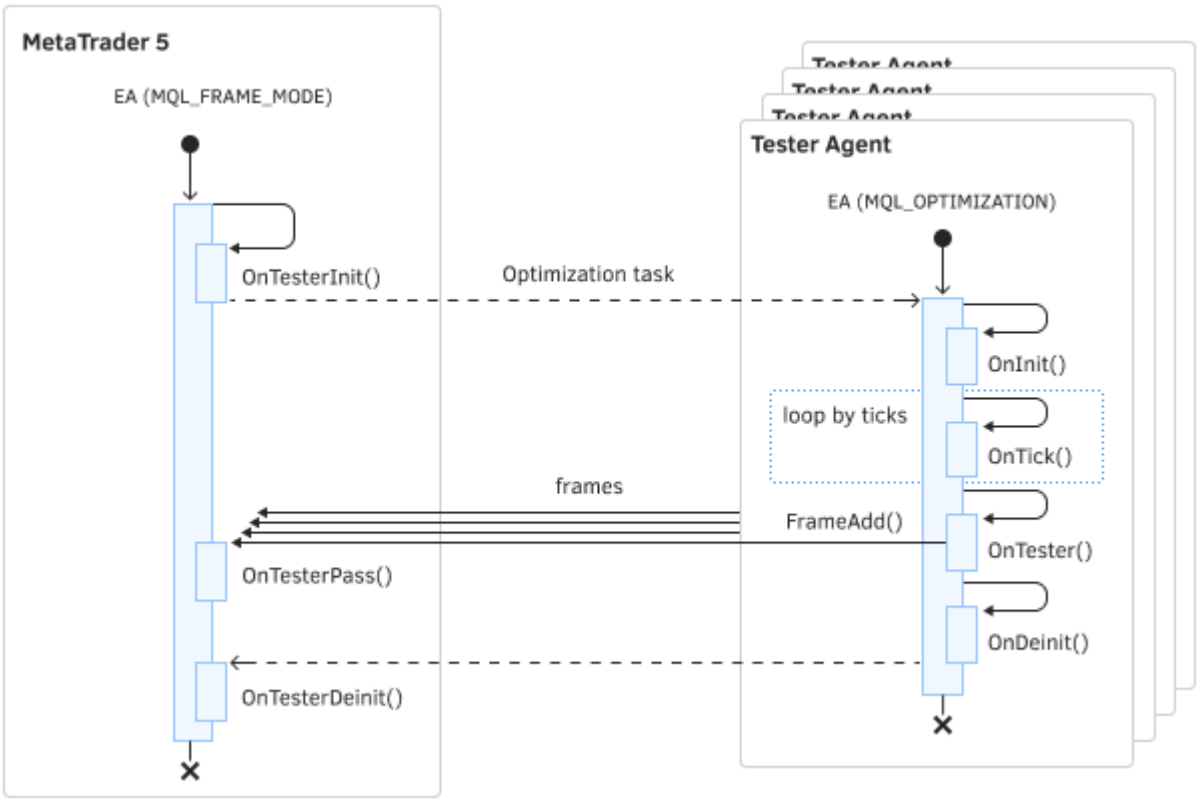
```
void OnTesterDeinit(void)
```

The *OnTesterDeinit* function is called upon completion of the Expert Advisor optimization.

The function is intended for the final processing of applied optimization results. For example, if a file was opened in *OnTesterInit* to write the contents of frames, then it needs to be closed in *OnTesterDeinit*.

void OnTesterPass(void)

The *OnTesterPass* event is automatically generated when a data frame arrives during optimization. The function allows the processing of application data received from Expert Advisor instances running on agents during optimization. A frame from the testing agent must be sent from the *OnTester* handler using the *FrameAdd* function.



The diagram shows the sequence of events when optimizing Expert Advisors

A standard set of financial statistics about each test pass is sent from the agents to the terminal automatically. The Expert Advisor is not required to send anything using *FrameAdd* if it doesn't need it. If frames are not used, the *OnTesterPass* handler will not be called.

By using *OnTesterPass*, you can dynamically process the optimization results "on the go", for example, display them on a chart in the terminal or add them to a file for subsequent batch processing.

To demonstrate the capabilities of *OnTester* event handlers, we first need to learn the functions for working with frames. They are presented in the following sections.

6.5.10 Sending data frames from agents to the terminal

MQL5 provides a group of functions for organizing the transfer and processing of your own (applied) optimization results, in addition to standard financial indicators and statistics. One of them, *FrameAdd*, is designed to send data from testing agents. Other functions are intended to receive data in the terminal.

The data exchange format is based on frames. This is a special internal structure that an Expert Advisor can fill in the tester based on an array of a simple type (which does not contain strings, class objects, or dynamic arrays) or using a file with a specified name (the file must first be created in the agent's sandbox). By calling the *FrameAdd* function multiple times, the Expert Advisor can send a series of frames to the terminal. There are no limits on the number of frames.

There are two versions of the *FrameAdd* function.

```
bool FrameAdd(const string name, ulong id, double value, const string filename)
bool FrameAdd(const string name, ulong id, double value, const void &data[])
```

The function adds a data frame to the buffer to be sent to the terminal. The *name* and *id* parameters are public labels that can be used to filter frames in the *FrameFilter* function. The *value* parameter allows you to pass an arbitrary numeric value that can be used when one value is enough. More bulky data is indicated either in the *data* array (may be an array of simple structures) or in a file named *filename*.

If there is no bulk data to transfer (for example, you only need to transfer the status of the process), use the first form of the function and specify NULL instead of a string with the file name or the second form with a dummy array of zero size.

The function returns *true* in case of success.

The function can only be called in the *OnTester* handler.

The function has no effect when called during a simple test, that is, outside of optimization.

> You can send data only from agents to the terminal. There are no mechanisms in MQL5 for sending data in the opposite direction during optimization. All data that the Expert Advisor wants to send to agents must be prepared and available (in the form of input parameters or files connected by directives) before starting the optimization.

We will look at an example of using *FrameAdd* after we get familiar with the functions of the host in the next section.

6.5.11 Getting data frames in terminal

Frames sent from testing agents by the *FrameAdd* function are delivered into the terminal and written in the order of receipt to an mqd file having the name of the Expert Advisor into the folder *terminal_directory/MQL5/Files/Tester*. The arrival of one or more frames at once generates the *OnTesterPass* event.

The MQL5 API provides 4 functions for analyzing and reading frames: *FrameFirst*, *FrameFilter*, *FrameNext*, and *FrameInputs*. All functions return a boolean value with an indication of success (*true*) or error (*false*).

To access existing frames, the kernel maintains the metaphor of an internal pointer to the current frame. The pointer automatically moves forward when the next frame is read by the *FrameNext* function, but it can be returned to the beginning of all frames with *FrameFirst* or *FrameFilter*. Thus, an MQL program can organize the iteration of frames in a loop until it has looked through all the frames. This process can be repeated if necessary, for example, by applying different filters in *OnTesterDeinit*.

bool FrameFirst()

The *FrameFirst* function sets the internal frame reading pointer to the beginning and resets the filter (if it was previously set using the *FrameFilter* function).

In theory, for a single reception and processing of all frames, it is not necessary to call *FrameFirst*, since the pointer is already at the beginning when the optimization starts.

bool FrameFilter(const string name, ulong id)

It sets the frame reading filter and sets the internal frame pointer to the beginning. The filter will affect which frames are included in subsequent calls of *FrameNext*.

If an empty string is passed as the first parameter, the filter will work only by a numeric parameter, that is, all frames with the specified *id*. If the value of the second parameter is equal to ULONG_MAX, then only the text filter works.

Calling *FrameFilter("", ULONG_MAX)* is equivalent to calling *FrameFirst()*, which is equivalent to the absence of a filter.

> If you call *FrameFirst* or *FrameFilter* in *OnTesterPass*, make sure this is really what you need: the code probably contains a logical error as it is possible to loop, read the same frame, or increase the computational load exponentially.

bool FrameNext(ulong &pass, string &name, ulong &id, double &value)
bool FrameNext(ulong &pass, string &name, ulong &id, double &value, void &data[])

The *FrameNext* function reads one frame and moves the pointer to the next one. The *pass* parameter will have the optimization pass number recorded in it. The *name*, *id*, and *value* parameters will receive the values passed in the corresponding parameters of the *FrameAdd* function.

It is important to note that the function can return *false* while operating normally when there are no more frames to read. In this case, the built-in variable *_LastError* contains the value 4000 (it has no built-in notation).

No matter which form of the *FrameAdd* function was used to send data, the contents of the file or array will be placed in the receiving *data* array. The type of the receiving array must match the type of the sent array, and there are certain nuances in the case of sending a file.

A binary file (FILE_BIN) should preferably be accepted in a byte array *uchar* to ensure compatibility with any size (because other larger types may not be a multiple of the file size). If the file size (in fact, the size of the data block in the received frame) is not a multiple of the size of the receiving array type, the *FrameNext* function will not read the data and will return an INVALID_ARRAY (4006) error.

A *Unicode* text file (FILE_TXT or FILE_CSV without FILE_ANSI modifier) should be accepted into an array of *ushort* type and then converted to a string by calling *ShortArrayToString*. An ANSI text file should be received in a *uchar* array and converted using *CharArrayToString*.

bool FrameInputs(ulong pass, string &parameters[], uint &count)

The *FrameInputs* function allows you to get descriptions and values of Expert Advisor *input* parameters on which the pass with the specified pass number is formed. The *parameters* string array will be filled with lines like "ParameterNameN=ValueParameterN". The *count* parameter will be filled with the number of elements in the *parameters* array.

The calls of these four functions are only allowed inside the *OnTesterPass* and *OnTesterDeinit* handlers.

Frames can arrive to the terminal in batches, in which case it takes time to deliver them. So, it is not necessary that all of them have time to generate the *OnTesterPass* event and will be processed until the end of the optimization. In this regard, in order to guarantee the receipt of all late frames, it is necessary to place a block of code with their processing (using the *FrameNext* function) in *OnTesterDeinit*.

Consider a simple example *FrameTransfer.mq5*.

The Expert Advisor has four test parameters. All of them, except for the last string, can be included in the optimization.

```
input bool Parameter0;
input long Parameter1;
input double Parameter2;
input string Parameter3;
```

However, to simplify the example, the number of steps for parameters *Parameter1* and *Parameter2* is limited to 10 (for each). Thus, if you do not use *Parameter0*, the maximum number of passes is 121. *Parameter3* is an example of a parameter that cannot be included in the optimization.

The Expert Advisor does not trade but generates random data that mimics arbitrary application data. Do not use randomization like this in your work projects: it is only suitable for demonstration.

```
ulong startup; // track the time of one run (just like demo data)

int OnInit()
{
   startup = GetMicrosecondCount();
   MathSrand((int)startup);
   return INIT_SUCCEEDED;
}
```

Data is sent in two types of frames: from a file and from an array. Each type has its own identifier.

```
#define MY_FILE_ID 100
#define MY_TIME_ID 101

double OnTester()
{
 // send file in one frame
   const static string filename = "binfile";
   int h = FileOpen(filename, FILE_WRITE | FILE_BIN | FILE_ANSI);
   FileWriteString(h, StringFormat("Random: %d", MathRand()));
   FileClose(h);
   FrameAdd(filename, MY_FILE_ID, MathRand(), filename);

 // send array in another frame
   ulong dummy[1];
   dummy[0] = GetMicrosecondCount() - startup;
   FrameAdd("timing", MY_TIME_ID, 0, dummy);

   return (Parameter2 + 1) * (Parameter1 + 2);
}
```

The file is written as binary, with simple strings. The result (criterion) of *OnTester* is a simple arithmetic expression involving *Parameter1* and *Parameter2*.

On the receiving side, in the Expert Advisor instance running in the service mode on the terminal chart, we collect data from all frames with files and put them into a common CSV file. The file is opened in the handler *OnTesterInit*.

```
int handle; // file for collecting applied results
void OnTesterInit()
{
   handle = FileOpen("output.csv", FILE_WRITE | FILE_CSV | FILE_ANSI, ",");
}
```

As mentioned earlier, all frames may not have time to get into the handler *OnTesterPass*, and they need to be additionally checked in *OnTesterDeinit*. Therefore, we have implemented one helper function *ProcessFileFrames*, which we will call from *OnTesterPass*, and from *OnTesterDeinit*.

Inside *ProcessFileFrames* we keep our internal counter of processed frames, *framecount*. Using it as an example, we will make sure that the order of arrival of frames and the numbering of test passes often do not match.

```
void ProcessFileFrames()
{
   static ulong framecount = 0;
   ...
```

To receive frames in the function, the variables necessary according to the prototype *FrameNext* are described. The receiving data array is described here as *uchar*. If we were to write some structures to our binary file, we could take them directly into an array of structures of the same type.

```
   ulong   pass;
   string  name;
   long    id;
   double  value;
   uchar   data[];
   ...
```

The following describes the variables for obtaining the Expert Advisor inputs for the current pass to which the frame belongs.

```
   string  params[];
   uint    count;
   ...
```

We then read frames in a loop with *FrameNext*. Recall that several frames can enter the handler at once, so a loop is needed. For each frame, we output to the terminal log the pass number, the name of the frame, and the resulting *double* value. We skip frames with an ID other than MY_FILE_ID and will process them later.

```
   ResetLastError();

   while(FrameNext(pass, name, id, value, data))
   {
      PrintFormat("Pass: %lld Frame: %s Value:%f", pass, name, value);
      if(id != MY_FILE_ID) continue;
      ...
   }

   if(_LastError != 4000 && _LastError != 0)
   {
      Print("Error: ", E2S(_LastError));
   }
}
```

For frames with MY_FILE_ID, we do the following: query the input variables, find out which ones are included in the optimization, and save their values to a common CSV file along with the information from the frame. When the frame count is 0, we form the header of the CSV file in the *header* variable. In all frames, the current (new) record for the CSV file is formed in the *record* variable.

```
void ProcessFileFrames()
{
   ...
      if(FrameInputs(pass, params, count))
      {
         string header, record;
         if(framecount == 0) // prepare CSV header
         {
            header = "Counter,Pass ID,";
         }
         record = (string)framecount + "," + (string)pass + ",";
         // collect optimized parameters and their values
         for(uint i = 0; i < count; i++)
         {
            string name2value[];
            int n = StringSplit(params[i], '=', name2value);
            if(n == 2)
            {
               long pvalue, pstart, pstep, pstop;
               bool enabled = false;
               if(ParameterGetRange(name2value[0],
                  enabled, pvalue, pstart, pstep, pstop))
               {
                  if(enabled)
                  {
                     if(framecount == 0) // prepare CSV header
                     {
                        header += name2value[0] + ",";
                     }
                     record += name2value[1] + ","; // data field
                  }
               }
            }
         }
         if(framecount == 0) // prepare CSV header
         {
            FileWriteString(handle, header + "Value,File Content\n");
         }
         // write data to CSV
         FileWriteString(handle, record + DoubleToString(value) + ","
            + CharArrayToString(data) + "\n");
      }
      framecount++;
   ...
}
```

Calling *ParameterGetRange* could also be done more efficiently, only with a zero value of *framecount*. You can try to do so.

In the *OnTesterPass* handler, we just call *ProcessFileFrames*.

```
void OnTesterPass()
{
   ProcessFileFrames(); // standard processing of frames on the go
}
```

Additionally, we call the same function from *OnTesterDeinit* and close the CSV file.

```
void OnTesterDeinit()
{
   ProcessFileFrames(); // pick up late frames
   FileClose(handle);   // close the CSV file
   ..
}
```

In *OnTesterDeinit*, we process frames with MY_TIME_ID. The durations of test passes is delivered in these frames, and the average duration of one pass is calculated here. In theory, it makes sense to do this only for analysis in your program, since for the user the duration of the passes is already displayed by the tester in the log.

```
void OnTesterDeinit()
{
   ...
   ulong   pass;
   string  name;
   long    id;
   double  value;
   ulong   data[]; // same array type as sent

   FrameFilter("timing", MY_TIME_ID); // rewind to the first frame

   ulong count = 0;
   ulong total = 0;
   // cycle through 'timing' frames only
   while(FrameNext(pass, name, id, value, data))
   {
      if(ArraySize(data) == 1)
      {
         total += data[0];
      }
      else
      {
         total += (ulong)value;
      }
      ++count;
   }
   if(count > 0)
   {
      PrintFormat("Average timing: %lld", total / count);
   }
}
```

The Expert Advisor is ready. Let's enable the complete optimization for it (because the total number of options is artificially limited and is too small for the genetic algorithm). We can choose open prices only

since the Expert Advisor does not trade. Because of this, you should choose a custom criterion (all other criteria will give 0). For example, let's set the range *Parameter1* from 1 to 10 in single steps, and *Parameter2* is set from -0.5 to +0.5 in steps of 0.1.

Let's run the optimization. In the expert log in the terminal, we will see entries about received frames of the form:

```
Pass: 0 Frame: binfile Value:5105.000000
Pass: 0 Frame: timing Value:0.000000
Pass: 1 Frame: binfile Value:28170.000000
Pass: 1 Frame: timing Value:0.000000
Pass: 2 Frame: binfile Value:17422.000000
Pass: 2 Frame: timing Value:0.000000
...
Average timing: 1811
```

The corresponding lines with pass numbers, parameter values and frame contents will appear in the output.csv file:

```
Counter,Pass ID,Parameter1,Parameter2,Value,File Content
0,0,0,-0.5,5105.00000000,Random: 87
1,1,1,-0.5,28170.00000000,Random: 64
2,2,2,-0.5,17422.00000000,Random: 61
...
37,35,2,-0.2,6151.00000000,Random: 68
38,62,7,0.0,17422.00000000,Random: 61
39,36,3,-0.2,16899.00000000,Random: 71
40,63,8,0.0,17422.00000000,Random: 61
...
117,116,6,0.5,27648.00000000,Random: 74
118,117,7,0.5,16899.00000000,Random: 71
119,118,8,0.5,17422.00000000,Random: 61
120,119,9,0.5,28170.00000000,Random: 64
```

Obviously, our internal numbering (column *Count*) goes in order, and the pass numbers *Pass ID* can be mixed (this depends on many factors of parallel processing of job batches by agents). In particular, the batch of tasks can be the first to finish the agent to which the tasks with higher sequence numbers were assigned: in this case, the numbering in the file will start from the higher passes.

In the tester's log, you can check service statistics by frames.

```
242 frames (42.78 Kb total, 181 bytes per frame) received
local 121 tasks (100%), remote 0 tasks (0%), cloud 0 tasks (0%)

```

It is important to note that during genetic optimization, run numbers are presented in the optimization report as a pair *(generation number, copy number)*, while the pass number obtained in the *FrameNext* function is *ulong*. In fact, it is the pass number in batch jobs in the context of the current optimization run. MQL5 does not provide a means to match pass numbering with a genetic report. For this purpose, the checksums of the input parameters of each pass should be calculated. Opt files with an optimization cache already contain such a field with an MD5 hash.

6.5.12 Preprocessor directives for the tester

In the section on General properties of programs, we first become acquainted with *#property* directives in MQL programs. Then we met directives intended for scripts, services, and indicators. There is also a group of directives for the tester. We have already mentioned some of them. For example, *tester_everytick_calculate* affects the calculation of indicators.

The following table lists all tester directives with explanations.

Directive	Description
tester_indicator "string"	The name of the custom indicator in the format "indicator_name.ex5"
tester_file "string"	File name in the format "file_name.extension" with the initial data required for the program test
tester_library "string"	Library name with an extension such as "library.ex5" or "library.dll"
tester_set "string"	File name in the format "file_name.set" with settings for values and ranges of optimization of program input parameters
tester_no_cache	Disabling reading the existing cache of previous optimizations (opt files)
tester_everytick_calculate	Disabling the resource-saving mode for calculating indicators in the tester

The last two directives have no arguments. All others expect a double-quoted string with the name of a file of one type or another. It also follows from this that directives can be repeated with different files, i.e., you can include several settings files or several indicators.

The *tester_indicator* directive is required to connect to the testing process those indicators that are not mentioned in the source code of the program under test in the form of constant strings (literals). As a rule, the required indicator can be determined automatically by the compiler from *iCustom* calls if its name is explicitly specified in the corresponding parameter, for example, *iCustom(symbol, period, "indicator_name",...)*. However, this is not always the case.

Let's say we are writing a universal Expert Advisor that can use different moving average indicators, not just the standard built-in ones. Then we can create an input variable to specify the name of the indicator by the user. Then, the *iCustom* call will turn into *iCustom(symbol, period, CustomIndicatorName,...)*, where *CustomIndicatorName* is an input variable of the Expert Advisor, the content of which is not known at the time of compilation. Moreover, the developer in this case is likely to apply *IndicatorCreate* instead of *iCustom*, since the number and types of indicator parameters must also be configured. In such cases, to debug the program or demonstrate it with a specific indicator, we should provide the name to the tester using the *tester_indicator* directive.

> The need to report indicator names in the source code significantly limits the ability to test such universal programs that can connect various indicators online.

Without the *tester_indicator* directive, the terminal will not be able to send an indicator to the agent that is not explicitly declared in the source code, as a result of which the dependent program will lose part or all of its functionality.

The *tester_file* directive allows you to specify a file that will be transferred to the agents and placed in the sandbox before testing. The content and type of the file is not regulated. For example, these can be the weights of a pre-trained neural network, pre-collected Depth of Market data (because such data cannot be reproduced by the tester), and so on.

> Note, that the file from the *tester_file* directive is only read if it existed at compile time. If the source code was compiled when there was no corresponding file, then its appearance in the future will no longer help: the compiled program will be sent to the agent without an auxiliary file. Therefore, for example, if the file specified in *tester_file* is generated in *OnTesterInit*, you should make sure that the file with the given name already existed at the time of compilation, even if it was empty. We will demonstrate this below.

Please note that the compiler does not generate warnings if the file specified in the *tester_file* directive does not exist.

The connected files must be in the terminal's sandbox" *MQL5/Files/*.

The *tester_library* directive informs the tester about the need to transfer the library, which is an auxiliary program that can only work in the context of another MQL program, to the agents. We will talk about libraries in detail in a separate section.

The libraries required for testing are determined automatically by the *#import* directives in the source code. However, if any library is used by an external indicator, then this property must be enabled. The library can be both with the *dll* extension, as well as with the *ex5* extension.

The *tester_set* directive operates with *set* files with MQL program settings. The file specified in the directive will become available from the context menu of the tester and will allow the user to quickly apply the settings.

If the name is specified without a path, the *set* file must be in the same directory as the Expert Advisor. This is somewhat unexpected, because the default directory for *set* files is *Presets*, and this is where they are saved by commands from the terminal interface. To connect the *set* file from the given directory, you must explicitly specify it in the directive and precede it with a slash, which indicates the absolute path inside the MQL5 folder.

```
#property tester_set "/Presets/xyz.set"
```

When there is no leading slash, the path is relative to where the source text was placed.

> Immediately after adding the file and recompiling the program, you need to reselect the Expert Advisor in the tester; otherwise, the file will not be picked up!

If you specify the Expert Advisor name and version number as "*<expert_name>_<number>.set*" in the name of the *set* file, then it will automatically be added to the parameter version download menu under the version number *<number>*. For example, the name "*MACD Sample_4.set*" means that it is a *set* file for the Expert Advisor "*MACD Sample.mq5*" with version number 4.

Those interested can study the format of *set* files: to do this, manually save the testing/optimization settings in the strategy tester and then open the file created in this way in a text editor.

Now let's look at the directive *tester_no_cache*. When performing optimization, the strategy tester saves all the results of the performed passes to the optimization cache (files with the extension *opt*), in which the test result is stored for each set of input parameters. This allows, when re-optimizing on the same parameters, to take ready-made results without re-calculation and time wasting.

However, for some tasks, such as mathematical calculations, it may be necessary to perform calculations regardless of the presence of ready-made results in the optimization cache. In this case, in the source code, you must include the property *tester_no_cache*. At the same time, the test results themselves will still be stored in the cache so that you can see all the data on the completed passes in the strategy tester.

The directive *tester_everytick_calculate* is designed to enable the indicator calculation mode on each tick in the tester.

By default, indicators are calculated in the tester only when they are accessed for data, i.e., when the values of indicator buffers are requested. This gives a significant speed-up in testing and optimization if you do not need to get the indicator values at each tick.

However, some programs may require indicators to be recalculated on every tick. It is in such cases that the property *tester_everytick_calculate* is useful.

Indicators in the strategy tester are also forced to be calculated on each tick in the following cases:

- when testing in visual mode
- if there are the *EventChartCustom*, *OnChartEvent*, or *OnTimer* functions in the indicator

This property applies only to operations in the strategy tester. In the terminal, indicators are always calculated on each incoming tick.

The directive has actually been used in the *FrameTransfer.mq5* Expert Advisor:

```
#property tester_set "FrameTransfer.set"
```

We just didn't focus on it. The file "*FrameTransfer.set*" is located next to the source code. In the same Expert Advisor, we also needed another directive from the above table:

```
#property tester_no_cache
```

In addition, let's consider an example of a directive *tester_file*. Earlier in the section on auto-tuning of Expert Advisor parameters when optimizing, we introduced *BandOsMApro.mq5*, in which it was necessary to introduce several shadow parameters to pass optimization ranges to our source code running on agents.

The *tester_file* directive will allow us to get rid of these extra parameters. Let's name the new version *BandOsMAprofile.mq5*.

Since we are now familiar with the directive *tester_set*, let's add to the new version the previously mentioned file */Presets/MQL5Book/BandOsMA.set*.

```
#property tester_set "/Presets/MQL5Book/BandOsMA.set"
```

Information about the range and step of changing periods of *FastOsMA* and *SlowOsMA* will be saved to file *BandOsMAprofile.csv*" instead of three additional input parameters *FastShadow4Optimization*, *SlowShadow4Optimization*, *StepsShadow4Optimization*.

```
#define SETTINGS_FILE "BandOsMAprofile.csv"
#property tester_file SETTINGS_FILE

const string SettingsFile = SETTINGS_FILE;
```

Shadow setting *FastSlowCombo4Optimization* is still needed for a complete enumeration of allowed combinations of periods.

```
input group "A U X I L I A R Y"
sinput int FastSlowCombo4Optimization = 0;   // (reserved for optimization)
```

Recall that we find its range for optimization in the *Iterate* function. The first time we call it in *OnTesterInit* with a complete enumeration of combinations of fast and slow periods.

Basically, we could store all valid combinations in the array of structures *PairOfPeriods* and write it to a binary file for transmission to agents. Then, on the agents, our Expert Advisor could read the ready array from the file and by the *FastSlowCombo4Optimization* index extract the corresponding pair of *FastOsMA* and *SlowOsMA* from the array.

Instead, we will focus on a minimal change in the working logic of the program: we will continue to restore a couple of periods due to the second call *Iterate* in the *OnInit* handler. This time, we will get the range and step of enumeration of period values not from the shadow parameters, but from the CSV file.

Here are the changes to *OnTesterInit*.

```
int OnTesterInit()
{
   ...
         // check if the file already exists before compiling
         // - if not, the tester will not be able to send it to agents
          const bool preExisted = FileIsExist(SettingsFile);

          // write the settings to a file for transfer to copy programs on agents
          int handle = FileOpen(SettingsFile, FILE_WRITE | FILE_CSV | FILE_ANSI, ",");
          FileWrite(handle, "FastOsMA", start1, step1, stop1);
          FileWrite(handle, "SlowOsMA", start2, step2, stop2);
          FileClose(handle);

          if(!preExisted)
          {
             PrintFormat("Required file %s is missing. It has been just created."
                " Please restart again.",
                SettingsFile);
             ChartClose();
             return INIT_FAILED;
          }
   ...
   return INIT_SUCCEEDED;
}
```

Note that we have made the *OnTesterInit* handler with the return type *int*, which makes it possible to cancel optimization if the file does not exist. However, in any case, the actual data is written to the file, so if it did not exist, it is now created, and the subsequent start of the optimization will definitely be successful.

If you want to skip this step, you can create an empty file *MQL5/Files/BandOsMAprofile.csv* beforehand.

The *OnInit* handler has been changed as follows.

```
int OnInit()
{
   if(FastOsMA >= SlowOsMA) return INIT_PARAMETERS_INCORRECT;

   PairOfPeriods p = {FastOsMA, SlowOsMA}; // default initial parameters
   int handle = FileOpen(SettingsFile, FILE_READ | FILE_TXT | FILE_ANSI);

   // during optimization, a file with shadow parameters is needed
   if(MQLInfoInteger(MQL_OPTIMIZATION) && handle == INVALID_HANDLE)
   {
      return INIT_PARAMETERS_INCORRECT;
   }

   if(handle != INVALID_HANDLE)
   {
      if(FastSlowCombo4Optimization != -1)
      {
         // if there is a shadow copy, read the period values from it
         const string line1 = FileReadString(handle);
         string settings[];
         if(StringSplit(line1, ',', settings) == 4)
         {
            int FastStart = (int)StringToInteger(settings[1]);
            int FastStep = (int)StringToInteger(settings[2]);
            int FastStop = (int)StringToInteger(settings[3]);
            const string line2 = FileReadString(handle);
            if(StringSplit(line2, ',', settings) == 4)
            {
               int SlowStart = (int)StringToInteger(settings[1]);
               int SlowStep = (int)StringToInteger(settings[2]);
               int SlowStop = (int)StringToInteger(settings[3]);
               p = Iterate(FastStart, FastStop, FastStep,
                  SlowStart, SlowStop, SlowStep, FastSlowCombo4Optimization);
               PrintFormat("MA periods are restored from shadow: FastOsMA=%d SlowOsMA
                  p.fast, p.slow);
            }
         }
      }
      FileClose(handle);
   }
```

When running single tests after optimization, we will see decoded period values in the log *FastOsMA* and *SlowOsMA* based on the optimized value *FastSlowCombo4Optimization*. In the future, we can substitute these values in the period parameters, and delete the csv file. We also provided that the file will not be taken into account if *FastSlowCombo4Optimization* is set to -1.

6.5.13 Managing indicator visibility: TesterHideIndicators

By default, the visual testing chart shows all the indicators that are created in the Expert Advisor being tested. Also, these indicators are shown on the chart, which automatically opens at the end of testing.

All this applies only to those indicators that are directly created in your code: nested indicators that can be used in the calculation of the main indicators do not apply here.

The visibility of indicators is not always desirable from the developer's point of view, who may want to hide the implementation details of an Expert Advisor. In such cases, the function *TesterHideIndicators* will disable the display of the used indicators on the chart.

void TesterHideIndicators(bool hide)

Boolean parameter *hide* instructs either to hide (by value *true*) or display (by value *false*) indicators. The set state is remembered by the MQL program execution environment until it is changed by calling the function again with the inverse parameter value. The current state of this setting affects all newly created indicators.

In other words, the function *TesterHideIndicators* with the required flag value *hide* should be called before creating descriptors of the corresponding indicators. In particular, after calling the function with the *true* parameter, new indicators will be marked with a hidden flag and will not be shown during visual testing and on the chart, which is automatically opened when testing is completed.

To disable the mode of hiding newly created indicators, call *TesterHideIndicators* with *false*.

The function is applicable only in the tester.

The function has some specifics related to its performance, provided that special tpl templates are created for the tester or Expert Advisor in the folder */MQL5/Profiles/Templates*.

If there is a special template in the folder *<expert_name>.tpl*, then during visual testing and on the testing chart, only indicators from this template will be shown. In this case, no indicators used in the tested Expert Advisor will be displayed, even if the function was called in the Expert Advisor code *TesterHideIndicators* with *false*.

If there is a template in the *tester.tpl* folder, then during visual testing and on the testing chart, indicators from the *tester.tpl* template will be shown, plus those indicators from the Expert Advisor that are not prohibited by the *TesterHideIndicators* call. The *TesterHideIndicators* function does not affect the indicators in the template.

If there is no template *tester.tpl*, but there is a template *default.tpl*, then the indicators from it are processed according to a similar principle.

We will demonstrate how the function works in the Big Expert Advisor example a little later.

6.5.14 Emulation of deposits and withdrawals

The MetaTrader 5 tester allows you to emulate deposit and withdrawal operations. This allows you to experiment with some money management systems.

bool TesterDeposit(double money)

The *TesterDeposit* function replenishes the account in the process of testing for the size of the deposited amount in the money parameter. The amount is indicated in the test deposit currency.

bool TesterWithdrawal(double money)

The *TesterWithdrawal* function makes withdrawals equal to *money*.

Both functions return *true* as a sign of success.

As an example, let's consider an Expert Advisor based on the "carry trade" strategy. For it, we need to select a symbol with large positive swaps in one of the trading directions, for example, buying AUDUSD. The Expert Advisor will open one or more positions in the specified direction. Unprofitable positions will be held for the sake of accumulating swaps on them. Profitable positions will be closed upon reaching a predetermined amount of profit per lot. Earned swaps will be withdrawn from the account. The source code is available in the *CrazyCarryTrade.mq5* file.

In the input parameters, the user can select the direction of trade, the size of one trade (0 by default, which means the minimum lot), and the minimum profit per lot, at which a profitable position will be closed.

```
enum ENUM_ORDER_TYPE_MARKET
{
   MARKET_BUY = ORDER_TYPE_BUY,
   MARKET_SELL = ORDER_TYPE_SELL
};

input ENUM_ORDER_TYPE_MARKET Type;
input double Volume;
input double MinProfitPerLot = 1000;
```

First, let's test in the handler *OnInit* the performance of functions *TesterWithdrawal* and *TesterDeposit*. In particular, an attempt to withdraw a double balance will result in error 10019.

```
int OnInit()
{
   PRTF(TesterWithdrawal(AccountInfoDouble(ACCOUNT_BALANCE) * 2));
   /*
   not enough money for 20 000.00 withdrawal (free margin: 10 000.00)
   TesterWithdrawal(AccountInfoDouble(ACCOUNT_BALANCE)*2)=false / MQL_ERROR::10019(10
   */
   ...
```

But the subsequent withdrawals and crediting back of 100 units of the account currency will be successful.

```
   PRTF(TesterWithdrawal(100));
   /*
   deal #2 balance -100.00 [withdrawal] done
   TesterWithdrawal(100)=true / ok
   */
   PRTF(TesterDeposit(100)); // return the money
   /*
   deal #3 balance 100.00 [deposit] done
   TesterDeposit(100)=true / ok
   */
   return INIT_SUCCEEDED;
}
```

In the *OnTick* handler, let's check the availability of positions using *PositionFilter* and fill the *values* array with their current profit/loss and accumulated swaps.

```
void OnTick()
{
   const double volume = Volume == 0 ?
      SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volume;
   ENUM_POSITION_PROPERTY_DOUBLE props[] = {POSITION_PROFIT, POSITION_SWAP};
   double values[][2];
   ulong tickets[];
   PositionFilter pf;
   pf.select(props, tickets, values, true);
   ...
```

When there are no positions, we open one in a predefined direction.

```
   if(ArraySize(tickets) == 0) // no positions
   {
      MqlTradeRequestSync request1;
      (Type == MARKET_BUY ? request1.buy(volume) : request1.sell(volume));
   }
   else
   {
      ... // there are positions - see the next box
   }
```

When there are positions, we go through them in a cycle and close those for which there is sufficient profit (adjusted for swaps). While doing so, we also sum up the swaps of closed positions and total losses. Since swaps grow in proportion to time, we use them as an amplifying factor for closing "old" positions. Thus, it is possible to close with a loss.

```
      double loss = 0, swaps = 0;
      for(int i = 0; i < ArraySize(tickets); ++i)
      {
         if(values[i][0] + values[i][1] * values[i][1] >= MinProfitPerLot * volume)
         {
            MqlTradeRequestSync request0;
            if(request0.close(tickets[i]) && request0.completed())
            {
               swaps += values[i][1];
            }
         }
         else
         {
            loss += values[i][0];
         }
      }
      ...
```

If the total losses increase, we periodically open additional positions, but we do it less often when there are more positions, in order to somehow control the risks.

```
      if(loss / ArraySize(tickets) <= -MinProfitPerLot * volume * sqrt(ArraySize(tick
      {
         MqlTradeRequestSync request1;
         (Type == MARKET_BUY ? request1.buy(volume) : request1.sell(volume));
      }
      ...
```

Finally, we remove swaps from the account.

```
      if(swaps >= 0)
      {
         TesterWithdrawal(swaps);
      }
```

In the *OnDeinit* handler, we display statistics on deductions.

```
void OnDeinit(const int)
{
   PrintFormat("Deposit: %.2f Withdrawals: %.2f",
      TesterStatistics(STAT_INITIAL_DEPOSIT),
      TesterStatistics(STAT_WITHDRAWAL));
}
```

For example, when running the Expert Advisor with default settings for the period from 2021 to the beginning of 2022, we get the following result for AUDUSD:

```
final balance 10091.19 USD
Deposit: 10000.00 Withdrawals: 197.42
```

Here is what the report and graph look like.

Bars	8270	Ticks	1956175	Symbols	1
Initial Deposit	10 000.00				
Total Net Profit	91.19	Balance Drawdow...	0.00	Equity Drawdown ...	227.74

Expert report with withdrawals from the account

Thus, when trading a minimum lot and loading a deposit of no more than 1% for a little over a year, we managed to withdraw about 200 USD.

6.5.15 Forced test stop: TesterStop

If necessary, depending on the conditions observed, the developer can stop testing the Expert Advisor earlier. For example, this can be done when a specified number of losing deals or a drawdown level is reached. For this purpose, the API provides the *TesterStop* function.

void TesterStop()

The function gives a command to terminate the tester, i.e., the stop will occur only after the program returns control to the execution environment.

Calling *TesterStop* is considered a normal end of testing, and so this will call the *OnTester* function and return all accumulated trading statistics and the value of the optimization criterion to the strategy tester.

There is also an alternative regular way to interrupt testing: using the previously considered *ExpertRemove* function. The call of *ExpertRemove* also returns trading statistics collected by the time the function is called. However, there are some differences.

As a result of the *ExpertRemove* call, the Expert Advisor is unloaded from the agent's memory. Therefore, if you need to run a new pass with a new set of parameters, some time will be taken to reload the MQL program. When using *TesterStop*, this does not happen, and this method is preferable in terms of performance.

On the other hand, the *ExpertRemove* call sets the *_IsStopped* stop flag in the MQL program, which can be used in a standard way in different parts of the program for finalizing ("cleaning up" resources). But calling *TesterStop* does not set this flag, and therefore the developer may need to introduce their own global variable to indicate early termination and handle it in a specific way.

> It is important to note that *TesterStop* is designed to stop only one pass of the tester.
>
> MQL5 does not provide functions for the early termination of optimization. Therefore, for example, if your Expert Advisor detects that the optimization has been launched on the wrong tick generation model, and this can be detected only after the optimization has been launched (*OnTesterInit* does not help here), then the *TesterStop* or *ExpertRemove* calls will interrupt new passes, but the passes themselves will continue to be initiated, generating mass null results. We will see it in the section Big Expert Advisor example, which will use protection from launching at open prices.
>
> It could be assumed that the *ExpertRemove* call in the Expert Advisor instance running in the terminal and actually serving an optimization manager would stop the optimization. But this is not the case. Even closing the chart with this Expert Advisor working in the frame mode does not stop the optimization.

It is suggested that you try these functions in action yourself.

6.5.16 Big Expert Advisor example

To generalize and consolidate knowledge about the capabilities of the tester, let's consider a large example of an Expert Advisor step by step. In this example, we will summarize the following aspects:

- Using multiple symbols, including the synchronization of bars

- Using an indicator from an Expert Advisor
- Using events
- Independent calculation of the main trading statistics
- Calculation of the R2 custom optimization criterion adjusted for variable lots
- Sending and processing frames with application data (trade reports broken down by symbols)

We will use *MultiMartingale.mq5* as the technical base for the Expert Advisor but we will make it less risky by switching to trading multi-currency overbought/oversold signals and increasing lots only as an optional addition. Previously, in *BandOsMA.mq5*, we have already seen how to operate based on indicator trading signals. This time we will use *UseUnityPercentPro.mq5* as the signal indicator. However, we need to modify it first. Let's call the new version *UnityPercentEvent.mq5*.

UnityPercentEvent.mq5

Recall the essence of the *Unity* indicator. It calculates the relative strength of currencies or tickers included in a set of given instruments (it is assumed that all instruments have a common currency through which conversion is possible). On each bar, readings are formed for all currencies: some will be more expensive, some will be cheaper, and the two extreme elements are in a borderline state. Further along, two essentially opposite strategies can be considered for them:

- Further breakdown (confirmation and continuation of a strong movement to the sides)
- Pullback (reversal of movement towards the center due to overbought and oversold)

To trade any of these signals, we must make a working symbol of two currencies (or tickers in general), if there is something suitable for this combination in the Market Watch. For example, if the upper line of the indicator belongs to EUR and the lower line belongs to USD, they correspond to the EURUSD pair, and according to the breakout strategy we should buy it but according to the rebound strategy, we should sell it.

> In a more general case, for example, when CFDs or commodities with a common quote currency are indicated in the indicator's basket of working instruments, it is not always possible to create a real instrument. For such cases, it would be necessary to make the Expert Advisor more complicated by introducing trading synthetics (compound positions), but we will not do this here and will limit ourselves to the Forex market, where almost all cross rates are usually available.

Thus, the Expert Advisor must not only read all indicator buffers but also find out the names of currencies, which correspond to the maximum and minimum values. And here we have a small obstacle.

MQL5 does not allow reading the names of third-party indicator buffers and in general, any line properties other than integer ones. There are three functions for setting properties: *PlotIndexSetInteger*, *PlotIndexSetDouble*, and *PlotIndexSetString*, but there is only one function for reading them: *PlotIndexGetInteger*.

In theory, when MQL programs compiled into a single trading complex are created by the same developer, this is not a big problem. In particular, we could separate a part of the indicator's source code into a header file and include it not only in the indicator but also in the Expert Advisor. Then in the Expert Advisor, it would be possible to repeat the analysis of the indicator's input parameters and restore the list of currencies, completely similar to that created by the indicator. Duplicating calculations is not very pretty, but it would work. However, a more universal solution is also required when the indicator has a different developer, and they do not want to disclose the algorithm or plan to change it in the future (then the compiled versions of the indicator and the Expert Advisor will become incompatible). Such a "docking" of other people's indicators with one's own, or an Expert Advisor

ordered from a freelance service is a very common practice. Therefore, the indicator developer should make it as integration-friendly as possible.

One of the possible solutions is for the indicator to send messages with the numbers and names of buffers after initialization.

This is how it's done in the *OnInit* handler of the *UnityPercentEvent.mq5* indicator (the code below is shown in a shorted form since almost nothing has changed).

```
int OnInit()
{
   // find the common currency for all pairs
   const string common = InitSymbols();
   ...
   // set up the displayed lines in the currency cycle
   int replaceIndex = -1;
   for(int i = 0; i <= SymbolCount; i++)
   {
      string name;
      // change the order so that the base (common) currency goes under index 0,
      // the rest depends on the order in which the pairs are entered by the user
      if(i == 0)
      {
         name = common;
         if(name != workCurrencies.getKey(i))
         {
            replaceIndex = i;
         }
      }
      else
      {
         if(common == workCurrencies.getKey(i) && replaceIndex > -1)
         {
            name = workCurrencies.getKey(replaceIndex);
         }
         else
         {
            name = workCurrencies.getKey(i);
         }
      }

      // set up rendering of buffers
      PlotIndexSetString(i, PLOT_LABEL, name);
      ...
      // send indexes and buffer names to programs where they are needed
      EventChartCustom(0, (ushort)BarLimit, i, SymbolCount + 1, name);
   }
   ...
}
```

Compared to the original version, only one line has been added here. It contains the *EventChartCustom* call. The input variable *BarLimit* is used as the identifier of the indicator copy (of which there may

potentially be several). Since the indicator will be called from the Expert Advisor and will not be displayed to the user, it is enough to indicate a small positive number, at least 1, but we will have, for example, 10.

Now the indicator is ready and its signals can be used in third-party Expert Advisors. Let's start developing the Expert Advisor *UnityMartingale.mq5*. To simplify the presentation, we will divide it into 4 stages, gradually adding new blocks. We will have three preliminary versions and one final version.

UnityMartingaleDraft1.mq5

In the first stage, for the version *UnityMartingaleDraft1.mq5*, let's use *MultiMartingale.mq5* as the basis and modify it.

We will rename the former input variable *StartType* which determined the direction of the first deal in the series into *SignalType*. It will be used to choose between the considered strategies BREAKOUT and PULLBACK.

```
enum SIGNAL_TYPE
{
   BREAKOUT,
   PULLBACK
};
...
input SIGNAL_TYPE StartType = 0; // SignalType
```

To set up the indicator, we need a separate group of input variables.

```
input group "U N I T Y   S E T T I N G S"
input string UnitySymbols = "EURUSD,GBPUSD,USDCHF,USDJPY,AUDUSD,USDCAD,NZDUSD";
input int UnityBarLimit = 10;
input ENUM_APPLIED_PRICE UnityPriceType = PRICE_CLOSE;
input ENUM_MA_METHOD UnityPriceMethod = MODE_EMA;
input int UnityPricePeriod = 1;
```

Please note that the *UnitySymbols* parameter contains a list of cluster instruments for building an indicator, and usually differs from the list of working instruments that we want to trade. Traded instruments are still set in the *WorkSymbols* parameter.

For example, by default, we pass a set of major *Forex* currency pairs to the indicator, and therefore we can indicate as trading not only the main pairs but also any crosses. It usually makes sense to limit this set to instruments with the best trading conditions (in particular, small or moderate spreads). In addition, it is desirable to avoid distortions, i.e., to keep an equal amount of each currency in all pairs, thereby statistically neutralizing the potential risks of choosing an unsuccessful direction for one of the currencies.

Next, we wrap the indicator control in the *UnityController* class. In addition to the indicator *handle*, the class fields store the following data:

- The number of indicator *buffers*, which will be received from messages from the indicator after its initialization
- The *bar* number from which the data is being read (usually the current incomplete is 0, or the last completed is 1)
- The *data* array with values read from indicator buffers on the specified bar
- The last read time *lastRead*

- Flag of operation by ticks or bars *tickwise*

In addition, the class uses the *MultiSymbolMonitor* object to synchronize the bars of all involved symbols.

```
class UnityController
{
   int handle;
   int buffers;
   const int bar;
   double data[];
   datetime lastRead;
   const bool tickwise;
   MultiSymbolMonitor sync;
   ...
```

In the constructor, which accepts all parameters for the indicator through arguments, we create the indicator and set up the *sync* object.

```
public:
   UnityController(const string symbolList, const int offset, const int limit,
      const ENUM_APPLIED_PRICE type, const ENUM_MA_METHOD method, const int period):
      bar(offset), tickwise(!offset)
   {
      handle = iCustom(_Symbol, _Period, "MQL5Book/p6/UnityPercentEvent",
         symbolList, limit, type, method, period);
      lastRead = 0;

      string symbols[];
      const int n = StringSplit(symbolList, ',', symbols);
      for(int i = 0; i < n; ++i)
      {
         sync.attach(symbols[i]);
      }
   }

   ~UnityController()
   {
      IndicatorRelease(handle);
   }
   ...
```

The number of buffers is set by the *attached* method. We will call it upon receiving a message from the indicator.

```
   void attached(const int b)
   {
      buffers = b;
      ArrayResize(data, buffers);
   }
```

A special method *isReady* returns *true* when the last bars of all symbols have the same time. Only in the state of such synchronization will we get the correct values of the indicator. It should be noted that the

same schedule of trading sessions for all instruments is assumed here. If this is not the case, the timing analysis needs to be changed.

```
bool isReady()
{
   return sync.check(true) == 0;
}
```

We define the current time in different ways depending on the indicator operation mode: when recalculating on each tick (*tickwise* equals *true*), we use the server time, and when recalculated once per bar, we use the opening time of the last bar.

```
datetime lastTime() const
{
   return tickwise ? TimeTradeServer() : iTime(_Symbol, _Period, 0);
}
```

The presence of this method will allow us to exclude reading the indicator if the current time has not changed and, accordingly, the last read data stored in the *data* buffer is still relevant. And this is how the reading of indicator buffers is organized in the *read* method. We only need one value of each buffer for the bar with the *bar* index.

```
bool read()
{
   if(!buffers) return false;
   for(int i = 0; i < buffers; ++i)
   {
      double temp[1];
      if(CopyBuffer(handle, i, bar, 1, temp) == 1)
      {
         data[i] = temp[0];
      }
      else
      {
         return false;
      }
   }
   lastRead = lastTime();
   return true;
}
```

In the end, we just save the reading time into the *lastRead* variable. If it is empty or not equal to the new current time, accessing the controller data in the following methods will cause the indicator buffers to be read using *read*.

The main external methods of the controller are *getOuterIndices* to get the indexes of the maximum and minimum values and the operator '[]' to read the values.

```
   bool isNewTime() const
   {
      return lastRead != lastTime();
   }

   bool getOuterIndices(int &min, int &max)
   {
      if(isNewTime())
      {
         if(!read()) return false;
      }
      max = ArrayMaximum(data);
      min = ArrayMinimum(data);
      return true;
   }

   double operator[](const int buffer)
   {
      if(isNewTime())
      {
         if(!read())
         {
            return EMPTY_VALUE;
         }
      }
      return data[buffer];
   }
};
```

Previously, the Expert Advisor *BandOsMA.mq5* introduced the concept of the *TradingSignal* interface.

```
interface TradingSignal
{
   virtual int signal(void);
};
```

Based on it, we will describe the implementation of the signal using the *UnityPercentEvent* indicator. The controller object *UnityController* is passed to the constructor. It also indicates the indexes of currencies (buffers), the signals for which we want to track. We will be able to create an arbitrary set of different signals for the selected working symbols.

```
class UnitySignal: public TradingSignal
{
   UnityController *controller;
   const int currency1;
   const int currency2;

public:
   UnitySignal(UnityController *parent, const int c1, const int c2):
      controller(parent), currency1(c1), currency2(c2) { }

   virtual int signal(void) override
   {
      if(!controller.isReady()) return 0; // waiting for bars synchronization
      if(!controller.isNewTime()) return 0; // waitng for time to change

      int min, max;
      if(!controller.getOuterIndices(min, max)) return 0;

      // overbought
      if(currency1 == max && currency2 == min) return +1;
      // oversold
      if(currency2 == max && currency1 == min) return -1;
      return 0;
   }
};
```

The *signal* method returns 0 in an uncertain situation and +1 or -1 in overbought and oversold states of two specific currencies.

To formalize trading strategies, we used the *TradingStrategy* interface.

```
interface TradingStrategy
{
   virtual bool trade(void);
};
```

In this case, the *UnityMartingale* class is created on its basis, which largely coincides with *SimpleMartingale* from *MultiMartingale.mq5*. We will only show the differences.

```
class UnityMartingale: public TradingStrategy
{
protected:
   ...
   AutoPtr<TradingSignal> command;

public:
   UnityMartingale(const Settings &state, TradingSignal *signal)
   {
      ...
      command = signal;
   }
   virtual bool trade() override
   {
      ...
      int s = command[].signal(); // get controller signal
      if(s != 0)
      {
         if(settings.startType == PULLBACK) s *= -1; // reverse logic for bounce
      }
      ulong ticket = 0;
      if(position[] == NULL) // clean start - there were (and is) no positions
      {
         if(s == +1)
         {
            ticket = openBuy(settings.lots);
         }
         else if(s == -1)
         {
            ticket = openSell(settings.lots);
         }
      }
      else
      {
         if(position[].refresh()) // position exists
         {
            if((position[].get(POSITION_TYPE) == POSITION_TYPE_BUY && s == -1)
            || (position[].get(POSITION_TYPE) == POSITION_TYPE_SELL && s == +1))
            {
               // signal in the other direction - we need to close
               PrintFormat("Opposite signal: %d for position %d %lld",
                  s, position[].get(POSITION_TYPE), position[].get(POSITION_TICKET));
               if(close(position[].get(POSITION_TICKET)))
               {
                  // position = NULL; - save the position in the cache
               }
               else
               {
                  position[].refresh(); // control possible closing errors
               }
            }
```

```
            else
            {
               // the signal is the same or absent - "trailing"
               position[].update();
               if(trailing[]) trailing[].trail();
            }
         }
         else // no position - open a new one
         {
            if(s == 0) // no signals
            {
               // here is the full logic of the old Expert Advisor:
               // - reversal for martingale loss
               // - continuation by the initial lot in a profitable direction
               ...
            }
            else // there is a signal
            {
               double lots;
               if(position[].get(POSITION_PROFIT) >= 0.0)
               {
                  lots = settings.lots; // initial lot after profit
               }
               else // increase the lot after the loss
               {
                  lots = MathFloor((position[].get(POSITION_VOLUME) * settings.factor

                  if(lotsLimit < lots)
                  {
                     lots = settings.lots;
                  }
               }

               ticket = (s == +1) ? openBuy(lots) : openSell(lots);
            }
         }
      }
   }
   ...
}
```

The trading part is ready. It remains to consider the initialization. An autopointer to the *UnityController* object and the array with currency names are described at the global level. The pool of trading systems is completely similar to the previous developments.

```
AutoPtr<TradingStrategyPool> pool;
AutoPtr<UnityController> controller;

int currenciesCount;
string currencies[];
```

In the *OnInit* handler, we create the *UnityController* object and wait for the indicator to send the distribution of currencies by buffer indexes.

```
int OnInit()
{
   currenciesCount = 0;
   ArrayResize(currencies, 0);

   if(!StartUp(true)) return INIT_PARAMETERS_INCORRECT;

   const bool barwise = UnityPriceType == PRICE_CLOSE && UnityPricePeriod == 1;
   controller = new UnityController(UnitySymbols, barwise,
      UnityBarLimit, UnityPriceType, UnityPriceMethod, UnityPricePeriod);
   // waiting for messages from the indicator on currencies in buffers
   return INIT_SUCCEEDED;
}
```

If the price type PRICE_CLOSE and a single period are selected in the indicator input parameters, the calculation in the controller will be performed once per bar. In all other cases, the signals will be updated by ticks, but not more often than once per second (recall the implementation of the *lastTime* method in the controller).

The helper method *StartUp* generally does the same thing as the old *OnInit* handler in the Expert Advisor *MultiMartingale*. It fills the *Settings* structure with settings, checking them for correctness and creating a pool of trading systems *TradingStrategyPool*, consisting of objects of the *UnityMartingale* class for different trading symbols *WorkSymbols*. However, now this process is divided into two stages due to the fact that we need to wait for information about the distribution of currencies among buffers. Therefore, the *StartUp* function has an input parameter denoting a call from *OnInit* and later from *OnChartEvent*.

When analyzing the source code of *StartUp*, it is important to remember that the initialization is different for the cases when we trade only one instrument that matches the current chart and when a basket of instruments is specified. The first mode is active when *WorkSymbols* is an empty line. It is convenient for optimizing an Expert Advisor for a specific instrument. Having found the settings for several instruments, we can combine them in *WorkSymbols*.

```
bool StartUp(const bool init = false)
{
   if(WorkSymbols == "")
   {
      Settings settings =
      {
         UseTime, HourStart, HourEnd,
         Lots, Factor, Limit,
         StopLoss, TakeProfit,
         StartType, Magic, SkipTimeOnError, Trailing, _Symbol
      };

      if(settings.validate())
      {
         if(init)
         {
            Print("Input settings:");
            settings.print();
         }
      }
      else
      {
         if(init) Print("Wrong settings, please fix");
         return false;
      }
      if(!init)
      {
         ...// creating a trading system based on the indicator
      }
   }
   else
   {
      Print("Parsed settings:");
      Settings settings[];
      if(!Settings::parseAll(WorkSymbols, settings))
      {
         if(init) Print("Settings are incorrect, can't start up");
         return false;
      }
      if(!init)
      {
         ...// creating a trading system based on the indicator
      }
   }
   return true;
}
```

The *StartUp* function in *OnInit* is called with the *true* parameter, which means only checking the correctness of the settings. The creation of a trading system object is delayed until a message is received from the indicator in *OnChartEvent*.

```
void OnChartEvent(const int id,
   const long &lparam, const double &dparam, const string &sparam)
{
   if(id == CHARTEVENT_CUSTOM + UnityBarLimit)
   {
      PrintFormat("%lld %f '%s'", lparam, dparam, sparam);
      if(lparam == 0) ArrayResize(currencies, 0);
      currenciesCount = (int)MathRound(dparam);
      PUSH(currencies, sparam);
      if(ArraySize(currencies) == currenciesCount)
      {
         if(pool[] == NULL)
         {
            start up(); // indicator readiness confirmation
         }
         else
         {
            Alert("Repeated initialization!");
         }
      }
   }
}
```

Here we remember the number of currencies in the global variable *currenciesCount* and store them in the *currencies* array, after which we call *StartUp* with the *false* parameter (default value, therefore omitted). Messages arrive from the queue in the order in which they exist in the indicator's buffers. Thus, we get a match between the index and the name of the currency.

When *StartUp* is called again, an additional code is executed:

```
bool StartUp(const bool init = false)
{
   if(WorkSymbols == "") // one current symbol
   {
      ...
      if(!init) // final initialization after OnInit
      {
         controller[].attached(currenciesCount);
         // split _Symbol into 2 currencies from the currencies array []
         int first, second;
         if(!SplitSymbolToCurrencyIndices(_Symbol, first, second))
         {
            PrintFormat("Can't find currencies (%s %s) for %s",
               (first == -1 ? "base" : ""), (second == -1 ? "profit" : ""), _Symbol);
            return false;
         }
         // create a pool from a single strategy
         pool = new TradingStrategyPool(new UnityMartingale(settings,
            new UnitySignal(controller[], first, second)));
      }
   }
   else // symbol basket
   {
      ...
      if(!init) // final initialization after OnInit
      {
         controller[].attached(currenciesCount);

         const int n = ArraySize(settings);
         pool = new TradingStrategyPool(n);
         for(int i = 0; i < n; i++)
         {
            ...
            // split settings[i].symbol into 2 currencies from currencies[]
            int first, second;
            if(!SplitSymbolToCurrencyIndices(settings[i].symbol, first, second))
            {
               PrintFormat("Can't find currencies (%s %s) for %s",
                  (first == -1 ? "base" : ""), (second == -1 ? "profit" : ""),
                  settings[i].symbol);
            }
            else
            {
               // add a strategy to the pool on the next trading symbol
               pool[].push(new UnityMartingale(settings[i],
                  new UnitySignal(controller[], first, second)));
            }
         }
      }
   }
```

The helper function *SplitSymbolToCurrencyIndices* selects the base currency and profit currency of the passed symbol and finds their indexes in the *currencies* array. Thus, we get the reference data for generating signals in *UnitySignal* objects. Each of them will have its own pair of currency indexes.

```
bool SplitSymbolToCurrencyIndices(const string symbol, int &first, int &second)
{
   const string s1 = SymbolInfoString(symbol, SYMBOL_CURRENCY_BASE);
   const string s2 = SymbolInfoString(symbol, SYMBOL_CURRENCY_PROFIT);
   first = second = -1;
   for(int i = 0; i < ArraySize(currencies); ++i)
   {
      if(currencies[i] == s1) first = i;
      else if(currencies[i] == s2) second = i;
   }

   return first != -1 && second != -1;
}
```

In general, the Expert Advisor is ready.

You can see that in the last examples of Expert Advisors we have classes of strategies and classes of trading signals. We deliberately made them descendants of generic interfaces *TradingStrategy* and *TradingSignal* in order to subsequently be able to collect collections of compatible but different implementations that can be combined in the development of future Expert Advisors. Such unified concrete classes should usually be separated into separate header files. In our examples, we did not do this for the sake of simplifying the step-by-step modification.

However, the described approach is standard for OOP. In particular, as we mentioned in the section on creating Expert Advisor drafts, along with MetaTrader 5 comes a *framework* of header files with standard classes of trading operations, signal indicators, and money management, which are used in the MQL Wizard. Other similar solutions are published on the *mql5.com* site in the articles and the Code Base section.

You can use the ready-made class hierarchies as the basis for your projects, provided they are suitable in terms of capabilities and ease of use.

To complete the picture, we wanted to introduce our own R2-based optimization criterion in the Expert Advisor. To avoid the contradiction between the linear regression in the R2 calculation formula and the variable lots that are included in our strategy, we will calculate the coefficient not for the usual balance line but for its cumulative increments normalized by lot sizes in each trade.

To do this, in the *OnTester* handler, we select deals with the types DEAL_TYPE_BUY and DEAL_TYPE_SELL and with the direction OUT. We will request all deal properties that form the financial result (profit/loss), i.e., DEAL_PROFIT, DEAL_SWAP, DEAL_COMMISSION, DEAL_FEE, as well as their DEAL_VOLUME volume.

```
#define STAT_PROPS 5 // number of requested deal properties

double OnTester()
{
   HistorySelect(0, LONG_MAX);

   const ENUM_DEAL_PROPERTY_DOUBLE props[STAT_PROPS] =
   {
      DEAL_PROFIT, DEAL_SWAP, DEAL_COMMISSION, DEAL_FEE, DEAL_VOLUME
   };
   double expenses[][STAT_PROPS];
   ulong tickets[]; // needed because of 'select' method prototype, but useful for de

   DealFilter filter;
   filter.let(DEAL_TYPE, (1 << DEAL_TYPE_BUY) | (1 << DEAL_TYPE_SELL), IS::OR_BITWISE
      .let(DEAL_ENTRY, (1 << DEAL_ENTRY_OUT) | (1 << DEAL_ENTRY_INOUT) | (1 << DEAL_E
      IS::OR_BITWISE)
      .select(props, tickets, expenses);
   ...
```

Next, in the *balance* array, we accumulate profits/losses normalized by trading volumes and calculate the criterion R2 for it.

```
   const int n = ArraySize(tickets);
   double balance[];
   ArrayResize(balance, n + 1);
   balance[0] = TesterStatistics(STAT_INITIAL_DEPOSIT);

   for(int i = 0; i < n; ++i)
   {
      double result = 0;
      for(int j = 0; j < STAT_PROPS - 1; ++j)
      {
         result += expenses[i][j];
      }
      result /= expenses[i][STAT_PROPS - 1]; // normalize by volume
      balance[i + 1] = result + balance[i];
   }
   const double r2 = RSquaredTest(balance);
   return r2 * 100;
}
```

The first version of the Expert Advisor is basically ready. We have not included the check for the tick model using *TickModel.mqh*. It is assumed that the Expert Advisor will be tested when generating ticks in the OHLC M1 mode or better. When the "open prices only" model is detected, the Expert Advisor will send a special frame with an error status to the terminal and unload itself from the tester. Unfortunately, this will only stop this pass, but the optimization will continue. Therefore, the copy of the Expert Advisor that runs in the terminal issues an "alert" for the user to interrupt the optimization manually.

```
void OnTesterPass()
{
   ulong   pass;
   string  name;
   long    id;
   double  value;
   uchar   data[];
   while(FrameNext(pass, name, id, value, data))
   {
      if(name == "status" && id == 1)
      {
         Alert("Please stop optimization!");
         Alert("Tick model is incorrect: OHLC M1 or better is required");
         // it would be logical if the next call would stop all optimization,
         // but it is not
         ExpertRemove();
      }
   }
}
```

You can optimize SYMBOL SETTINGS parameters for any symbol and repeat the optimization for different symbols. At the same time, the COMMON SETTINGS and UNITY SETTINGS groups should always contain the same settings, because they apply to all symbols and instances of trading systems. For example, *Trailing* must be either enabled or disabled for all optimizations. Also note that the input variables for a single symbol (i.e. the SYMBOL SETTINGS group) have an effect only while *WorkSymbols* contains an empty string. Therefore, at the optimization stage, you should keep it empty.

For example, to diversify risks, you can consistently optimize an Expert Advisor on completely independent pairs: EURUSD, AUDJPY, GBPCHF, NZDCAD, or in other combinations. Three set files with examples of private settings are connected to the source code.

```
#property tester_set "UnityMartingale-eurusd.set"
#property tester_set "UnityMartingale-gbpchf.set"
#property tester_set "UnityMartingale-audjpy.set"
```

In order to trade on three symbols at once, these settings should be "packed" into a common parameter *WorkSymbols*:

```
EURUSD+0.01*1.6^5(200,200)[17,21];GBPCHF+0.01*1.2^8(600,800)[7,20];AUDJPY+0.01*1.2^8(
```

This setting is also included in a separate file.

```
#property tester_set "UnityMartingale-combo.set"
```

One of the problems with the current version of the Expert Advisor is that the tester report will provide general statistics for all symbols (more precisely, for all trading strategies, since we can include different classes in the pool), while it would be interesting for us to monitor and evaluate each component of the system separately.

To do this, you need to learn how to independently calculate the main financial indicators of trading, by analogy with how the tester does it for us. We will deal with this at the second stage of the Expert Advisor development.

UnityMartingaleDraft2.mq5

Statistics calculation might be needed quite frequently, so we will implement it in a separate header file *TradeReport.mqh*, where we organize the source code into the appropriate classes.

Let's call the main class *TradeReport*. Many trading variables depend on balance and free margin (equity) curves. Therefore, the class contains variables for tracking the current balance and profit, as well as a constantly updated array with the balance history. We will not store the history of equity, because it can change on every tick, and it is better to calculate it right on the go. We will see a little later the reason for having the balance curve.

```
class TradeReport
{
   double balance;     // current balance
   double floating;    // current floating profit
   double data[];      // full balance curve - prices
   datetime moments[]; // and date/time
   ...
```

Changing and reading class fields is done using methods, including the constructor, in which the balance is initialized by the ACCOUNT_BALANCE property.

```
   TradeReport()
   {
      balance = AccountInfoDouble(ACCOUNT_BALANCE);
   }

   void resetFloatingPL()
   {
      floating = 0;
   }

   void addFloatingPL(const double pl)
   {
      floating += pl;
   }

   void addBalance(const double pl)
   {
      balance += pl;
   }

   double getCurrent() const
   {
      return balance + floating;
   }
   ...
```

These methods will be needed to iteratively calculate equity drawdown (on the fly). The *data* balance array will be required for a one-time calculation of the balance drawdown (we will do this at the end of the test).

Based on the fluctuations of the curve (it does not matter, balance or equity), absolute and relative drawdown should be calculated using the same algorithm. Therefore, this algorithm and the internal

variables necessary for it, which store intermediate states, are implemented in the nested structure *DrawDown*. The below code shows its main methods and properties.

```
struct DrawDown
{
   double
   series_start,
   series_min,
   series_dd,
   series_dd_percent,
   series_dd_relative_percent,
   series_dd_relative;
   ...
   void reset();
   void calcDrawdown(const double &data[]);
   void calcDrawdown(const double amount);
   void print() const;
};
```

The first *calcDrawdown* method calculates drawdowns when we know the entire array and this will be used for balance. The second *calcDrawdown* method calculates the drawdown iteratively: each time it is called, it is told the next value of the series, and this will be used for equity.

In addition to the drawdown, as we know, there are a large number of standard statistics for reports, but we will support only a few of them to begin with. To do this, we describe the corresponding fields in another nested structure, *GenericStats*. It is inherited from *DrawDown* because we still need the drawdown in the report.

```
struct GenericStats: public DrawDown
{
   long deals;
   long trades;
   long buy_trades;
   long wins;
   long buy_wins;
   long sell_wins;

   double profits;
   double losses;
   double net;
   double pf;
   double average_trade;
   double recovery;
   double max_profit;
   double max_loss;
   double sharpe;
   ...
```

By the names of the variables, it is easy to guess what standard metrics they correspond to. Some metrics are redundant and therefore omitted. For example, given the total number of trades (*trades*) and the number of buy ones among them (*buy_trades*), we can easily find the number of sell trades (*trades - sell_trades*). The same goes for complementary win/loss statistics. Winning and losing streaks are not counted. Those who wish can supplement our report with these indicators.

For unification with the general statistics of the tester, there is the *fillByTester* method which fills all fields through the *TesterStatistics* function. We will use it later.

```
      void fillByTester()
      {
         deals = (long)TesterStatistics(STAT_DEALS);
         trades = (long)TesterStatistics(STAT_TRADES);
         buy_trades = (long)TesterStatistics(STAT_LONG_TRADES);
         wins = (long)TesterStatistics(STAT_PROFIT_TRADES);
         buy_wins = (long)TesterStatistics(STAT_PROFIT_LONGTRADES);
         sell_wins = (long)TesterStatistics(STAT_PROFIT_SHORTTRADES);

         profits = TesterStatistics(STAT_GROSS_PROFIT);
         losses = TesterStatistics(STAT_GROSS_LOSS);
         net = TesterStatistics(STAT_PROFIT);
         pf = TesterStatistics(STAT_PROFIT_FACTOR);
         average_trade = TesterStatistics(STAT_EXPECTED_PAYOFF);
         recovery = TesterStatistics(STAT_RECOVERY_FACTOR);
         sharpe = TesterStatistics(STAT_SHARPE_RATIO);
         max_profit = TesterStatistics(STAT_MAX_PROFITTRADE);
         max_loss = TesterStatistics(STAT_MAX_LOSSTRADE);

         series_start = TesterStatistics(STAT_INITIAL_DEPOSIT);
         series_min = TesterStatistics(STAT_EQUITYMIN);
         series_dd = TesterStatistics(STAT_EQUITY_DD);
         series_dd_percent = TesterStatistics(STAT_EQUITYDD_PERCENT);
         series_dd_relative_percent = TesterStatistics(STAT_EQUITY_DDREL_PERCENT);
         series_dd_relative = TesterStatistics(STAT_EQUITY_DD_RELATIVE);
      }
   };
```

Of course, we need to implement our own calculation for those separate balances and equity of trading systems that the tester cannot calculate. Prototypes of *calcDrawdown* methods have been presented above. During operation, they fill in the last group of fields with the "series_dd" prefix. Also, the *TradeReport* class contains a method for calculating the Sharpe ratio. As input, it takes a series of numbers and a risk-free funding rate. The complete source code can be found in the attached file.

```
   static double calcSharpe(const double &data[], const double riskFreeRate = 0);
```

As you might guess, when calling this method, the relevant member array of the *TradeReport* class with balances will be passed in the *data* parameter. The process of filling this array and calling the above methods for specific indicators occurs in the *calcStatistics* method (see below). An object filter of deals is passed to it as input (*filter*), initial deposit (*start*), and time (*origin*). It is assumed that the calling code will set up the filter in such a way that only trades of the trading system we are interested in fall under it.

The method returns a filled structure *GenericStats*, and in addition, it fills two arrays inside the *TradeReport* object, *data*, and *moments*, with balance values and time references of changes, respectively. We will need it in the final version of the Expert Advisor.

```
GenericStats calcStatistics(DealFilter &filter,
   const double start = 0, const datetime origin = 0,
   const double riskFreeRate = 0)
{
   GenericStats stats;
   ArrayResize(data, 0);
   ArrayResize(moments, 0);
   ulong tickets[];
   if(!filter.select(tickets)) return stats;

   balance = start;
   PUSH(data, balance);
   PUSH(moments, origin);

   for(int i = 0; i < ArraySize(tickets); ++i)
   {
      DealMonitor m(tickets[i]);
      if(m.get(DEAL_TYPE) == DEAL_TYPE_BALANCE) //deposit/withdrawal
      {
         balance += m.get(DEAL_PROFIT);
         PUSH(data, balance);
         PUSH(moments, (datetime)m.get(DEAL_TIME));
      }
      else if(m.get(DEAL_TYPE) == DEAL_TYPE_BUY
         || m.get(DEAL_TYPE) == DEAL_TYPE_SELL)
      {
         const double profit = m.get(DEAL_PROFIT) + m.get(DEAL_SWAP)
            + m.get(DEAL_COMMISSION) + m.get(DEAL_FEE);
         balance += profit;

         stats.deals++;
         if(m.get(DEAL_ENTRY) == DEAL_ENTRY_OUT
            || m.get(DEAL_ENTRY) == DEAL_ENTRY_INOUT
            || m.get(DEAL_ENTRY) == DEAL_ENTRY_OUT_BY)
         {
            PUSH(data, balance);
            PUSH(moments, (datetime)m.get(DEAL_TIME));
            stats.trades++;        // trades are counted by exit deals
            if(m.get(DEAL_TYPE) == DEAL_TYPE_SELL)
            {
               stats.buy_trades++; // closing with a deal in the opposite directio
            }
            if(profit >= 0)
            {
               stats.wins++;
               if(m.get(DEAL_TYPE) == DEAL_TYPE_BUY)
               {
                  stats.sell_wins++; // closing with a deal in the opposite direct
               }
               else
               {
```

```
                        stats.buy_wins++;
                     }
                  }
               }
               else if(!TU::Equal(profit, 0))
               {
                  PUSH(data, balance); // entry fee (if any)
                  PUSH(moments, (datetime)m.get(DEAL_TIME));
               }

               if(profit >= 0)
               {
                  stats.profits += profit;
                  stats.max_profit = fmax(profit, stats.max_profit);
               }
               else
               {
                  stats.losses += profit;
                  stats.max_loss = fmin(profit, stats.max_loss);
               }
            }
         }

         if(stats.trades > 0)
         {
            stats.net = stats.profits + stats.losses;
            stats.pf = -stats.losses > DBL_EPSILON ?
               stats.profits / -stats.losses : MathExp(10000.0); // NaN(+inf)
            stats.average_trade = stats.net / stats.trades;
            stats.sharpe = calcSharpe(data, riskFreeRate);
            stats.calcDrawdown(data);     // fill in all fields of the DrawDown substruc
            stats.recovery = stats.series_dd > DBL_EPSILON ?
               stats.net / stats.series_dd : MathExp(10000.0);
         }
         return stats;
      }
   };
```

Here you can see how we call *calcSharpe* and *calcDrawdown* to get the corresponding indicators on the array *data*. The remaining indicators are calculated directly in the loop inside *calcStatistics*.

The *TradeReport* class is ready, and we can expand the functionality of the Expert Advisor to the version *UnityMartingaleDraft2.mq5*.

Let's add new members to the *UnityMartingale* class.

```
class UnityMartingale: public TradingStrategy
{
protected:
   ...
   TradeReport report;
   TradeReport::DrawDown equity;
   const double deposit;
   const datetime epoch;
   ...
```

We need the *report* object in order to call *calcStatistics*, where the balance drawdown will be included. The *equity* object is required for an independent calculation of equity drawdown. The initial balance and date, as well as the beginning of the equity drawdown calculation, are set in the constructor.

```
public:
   UnityMartingale(const Settings &state, TradingSignal *signal):
      symbol(state.symbol), deposit(AccountInfoDouble(ACCOUNT_BALANCE)),
      epoch(TimeCurrent())
   {
      ...
      equity.calcDrawdown(deposit);
      ...
   }
```

Continuation of the calculation of drawdown by equity is done on the go, with each call to the *trade* method.

```
   virtual bool trade() override
   {
      ...
      if(MQLInfoInteger(MQL_TESTER))
      {
         if(position[])
         {
            report.resetFloatingPL();
            // after reset, sum all floating profits
            // why we call addFloatingPL for each existing position,
            // but this strategy has a maximum of 1 position at a time
            report.addFloatingPL(position[].get(POSITION_PROFIT)
               + position[].get(POSITION_SWAP));
            // after taking into account all the amounts - update the drawdown
            equity.calcDrawdown(report.getCurrent());
         }
      }
      ...
   }
```

This is not all that is needed for a correct calculation. We should take into account the floating profit or loss on top of the balance. The above code part only shows the *addFloatingPL* call, but the *TradeReport* class has also a method for modifying the balance: *addBalance*. However, the balance changes only when the position is closed.

Thanks to the OOP concept, closing a position in our situation corresponds to deleting the *position* object of the *PositionState* class. So why can't we intercept it?

The *PositionState* class does not provide any means for this, but we can declare a derived class *PositionStateWithEquity* with a special constructor and destructor.

When creating an object, not only the position identifier is passed to the constructor, but also a pointer to the report object to which information will need to be sent.

```
class PositionStateWithEquity: public PositionState
{
   TradeReport *report;

public:
   PositionStateWithEquity(const long t, TradeReport *r):
      PositionState(t), report(r) { }
   ...
```

In the destructor, we find all deals by the closed position ID, calculate the total financial result (together with commissions and other deductions), and then call *addBalance* for related the *report* object.

```
   ~PositionStateWithEquity()
   {
      if(HistorySelectByPosition(get(POSITION_IDENTIFIER)))
      {
         double result = 0;
         DealFilter filter;
         int props[] = {DEAL_PROFIT, DEAL_SWAP, DEAL_COMMISSION, DEAL_FEE};
         Tuple4<double, double, double, double> overheads[];
         if(filter.select(props, overheads))
         {
            for(int i = 0; i < ArraySize(overheads); ++i)
            {
               result += NormalizeDouble(overheads[i]._1, 2)
                  + NormalizeDouble(overheads[i]._2, 2)
                  + NormalizeDouble(overheads[i]._3, 2)
                  + NormalizeDouble(overheads[i]._4, 2);
            }
         }
         if(CheckPointer(report) != POINTER_INVALID) report.addBalance(result);
      }
   }
};
```

It remains to clarify one point – how to create *PositionStateWithEquity* class objects for positions instead of *PositionState*. To do this, it is enough to change the *new* operator in a couple of places where it is called in the *TradingStrategy* class.

```
   position = MQLInfoInteger(MQL_TESTER) ?
      new PositionStateWithEquity(tickets[0], &report) : new PositionState(tickets[0]
```

Thus, we have implemented the collection of data. Now we need to directly generate a report, that is, to call *calcStatistics*. Here we need to expand our *TradingStrategy* interface: we add the *statement* method to it.

```
interface TradingStrategy
{
   virtual bool trade(void);
   virtual bool statement();
};
```

Then, in this current implementation, intended for our strategy, we will be able to bring the work to its logical conclusion.

```
class UnityMartingale: public TradingStrategy
{
   ...
   virtual bool statement() override
   {
      if(MQLInfoInteger(MQL_TESTER))
      {
         Print("Separate trade report for ", settings.symbol);
         // equity drawdown should already be calculated on the fly
         Print("Equity DD:");
         equity.print();

         // balance drawdown is calculated in the resulting report
         Print("Trade Statistics (with Balance DD):");
         // configure the filter for a specific strategy
         DealFilter filter;
         filter.let(DEAL_SYMBOL, settings.symbol)
            .let(DEAL_MAGIC, settings.magic, IS::EQUAL_OR_ZERO);
           // zero "magic" number is needed for the last exit deal
           // - it is done by the tester itself
         HistorySelect(0, LONG_MAX);
         TradeReport::GenericStats stats =
            report.calcStatistics(filter, deposit, epoch);
         stats.print();
      }
      return false;
   }
   ...
```

The new method will simply print out all the calculated indicators in the log. By forwarding the same method through the pool of trading systems *TradingStrategyPool*, let's request separate reports for all symbols from the handler *OnTester*.

```
double OnTester()
{
   ...
   if(pool[] != NULL)
   {
      pool[].statement(); // ask all trading systems to display their results
   }
   ...
}
```

Let's check the correctness of our report. To do this, let's run the Expert Advisor in the tester, one symbol at a time, and compare the standard report with our calculations. For example, to set up *UnityMartingale-eurusd.set*, trading on EURUSD H1 we will get such indicators for 2021.

Bars	6232	Ticks	1474964	Symbols	1

Tester report for 2021, EURUSD H1

In the log, our version is displayed as two structures: *DrawDown* with equity drawdown and *GenericStats* with balance drawdown indicators and other statistics.

```
Separate trade report for EURUSD
Equity DD:
    [maxpeak] [minpeak] [series_start] [series_min] [series_dd] [series_dd_percent] »
[0]  10022.48  10017.03       10000.00      9998.20        6.23                0.06 »
» [series_dd_relative_percent] [series_dd_relative]
»                        0.06                6.23

Trade Statistics (with Balance DD):
    [maxpeak] [minpeak] [series_start] [series_min] [series_dd] [series_dd_percent] »
[0]  10022.40  10017.63       10000.00      9998.51        5.73                0.06 »
» [series_dd_relative_percent] [series_dd_relative] »
»                        0.06                5.73 »
» [deals] [trades] [buy_trades] [wins] [buy_wins] [sell_wins] [profits] [losses] [net
»     194       97           43     42         19          23     57.97   -39.62 18.3
» [average_trade] [recovery] [max_profit] [max_loss] [sharpe]
»            0.19       3.20         2.00      -2.01     0.15
```

It is easy to verify that these numbers match with the tester's report.

Now let's start trading on the same period for three symbols at once (setting *UnityMartingale-combo.set*).

In addition to EURUSD entries, structures for GBPCHF and AUDJPY will appear in the journal.

```

```

The tester report in this case will contain generalized data, so thanks to our classes, we have received previously inaccessible details.

However, looking at a pseudo-report in a log is not very convenient. Moreover, I would like to see a graphic representation of the balance line at the very least as its appearance often says more about the suitability of the system than dry statistics.

Let's improve the Expert Advisor by giving it the ability to generate visual reports in HTML format: after all, the tester's reports can also be exported to HTML, saved, and compared over time. In addition, in the future, such reports can be transmitted in frames to the terminal right during optimization, and the user will be able to start studying the reports of specific passes even before the completion of the entire process.

This will be the penultimate version of the example *UnityMartingaleDraft3.mq5*.

UnityMartingaleDraft3.mq5

Visualization of the trading report includes a balance line and a table with statistical indicators. We will not generate a complete report similar to the tester's report but will limit ourselves to the selected most important values. Our purpose is to implement a working mechanism that can then be customized in accordance with personal requirements.

We will arrange the basis of the algorithm in the form of the *TradeReportWriter* class (*TradeReportWriter.mqh*). The class will be able to store an arbitrary number of reports from different trading systems: each in a separate object *DataHolder*, which includes arrays of balance values and timestamps (*data* and *when*, respectively), the *stats* structure with statistics, as well as the title, color, and width of the line to display.

```
class TradeReportWriter
{
protected:
   class DataHolder
   {
   public:
      double data[];                    // balance changes
      datetime when[];                  // balance timestamps
      string name;                      // description
      color clr;                        // color
      int width;                        // line width
      TradeReport::GenericStats stats; // trading indicators
   };
   ...
```

We have an array of autopointers *curves* allocated for the objects of the *DataHolder* class. In addition, we will need common limits on amounts and terms to match the lines of all trading systems in the picture. This will be provided by the variables *lower*, *upper*, *start*, and *stop*.

```
   AutoPtr<DataHolder> curves[];
   double lower, upper;
   datetime start, stop;

public:
   TradeReportWriter(): lower(DBL_MAX), upper(-DBL_MAX), start(0), stop(0) { }
   ...
```

The *addCurve* method adds a balance line.

```
virtual bool addCurve(double &data[], datetime &when[], const string name,
   const color clr = clrNONE, const int width = 1)
{
   if(ArraySize(data) == 0 || ArraySize(when) == 0) return false;
   if(ArraySize(data) != ArraySize(when)) return false;
   DataHolder *c = new DataHolder();
   if(!ArraySwap(data, c.data) || !ArraySwap(when, c.when))
   {
      delete c;
      return false;
   }

   const double max = c.data[ArrayMaximum(c.data)];
   const double min = c.data[ArrayMinimum(c.data)];

   lower = fmin(min, lower);
   upper = fmax(max, upper);
   if(start == 0) start = c.when[0];
   else if(c.when[0] != 0) start = fmin(c.when[0], start);
   stop = fmax(c.when[ArraySize(c.when) - 1], stop);

   c.name = name;
   c.clr = clr;
   c.width = width;
   ZeroMemory(c.stats); // no statistics by default
   PUSH(curves, c);
   return true;
}
```

The second version of the *addCurve* method adds not only a balance line but also a set of financial variables in the *GenericStats* structure.

```
virtual bool addCurve(TradeReport::GenericStats &stats,
   double &data[], datetime &when[], const string name,
   const color clr = clrNONE, const int width = 1)
{
   if(addCurve(data, when, name, clr, width))
   {
      curves[ArraySize(curves) - 1].stats = stats;
      return true;
   }
   return false;
}
```

The most important class method which visualizes the report is made abstract.

```
virtual void render() = 0;
```

This makes it possible to implement many ways of displaying reports, for example, both, with recording to files of different formats, and with drawing directly on the chart. We will now restrict ourselves to the formation of HTML files since this is the most technologically advanced and widespread method.

The new class *HTMLReportWriter* has a constructor, the parameters of which specify the name of the file, as well as the size of the picture with balance curves. We will generate the image itself in the well-known SVG vector graphics format: it is ideal in this case since it is a subset of the XML language, which is HTML itself.

```
class HTMLReportWriter: public TradeReportWriter
{
   int handle;
   int width, height;

public:
   HTMLReportWriter(const string name, const int w = 600, const int h = 400):
      width(w), height(h)
   {
      handle = FileOpen(name,
         FILE_WRITE | FILE_TXT | FILE_ANSI | FILE_REWRITE);
   }

   ~HTMLReportWriter()
   {
      if(handle != 0) FileClose(handle);
   }

   void close()
   {
      if(handle != 0) FileClose(handle);
      handle = 0;
   }
   ...
```

Before turning to the main public *render* method, it is necessary to introduce the reader to one technology, which will be described in detail in the final Part 7 of the book. We are talking about resources: files and arrays of arbitrary data connected to an MQL program for working with multimedia (sound and images), embedding compiled indicators, or simply as a repository of application information. It is the latter option that we will now use.

The point is that it is better to generate an HTML page not entirely from MQL code, but based on a template (page template), into which the MQL code will only insert the values of some variables. This is a well-known technique in programming that allows you to separate the algorithm and the external representation of the program (or the result of its work). Due to this, we can separately experiment with the HTML template and MQL code, working with each of the components in a familiar environment. Specifically, MetaEditor is still not very suitable for editing web pages and viewing them, just like a standard browser does not know anything about MQL5 (although this can be fixed).

We will store HTML report templates in text files connected to the MQL5 source code as resources. The connection is made using a special directive *#resource*. For example, there is the following line in the file *TradeReportWriter.mqh*.

```
#resource "TradeReportPage.htm" as string ReportPageTemplate
```

It means that next to the source code there should be the file *TradeReportPage.htm*, which will become available in the MQL code as a string *ReportPageTemplate*. By extension, you can understand that the file is a web page. Here are the contents of this file with abbreviations (we do not have the task of

teaching the reader about web development, although, apparently, knowledge in this area can be useful for a trader as well). Indents are added to visually represent the nesting hierarchy of HTML tags; there are no indents in the file.

```
<!DOCTYPE html>
<html>
   <head>
      <title>Trade Report</title>
      <style>
         *{font: 9pt "Segoe UI";}
         .center{width:fit-content;margin:0 auto;}
         ...
      </style>
   </head>
   <body>
      <div class="center">
         <h1>Trade Report</h1>
         ~
      </div>
   </body>
   <script>
   ...
   </script>
</html>
```

The basics of the templates are chosen by the developer. There are a large number of ready-made HTML template systems, but they provide a lot of redundant features and are therefore too complex for our example. We will develop our own concept.

To begin with, let's note that most web pages have an initial part (header), a final part (footer), and useful information is located between them. The above draft report is no exception in this sense. It uses the tilde character '~' to indicate useful content. Instead, the MQL code will have to insert a balance image and a table with indicators. But the presence of '~' is not necessary, since the page can be a single whole, that is, the very useful middle part: after all, the MQL code can, if necessary, insert the result of processing one template into another.

> To complete the digression regarding HTML templates, let's pay attention to one more thing. In theory, a web page consists of tags that perform essentially different functions. Standard HTML tags tell the browser what to display. In addition to them, there are cascading styles (CSS), which describe how to display it. Finally, the page can have a dynamic component in the form of JavaScript scripts that interactively control both the first and second.
>
> Usually, these three components are templatized independently, i.e., for example, an HTML template, strictly speaking, should contain only HTML but not CSS or JavaScript. This allows ***"unbinding" the content, appearance, and behavior*** of the web page, which facilitates development (it is recommended to follow the same approach in MQL5!).
>
> However, in our example, we have included all the components in the template. In particular, in the above template, we see the tag <style> with styles CSS and tag <script> with some JavaScript functions, which are omitted. This is done to simplify the example, with an emphasis on MQL5 features rather than web development.

Having a web page template in the *ReportPageTemplate* variable connected as a resource, we can write the *render* method.

```
virtual void render() override
{
   string headerAndFooter[2];
   StringSplit(ReportPageTemplate, '~', headerAndFooter);
   FileWriteString(handle, headerAndFooter[0]);
   renderContent();
   FileWriteString(handle, headerAndFooter[1]);
}
...
```

It actually splits the page into upper and lower halves by the '~' character, displays them as is, and calls a helper method *renderContent* between them.

We have already described that the report will consist of a general picture with balance curves and tables with indicators of trading systems, so the implementation *renderContent* is natural.

```
private:
   void renderContent()
   {
      renderSVG();
      renderTables();
   }
```

Image generation inside *renderSVG* is based on yet another template file *TradeReportSVG.htm*, which binds to a string variable *SVGBoxTemplate*:

```
#resource "TradeReportSVG.htm" as string SVGBoxTemplate
```

The content of this template is the last one we list here. Those who wish can look into the source codes of the rest of the templates themselves.

```
<span id="params" style="display:block;width:%WIDTH%px;text-align:center;"></span>
<a id="main" style="display:block;text-align:center;">
   <svg width="%WIDTH%" height="%HEIGHT%" xmlns="http://www.w3.org/2000/svg">
      <style>.legend {font: bold 11px Consolas;}</style>
      <rect x="0" y="0" width="%WIDTH%" height="%HEIGHT%"
         style="fill:none; stroke-width:1; stroke: black;"/>
      ~
   </svg>
</a>
```

In the code of the *renderSVG* method, we'll see the familiar trick of splitting the content into two blocks "before" and "after" the tilde, but there's something new here.

```
void renderSVG()
{
   string headerAndFooter[2];
   if(StringSplit(SVGBoxTemplate, '~', headerAndFooter) != 2) return;
   StringReplace(headerAndFooter[0], "%WIDTH%", (string)width);
   StringReplace(headerAndFooter[0], "%HEIGHT%", (string)height);
   FileWriteString(handle, headerAndFooter[0]);

   for(int i = 0; i < ArraySize(curves); ++i)
   {
      renderCurve(i, curves[i][].data, curves[i][].when,
         curves[i][].name, curves[i][].clr, curves[i][].width);
   }

   FileWriteString(handle, headerAndFooter[1]);
}
```

At the top of the page, in the string *headerAndFooter[0]*, we are looking for substrings of the special form "%WIDTH%" and "%HEIGHT%", and replacing them with the required width and height of the image. It is by this principle that value substitution works in our templates. For example, in this template, these substrings actually occur in the *rect* tag:

```
<rect x="0" y="0" width="%WIDTH%" height="%HEIGHT%" style="fill:none; stroke-width:1;
```

Thus, if the report is ordered with a size of 600 by 400, the line will be converted to the following:

```
<rect x="0" y="0" width="600" height="400" style="fill:none; stroke-width:1; stroke:
```

This will display a 1-pixel thick black border of the specified dimensions in the browser.

The generation of tags for drawing specific balance lines is handled by the *renderCurve* method, to which we pass all the necessary arrays and other settings (name, color, and thickness). We will leave this method and other highly specialized methods (*renderTables*, *renderTable*) for independent study.

Let's return to the main module of the *UnityMartingaleDraft3.mq5* Expert Advisor. Set the size of the image of the balance graphs and connect *TradeReportWriter.mqh*.

```
#define MINIWIDTH  400
#define MINIHEIGHT 200

#include <MQL5Book/TradeReportWriter.mqh>
```

In order to "connect" the strategies with the report builder, you will need to modify the *statement* method in the *TradingStrategy* interface: pass a pointer to the *TradeReportWriter* object, which the calling code can create and configure.

```
interface TradingStrategy
{
   virtual bool trade(void);
   virtual bool statement(TradeReportWriter *writer = NULL);
};
```

Now let's add some lines in the specific implementation of this method in our *UnityMartingale* strategy class.

```
class UnityMartingale: public TradingStrategy
{
   ...
   TradeReport report;
   ...
   virtual bool statement(TradeReportWriter *writer = NULL) override
   {
      if(MQLInfoInteger(MQL_TESTER))
      {
         ...
         // it's already been done
         DealFilter filter;
         filter.let(DEAL_SYMBOL, settings.symbol)
            .let(DEAL_MAGIC, settings.magic, IS::EQUAL_OR_ZERO);
         HistorySelect(0, LONG_MAX);
         TradeReport::GenericStats stats =
            report.calcStatistics(filter, deposit, epoch);
         ...
         // adding this
         if(CheckPointer(writer) != POINTER_INVALID)
         {
            double data[];               // balance values
            datetime time[];             // balance points time to synchronize curves
            report.getCurve(data, time); // fill in the arrays and transfer to write
            return writer.addCurve(stats, data, time, settings.symbol);
         }
         return true;
      }
      return false;
   }
```

It all comes down to getting an array of balance and a structure with indicators from the *report* object (class *TradeReport*) and passing to the *TradeReportWriter* object, calling *addCurve*.

Of course, the pool of trading strategies ensures the transfer of the same object *TradeReportWriter* to all strategies to generate a combined report.

```
class TradingStrategyPool: public TradingStrategy
{
   ...
   virtual bool statement(TradeReportWriter *writer = NULL) override
   {
      bool result = false;
      for(int i = 0; i < ArraySize(pool); i++)
      {
         result = pool[i][].statement(writer) || result;
      }
      return result;
   }
```

Finally, the *OnTester* handler has undergone the largest modification. The following lines would suffice to generate an HTML report of trading strategies.

```
double OnTester()
{
   ...
   const static string tempfile = "temp.html";
   HTMLReportWriter writer(tempfile, MINIWIDTH, MINIHEIGHT);
   if(pool[] != NULL)
   {
      pool[].statement(&writer); // ask strategies to report their results
   }
   writer.render(); // write the received data to a file
   writer.close();
}
```

However, for clarity and user convenience, it would be great to add to the report a general balance curve, as well as a table with general indicators. It makes sense to output them only when several symbols are specified in the Expert Advisor settings because otherwise, the report of one strategy coincides with the general one in the file.

This required a little more code.

```
double OnTester()
{
   ...
   // had it before
   DealFilter filter;
   // set up the filter and fill in the array of deals based on it tickets
   ...
   const int n = ArraySize(tickets);

   // add this
   const bool singleSymbol = WorkSymbols == "";
   double curve[];    // total balance curve
   datetime stamps[]; // date and time of total balance points

   if(!singleSymbol) // the total balance is displayed only if there are several symb
   {
      ArrayResize(curve, n + 1);
      ArrayResize(stamps, n + 1);
      curve[0] = TesterStatistics(STAT_INITIAL_DEPOSIT);

      // MQL5 does not allow to know the test start time,
      // this could be found out from the first transaction,
      // but it is outside the filter conditions of a specific system,
      // so let's just agree to skip time 0 in calculations
      stamps[0] = 0;
   }

   for(int i = 0; i < n; ++i) // deal cycle
   {
      double result = 0;
      for(int j = 0; j < STAT_PROPS - 1; ++j)
      {
         result += expenses[i][j];
      }
      if(!singleSymbol)
      {
         curve[i + 1] = result + curve[i];
         stamps[i + 1] = (datetime)HistoryDealGetInteger(tickets[i], DEAL_TIME);
      }
      ...
   }
   if(!singleSymbol) // send the tester's statistics and the overall curve to the rep
   {
      TradeReport::GenericStats stats;
      stats.fillByTester();
      writer.addCurve(stats, curve, stamps, "Overall", clrBlack, 3);
   }
   ...
}
```

Let's see what we got. If we run the Expert Advisor with settings *UnityMartingale-combo.set*, we will have the *temp.html* file in the *MQL5/Files* folder of one of the agents. Here's what it looks like in the browser.

HTML report for Expert Advisor with multiple trading strategies/symbols

Now that we know how to generate reports on one test pass, we can send them to the terminal during optimization, select the best ones on the go, and present them to the user before the end of the whole process. All reports will be put in a separate folder inside *MQL5/Files* of the terminal. The folder will

receive a name containing the symbol and timeframe from the tester's settings, as well as the name of the Expert Advisor.

UnityMartingale.mq5

As we know, to send a file to the terminal, it is enough to call the function *FrameAdd*. We have already generated the file within the framework of the previous version.

```
double OnTester()
{
   ...
   if(MQLInfoInteger(MQL_OPTIMIZATION))
   {
      FrameAdd(tempfile, 0, r2 * 100, tempfile);
   }
}
```

In the receiving Expert Advisor instance, we will perform the necessary preparation. Let's describe the structure *Pass* with the main parameters of each optimization pass.

```
struct Pass
{
   ulong id;          // pass number
   double value;      // optimization criterion value
   string parameters; // optimized parameters as list 'name=value'
   string preset;     // text to generate set-file (with all parameters)
};
```

In the *parameters* strings, "name=value" pairs are connected with the '&' symbol. This will be useful for the interaction of web pages of reports in the future (the '&' symbol is the standard for combining parameters in web addresses). We did not describe the format of set files, but the following source code that forms the *preset* string allows you to study this issue in practice.

As frames arrive, we will write improvements according to the optimization criterion to the *TopPasses* array. The current best pass will always be the last pass in the array and is also available in the *BestPass* variable.

```
Pass TopPasses[];     // stack of constantly improving passes (last one is best)
Pass BestPass;        // current best pass
string ReportPath;    // dedicated folder for all html files of this optimization
```

In the handler *OnTesterInit* let's create a folder name.

```
void OnTesterInit()
{
   BestPass.value = -DBL_MAX;
   ReportPath = _Symbol + "-" + PeriodToString(_Period) + "-"
      + MQLInfoString(MQL_PROGRAM_NAME) + "/";
}
```

In the *OnTesterPass* handler, we will sequentially select only those frames in which the indicator has improved, find for them the values of optimized and other parameters, and add all this information to the *Pass* array of structures.

```
void OnTesterPass()
{
   ulong   pass;
   string  name;
   long    id;
   double  value;
   uchar   data[];

   // input parameters for the pass corresponding to the current frame
   string  params[];
   uint    count;

   while(FrameNext(pass, name, id, value, data))
   {
      // collect passes with improved stats
      if(value > BestPass.value && FrameInputs(pass, params, count))
      {
         BestPass.preset = "";
         BestPass.parameters = "";
         // get optimized and other parameters for generating a set-file
         for(uint i = 0; i < count; i++)
         {
            string name2value[];
            int n = StringSplit(params[i], '=', name2value);
            if(n == 2)
            {
               long pvalue, pstart, pstep, pstop;
               bool enabled = false;
               if(ParameterGetRange(name2value[0], enabled, pvalue, pstart, pstep, ps
               {
                  if(enabled)
                  {
                     if(StringLen(BestPass.parameters)) BestPass.parameters += "&";
                     BestPass.parameters += params[i];
                  }

                  BestPass.preset += params[i] + "||" + (string)pstart + "||"
                    + (string)pstep + "||" + (string)pstop + "||"
                    + (enabled ? "Y" : "N") + "<br>\n";
               }
               else
               {
                  BestPass.preset += params[i] + "<br>\n";
               }
            }
         }

         BestPass.value = value;
         BestPass.id = pass;
         PUSH(TopPasses, BestPass);
         // write the frame with the report to the HTML file
```

```
            const string text = CharArrayToString(data);
            int handle = FileOpen(StringFormat(ReportPath + "%06.3f-%lld.htm", value, pa
               FILE_WRITE | FILE_TXT | FILE_ANSI);
            FileWriteString(handle, text);
            FileClose(handle);
         }
      }
   }
```

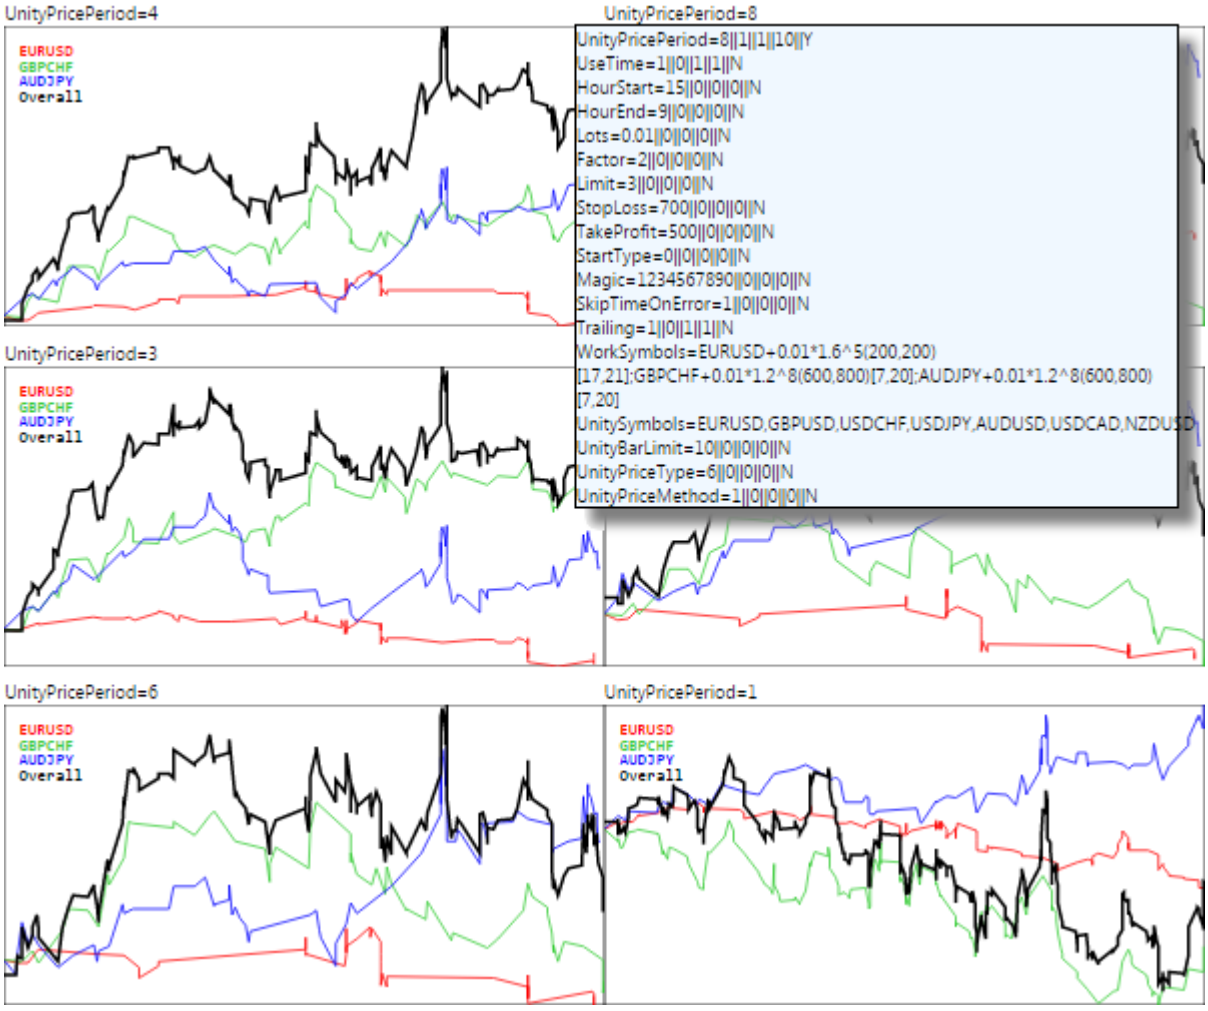
The resulting reports with improvements are saved in files with names that include the value of the optimization criterion and the pass number.

Now comes the most interesting. In the *OnTesterDeinit* handler, we can form a common HTML file (*overall.htm*), which allows you to see all the reports at once (or, say, the top 100). It uses the same scheme with templates that we covered earlier.

```
#resource "OptReportPage.htm" as string OptReportPageTemplate
#resource "OptReportElement.htm" as string OptReportElementTemplate

void OnTesterDeinit()
{
   int handle = FileOpen(ReportPath + "overall.htm",
      FILE_WRITE | FILE_TXT | FILE_ANSI, 0, CP_UTF8);
   string headerAndFooter[2];
   StringSplit(OptReportPageTemplate, '~', headerAndFooter);
   StringReplace(headerAndFooter[0], "%MINIWIDTH%", (string)MINIWIDTH);
   StringReplace(headerAndFooter[0], "%MINIHEIGHT%", (string)MINIHEIGHT);
   FileWriteString(handle, headerAndFooter[0]);
   // read no more than 100 best records from TopPasses
   for(int i = ArraySize(TopPasses) - 1, k = 0; i >= 0 && k < 100; --i, ++k)
   {
      string p = TopPasses[i].parameters;
      StringReplace(p, "&", " ");
      const string filename = StringFormat("%06.3f-%lld.htm",
         TopPasses[i].value, TopPasses[i].id);
      string element = OptReportElementTemplate;
      StringReplace(element, "%FILENAME%", filename);
      StringReplace(element, "%PARAMETERS%", TopPasses[i].parameters);
      StringReplace(element, "%PARAMETERS_SPACED%", p);
      StringReplace(element, "%PASS%", IntegerToString(TopPasses[i].id));
      StringReplace(element, "%PRESET%", TopPasses[i].preset);
      StringReplace(element, "%MINIWIDTH%", (string)MINIWIDTH);
      StringReplace(element, "%MINIHEIGHT%", (string)MINIHEIGHT);
      FileWriteString(handle, element);
   }
   FileWriteString(handle, headerAndFooter[1]);
   FileClose(handle);
}
```

The following image shows what the overview web page looks like after optimizing *UnityMartingale.mq5* by *UnityPricePeriod* parameter in multicurrency mode.



Overview web page with trading reports of the best optimization passes

For each report, we display only the upper part, where the balance chart falls. This part is the most convenient to get an estimate by just looking at it.

Lists of optimized parameters ("name=value&name=value...") are displayed above each graph. Pressing on a line opens a block with the text for the set file of all the settings of this pass. If you click inside a block, its contents will be copied to the clipboard. It can be saved in a text editor and thus get a ready-made set file.

Clicking on the chart will take you to the specific report page, along with the scorecards (given above).

At the end of the section, we touch on one more question. Earlier we promised to demonstrate the effect of the *TesterHideIndicators* function. The *UnityMartingale.mq5* Expert Advisor currently uses the *UnityPercentEvent.mq5* indicator. After any test, the indicator is displayed on the opening chart. Let's suppose that we want to hide from the user the mechanism of the Expert Advisor's work and from where it takes signals. Then you can call the function *TesterHideIndicators* (with the *true* parameter) in the handler *OnInit*, before creating the object *UnityController*, in which the descriptor is received through *iCustom*.

```
int OnInit()
{
   ...
   TesterHideIndicators(true);
   ...
   controller = new UnityController(UnitySymbols, barwise,
      UnityBarLimit, UnityPriceType, UnityPriceMethod, UnityPricePeriod);
   return INIT_SUCCEEDED;
}
```

This version of the Expert Advisor will no longer display the indicator on the chart. However, it is not very well hidden. If we look into the tester's log, we will see lines about loaded programs among a lot of useful information: first, a message about loading the Expert Advisor itself, and a little later, about loading the indicator.

```
...
expert file added: Experts\MQL5Book\p6\UnityMartingale.ex5.
...
program file added: \Indicators\MQL5Book\p6\UnityPercentEvent.ex5.
...
```

Thus, a meticulous user can find out the name of the indicator. This possibility can be eliminated by the resource mechanism, which we have already mentioned in passing in the context of web page blanks. It turns out that the compiled indicator can also be embedded into an MQL program (in an Expert Advisor or another indicator) as a resource. And such resource programs are no longer mentioned in the tester's log. We will study the resources in detail in the 7th Part of the book, and now we will show the lines associated with them in the final version of our Expert Advisor.

First of all, let's describe the resource with the *#resource* indicator directive. In fact, it simply contains the path to the compiled indicator file (obviously, it must already be compiled beforehand), and here it is mandatory to use double backslashes as delimiters as forward single slashes in resource paths are not supported.

```
#resource "\\Indicators\\MQL5Book\\p6\\UnityPercentEvent.ex5"
```

Then, in the lines with the *iCustom* call, we replace the previous operator:

```
   UnityController(const string symbolList, const int offset, const int limit,
      const ENUM_APPLIED_PRICE type, const ENUM_MA_METHOD method, const int period):
      bar(offset), tickwise(!offset)
   {
      handle = iCustom(_Symbol, _Period,
         "MQL5Book/p6/UnityPercentEvent",                    // <---
         symbolList, limit, type, method, period);
      ...
```

By exactly the same, but with a link to the resource (note the syntax with a leading pair of colons '::' which is necessary to distinguish between ordinary paths in the file system and paths within resources).

```
UnityController(const string symbolList, const int offset, const int limit,
   const ENUM_APPLIED_PRICE type, const ENUM_MA_METHOD method, const int period):
   bar(offset), tickwise(!offset)
{
   handle = iCustom(_Symbol, _Period,
      "::Indicators\\MQL5Book\\p6\\UnityPercentEvent.ex5",  // <---
      symbolList, limit, type, method, period);
   ...
```

Now the compiled version of the Expert Advisor can be delivered to users on its own, without a separate indicator, since it is hidden inside the Expert Advisor. This does not affect its performance in any way, but taking into account the *TesterHideIndicators* challenge, the internal device is hidden. It should be remembered that if the indicator is then updated, the Expert Advisor will also need to be recompiled.

6.5.17 Mathematical calculations

The tester in the MetaTrader 5 terminal can be used not only to test trading strategies but also for mathematical calculations. To do this, select the appropriate mode in the tester settings, in the Simulation drop-down list. This is the same list where we select the tick generation method, but in this case, the tester will not generate ticks or quotes, or even connect the trading environment (trading account and symbols).

The choice between the full enumeration of parameters and a genetic algorithm depends on the size of the search space. For the optimization criterion, select "Custom max". Other input fields in the tester settings (such as date range or delays) are not important and are therefore automatically disabled.

In the "Mathematical calculations" mode, each test agent run is performed with a call of only three functions: *OnInit*, *OnTester*, *OnDeinit*.

A typical mathematical problem for solving in the MetaTrader 5 tester is finding an extremum for a function of many variables. To solve it, it is necessary to declare the function parameters in the form of input variables and place the block for calculating its values in *OnTester*.

The value of the function for a specific set of input variables is returned as an output value of *OnTester*. Do not use any built-in functions other than math functions in calculations.

It must be remembered that when optimizing, the maximum value of the *OnTester* function is always sought. Therefore, if you need to find the minimum, you should return the inverse values or the values multiplied by -1 values.

To understand how this works, let's take as an example a relatively simple function of two variables with one maximum. Let's describe it in the *MathCalc.mq5* Expert Advisor algorithm.

It is usually assumed that we do not know the representation of the function in an analytical form, otherwise, it would be possible to calculate its extrema. But now let's take a well-known formula to make sure the answer is correct.

```
input double X1;
input double X2;

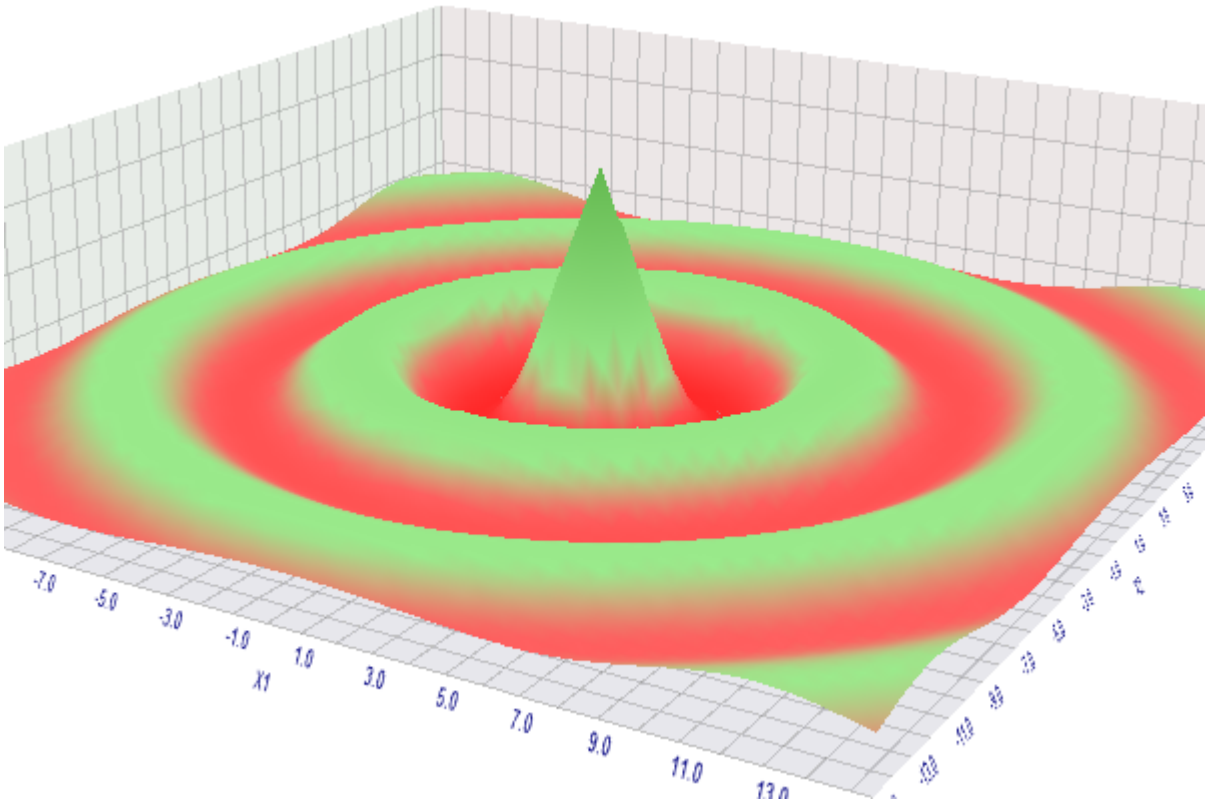
double OnTester()
{
   const double r = 1 + sqrt(X1 * X1 + X2 * X2);
   return sin(r) / r;
}
```

The Expert Advisor is accompanied by the *MathCalc.set* file with parameters for optimization: arguments X1 and X2 are iterated in the ranges [-15, +15] with a step of 0.5.

Let's run the optimization and see the solution in the optimization table. The best pass gives the correct result:

```
  X1=0.0
  X2=0.0
OnTester result 0.8414709848078965
```

On the optimization chart, you can turn on the 3D mode and access the shape of the surface visually.



The result of optimization (maximization) of a function in the mathematical calculations mode

At the same time, the use of the tester in the mathematical calculations mode is not limited to purely scientific research. On its basis, in particular, it is possible to organize the optimization of trading systems using alternative well-known optimization methods, such as the "particle swarm" or "simulated annealing" method. Of course, to do this, you will need to upload the history of quotes or ticks to files and connect them to the tested Expert Advisor, as well as emulate the execution of trades, accounting for positions and funds. This routine work can be attractive due to the fact that you can freely customize the optimization process (as opposed to the built-in "black box" with a genetic algorithm) and control resources (primarily RAM).

6.5.18 Debugging and profiling

The MetaTrader 5 tester is useful not only for testing the profitability of trading strategies but also for debugging MQL programs. Error detection is primarily associated with the ability to reproduce the problem situation. If we could only run MQL programs online, debugging and analyzing source code execution would require an unrealistic amount of effort. However, the tester allows you to "run" programs on arbitrary sections of history, change account settings and trading symbols.

Recall that in MetaEditor there are 2 commands in the *Debug* menu:

- *Start/Continue on real data* (F5)
- *Start/Continue on historical data* (Ctrl-F5)

In both cases, the program is promptly recompiled in a special way with additional debugging information in the ex5 file and then launched directly in the terminal (first option) or in the tester (second option).

When debugging in the tester, you can use both quick (background) mode and visual mode. This setting is provided in the *Setting* dialog on the *Debug/Profile* tab: enable or disable the flag *Use visual mode for debugging on history*. The environment and settings of the program being debugged can be taken directly from the tester (as they were last set for this program) or in the same dialog in the input fields under the flag *Use specified settings* (for them to work, the flag must be enabled).

You can pre-set breakpoints (F9) on operators in the part where something is supposedly starting to work wrong. The tester will pause the process when it reaches the specified location in the source code.

Please note that in the tester, the number of history bars loaded at startup depends on different factors (including timeframe, day number within a year, etc.) and can vary significantly. If necessary, move the start time of the test back in time.

In addition to obvious bugs that cause the program to stop or explicitly malfunction, there is a class of subtle bugs that negatively affect performance. As a rule, they are not so obvious, but turn into problems as the amount of data processed increases, for example, on trading accounts with a very long history, or on charts with a large number of markup objects.

To find "bottlenecks" in terms of performance, the debugger provides a source code profiling mechanism. It can also be performed online or in the tester, and the latter is especially valuable, as it allows you to significantly compress the time. The corresponding commands are also available in the debug menu.

- *Start profiling on real data*
- *Start profiling on historical data*

For profiling, the program is also pre-compiled with special settings, so don't forget to compile the program again in normal mode after debugging or profiling is complete (especially if you plan to send it to a client or upload it to the MQL5 Market).

As a result of profiling in MetaEditor, you will receive time statistics of your code execution, broken down by lines and functions (methods). As a result, it will become clear what exactly slows down the program. The next stage of development is usually source code *refactoring*, i.e., its rewriting using improved algorithms, data structures, or other principles of the constructive organization of modules (components). Unfortunately, a significant part of the time in programming is spent on rewriting existing code, finding and fixing errors.

The program itself can, if necessary, find out its mode of operation and adapt its behavior to the environment (for example, when run in the tester, it will not try to download data from the Internet, since this feature is disabled, but will read them from a certain file).

At the compilation stage, the debug and production versions of the program can be formed differently due to preprocessor macros _DEBUG and _RELEASE.

At the program execution stage, its modes can be distinguished using the *MQLInfoInteger* function options.

The following table summarizes all available combinations that affect runtime specifics.

Runtime\ flags	MQL_DEBUG	MQL_PROFILER	Normal(release)
Online	+	+	+
Tester (MQL_TESTER)	+	+	+
Tester (MQL_TESTER+MQL_VISUAL_MODE)	+	-	+

Profiling in the tester is only possible without the visual mode, so you should measure operations with charts and objects online.

Debugging is not allowed during the optimization process, including special handlers *OnTesterInit*, *OnTesterDeinit*, and *OnTesterPass*. If you need to check their performance, consider calling their code under other conditions.

6.5.19 Limitations of functions in the tester

When using the tester, you should take into account some restrictions imposed on built-in functions. Some of the MQL5 API functions are never executed in the strategy tester and some work only in single passes but not during optimization.

So, to increase performance when optimizing Expert Advisors, the *Comment*, *Print*, and *PrintFormat* functions are not executed.

The exception is the use of these functions inside the *OnInit* handler which is done to make it easier to find possible causes of initialization errors.

Functions that provide interaction with the "world" are not executed in the strategy tester. These include *MessageBox*, *PlaySound*, *SendFTP*, *SendMail*, *SendNotification*, *WebRequest*, and functions for working with sockets.

In addition, many functions for working with charts and objects have no effect. In particular, you will not be able to change the symbol or period of the current chart by calling *ChartSetSymbolPeriod*, list all indicators (including subordinate ones) with *ChartIndicatorGet*, work with templates *ChartSaveTemplate*, and so on.

In the tester, even in the visual mode, interactive chart, object, keyboard and mouse events are not generated for the *OnChartEvent* handler.

Part 7. Advanced MQL5 Tools

In this part of the book, we will learn about additional MQL5 API features in various areas that may be required when developing programs for the MetaTrader 5 environment. Some of them are of an applied trading nature, for example, custom financial instruments or the built-in economic calendar. Others represent universal technologies that can be useful everywhere: network functions, databases, cryptography, etc.

In addition, we will consider extending MQL programs using resources which are files of an arbitrary type that can be embedded in the code and contain multimedia, "heavy" settings from external programs (for example, ready-made machine learning models or neural network configurations) or other MQL programs (indicators) in a compiled form.

A couple of chapters will be devoted to the modular development of MQL programs. In this context, we will consider a special program type – libraries, which can be connected to other MQL programs to provide ready-made sets of specific APIs in closed form but which cannot be used standalone. We will also explore the possibilities for organizing the process of developing software complexes and combining logically interrelated programs into projects.

Finally, we will present integration with other software environments, in particular, with Python.

The book does not cover some highly specialized topics that may be of interest to advanced users, such as hardware capabilities for parallel computing using OpenCL, as well as 2D and 3D graphics based on DirectX. It is suggested that you familiarize yourself with these technologies using the documentation and articles on the mql5.com website.

MQL5 Programming for Traders – Source Codes from the Book. Part 7

Examples from the book are also available in the public project \MQL5\Shared Projects\MQL5Book

7.1 Resources

The operation of MQL programs may require many auxiliary resources, which are arrays of application data or files of various types, including images, sounds, and fonts. The MQL development environment allows you to include all such resources in the executable file at the compilation stage. This eliminates the need for their parallel transfer and installation along with the main program and makes it a complete self-sufficient product that is convenient for the end user.

In this chapter, we will learn how to describe different types of resources and built-in functions for subsequent operations with connected resources.

Raster images, represented as arrays of points (pixels) in the widely recognized BMP format, hold a unique position among resources. The MQL5 API allows the creation, manipulation, and dynamic display of these graphic resources on charts.

Earlier, we already discussed graphical objects and, in particular, objects of types OBJ_BITMAP and OBJ_BITMAP_LABEL that are useful for designing user interfaces. For these objects, there is the OBJPROP_BMPFILE property that specifies the image as a file or resource. Previously, we only considered examples with files. Now we will learn how to work with resource images.

7.1.1 Describing resources using the #resource directive

To include a resource file in the compiled program version, use the *#resource* directive in the source code. The directive has different forms depending on the file type. In any case, the directive contains the *#resource* keyword followed by a constant string.

```
#resource "path_file_name"
```

The *#resource* command instructs the compiler to include (in binary format *ex5*) a file with the specified name and, optionally, location (at the time of compilation) into the executable program being generated. The path is optional: if the string contains only the file name, it is searched in the directory next to the compiled source code. If there is a path in the string, the rules described below apply.

The compiler looks for the resource at the specified path in the following sequence:

- If the path is preceded by a backslash '\\' (it must be doubled, since a single backslash is a control character; in particular, '\' is used for newlines '\r', '\n' and tabs '\t'), then the resource is searched starting from the MQL5 folder inside the terminal data directory.
- If there is no backslash, then the resource is searched relative to the location of the source file in which this resource is registered.

Note that in constant strings with resource paths, you must use double backslashes as separators. Forward single slashes are not supported here, unlike paths in the file system.

For example:

```
#resource "\\Images\\euro.bmp" // euro.bmp is in /MQL5/Images/
#resource "picture.bmp"        // picture.bmp is in the same directory,
                               // where the source file is (mq5 or mqh)
#resource "Resource\\map.bmp"  // map.bmp is in the Resource subfolder of the directo
                               // where the source file is (mq5 or mqh)
```

If the resource is declared with a relative path in the mqh header file, the path is considered relative to this mqh file and not to the mq5 file of the program being compiled.

The substrings "..\\" and ":\\" are not allowed in the resource path.

Using a few directives, you can, for example, put all the necessary pictures and sounds directly into the ex5 file. Then, to run such a program in another terminal, you do not need to transfer them separately. We will consider programmatic ways of accessing resources from MQL5 in the following sections.

The length of the constant string "path_file_name" must not exceed 63 characters. The resource file size cannot be more than 128 Mb. Resource files are automatically compressed before being included in the executable.

After the resource is declared by the *#resource* directive, it can be used in any part of the program. The name of the resource becomes the constant string specified in the directive without a slash at the beginning (if any), and a special sign of the resource (two colons, "::") should be added before the contents of the string.

Below we present examples of resources, with their names in the comments.

```
#resource "\\Images\\euro.bmp"          // resource name - ::Images\\euro.bmp
#resource "picture.bmp"                 // resource name - ::picture.bmp
#resource "Resource\\map.bmp"           // resource name - ::Resource\\map.bmp
#resource "\\Files\\Pictures\\good.bmp" // resource name - ::Files\\Pictures\\good.bm
#resource "\\Files\\demo.wav";          // resource name - ::Files\\demo.wav"
#resource "\\Sounds\\thrill.wav";       // resource name - ::Sounds\\thrill.wav"
```

Further in the MQL code, you can refer to these resources as follows (here, only the *ObjectSetString* and *PlaySound* functions are already known to us, but there are other options like *ResourceReadImage*, which will be described in the following sections).

```
ObjectSetString(0, bitmap_name, OBJPROP_BMPFILE, 0, "::Images\\euro.bmp");
...
ObjectSetString(0, my_bitmap, OBJPROP_BMPFILE, 0, "::picture.bmp");
...
ObjectSetString(0, bitmap_label, OBJPROP_BMPFILE, 0, "::Resource\\map.bmp");
ObjectSetString(0, bitmap_label, OBJPROP_BMPFILE, 1, "::Files\\Pictures\\good.bmp");
...
PlaySound("::Files\\demo.wav");
...
PlaySound("::Sounds\\thrill.wav");
```

It should be noted that when setting an image from a resource to OBJ_BITMAP and OBJ_BITMAP_LABEL objects, the value of the OBJPROP_BMPFILE property cannot be changed manually (in the object's properties dialog).

Note that wav files are set by default for the *PlaySound* function relative to the *Sounds* folder (or its subfolders) located in the terminal's data directory. At the same time, resources (including sound ones), if they are described with a leading slash in the path, are searched inside the MQL5 directory. Therefore, in the example above, the "\\Sounds\\thrill.wav" string refers to the file *MQL5/Sounds/thrill.wav* and not to *Sounds/thrill.wav* relative to the data directory (there is indeed the *Sounds* directory with standard terminal sounds).

The simple syntax of the *#resource* directive discussed above allows the description of only image resources (BMP format) and sound resources (WAV format). Attempting to describe a file of a different type as a resource will result in an "unknown resource type" error.

As a result of *#resource* directive processing, the files in fact become embedded into the executable binary program and become accessible by the resource name. Moreover, you should pay attention to a special property of such resources which is their public availability from other programs (more on this in the next section).

MQL5 also supports another way of embedding a file in a program: in the form of a resource variable. This method uses extended syntax of the *#resource* directive and allows you to connect not only BMP or WAV files but also others, for example, text or an array of structures.

We will analyze a practical example of connecting resources in a couple of sections.

7.1.2 Shared use of resources of different MQL programs

The resource name is unique throughout the terminal. Later we will learn how to create resources not at the compilation stage (by the *#resource* directive) but dynamically, using the *ResourceCreate* function. In any case, the resource is declared in the context of the program that creates it, so that

the uniqueness of the full name is provided automatically by binding to the file system (path and name of a specific file *ex5*).

In addition to containing and using resources, an MQL program can also access the resources of another compiled program (ex5 file). This is possible provided that the program using the resource knows the location path and the name of another program containing the required resource, as well as the name of this resource.

Thus, the terminal provides an important property of resources which is their shared use: resources from one ex5 file can be used in many other programs.

In order to use a resource from a third-party ex5 file, it must be specified in the form "path_file_name.ex5::resource_name". For example, let's say the script *DrawingScript.mq5* refers to a specified image resource in the file *triangle.bmp*:

```
#resource "\\Files\\triangle.bmp"
```

Then its name for use in the actual script will look like "::Files\\triangle.bmp".

To use the same resource from another program, for example, an Expert Advisor, the resource name should be preceded by the path of the ex5 script file relative to the MQL5 folder in the terminal data directory, as well as the name of the script itself (in the compiled form, *DrawingScript.ex5*). Let the script be in the standard *MQL5/Scripts/* folder. In this case, the image should be accessed using the "\\Scripts\\DrawingScript.ex5::Files\\triangle.bmp" string. The ".ex5" extension is optional.

If, when accessing the resource of another ex5 file, the path to this file is not specified, then such a file is searched in the same folder where the program requesting the resource is located. For example, if we assume that the same Expert Advisor is in the standard *MQL5/Experts/* folder, and it queries a resource without specifying the path (for example, "DrawingScript.ex5::Files\\triangle.bmp"), then *DrawingScript.ex5* will be searched in the *MQL5/Experts/* folder.

Due to the shared use of resources, their dynamic creation and updating can be used to exchange data between MQL programs. This happens right in memory and is therefore a good alternative to files or global variables.

Please note that to load a resource from an MQL program, you do not need to run it: to read resources, it is enough to have an ex5 file with resources.

An important exception during which report sharing is not possible is when a resource is described in the form of a resource variable.

7.1.3 Resource variables

The *#resource* directive has a special form with which external files can be declared as resource variables and accessed within the program as normal variables of the corresponding type. The declaration format is:

```
#resource "path_file_name" as resource_variable_type resource_variable_name
```

Here are some examples of declarations:

```
#resource "data.bin" as int Data[]           //array of int type with data from the f
#resource "rates.dat" as MqlRates Rates[]    // array of MqlRates structures from the
#resource "data.txt" as string Message       // line with the contents of the file da
#resource "image.bmp" as bitmap Bitmap1[]    // one-dimensional array with image pixe
                                             // from file image.bmp
#resource "image.bmp" as bitmap Bitmap2[][]  // two-dimensional array with the same i
```

Let's give some explanations. Resource variables are constants (they cannot be modified in MQL5 code). For example, to edit images before displaying on the screen, you should create copies of resource array variables.

For text files (resources of type *string*) the encoding is automatically determined by the presence of a BOM header. If there is no BOM, then the encoding is determined by the contents of the file. ANSI, UTF-8, and UTF-16 encodings are supported. When reading data from files, all strings are converted to Unicode.

The use of resource string variables can greatly facilitate the writing of programs based not only on pure MQL5 but also on additional technologies. For example, you can write OpenCL code (which is supported in MQL5 as an extension) in a separate file and then include it as a string in the resources of an MQL program. In the big Expert Advisor example, we've already used resource strings to include HTML templates.

For images, a special *bitmap* type has been introduced; this type has several features.

The *bitmap* type describes a single dot or pixel in an image and is represented by a 4-byte unsigned integer (*uint*). The pixel contains 4 bytes that correspond to the color components in ARGB or XRGB format (one letter = one byte), where R is red, G is green, B is blue, A is transparency (alpha channel), X is an is ignored byte (no transparency). Transparency can be used for various effects when overlaying images on a chart and on top of each other.

We will study the definition of ARGB and XRGB formats in the section on dynamic creation of graphic resources (see *ResourceCreate*). For example, for ARGB, the hexadecimal number 0xFFFF0000 specifies a fully opaque pixel (highest byte is 0xFF) of red color (the next byte is also 0xFF), and the next bytes for the green and blue components are zero.

It is important to note that the pixel color encoding is different from the byte representation of type *color*. Let's recall that the value of type *color* can be written in hexadecimal form as follows: 0x00BBGGRR, where BB, GG, RR are the blue, green and red components, respectively (in each byte, the value 255 gives the maximum intensity of the component). With a similar record of a pixel, there is a reverse byte order: 0xAARRGGBB. Full transparency is obtained when the high byte (here denoted AA) is 0 and the value 255 is a solid color. The *ColorToARGB* function can be used to convert *color* to ARGB.

BMP files can have various encoding methods (if you create or edit them in any editor, check this issue in the documentation of this program). MQL5 resources do not support all existing encoding methods. You can check if a particular file is supported using the *ResourceCreate* function. Specifying an unsupported BMP format file in the directive will result in a compilation error.

When loading a file with 24-bit color encoding, all pixels of the alpha channel component are set to 255 (opaque). When loading a file with a 32-bit color encoding without an alpha channel, it also implies no transparency, that is, for all image pixels, the alpha channel component is set to 255. When loading a 32-bit color-coded file with an alpha channel, no pixel manipulation takes place.

Images can be described by both one-dimensional and two-dimensional arrays. This only affects the addressing method, while the amount of memory occupied will be the same. In both cases, the array sizes are automatically set based on the data from the BMP file. The size of a one-dimensional array will be equal to the product of the height and the width of the image *(height * width)*, and a two-dimensional array will get separate dimensions *[height][width]*: the first index is the line number, the second is a dot in the line.

> Attention! When declaring a resource linked to a resource variable, the only way to access the resource is through that variable, and the standard way of reading through the name "::resource_name" (or more generally "path_file_name.ex5::resource_name") no longer works. This also means that such resources cannot be used as shared resources from other programs.

Let's consider two indicators as an example; both are bufferless. This MQL program type was chosen only for reasons of convenience because it can be applied to the chart without conflict in addition to other indicators while an Expert Advisor would require a chart without another Expert Advisor. In addition, they remain on the chart and are available for subsequent settings changes, unlike scripts.

The *BmpOwner.mq5* indicator contains a description of three resources:

- An image "search1.bmp" with a simple *#resource* directive which is accessible from other programs
- An image "search2.bmp" as a resource array variable of type *bitmap*, inaccessible from the outside
- A text file "message.txt" as a resource string for displaying a warning to the user

Both images are not used in any way within this indicator. The warning line is required in the *OnInit* function to call *Alert* since the indicator is not intended for independent use but only acts as a provider of an image resource.

> If the resource variable is not used in the source code, the compiler may not include the resource at all in the binary code of the program, but this does not apply to images.

```
#resource "search1.bmp"
#resource "search2.bmp" as bitmap image[]
#resource "message.txt" as string Message
```

All three files are located in the same directory where the indicator source is located: *MQL5/Indicators/MQL5Book/p7/*.

If the user tries to run the indicator, it displays a warning and immediately stops working. The warning is contained in the Message resource string variable.

```
int OnInit()
{
   Alert(Message); // equivalent to the following line of the code
   // Alert("This indicator is not intended to run, it holds a bitmap resource");

   // remove the indicator explicitly, because otherwise it remains "hanging" on the
   ChartIndicatorDelete(0, 0, MQLInfoString(MQL_PROGRAM_NAME));
   return INIT_FAILED;
}
```

In the second indicator *BmpUser.mq5*, we will try to use the external resources specified in the input variables *ResourceOff* and *ResourceOn*, to display in the OBJ_BITMAP_LABEL object.

```
input string ResourceOff = "BmpOwner.ex5::search1.bmp";
input string ResourceOn = "BmpOwner.ex5::search2.bmp";
```

By default, the state of the object is disabled/released ("Off"), and the image for it is taken from the previous indicator "BmpOwner.ex5::search1.bmp". This path and resource name are similar to the full notation "\\Indicators\\MQL5Book\\p7\\BmpOwner.ex5::search1.bmp". The short form is acceptable here, given that the indicators are located next to each other. If you subsequently open the object properties dialog, you will see the full notation in the *Bitmap file (On/Off)* fields.

For the pressed state, in *ResourceOn* we should read the resource "BmpOwner.ex5::search2.bmp" (let's see what happens).

In other input variables, you can select the corner of the chart, relative to which the positioning of the image is set, and the horizontal and vertical indents.

```
input int X = 25;
input int Y = 25;
input ENUM_BASE_CORNER Corner = CORNER_RIGHT_LOWER;
```

The creation of the OBJ_BITMAP_LABEL object and the setting of its properties, including the resource name as a picture for OBJPROP_BMPFILE, are performed in *OnInit*.

```
const string Prefix = "BMP_";
const ENUM_ANCHOR_POINT Anchors[] =
{
   ANCHOR_LEFT_UPPER,
   ANCHOR_LEFT_LOWER,
   ANCHOR_RIGHT_LOWER,
   ANCHOR_RIGHT_UPPER
};

void OnInit()
{
   const string name = Prefix + "search";
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);

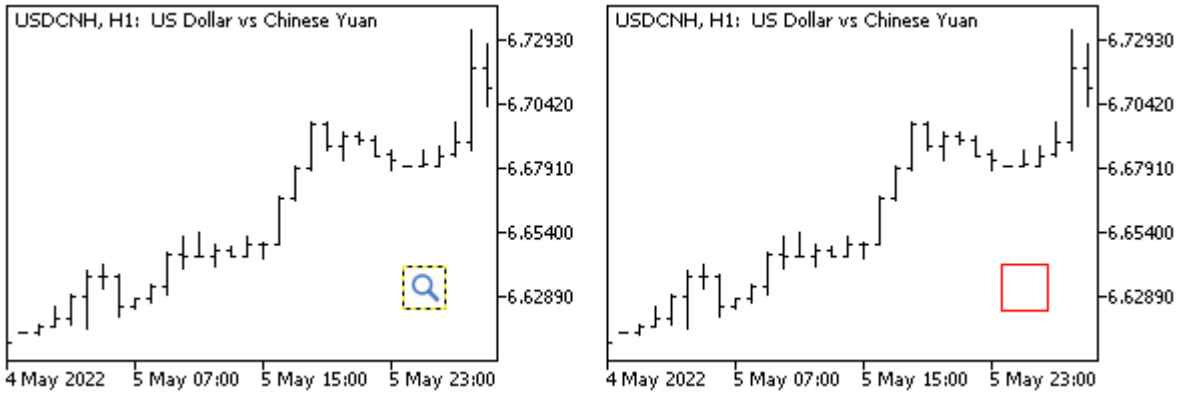
   ObjectSetString(0, name, OBJPROP_BMPFILE, 0, ResourceOn);
   ObjectSetString(0, name, OBJPROP_BMPFILE, 1, ResourceOff);
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, X);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, Y);
   ObjectSetInteger(0, name, OBJPROP_CORNER, Corner);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, Anchors[(int)Corner]);
}
```

Recall that when specifying images in OBJPROP_BMPFILE, the pressed state is indicated by modifier 0, and the released (unpressed) state (by default) is indicated by modifier 1, which is somewhat unexpected.

The *OnDeinit* handler deletes the object when unloading the indicator.

```
void OnDeinit(const int)
{
   ObjectsDeleteAll(0, Prefix);
}
```

Let's compile both indicators and run *BmpUser.ex5* with default settings. The image of the graphic file *search1.bmp* should appear on the chart (see on the left).



Normal (left) and wrong (right) display of graphic resources in an object on a chart

If you click on the picture, that is, switch it to the pressed state, the program will try to access the "BmpOwner.ex5::search2.bmp" resource (which is unavailable due to the resource array *bitmap* attached to it). As a result, we will see a red square, indicating an empty object without a picture (see above, on the right). A similar situation will always occur if the input parameter specifies a path or name with a knowingly non-existent or non-shared resource. You can create your own program, describe in it a resource that refers to some existing bmp file, and then specify in the indicator input parameters *BmpUser*. In this case, the indicator will be able to display the picture on the chart.

7.1.4 Connecting custom indicators as resources

For operation, MQL programs may require one or more custom indicators. All of these can be included as resources in the ex5 executable, making it easy to distribute and install.

The *#resource* directive with the description of the nested indicator has the following format:

```
#resource "path_indicator_name.ex5"
```

The rules for setting and searching for the specified file are the same as for all resources generally.

We have already used this feature in the big Expert Advisor example, in the final version of *UnityMartingale.mq5*.

```
#resource "\\Indicators\\MQL5Book\\p6\\UnityPercentEvent.ex5"
```

In that Expert Advisor, instead of the indicator name, this resource was passed to the *iCustom* function: "::Indicators\\MQL5Book\\p6\\UnityPercentEvent.ex5".

The case when a custom indicator in the *OnInit* function creates one or more instances of itself requires separate consideration (if this technical solution itself seems strange, we will give a practical example after the introductory examples).

As we know, to use a resource from an MQL program, it must be specified in the following form: path_file_name.ex5::resource_name. For example, if the *EmbeddedIndicator.ex5* indicator is included as

a resource in another indicator *MainIndicator.mq5* (more precisely, in its binary image *MainIndicator.ex5*), then the name specified when calling itself via *iCustom* can no longer be short, without a path, and the path must include the location of the "parent" indicator inside the MQL5 folder. Otherwise, the system will not be able to find the nested indicator.

Indeed, under normal circumstances, an indicator can call itself using, for example, the operator *iCustom(_Symbol, _Period, myself,...)*, where *myself* is a string equal to either *MQLInfoString(MQL_PROGRAM_NAME)* or the name that was previously assigned to the INDICATOR_SHORTNAME property in the code. But when the indicator is located inside another MQL program as a resource, the name no longer refers to the corresponding file because the file that served as a prototype for the resource remained on the computer where the compilation was performed, and on the user's computer there is only the file *MainIndicator.ex5*. This will require some analysis of the program environment when starting the program.

Let's see this in practice.

To begin with, let's create an indicator *NonEmbeddedIndicator.mq5*. It is important to note that it is located in the folder *MQL5/Indicators/MQL5Book/p7/SubFolder/*, i.e. in a *SubFolder* relative to the folder *p7* allocated for all indicators of this Part of the book. This is done intentionally to emulate a situation where the compiled file is not present on the user's computer. Now we will see how it works (or rather, demonstrates the problem).

The indicator has a single input parameter *Reference*. Its purpose is to count the number of copies of itself: when first created, the parameter equals 0, and the indicator will create its own copy with the parameter value of 1. The second copy, after "seeing" the value 1, will no longer create another copy (otherwise we would quickly run out of resources without the boundary condition for stopping reproduction).

```
input int Reference = 0;
```

The *handle* variable is reserved for the handle of the copy indicator.

```
int handle = 0;
```

In the handler *OnInit*, for clarity, we first display the name and path of the MQL program.

```
int OnInit()
{
   const string name = MQLInfoString(MQL_PROGRAM_NAME);
   const string path = MQLInfoString(MQL_PROGRAM_PATH);
   Print(Reference);
   Print("Name: " + name);
   Print("Full path: " + path);
   ...
```

Next comes the code suitable for self-launching a separate indicator (existing in the form of the familiar file *NonEmbeddedIndicator.ex5*).

```
   if(Reference == 0)
   {
      handle = iCustom(_Symbol, _Period, name, 1);
      if(handle == INVALID_HANDLE)
      {
         return INIT_FAILED;
      }
   }
   Print("Success");
   return INIT_SUCCEEDED;
}
```

We could successfully place such an indicator on the chart and receive entries of the following kind in the log (you will have your own file system paths):

```
0
Name: NonEmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\SubFolder\NonEmbedded
Success
1
Name: NonEmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\SubFolder\NonEmbedded
Success
```

The copy started successfully just by using the name "NonEmbeddedIndicator".

Let's leave this indicator for now and create a second one, *FaultyIndicator.mq5*, into which we will include the first indicator as a resource (pay attention to the specification of *subfolder* in the relative path of the resource; this is necessary because the *FaultyIndicator.mq5* indicator is located in the folder one level up: *MQL5/Indicators/MQL5Book/p7/*).

```
// FaultyIndicator.mq5
#resource "SubFolder\\NonEmbeddedIndicator.ex5"

int handle;

int OnInit()
{
   handle = iCustom(_Symbol, _Period, "::SubFolder\\NonEmbeddedIndicator.ex5");
   if(handle == INVALID_HANDLE)
   {
      return INIT_FAILED;
   }
   return INIT_SUCCEEDED;
}
```

If you try to run the compiled *FaultyIndicator.ex5*, an error will occur:

```
0
Name: NonEmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\FaultyIndicator.ex5 »
»  ::SubFolder\NonEmbeddedIndicator.ex5
cannot load custom indicator 'NonEmbeddedIndicator' [4802]
```

When a copy of a nested indicator is launched, it is searched for in the folder of the main indicator, in which the resource is described. But there is no file *NonEmbeddedIndicator.ex5* because the required resource is inside *FaultyIndicator.ex5*.

To solve the problem, we modify *NonEmbeddedIndicator.mq5*. First of all, let's give it another, more appropriate name, *EmbeddedIndicator.mq5*. In the source code, we need to add a helper function *GetMQL5Path*, which can isolate the relative part inside the MQL5 folder from the general path of the launched MQL program (this part will also contain the name of the resource if the indicator is launched from a resource).

```
// EmbeddedIndicator.mq5
string GetMQL5Path()
{
   static const string MQL5 = "\\MQL5\\";
   static const int length = StringLen(MQL5) - 1;
   static const string path = MQLInfoString(MQL_PROGRAM_PATH);
   const int start = StringFind(path, MQL5);
   if(start != -1)
   {
      return StringSubstr(path, start + length);
   }
   return path;
}
```

Taking into account the new function, we will change the *iCustom* call in the *OnInit* handler.

```
int OnInit()
{
   ...
   const string location = GetMQL5Path();
   Print("Location in MQL5:" + location);
   if(Reference == 0)
   {
      handle = iCustom(_Symbol, _Period, location, 1);
      if(handle == INVALID_HANDLE)
      {
         return INIT_FAILED;
      }
   }
   return INIT_SUCCEEDED;
}
```

Let's make sure that this edit did not break the launch of the indicator. Overlaying on a chart results in the expected lines appearing in the log:

```
0
Name: EmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\SubFolder\EmbeddedInd
Location in MQL5:\Indicators\MQL5Book\p7\SubFolder\EmbeddedIndicator.ex5
Success
1
Name: EmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\SubFolder\EmbeddedInd
Location in MQL5:\Indicators\MQL5Book\p7\SubFolder\EmbeddedIndicator.ex5
Success
```

Here we added debug output of the relative path that the *GetMQL5Path* function received. This line is now used in *iCustom*, and it works in this mode: a copy has been created.

Now let's embed this indicator as a resource into another indicator in the *MQL5Book/p7* folder with the name *MainIndicator.mq5*. *MainIndicator.mq5* is completely identical to *FaultyIndicator.mq5* except for the connected resource.

```
                                                                  // MainIndicator.mq5
#resource "SubFolder\\EmbeddedIndicator.ex5"
...
int OnInit()
{
   handle = iCustom(_Symbol, _Period, "::SubFolder\\EmbeddedIndicator.ex5");
   ...
}
```

Let's compile and run it. Entries appear in the log with a new relative path that includes the nested resource.

```
0
Name: EmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\MainIndicator.ex5 »
»  ::SubFolder\EmbeddedIndicator.ex5
Location in MQL5:\Indicators\MQL5Book\p7\MainIndicator.ex5::SubFolder\EmbeddedIndicat
Success
1
Name: EmbeddedIndicator
Full path: C:\Program Files\MT5East\MQL5\Indicators\MQL5Book\p7\MainIndicator.ex5 »
»  ::SubFolder\EmbeddedIndicator.ex5
Location in MQL5:\Indicators\MQL5Book\p7\MainIndicator.ex5::SubFolder\EmbeddedIndicat
Success
```

As we can see, this time the nested indicator successfully created a copy of itself, as it used a qualified name with a relative path and a resource name "\\Indicators\\MQL5Book\\p7\\MainIndicator.ex5::SubFolder\\EmbeddedIndicator.ex5".

> During multiple experiments with launching this indicator, please note that nested copies are not immediately unloaded from the chart after the main indicator is removed. Therefore, restarts should be performed only after we waited for unloading to happen: otherwise, copies still running will be reused, and the above initialization lines will not appear in the log. To control the unloading, a printout of the *Reference* value has been added to the *OnDeinit* handler.

We promised to show that creating a copy of the indicator is not something extraordinary. As an applied demonstration of this technique, we use the indicator *DeltaPrice.mq5* which calculates the

difference in price increments of a given order. Order 0 means no differentiation (only to check the original time series), 1 means single differentiation, 2 means double differentiation, and so on.

The order is specified in the input parameter *Differentiating*.

```
input int Differencing = 1;
```

The difference series will be displayed in a single buffer in the subwindow.

```
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1

#property indicator_type1 DRAW_LINE
#property indicator_color1 clrDodgerBlue
#property indicator_width1 2
#property indicator_style1 STYLE_SOLID

double Buffer[];
```

In the *OnInit*, handler we set up the buffer and create the same indicator, passing the value reduced by 1 in the input parameter.

```
#include <MQL5Book/AppliedTo.mqh> // APPLIED_TO_STR macro

int handle = 0;

int OnInit()
{
   const string label = "DeltaPrice (" + (string)Differencing + "/"
      + APPLIED_TO_STR() + ")";
   IndicatorSetString(INDICATOR_SHORTNAME, label);
   PlotIndexSetString(0, PLOT_LABEL, label);

   SetIndexBuffer(0, Buffer);
   if(Differencing > 1)
   {
      handle = iCustom(_Symbol, _Period, GetMQL5Path(), Differencing - 1);
      if(handle == INVALID_HANDLE)
      {
         return INIT_FAILED;
      }
   }
   return INIT_SUCCEEDED;
}
```

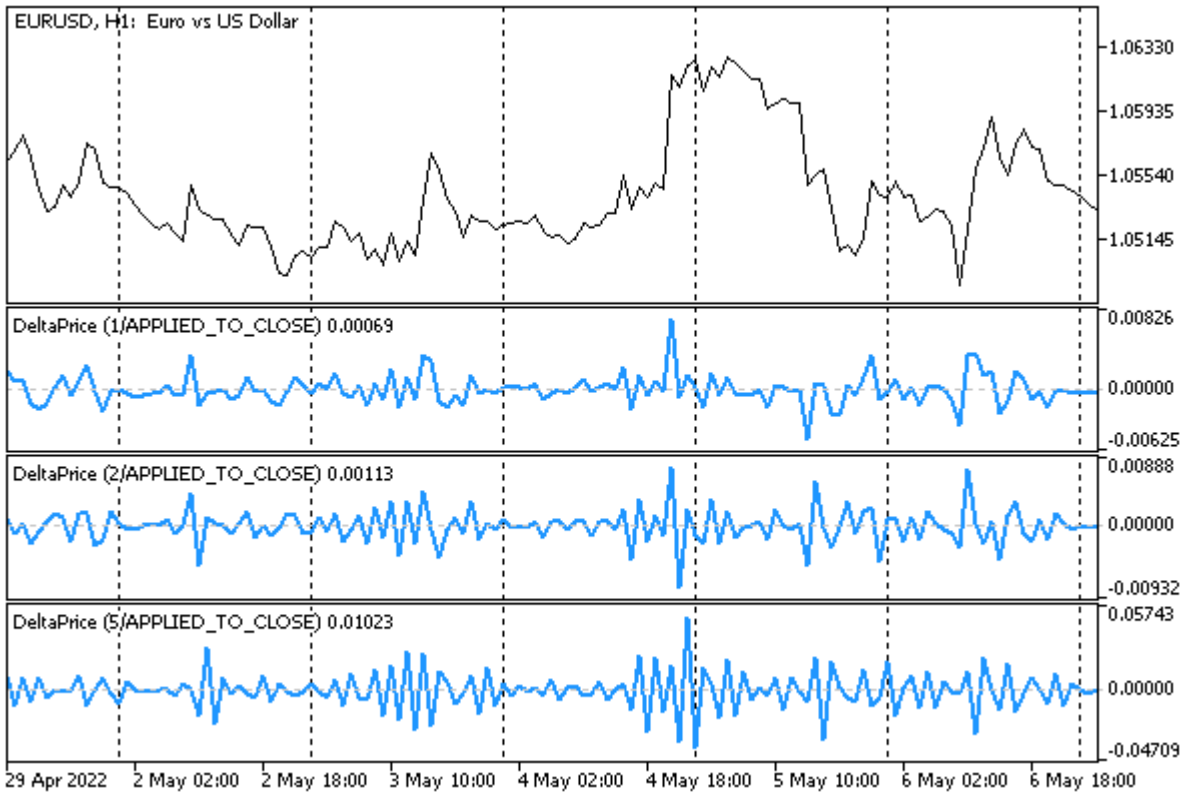
To avoid potential problems with embedding the indicator as a resource, we use the already proven function *GetMQL5Path*.

In the *OnCalculate* function, we perform the operation of subtracting neighboring values of the time series. When *Differentiating* equals 1, the operands are elements of the *price* array. With a larger value of *Differentiating*, we read the buffer of the indicator copy created for the previous order.

```
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   for(int i = fmax(prev_calculated - 1, 1); i < rates_total; ++i)
   {
      if(Differencing > 1)
      {
         static double value[2];
         CopyBuffer(handle, 0, rates_total - i - 1, 2, value);
         Buffer[i] = value[1] - value[0];
      }
      else if(Differencing == 1)
      {
         Buffer[i] = price[i] - price[i - 1];
      }
      else
      {
         Buffer[i] = price[i];
      }
   }
   return rates_total;
}
```

The initial type of differentiated price is set in the indicator settings dialog in the *Apply to* drop-down list. By default, this is the *Close* price.

This is how several copies of the indicator look on the chart with different orders of differentiation.



Difference in Close prices of different orders

7.1.5 Dynamic resource creation: ResourceCreate

The *#resource* directives embed resources into the program at the compilation stage, and therefore they can be called static. However, it often becomes necessary to generate resources (create completely new or modify existing ones) at the stage of program execution. For these purposes, MQL5 provides the *ResourceCreate* function. The resources created with the help of this function will be called dynamic.

The function has two forms: the first one allows you to load pictures and sounds from files, and the second one is designed to create bitmap images based on an array of pixels prepared in memory.

bool ResourceCreate(const string resource, const string filepath)

The function loads the resource named *resource* from a file located at *filepath*. If the path starts with a backslash '\' (in constant strings it should be doubled: "\\path\\name.ext"), then the file is searched at this path relative to the MQL5 folder in the terminal data directory (for example, "\\Files \\CustomSounds\\Hello.wav" refers to *MQL5/Files/CustomSounds/Hello.wav*). If there is no backslash, then the resource is searched starting from the folder where the executable file from which we call the function is located.

The path can point to a static resource hardwired into a third-party or current MQL program. For example, a certain script is able to create a resource based on a picture from the indicator *BmpOwner.mq5* discussed in the section on Resource variables.

```
ResourceCreate("::MyImage", "\\Indicators\\MQL5Book\\p7\\BmpOwner.ex5::search1.bmp");
```

The resource name in the *resource* parameter may contain an initial double colon (although this is not required, because if it is not present, the "::" prefix will be added to the name automatically). This ensures the unification of the use of one line for declaring a resource in the *ResourceCreate* call, as well as for subsequent access to it (for example, when setting the OBJPROP_BMPFILE property).

Of course, the above statement for creating a dynamic resource is redundant if we just want to load a third-party image resource into our object on the chart, since it is enough to directly assign the string "\\Indicators\\MQL5Book\\p7\\BmpOwner.ex5:" to the OBJPROP_BMPFILE property: search1.bmp". However, if you need to edit an image, a dynamic resource is indispensable. Next, we will show an example in the section Reading and modifying resource data.

Dynamic resources are publicly available from other MQL programs by their full name, which includes the path and name of the program that created the resource. For example, if the previous *ResourceCreate* call was produced by the script *MQL5/Scripts/MyExample.ex5*, then another MQL program can access the same resource using the full link "\\Scripts\\MyExample.ex5::MyImage", and any other script in the same folder can access the shorthand "MyExample.ex5::MyImage" (here the relative path is simply degenerate). The rules for writing full (from the MQL5 root folder) and relative paths were given above.

The *ResourceCreate* function returns a boolean indicator of success (*true*) or error (*false*) as a result of execution. The error code, as usual, can be found in the *_LastError* variable. Specifically, you are likely to receive the following errors:

- ERR_RESOURCE_NAME_DUPLICATED (4015) – matching names of the dynamic and static resources

- ERR_RESOURCE_NOT_FOUND (4016) – the given resource/file from the *filepath* parameter is not found
- ERR_RESOURCE_UNSUPPOTED_TYPE (4017) – unsupported resource type or size more than 2 GB
- ERR_RESOURCE_NAME_IS_TOO_LONG (4018) – resource name exceeds 63 characters

All this applies not only to the first form of the function but also to the second.

bool ResourceCreate(const string resource, const uint &data[], uint img_width, uint img_height, uint data_xoffset, uint data_yoffset, uint data_width, ENUM_COLOR_FORMAT color_format)

The *resource* parameter still means the name of the new resource, and the content of the image is given by the rest of the parameters.

The *data* array may be one-dimensional (*data[]*) or two-dimensional (*data[][]*): it passes dots (pixels) of the raster. The parameters *img_width* and *img_height* set the dimensions of the displayed image (in pixels). These sizes may be less than the physical size of the image in the *data* array, due to which the effect of framing is achieved when only a part of the original image is output. The *data_xoffset* and *data_yoffset* parameters determine the coordinate of the upper left corner of the "frame".

The *data_width* parameter means the full width of the original image (in the *data* array). A value of 0 implies that this width is the same as *img_width*. The *data_width* parameter makes sense only when specifying a one-dimensional array in the *data* parameter, since for a two-dimensional array its dimensions are known in both dimensions (in this case, the *data_width* parameter is ignored and is assumed equal to the second dimension of the *data[][]* array).

In the most common case, when you want to display the image in full ("as is"), use the following syntax:

```
ResourceCreate(name, data, width, height, 0, 0, 0, ...);
```

For example, if the program has a static resource described as a two-dimensional *bitmap* array:

```
#resource "static.bmp" as bitmap data[][]
```

Then the creation of a dynamic resource based on it can be performed in the following way:

```
ResourceCreate("dynamic", data, ArrayRange(data, 1), ArrayRange(data, 0), 0, 0, 0, ..
```

Creating a dynamic resource based on a static one is in demand not only when direct editing is required, but also to control how colors are processed when displaying a resource. This mode is selected using the last parameter of the function: *color_format*. It uses the ENUM_COLOR_FORMAT enumeration.

Identifier	Description
COLOR_FORMAT_XRGB_NOALPHA	The alpha channel component (transparency) is ignored
COLOR_FORMAT_ARGB_RAW	Color components are not processed by the terminal
COLOR_FORMAT_ARGB_NORMALIZE	Color components are processed by the terminal (see below)

In the COLOR_FORMAT_XRGB_NOALPHA mode, the image is displayed without effects: each point is displayed in a solid color (this is the fastest way to draw). The other two modes display pixels taking into account the transparency in the high byte of each pixel but have different effects. In the case of

COLOR_FORMAT_ARGB_NORMALIZE, the terminal performs the following transformations of the color components of each point when preparing the raster at the time of the *ResourceCreate* call:

```
R = R * A / 255
G = G * A / 255
B = B * A / 255
A = A
```

Static image resources in *#resource* directives are connected with the help of COLOR_FORMAT_ARGB_NORMALIZE.

In a dynamic resource, the array size is limited by the value of INT_MAX bytes (2147483647, 2 Gb), which significantly exceeds the limit imposed by the compiler when processing the static directive *#resource*: the file size cannot exceed 128 Mb.

If the second version of the function is called to create a resource with the same name, but with changing other parameters (the contents of the pixel array, width, height, or offset), then the new resource is not recreated, but the existing one is simply updated. Only the program owning the resource (the program that created it in the first place) can modify a resource in this way.

> If, when creating dynamic resources from different copies of the program running on different charts, you need your own resource in each copy, you should add *ChartID* to the name of the resource.

To demonstrate the dynamic creation of images in various color schemes, we propose to disassemble the script *ARGBbitmap.mq5*.

The image "argb.bmp" is statically attached to it.

```
#resource "argb.bmp" as bitmap Data[][]
```

The user selects the color formatting method by the *ColorFormat* parameter.

```
input ENUM_COLOR_FORMAT ColorFormat = COLOR_FORMAT_XRGB_NOALPHA;
```

The name of the object in which the image will be displayed and the name of the dynamic resource are described by the variables *BitmapObject* and *ResName*.

```
const string BitmapObject = "BitmapObject";
const string ResName = "::image";
```

Below is the main function of the script.

```
void OnStart()
{
   ResourceCreate(ResName, Data, ArrayRange(Data, 1), ArrayRange(Data, 0),
      0, 0, 0, ColorFormat);

   ObjectCreate(0, BitmapObject, OBJ_BITMAP_LABEL, 0, 0, 0);
   ObjectSetInteger(0, BitmapObject, OBJPROP_XDISTANCE, 50);
   ObjectSetInteger(0, BitmapObject, OBJPROP_YDISTANCE, 50);
   ObjectSetString(0, BitmapObject, OBJPROP_BMPFILE, ResName);

   Comment("Press ESC to stop the demo");
   const ulong start = TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE);
   while(!IsStopped()  // waiting for the user's command to end the demo
   && TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE) == start)
   {
      Sleep(1000);
   }

   Comment("");
   ObjectDelete(0, BitmapObject);
   ResourceFree(ResName);
}
```

The script creates a new resource in the specified color mode and assigns it to the OBJPROP_BMPFILE property of an object of type OBJ_BITMAP_LABEL. Next, the script waits for the user to explicitly stop the script or press *Esc* and then deletes the object (by calling *ObjectDelete*) and the resource using the *ResourceFree* function. Note that deleting an object does not automatically delete the resource. That is why we need the *ResourceFree* function which we will discuss in the next section.

If we don't call *ResourceFree*, then dynamic resources remain in the terminal's memory even after the MQL program terminates, right up until the terminal is closed. This makes it possible to use them as repositories or a means for exchanging information between MQL programs.

A dynamic resource created using the second form of *ResourceCreate* does not have to carry an image. The *data* array may contain arbitrary data if we don't use it for rendering. In this case, it is important to set the COLOR_FORMAT_XRGB_NOALPHA scheme. We will show such an example at some point.

In the meantime, let's check how the *ARGBbitmap.mq5* script works.

The above picture "argb.bmp" contains information about transparency: the upper left corner has a completely transparent background, and the transparency fades out diagonally towards the lower right corner.

The following images show the results of running the script in three different modes.

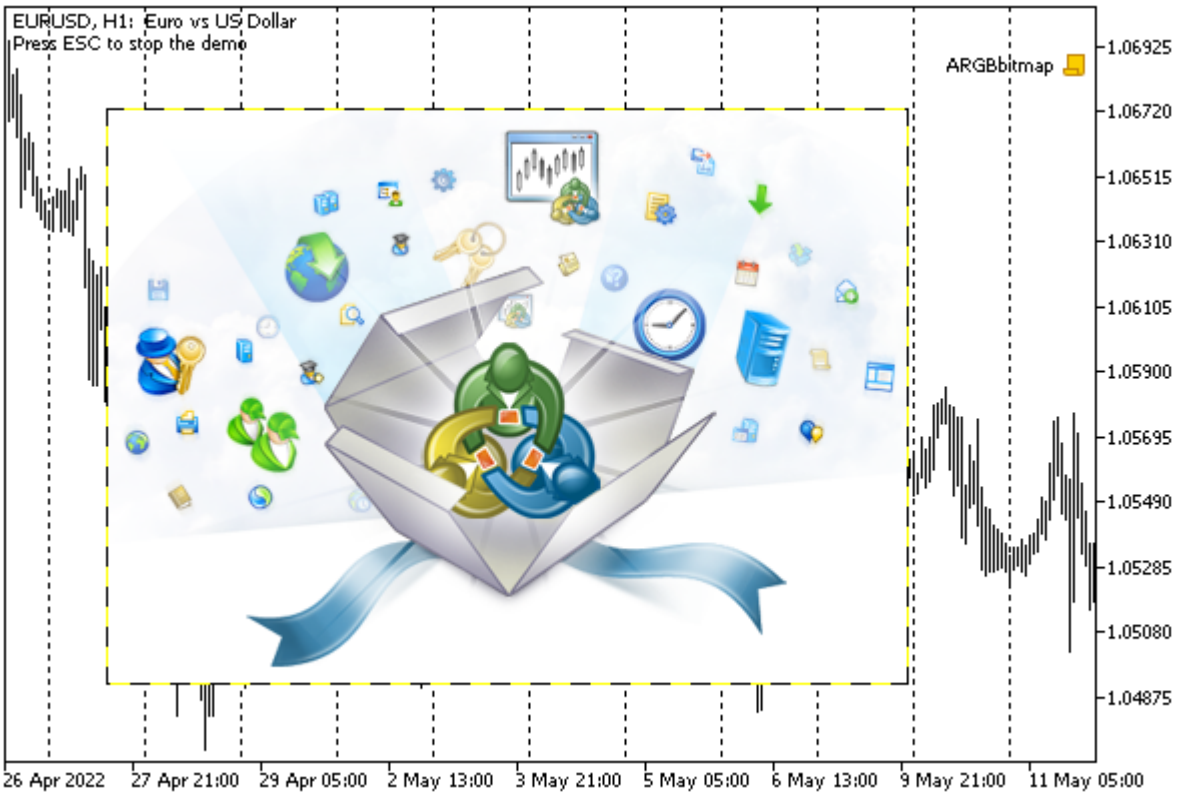


Image output in color format COLOR_FORMAT_XRGB_NOALPHA

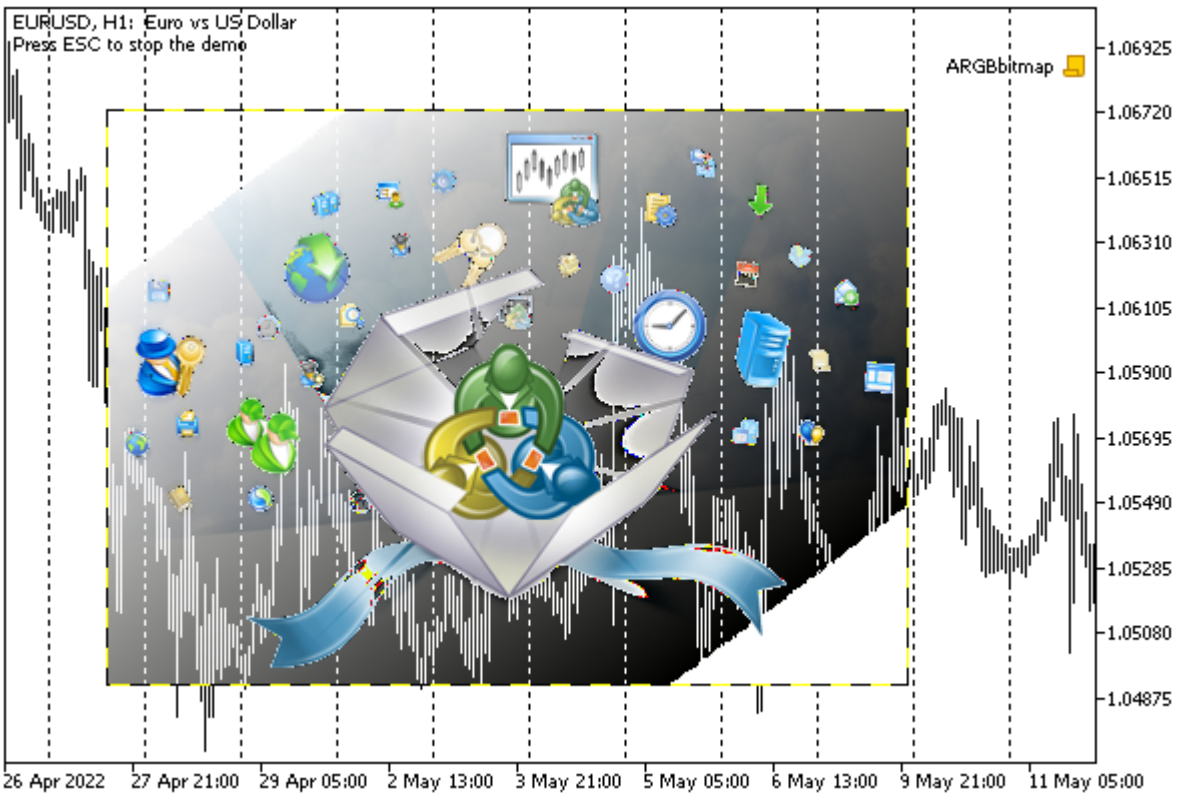

Image output in color format COLOR_FORMAT_ARGB_RAW

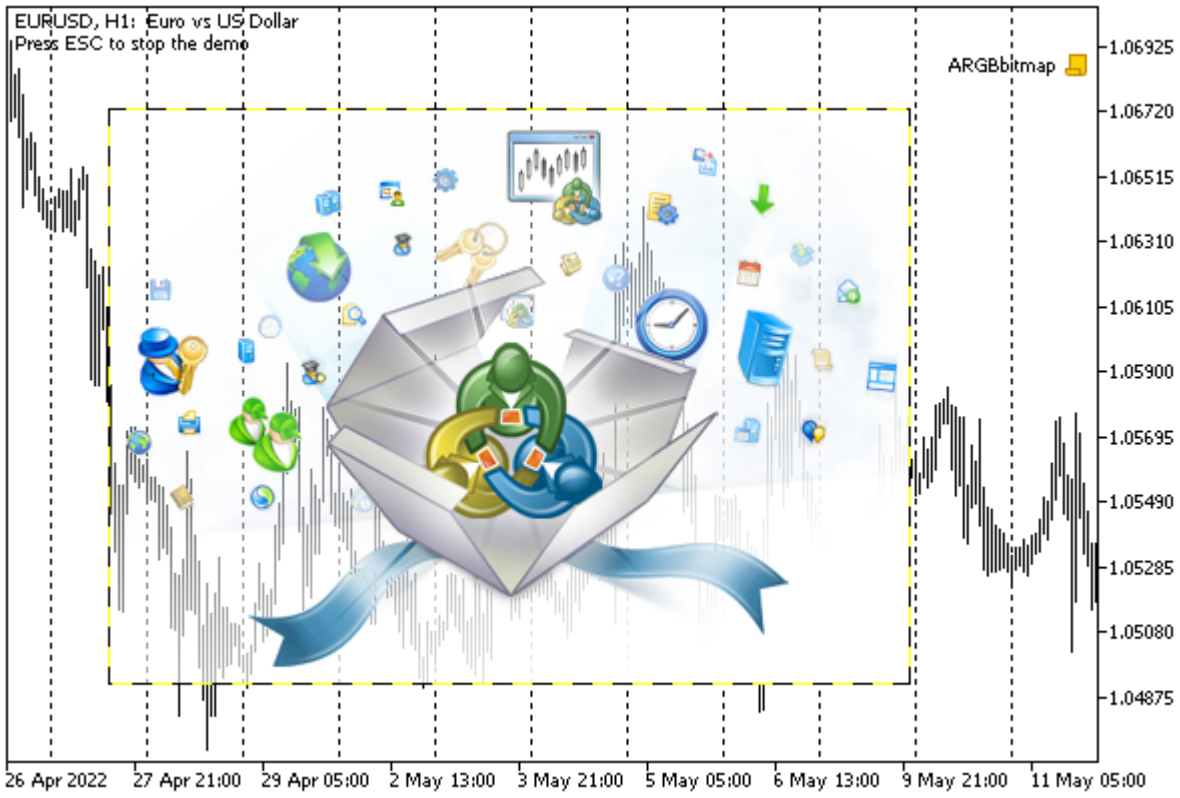

Image output in color format COLOR_FORMAT_ARGB_NORMALIZE

7.1.6 Deleting dynamic resources: ResourceFree

The *ResourceFree* function removes the previously created dynamic resource and frees the memory it occupies. If you don't call *ResourceFree*, the dynamic resource will remain in memory until the end of the current terminal session. This can be used as a convenient way to store data, but for regular work with images, it is recommended to release them when the need for them disappears.

Graphical objects attached to the resource being deleted will be displayed correctly even after its deletion. However, newly created graphical objects (OBJ_BITMAP and OBJ_BITMAP_LABEL) will no longer be able to use the deleted resource.

bool ResourceFree(const string resource)

The resource name is set in the *resource* parameter and must start with "::".

The function returns an indicator of success (*true*) or error (*false*).

The function deletes only dynamic resources created by the given MQL program, but not "third-party" ones.

In the previous section, we saw an example of the script *ARGBbitmap.mq5*, which called *ResourceFree* upon completion of its operation.

7.1.7 Reading and modifying resource data: ResourceReadImage

The *ResourceReadImage* function allows reading the data of the resource created by the *ResourceCreate* function or embedded into the executable at compile time according to the *#resource*

directive. Despite the suffix "Image" in the name, the function works with any data arrays, including custom ones (see the example of *Reservoir.mq5* below).

bool ResourceReadImage(const string resource, uint &data[], uint &width, uint &height)

The name of the resource is specified in the *resource* parameter. To access your own resources, the short form "::resource_name" is sufficient. To read a resource from another compiled file, you need the full name followed by the path according to the path resolution rules described in the section on resources. In particular, a path starting with a backslash means the path from the MQL5 root folder (this way "\\path\\filename.ex5::resource_name" is searched for in the file */MQL5/path/filename.ex5* under the name "resource_name"), and the path without this leading character means the path relative to the folder where the executed program is located.

The internal information of the resource will be written into the receiving *data* array, and the *width* and *height* parameters will receive, respectively, the width and height, that is, the size of the array (*width*height*) indirectly. Separately, *width* and *height* are only relevant if the image is stored in the resource. The array must be dynamic or fixed, but of sufficient size. Otherwise, we will get a SMALL_ARRAY (5052) error.

If in the future you want to create a graphic resource based on the *data* array, then the source resource should use the COLOR_FORMAT_ARGB_NORMALIZE or COLOR_FORMAT_XRGB_NOALPHA color format. If the *data* array contains arbitrary application data, use COLOR_FORMAT_XRGB_NOALPHA.

As a first example, let's consider the script *ResourceReadImage.mq5*. It demonstrates several aspects of working with graphic resources:

- Creating an image resource from an external file
- Reading and modifying the data of this image in another dynamically created resource
- Preserving created resources in the terminal memory between script launches
- Using resources in objects on the chart
- Deleting an object and resources

Image modifying in this particular case means the inversion of all colors (as the most visual).

All of the above methods of work are performed in three stages: each stage is performed in one run of the script. The script determines the current stage by analyzing the available resources and the object:

1. In the absence of the required graphic resources, the script will create them (one original image and one inverted image).
2. If there are resources but there is no graphic object, the script will create an object with two images from the first step for on/off states (they can be switched by mouse click).
3. If there is an object, the script will delete the object and resources.

The main function of the script starts by defining the names of the resources and of the object on the chart.

```
void OnStart()
{
   const static string resource = "::Images\\pseudo.bmp";
   const static string inverted = resource + "_inv";
   const static string object = "object";
   ...
```

Note that we have chosen a name for the original resource that looks like the location of the *bmp* file in the standard *Images* folder, but there is no such file. This emphasizes the virtual nature of resources and allows you to make substitutions to meet technical requirements or to make it difficult to reverse engineer your programs.

The next *ResourceReadImage* call is used to check if the resource already exists. In the initial state (on the first run), we will get a negative result (*false*) and start the first step: we create the original resource from the file "\\Images\\dollar.bmp", and then invert it in a new resource with the "_inv" suffix.

```
   uint data[], width, height;
   // check for resource existence
   if(!PRTF(ResourceReadImage(resource, data, width, height)))
   {
      Print("Initial state: Creating 2 bitmaps");
      PRTF(ResourceCreate(resource, "\\Images\\dollar.bmp")); // try "argb.bmp"
      ResourceCreateInverted(resource, inverted);
   }
   ...
```

The source code of the helper function *ResourceCreateInverted* will be presented below.

If the resource is found (second run), the script checks for the existence of the object and, if necessary, creates it, including setting properties with image resources in the *ShowBitmap* function (see below).

```
   else
   {
      Print("Resources (bitmaps) are detected");
      if(PRTF(ObjectFind(0, object) < 0))
      {
         Print("Active state: Creating object to draw 2 bitmaps");
         ShowBitmap(object, resource, inverted);
      }
      ...
```

If both the resources and the object are already on the chart, then we are at the final stage and must remove all resources.

```
      else
      {
         Print("Cleanup state: Removing object and resources");
         PRTF(ObjectDelete(0, object));
         PRTF(ResourceFree(resource));
         PRTF(ResourceFree(inverted));
      }
   }
}
```

The *ResourceCreateInverted* function uses the *ResourceReadImage* call to get an array of pixels and then inverts the color into them using the '^' (XOR) operator and an operand with all singular bits in the color components.

```
bool ResourceCreateInverted(const string resource, const string inverted)
{
   uint data[], width, height;
   PRTF(ResourceReadImage(resource, data, width, height));
   for(int i = 0; i < ArraySize(data); ++i)
   {
      data[i] = data[i] ^ 0x00FFFFFF;
   }
   return PRTF(ResourceCreate(inverted, data, width, height, 0, 0, 0,
      COLOR_FORMAT_ARGB_NORMALIZE));
}
```

The new array *data* is transferred to *ResourceCreate* to create the second image.

The *ShowBitmap* function creates a graphic object in the usual way (in the lower right corner of the graph) and sets its properties for on and off states to the original and inverted images, respectively.

```
void ShowBitmap(const string name, const string resourceOn, const string resourceOff
{
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);

   ObjectSetString(0, name, OBJPROP_BMPFILE, 0, resourceOn);
   if(resourceOff != NULL) ObjectSetString(0, name, OBJPROP_BMPFILE, 1, resourceOff);
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, 50);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, 50);
   ObjectSetInteger(0, name, OBJPROP_CORNER, CORNER_RIGHT_LOWER);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_RIGHT_LOWER);
}
```

Since the newly created object is off by default, we will first see the inverted image and we can switch it to the original one on a mouse click. But let's remind you that our script performs actions step by step, and therefore, before the image appears on the chart, the script must be run twice. At all stages, the current status and actions performed (along with a success or error indication) are logged.

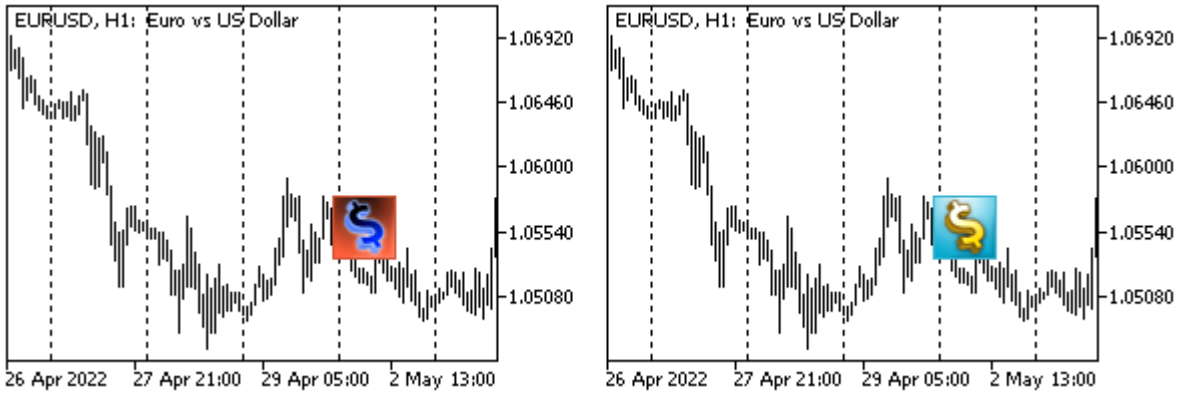
After the first launch, the following entries will appear in the log:

```
ResourceReadImage(resource,data,width,height)=false / RESOURCE_NOT_FOUND(4016)
Initial state: Creating 2 bitmaps
ResourceCreate(resource,\Images\dollar.bmp)=true / ok
ResourceReadImage(resource,data,width,height)=true / ok
ResourceCreate(inverted,data,width,height,0,0,0,COLOR_FORMAT_XRGB_NOALPHA)=true / ok
```

The logs indicate that the resources have not been found and that's why the script has created them. After the second run, the log will say that resources have been found (which were left in memory from the previous run of the script) but the object is not there yet, and the script will create it based on the resources.

```
ResourceReadImage(resource,data,width,height)=true / ok
Resources (bitmaps) are detected
ObjectFind(0,object)<0=true / OBJECT_NOT_FOUND(4202)
Active state: Creating object to draw 2 bitmaps
```

We will see an object and an image on the chart. Switching states is available by mouse click (events about changes of the state are not handled here).



Inverted and original images in an object on a chart

Finally, during the third run, the script will detect the object and delete all its developments.

```
ResourceReadImage(resource,data,width,height)=true / ok
Resources (bitmaps) are detected
ObjectFind(0,object)<0=false / ok
Cleanup state: Removing object and resources
ObjectDelete(0,object)=true / ok
ResourceFree(resource)=true / ok
ResourceFree(inverted)=true / ok
```

Then you can repeat the cycle.

The second example of the section will consider the use of resources for storing arbitrary application data, that is, a kind of clipboard inside the terminal (in theory, there can be any number of such buffers, since each of them is a separate named resource). Due to the universality of the problem, we will create the *Reservoir* class with the main functionality (in the file *Reservoir.mqh*), and on its basis we will write a demo script (*Reservoir.mq5*).

Before "diving" directly into Reservoir, let's introduce an auxiliary union *ByteOverlay* which will be required often. A union will allow any simple built-in type (including simple structures) to be converted to a byte array and vice versa. By "simple" we mean all built-in numeric types, date and time, enumerations, color, and boolean flags. However, objects and dynamic arrays are no longer simple and

will not be supported by our new storage (due to technical limitations of the platform). Strings are also not considered simple but for them, we will make an exception and will process them in a special way.

```
template<typename T>
union ByteOverlay
{
   uchar buffer[sizeof(T)];
   T value;

   ByteOverlay(const T &v)
   {
      value = v;
   }

   ByteOverlay(const uchar &bytes[], const int offset = 0)
   {
      ArrayCopy(buffer, bytes, 0, offset, sizeof(T));
   }
};
```

As we know, resources are built on the basis of arrays of type *uint*, so we describe such an array (*storage*) in the *Reservoir* class. There we will add all the data to be subsequently written to the resource. The current position in the array where data is written or read from is stored in the *offset* field.

```
class Reservoir
{
   uint storage[];
   int offset;
public:
   Reservoir(): offset(0) { }
   ...
```

To place an array of data of arbitrary type into *storage*, you can use the template method *packArray*. In the first half of it, we convert the passed array into a byte array using *ByteOverlay*.

```
   template<typename T>
   int packArray(const T &data[])
   {
      const int bytesize = ArraySize(data) * sizeof(T); // TODO: check for overflow
      uchar buffer[];
      ArrayResize(buffer, bytesize);
      for(int i = 0; i < ArraySize(data); ++i)
      {
         ByteOverlay<T> overlay(data[i]);
         ArrayCopy(buffer, overlay.buffer, i * sizeof(T));
      }
      ...
```

In the second half, we convert the byte array into a sequence of *uint* values, which are written in *storage* with an *offset*. The number of required elements *uint* is determined by taking into account whether there is a remainder after dividing the size of the data in bytes by the size of *uint*: optionally we add one additional element.

```
      const int size = bytesize / sizeof(uint) + (bool)(bytesize % sizeof(uint));
      ArrayResize(storage, offset + size + 1);
      storage[offset] = bytesize;       // write the size of the data before the data
      for(int i = 0; i < size; ++i)
      {
         ByteOverlay<uint> word(buffer, i * sizeof(uint));
         storage[offset + i + 1] = word.value;
      }

      offset = ArraySize(storage);

      return offset;
   }
```

Before the data itself, we write the size of the data in bytes: this is the smallest possible protocol for error checking when recovering data. In the future, it would be possible to write the *typename(T)* data in the *storage* as well.

The method returns the current position in the storage after writing.

Based on *packArray*, it's easy to implement a method to save strings:

```
int packString(const string text)
{
   uchar data[];
   StringToCharArray(text, data, 0, -1, CP_UTF8);
   return packArray(data);
}
```

There is also an option to store a separate number:

```
template<typename T>
int packNumber(const T number)
{
   T array[1] = {number};
   return packArray(array);
}
```

A method for restoring an array of arbitrary type T from the storage of type *uint* "loses" all operations in the opposite direction. If inconsistencies are found in the readable type and amount of data with the storage, the method returns 0 (an error sign). In normal mode, the current position in the array *storage* is returned (it is always greater than 0 if something was successfully read).

```
template<typename T>
int unpackArray(T &output[])
{
   if(offset >= ArraySize(storage)) return 0; // out of array bounds
   const int bytesize = (int)storage[offset];
   if(bytesize % sizeof(T) != 0) return 0;    // wrong data type
   if(bytesize > (ArraySize(storage) - offset) * sizeof(uint)) return 0;

   uchar buffer[];
   ArrayResize(buffer, bytesize);
   for(int i = 0, k = 0; i < ArraySize(storage) - 1 - offset
      && k < bytesize; ++i, k += sizeof(uint))
   {
      ByteOverlay<uint> word(storage[i + 1 + offset]);
      ArrayCopy(buffer, word.buffer, k);
   }

   int n = bytesize / sizeof(T);
   n = ArrayResize(output, n);
   for(int i = 0; i < n; ++i)
   {
      ByteOverlay<T> overlay(buffer, i * sizeof(T));
      output[i] = overlay.value;
   }

   offset += 1 + bytesize / sizeof(uint) + (bool)(bytesize % sizeof(uint));

   return offset;
}
```

Unpacking strings and numbers is done by calling *unpackArray*.

```
int unpackString(string &output)
{
   uchar bytes[];
   const int p = unpackArray(bytes);
   if(p == offset)
   {
      output = CharArrayToString(bytes, 0, -1, CP_UTF8);
   }
   return p;
}

template<typename T>
int unpackNumber(T &number)
{
   T array[1] = {};
   const int p = unpackArray(array);
   number = array[0];
   return p;
}
```

Simple helper methods allow you to find out the size of the storage and the current position in it, as well as clear it.

```
int size() const
{
   return ArraySize(storage);
}

int cursor() const
{
   return offset;
}

void clear()
{
   ArrayFree(storage);
   offset = 0;
}
```

Now we come to the most interesting: interaction with resources.

Having filled the *storage* array with application data, it is easy to "move" it to a provided resource.

```
bool submit(const string resource)
{
   return ResourceCreate(resource, storage, ArraySize(storage), 1,
      0, 0, 0, COLOR_FORMAT_XRGB_NOALPHA);
}
```

Also, we can just read data from a resource into an internal array *storage*.

```
bool acquire(const string resource)
{
   uint width, height;
   if(ResourceReadImage(resource, storage, width, height))
   {
      return true;
   }
   return false;
}
```

We will show in the script *Reservoir.mq5*, how to use it.

In the first half of *OnStart*, we describe the name for the storage resource and the class object *Reservoir*, and then sequentially "pack" into this object a string, structure *MqlTick*, and number *double*. The structure is "wrapped" in an array of one element to explicitly demonstrate the *packArray* method. In addition, we will then need to compare the restored data with the original ones, and MQL5 does not provide the '==' operator for structures. Therefore it will be more convenient to use the *ArrayCompare* function.

```
#include <MQL5Book/Reservoir.mqh>
#include <MQL5Book/PRTF.mqh>

void OnStart()
{
   const string resource = "::reservoir";

   Reservoir res1;
   string message = "message1";     // string to write to the resource
   PRTF(res1.packString(message));

   MqlTick tick1[1];                // add a simple structure
   SymbolInfoTick(_Symbol, tick1[0]);
   PRTF(res1.packArray(tick1));
   PRTF(res1.packNumber(DBL_MAX));  // real number
   ...
```

When all the necessary data is "packed" into the object, write it to the resource and clear the object.

```
   res1.submit(resource);           // create a resource with storage data
   res1.clear();                    // clear the object, but not the resource
```

In the second half of *OnStart* let's perform the reverse operations of reading data from the resource.

```
   string reply;                    // new variable for message
   MqlTick tick2[1];                // new structure for tick
   double result;                   // new variable for number

   PRTF(res1.acquire(resource));    // connect the object to the given resource
   PRTF(res1.unpackString(reply));  // read line
   PRTF(res1.unpackArray(tick2));   // read simple structure
   PRTF(res1.unpackNumber(result)); // read number

   // output and compare data element by element
   PRTF(reply);
   PRTF(ArrayCompare(tick1, tick2));
   ArrayPrint(tick2);
   PRTF(result == DBL_MAX);

   // make sure the storage is read completely
   PRTF(res1.size());
   PRTF(res1.cursor());
   ...
```

In the end, we clean up the resource, since this is a test. In practical tasks, an MQL program will most likely leave the created resource in memory so that it can be read by other programs. In the naming hierarchy, resources are declared nested in the program that created them. Therefore, for access from other programs, you must specify the name of the resource along with the name of the program and optionally the path (if the program-creator and the program-reader are in different folders). For example, to read a newly created resource from outside, the full path "\\Scripts\\MQL5Book\\p7\\Reservoir.ex5::reservoir" will do the job.

```
   PrintFormat("Cleaning up local storage '%s'", resource);
   ResourceFree(resource);
}
```

Since all major method calls are controlled by the PRTF macro, when we run the script, we will see a detailed progress "report" in the log.

```
res1.packString(message)=4 / ok
res1.packArray(tick1)=20 / ok
res1.packNumber(DBL_MAX)=23 / ok
res1.acquire(resource)=true / ok
res1.unpackString(reply)=4 / ok
res1.unpackArray(tick2)=20 / ok
res1.unpackNumber(result)=23 / ok
reply=message1 / ok
ArrayCompare(tick1,tick2)=0 / ok
                  [time]   [bid]   [ask] [last] [volume]    [time_msc] [flags] [volume
[0] 2022.05.19 23:09:32 1.05867 1.05873 0.0000        0 1653001772050       6       0
result==DBL_MAX=true / ok
res1.size()=23 / ok
res1.cursor()=23 / ok
Cleaning up local storage '::reservoir'
```

The data was successfully copied to the resource and then restored from there.

Programs can use this approach to exchange bulky data that does not fit in custom messages (eventsCHARTEVENT_CUSTOM+). It is enough to send in a string parameter *sparam* the name of the resource to read. To post back data, create your own resource with it and send a response message.

7.1.8 Saving images to a file: ResourceSave

The MQL5 API allows you to write a resource to a BMP file using the *ResourceSave* function. The framework currently only supports image resources.

bool ResourceSave(const string resource, const string filename)

The *resource* and *filename* parameters specify the name of the resource and file, respectively. The resource name must start with "::". The file name may contain a path relative to the folder *MQL5/Files*. If necessary, the function will create all intermediate subdirectories. If the specified file exists, it will be overwritten.

The function returns *true* in case of success.

To test the operation of this function, it is desirable to create an original image. We have exactly the right image for this.

As part of the study of OOP, in the chapter Classes and interfaces, we started a series of examples about graphic shapes: from the very first version *Shapes1.mq5* in the section about Class definition to the last version *Shapes6.mq5* in the section about Nested types. Drawing was not available to us then, until the chapter on graphical objects, where we were able to implement visualization in the script *ObjectShapesDraw.mq5*. Now, after studying the graphical resources, it's time for another "upgrade".

In the new version of the script *ResourceShapesDraw.mq5* we will draw the shapes. To make it easier to analyze the changes compared to the previous version, we will keep the same set of shapes: rectangle, square, oval, circle, and triangle. This is done to give an example, and not because something limits us in drawing: on the contrary, there is a potential for expanding the set of shapes, visual effects and labeling. We'll look at the features in a few examples, starting with the current one. However, please note that it is not possible to demonstrate the full range of applications within the scope of this book.

After the shapes are generated and drawn, we save the resulting resource to a file.

The basis of the shape class hierarchy is the *Shape* class which had a *draw* method.

```
class Shape
{
public:
   ...
   virtual void draw() = 0;
   ...
}
```

In derived classes, it was implemented on the basis of graphic objects, with calls to *ObjectCreate* and subsequent setup of objects using *ObjectSet* functions. The shared canvas of such a drawing was the chart itself.

Now we need to paint pixels in some shared resource according to the particular shape. It is desirable to allocate a common resource and methods for modifying pixels in it into a separate class or, better, an interface.

An abstract entity will allow us not to make links with the method of creating and configuring the resource. In particular, our next implementation will place the resource in an OBJ_BITMAP_LABEL object (as we have already done in this chapter), and for some, it may be enough to generate images in memory and save to disk without plotting (as many traders like to periodically capture states charts).

Let's call the interface *Drawing*.

```
interface Drawing
{
   void point(const float x1, const float y1, const uint pixel);
   void line(const int x1, const int y1, const int x2, const int y2, const color clr)
   void rect(const int x1, const int y1, const int x2, const int y2, const color clr)
};
```

Here are just three of the most basic methods for drawing, which are enough for this case.

The *point* method is public (which makes it possible to put a separate point), but in a sense, it is low-level since all the others will be implemented through it. That is why the coordinates in it are real, and the content of the pixel is a ready-made value of the *uint* type. This will allow, if necessary, to apply various anti-aliasing algorithms so that the shapes do not look stepped due to pixelation. Here we will not touch on this issue.

Taking into account an interface, the *Shape::draw* method turns into the following one:

```
virtual void draw(Drawing *drawing) = 0;
```

Then, in the *Rectangle* class, it's very easy to delegate the drawing of the rectangle to a new interface.

```
class Rectangle : public Shape
{
protected:
   int dx, dy; // size (width, height)
   ...
public:
   void draw(Drawing *drawing) override
   {
 // x, y - anchor point (center) in Shape
      drawing.rect(x - dx / 2, y - dy / 2, x + dx / 2, y + dy / 2, backgroundColor);
   }
};
```

More efforts are required to draw an ellipse.

```
class Ellipse : public Shape
{
protected:
   int dx, dy; // large and small radii
   ...
public:
   void draw(Drawing *drawing) override
   {
      // (x, y) - center
      const int hh = dy * dy;
      const int ww = dx * dx;
      const int hhww = hh * ww;
      int x0 = dx;
      int step = 0;

      // main horizontal diameter
      drawing.line(x - dx, y, x + dx, y, backgroundColor);

      // horizontal lines in the upper and lower half, symmetrically decreasing in le
      for(int j = 1; j <= dy; j++)
      {
         for(int x1 = x0 - (step - 1); x1 > 0; --x1)
         {
            if(x1 * x1 * hh + j * j * ww <= hhww)
            {
               step = x0 - x1;
               break;
            }
         }
         x0 -= step;
         drawing.line(x - x0, y - j, x + x0, y - j, backgroundColor);
         drawing.line(x - x0, y + j, x + x0, y + j, backgroundColor);
      }
   }
};
```

Finally, for the triangle, the rendering is implemented as follows.

```
class Triangle: public Shape
{
protected:
   int dx;  // one size, because triangles are equilateral
   ...
public:
   virtual void draw(Drawing *drawing) override
   {
      // (x, y) - center
      // R = a * sqrt(3) / 3
      // p0: x, y + R
      // p1: x - R * cos(30), y - R * sin(30)
      // p2: x + R * cos(30), y - R * sin(30)
      // Pythagorean height: dx * dx = dx * dx / 4 + h * h
      // sqrt(dx * dx * 3/4) = h
      const double R = dx * sqrt(3) / 3;
      const double H = sqrt(dx * dx * 3 / 4);
      const double angle = H / (dx / 2);

      // main vertical line (triangle height)
      const int base = y + (int)(R - H);
      drawing.line(x, y + (int)R, x, base, backgroundColor);

      // smaller vertical lines left and right, symmetrical
      for(int j = 1; j <= dx / 2; ++j)
      {
         drawing.line(x - j, y + (int)(R - angle * j), x - j, base, backgroundColor);
         drawing.line(x + j, y + (int)(R - angle * j), x + j, base, backgroundColor);
      }
   }
};
```

Now let's turn to the *MyDrawing* class which is derived from the *Drawing* interface. This is *MyDrawing* that must, guided by calls to interface methods in shapes, ensure that a certain resource is displayed in a bitmap. Therefore the class describes variables for the names of the graphical object (*object*) and resource (*sheet*), as well as the *data* array of type *uint* to store the image. In addition, we moved the *shapes* array of shapes, which was previously declared in the *OnStart* handler. Since *MyDrawing* is responsible for drawing all shapes, it is better to manage their set here.

```
class MyDrawing: public Drawing
{
   const string object;     // object with bitmap
   const string sheet;      // resource
   uint data[];             // pixels
   int width, height;       // dimensions
   AutoPtr<Shape> shapes[]; // figures/shapes
   const uint bg;           // background color
   ...
```

In the constructor, we create a graphical object for the size of the entire chart and allocate memory for the *data* array. The canvas is filled with zeros (meaning "black transparency") or whatever value is passed in the *background* parameter, after which a resource is created based on it. By default, the

resource name starts with the letter 'D' and includes the ID of the current chart, but you can specify something else.

```
public:
   MyDrawing(const uint background = 0, const string s = NULL) :
      object((s == NULL ? "Drawing" : s)),
      sheet("::" + (s == NULL ? "D" + (string)ChartID() : s)), bg(background)
   {
      width = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
      height = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS);
      ArrayResize(data, width * height);
      ArrayInitialize(data, background);

      ResourceCreate(sheet, data, width, height, 0, 0, width, COLOR_FORMAT_ARGB_NORMA

      ObjectCreate(0, object, OBJ_BITMAP_LABEL, 0, 0, 0);
      ObjectSetInteger(0, object, OBJPROP_XDISTANCE, 0);
      ObjectSetInteger(0, object, OBJPROP_YDISTANCE, 0);
      ObjectSetInteger(0, object, OBJPROP_XSIZE, width);
      ObjectSetInteger(0, object, OBJPROP_YSIZE, height);
      ObjectSetString(0, object, OBJPROP_BMPFILE, sheet);
   }
```

The calling code can find out the name of the resource using the *resource* method.

```
   string resource() const
   {
      return sheet;
   }
```

The resource and object are removed in the destructor.

```
   ~MyDrawing()
   {
      ResourceFree(sheet);
      ObjectDelete(0, object);
   }
```

The *push* method fills the array of shapes.

```
   Shape *push(Shape *shape)
   {
      shapes[EXPAND(shapes)] = shape;
      return shape;
   }
```

The *draw* method draws the shapes. It simply calls the *draw* method of each shape in the loop and then updates the resource and the chart.

```
void draw()
{
   for(int i = 0; i < ArraySize(shapes); ++i)
   {
      shapes[i][].draw(&this);
   }
   ResourceCreate(sheet, data, width, height, 0, 0, width, COLOR_FORMAT_ARGB_NORMA
   ChartRedraw();
}
```

Below are the most important methods which are the methods of the *Drawing* interface and which actually implement drawing.

Let's start with the *point* method, which we present in a simplified form for now (we will deal with the improvements later).

```
virtual void point(const float x1, const float y1, const uint pixel) override
{
   const int x_main = (int)MathRound(x1);
   const int y_main = (int)MathRound(y1);
   const int index = y_main * width + x_main;
   if(index >= 0 && index < ArraySize(data))
   {
      data[index] = pixel;
   }
}
```

Based on *point*, it is easy to implement line drawing. When the coordinates of the start and end points match in one of the dimensions, we use the *rect* method to draw since a straight line is a degenerate case of a rectangle of unit thickness.

```
virtual void line(const int x1, const int y1, const int x2, const int y2, const co
{
   if(x1 == x2) rect(x1, y1, x1, y2, clr);
   else if(y1 == y2) rect(x1, y1, x2, y1, clr);
   else
   {
      const uint pixel = ColorToARGB(clr);
      double angle = 1.0 * (y2 - y1) / (x2 - x1);
      if(fabs(angle) < 1) // step along the axis with the largest distance, x
      {
         const int sign = x2 > x1 ? +1 : -1;
         for(int i = 0; i <= fabs(x2 - x1); ++i)
         {
            const float p = (float)(y1 + sign * i * angle);
            point(x1 + sign * i, p, pixel);
         }
      }
      else // or y-step
      {
         const int sign = y2 > y1 ? +1 : -1;
         for(int i = 0; i <= fabs(y2 - y1); ++i)
         {
            const float p = (float)(x1 + sign * i / angle);
            point(p, y1 + sign * i, pixel);
         }
      }
   }
}
```

And here is the *rect* method.

```
virtual void rect(const int x1, const int y1, const int x2, const int y2, const co
{
   const uint pixel = ColorToARGB(clr);
   for(int i = fmin(x1, x2); i <= fmax(x1, x2); ++i)
   {
      for(int j = fmin(y1, y2); j <= fmax(y1, y2); ++j)
      {
         point(i, j, pixel);
      }
   }
}
```

Now we need to modify the *OnStart* handler, and the script will be ready.

First, we set up the chart (hide all elements). In theory, this is not necessary: it is left to match with the prototype script.

```
void OnStart()
{
   ChartSetInteger(0, CHART_SHOW, false);
   ...
```

Next, we describe the object of the *MyDrawing* class, generate a predefined number of random shapes (everything remains unchanged here, including the *addRandomShape* generator and the FIGURES macro equal to 21), draw them in the resource, and display them in the object on the chart.

```
   MyDrawing raster;

   for(int i = 0; i < FIGURES; ++i)
   {
      raster.push(addRandomShape());
   }

   raster.draw(); // display the initial state
   ...
```

In the example *ObjectShapesDraw.mq5*, we started an endless loop in which we moved the pieces randomly. Let's repeat this trick here. Here we will need to add the *MyDrawing* class since the array of shapes is stored inside it. Let's write a simple method *shake*.

```
class MyDrawing: public Drawing
{
public:
   ...
   void shake()
   {
      ArrayInitialize(data, bg);
      for(int i = 0; i < ArraySize(shapes); ++i)
      {
         shapes[i][].move(random(20) - 10, random(20) - 10);
      }
   }
   ...
};
```

Then, in *OnStart*, we can use the new method in a loop until the user stops the animation.

```
void OnStart()
{
   ...
   while(!IsStopped())
   {
      Sleep(250);
      raster.shake();
      raster.draw();
   }
   ...
}
```

At this point, the functionality of the previous example is virtually repeated. But we need to add image saving to a file. So let's add an input parameter *SaveImage*.

```
input bool SaveImage = false;
```

When it is set to true, check the performance of the *ResourceSave* function.

```
void OnStart()
{
   ...
   if(SaveImage)
   {
      const string filename = "temp.bmp";
      if(ResourceSave(raster.resource(), filename))
      {
         Print("Bitmap image saved: ", filename);
      }
      else
      {
         Print("Can't save image ", filename, ", ", E2S(_LastError));
      }
   }
}
```

Also, since we are talking about input variables, let the user select a background and pass the resulting value to the *MyDrawing* constructor.

```
input color BackgroundColor = clrNONE;
void OnStart()
{
   ...
   MyDrawing raster(BackgroundColor != clrNONE ? ColorToARGB(BackgroundColor) : 0);
   ...
}
```

So, everything is ready for the first test.

If you run the script *ResourceShapesDraw.mq5*, the chart will form an image like the following.

Bitmap of a resource with a set of random shapes

When comparing this image with what we saw in the example *ObjectShapesDraw.mq5*, it turns out that our new way of rendering is somewhat different from how the terminal displays objects. Although the shapes and colors are correct, the places where the shapes overlap are indicated in different ways.

Our script paints the shapes with the specified color, superimposing them on top of each other in the order they appear in the array. Later shapes overlap the earlier ones. The terminal, on the other hand, applies some kind of color mixing (inversion) in places of overlap.

Both methods have the right to exist, there are no errors here. However, is it possible to achieve a similar effect when drawing?

We have full control over the drawing process, so any effects can be applied to it not only the one from the terminal.

In addition to the original, simple way of drawing, let's implement a few more modes. All of them are summarized in the COLOR_EFFECT enumeration.

```
enum COLOR_EFFECT
{
   PLAIN,         // simple drawing with overlap (default)
   COMPLEMENT,    // draw with a complementary color (like in the terminal)
   BLENDING_XOR,  // mixing colors with XOR '^'
   DIMMING_SUM,   // "darken" colors with '+'
   LIGHTEN_OR,    // "lighten" colors with '|'
};
```

Let's add an input variable to select the mode.

```
input COLOR_EFFECT ColorEffect = PLAIN;
```

Let's support modes in the *MyDrawing* class. First, let's describe the corresponding field and method.

```
class MyDrawing: public Drawing
{
   ...
   COLOR_EFFECT xormode;
   ...
public:
   void setColorEffect(const COLOR_EFFECT x)
   {
      xormode = x;
   }
   ...
```

Then we improve the *point* method.

```
   virtual void point(const float x1, const float y1, const uint pixel) override
   {
      ...
      if(index >= 0 && index < ArraySize(data))
      {
         switch(xormode)
         {
         case COMPLEMENT:
            data[index] = (pixel ^ (1 - data[index])); // blending with complementary
            break;
         case BLENDING_XOR:
            data[index] = (pixel & 0xFF000000) | (pixel ^ data[index]); // direct mix
            break;
         case DIMMING_SUM:
            data[index] =  (pixel + data[index]); // "darkening" (SUM)
            break;
         case LIGHTEN_OR:
            data[index] =  (pixel & 0xFF000000) | (pixel | data[index]); // "lighteni
            break;
         case PLAIN:
         default:
            data[index] = pixel;
         }
      }
   }
```

You can try running the script in different modes and compare the results. Don't forget about the ability to customize the background. Here is an example of what lightening looks like.

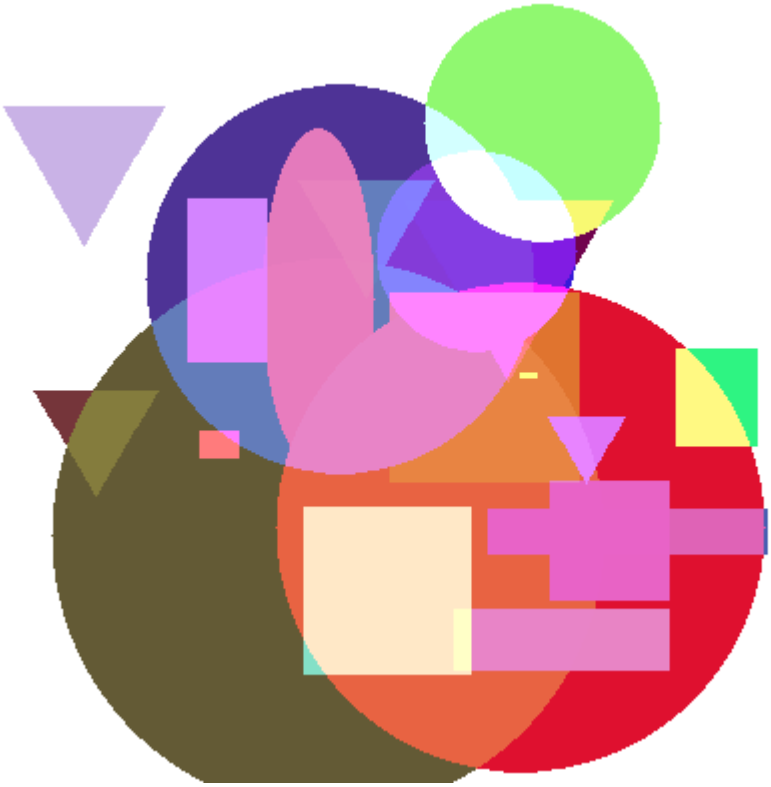


Image of shapes with lightening color mixing

To visually see the difference in effects, you can turn off color randomization and shape movement. The standard way of overlapping objects corresponds to the COMPLEMENT constant.

As a final experiment, enable the *SaveImage* option. In the *OnStart* handler, when generating the name of the file with the image, we now use the name of the current mode. We need to get a copy of the image on the chart in the file.

```
...
if(SaveImage)
{
   const string filename = EnumToString(ColorEffect) + ".bmp";
   if(ResourceSave(raster.resource(), filename))
   ...
```

For more sophisticated graphic constructions of our interface, *Drawing* may not be enough. Therefore, you can use ready-made drawing classes supplied with MetaTrader 5 or available in the mql5.com codebase. In particular, take a look at the file *MQL5/Include/Canvas/Canvas.mqh*.

7.1.9 Fonts and text output to graphic resources

In addition to rendering individual pixels in an array of a graphic resource, we can use built-in functions for displaying text. Functions allow you to change the current font and its characteristics (*TextSetFont*), get the dimensions of the rectangle in which the given string can be inscribed (*TextGetSize*), as well as directly insert the caption into the generated image (*TextOut*).

bool TextSetFont(const string name, int size, uint flags, int orientation = 0)

The function sets the font and its characteristics for subsequent drawing of text in the image buffer using the *TextOut* function (see further). The *name* parameter may contain the name of a built-in Windows font or a ttf font file (TrueType Font) connected by the resource directive (if the name starts with "::").

Size (*size*) can be specified in points (a typographic unit of measurement) or pixels (screen points). Positive values mean that the unit of measurement is a pixel, and negative values are measured in tenths of a point. Height in pixels will look different to users depending on the technical capabilities and settings of their monitors. The height in points will be approximately ("judging by eye") the same for everyone.

> A typographical point is a physical unit of length, traditionally equal to 1/72nd of an inch. Hence, 1 point is equal to 0.352778 millimeters. A pixel on the screen is a virtual measure of length. Its physical size depends on the hardware resolution of the screen. For example, with a screen density of 96 DPI (dots per inch), 1 pixel will take 0.264583 millimeters or 0.75 points. However, most modern displays have much higher DPI values and therefore smaller pixels. Because of this, operating systems, including Windows, have long had settings to increase the visible scale of interface elements. Thus, if you specify a size in points (negative values), the size of the text in pixels will depend on the display and scale settings in the operating system (for example, "standard" 100%, "medium" 125%, or "large" 150%).
>
> Zooming in causes the displayed pixels to be artificially enlarged by the system. This is equivalent to reducing the screen size in pixels, and the system applies the effective DPI to achieve the same physical size. If scaling is enabled, then it is the effective DPI that is reported to programs, including the terminal and then MQL programs. If necessary, you can find out the DPI of the screen from the TERMINAL_SCREEN_DPI property (see Screen specifications). However in reality, by setting the font size in points, we are relieved of the need to recalculate its size depending on the DPI, since the system will do it for us.

The default font is Arial and the default size is -120 (12 pt). Controls, in particular, built-in objects on charts also operate with font sizes in points. For example, if in an MQL program, you want to draw text of the same size as the text in the OBJ_LABEL object, which has a size of 10 points, you should use the parameter *size* equal to -100.

The *flags* parameter sets a combination of flags describing the style of the font. The combination is made up of a bitmask using the bitwise operator OR ('|'). Flags are divided into two groups: style flags and boldness flags.

The following table lists the style flags. They can be mixed.

Flag	Description
FONT_ITALIC	Italics
FONT_UNDERLINE	Underline
FONT_STRIKEOUT	Strikethrough

Boldness flags have relative weights corresponding to them (given to compare expected effects).

Flag	Description
FW_DONTCARE	0 (system default will be applied)
FW_THIN	100
FW_EXTRALIGHT, FW_ULTRALIGHT	200
FW_LIGHT	300
FW_NORMAL, FW_REGULAR	400
FW_MEDIUM	500
FW_SEMIBOLD, FW_DEMIBOLD	600
FW_BOLD	700
FW_EXTRABOLD, FW_ULTRABOLD	800
FW_HEAVY, FW_BLACK	900

Use only one of these values in a combination of flags.

The *orientation* parameter specifies the angle of the text in relation to the horizontal, in tenths of a degree. For example, orientation = 0 means normal text output, while orientation = 450 will result in a 45-degree tilt (counterclockwise).

Note that settings made in one *TextSetFont* call will affect all subsequent *TextOut* calls until they are changed.

The function returns *true* if successful or *false* if problems occur (for example, if the font is not found).

We will consider an example of using this function, as well as the two others after describing all of them.

bool TextGetSize(const string text, uint &width, uint &height)

The function returns the width and height of the line at the current font settings (this can be the default font or the one specified in the previous call to *TextSetFont*).

The *text* parameter passes a string in which length and width in pixels are required. Dimension values are written by the function based on references in the *width* and *height* parameters.

It should be noted that the rotation (skew) of the displayed text specified by the *orientation* parameter when *TextSetFont* is called does not affect the sizing in any way. In other words, if the text is supposed to be rotated by 45 degrees, then the MQL program itself must calculate the minimum square in which the text can fit. The *TextGetSize* function calculates the text size in a standard (horizontal) position.

bool TextOut(const string text, int x, int y, uint anchor, uint &data[], uint width, uint height, uint color, ENUM_COLOR_FORMAT color_format)

The function draws text in the graphic buffer at the specified coordinates taking into account the color, format, and previous settings (font, style, and orientation).

The text is passed in the *text* parameter and must be in the form of one line.

The *x* and *y* coordinates specified in pixels define the point in the graphics buffer where text is displayed. Which place of the generated inscription will be at the point (x, y) depends on the binding method in the *anchor* parameter (see further).

The buffer is represented by the *data* array, and although the array is one-dimensional, it stores a two-dimensional "canvas" with dimensions of *width* x *height* points. This array can be obtained from the *ResourceReadImage* function, or allocated by an MQL program. After all editing operations are completed, including text output, you should create a new resource based on this buffer or apply it to an already existing resource. In both cases, you should call *ResourceCreate*.

The color of the text and the way the color is handled are set by the parameters *color* and *color_format* (see ENUM_COLOR_FORMAT). Note that the type used for color is *uint*, i.e., to convey the *color*, it should be converted using *ColorToARGB*.

The anchoring method specified by the anchor parameter is a combination of two text positioning flags: vertical and horizontal.

Horizontal text position flags are:

- TA_LEFT – anchor to the left side of the bounding box
- TA_CENTER – anchor to the middle between the left and right sides of the rectangle
- TA_RIGHT – anchor to the right side of the bounding box

Vertical text position flags are:

- TA_TOP – anchor to the top side of the bounding box
- TA_VCENTER – anchor to the middle between the top and bottom side of the rectangle
- TA_BOTTOM – anchor to the bottom side of the bounding box

In total, there are 9 valid combinations of flags to describe the anchoring method.

The position of the output text relative to the anchor point

Here, the center of the picture contains a deliberately exaggerated large point in the generated image with coordinates (x, y). Depending on the flags, the text appears relative to this point at the specified positions (the content of the text corresponds to the applied anchoring method).

For ease of reference, all the inscriptions are made in the standard horizontal position. However, note that an angle could also be applied to any of them (*orientation*), and then the corresponding inscription would be rotated around the point. In this image, only the label centered on both dimensions is rotated.

These flags should not be confused with text alignment. The bounding box is always sized to fit the text, and its position relative to the anchor point is, in a sense, the opposite of the flag names.

Let's look at some examples using three functions.

To begin with, let's check the simplest options of setting the font boldness and style. The *ResourceText.mq5* script allows you to select the name of the font, its size, as well as the colors of the background and text in the input variables. The labels will be displayed on the chart for the specified number of seconds.

```
input string Font = "Arial";             // Font Name
input int    Size = -240;                // Size
input color  Color = clrBlue;            // Font Color
input color  Background = clrNONE;       // Background Color
input uint   Seconds = 10;               // Demo Time (seconds)
```

The name of each gradation of boldness will be displayed in the label text, so to simplify the process (by using *EnumToString*) the ENUM_FONT_WEIGHTS enumeration is declared.

```
enum ENUM_FONT_WEIGHTS
{
   _DONTCARE = FW_DONTCARE,
   _THIN = FW_THIN,
   _EXTRALIGHT = FW_EXTRALIGHT,
   _LIGHT = FW_LIGHT,
   _NORMAL = FW_NORMAL,
   _MEDIUM = FW_MEDIUM,
   _SEMIBOLD = FW_SEMIBOLD,
   _BOLD = FW_BOLD,
   _EXTRABOLD = FW_EXTRABOLD,
   _HEAVY = FW_HEAVY,
};

const int nw = 10; // number of different weights
```

The inscription flags are collected in the *rendering* array and random combinations are selected from it.

```
   const uint rendering[] =
   {
      FONT_ITALIC,
      FONT_UNDERLINE,
      FONT_STRIKEOUT
   };
   const int nr = sizeof(rendering) / sizeof(uint);
```

To get a random number in a range, there is an auxiliary function *Random*.

```
int Random(const int limit)
{
   return rand() % limit;
}
```

In the main function of the script, we find the size of the chart and create an OBJ_BITMAP_LABEL object that spans the entire space.

```
void OnStart()
{
   ...
   const string name = "FONT";
   const int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
   const int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS);

   // object for a resource with a picture filling the whole window
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_XSIZE, w);
   ObjectSetInteger(0, name, OBJPROP_YSIZE, h);
   ...
```

Next, we allocate memory for the image buffer, fill it with the specified background color (or leave it transparent, by default), create a resource based on the buffer, and bind it to the object.

```
   uint data[];
   ArrayResize(data, w * h);
   ArrayInitialize(data, Background == clrNONE ? 0 : ColorToARGB(Background));
   ResourceCreate(name, data, w, h, 0, 0, w, COLOR_FORMAT_ARGB_RAW);
   ObjectSetString(0, name, OBJPROP_BMPFILE, "::" + name);
   ...
```

Just in case, note that we can set the OBJPROP_BMPFILE property without a modifier (0 or 1) in the *ObjectSetString* call unless the object is supposed to switch between two states.

All font weights are listed in the *weights* array.

```
   const uint weights[] =
   {
      FW_DONTCARE,
      FW_THIN,
      FW_EXTRALIGHT, // FW_ULTRALIGHT,
      FW_LIGHT,
      FW_NORMAL,     // FW_REGULAR,
      FW_MEDIUM,
      FW_SEMIBOLD,   // FW_DEMIBOLD,
      FW_BOLD,
      FW_EXTRABOLD,  // FW_ULTRABOLD,
      FW_HEAVY,      // FW_BLACK
   };
   const int nw = sizeof(weights) / sizeof(uint);
```

In the loop, in order, we set the next gradation of boldness for each line using *TextSetFont*, preselecting a random style. A description of the font, including its name and weight, is drawn in the buffer using *TextOut*.

```
      const int step = h / (nw + 2);
      int cursor = 0;    // Y coordinate of the current "text line"

      for(int weight = 0; weight < nw; ++weight)
      {
         // apply random style
         const int r = Random(8);
         uint render = 0;
         for(int j = 0; j < 3; ++j)
         {
            if((bool)(r & (1 << j))) render |= rendering[j];
         }
         TextSetFont(Font, Size, weights[weight] | render);

         // generate font description
         const string text = Font + EnumToString((ENUM_FONT_WEIGHTS)weights[weight]);

         // draw text on a separate "line"
         cursor += step;
         TextOut(text, w / 2, cursor, TA_CENTER | TA_TOP, data, w, h,
            ColorToARGB(Color), COLOR_FORMAT_ARGB_RAW);
      }
      ...
```

Now update the resource and chart.

```
      ResourceCreate(name, data, w, h, 0, 0, w, COLOR_FORMAT_ARGB_RAW);
      ChartRedraw();
      ...
```

The user can stop the demonstration in advance.

```
      const uint timeout = GetTickCount() + Seconds * 1000;
      while(!IsStopped() && GetTickCount() < timeout)
      {
         Sleep(1000);
      }
```

Finally, the script deletes the resource and the object.

```
      ObjectDelete(0, name);
      ResourceFree("::" + name);
   }
```

The result of the script is shown in the following image.

Drawing text in different weights and styles

In the second example of *ResourceFont.mq5*, we will make the task more difficult by including a custom font as a resource and using text rotation in 90-degree increments.

The font file is located next to the script.

```
#resource "a_LCDNova3DCmObl.ttf"
```

The message can be changed in the input parameter.

```
input string Message = "Hello world!";    // Message
```

This time, the OBJ_BITMAP_LABEL will not occupy the entire window and is therefore centered both horizontally and vertically.

```
void OnStart()
{
   const string name = "FONT";
   const int w = (int)ChartGetInteger(0, CHART_WIDTH_IN_PIXELS);
   const int h = (int)ChartGetInteger(0, CHART_HEIGHT_IN_PIXELS);

   // object for a resource with a picture
   ObjectCreate(0, name, OBJ_BITMAP_LABEL, 0, 0, 0);
   ObjectSetInteger(0, name, OBJPROP_XDISTANCE, w / 2);
   ObjectSetInteger(0, name, OBJPROP_YDISTANCE, h / 2);
   ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_CENTER);
   ...
```

To begin with, the buffer of the minimum size is allocated, just to complete resource creation. Later we will expand it to fit the dimensions of the inscription, for which there are reserved variables *width* and *height*.

```
uint data[], width, height;
ArrayResize(data, 1);
ResourceCreate(name, data, 1, 1, 0, 0, 1, COLOR_FORMAT_ARGB_RAW);
ObjectSetString(0, name, OBJPROP_BMPFILE, "::" + name);
...
```

In a loop with the test time countdown, we need to change the orientation of the inscription, for which there is the *angle* variable (degrees will be scrolled in it). The orientation will change once per second, the count is in the *remain* variable.

```
const uint timeout = GetTickCount() + Seconds * 1000;
int angle = 0;
int remain = 10;
...
```

In the loop, we constantly change the rotation of the text, and in the text itself, we display a countdown counter of seconds. For each new inscription, its size is calculated using *TextGetSize*, based on which the buffer is reallocated.

```
   while(!IsStopped() && GetTickCount() < timeout)
   {
      // apply new angle
      TextSetFont("::a_LCDNova3DCmObl.ttf", -240, 0, angle * 10);

      // form the text
      const string text = Message + " (" + (string)remain-- + ")";

      // get the text size, allocate the array
      TextGetSize(text, width, height);
      ArrayResize(data, width * height);
      ArrayInitialize(data, 0);            // transparency

      // for vertical orientation, swap sizes
      if((bool)(angle / 90 & 1))
      {
         const uint t = width;
         width = height;
         height = t;
      }

      // adjust the size of the object
      ObjectSetInteger(0, name, OBJPROP_XSIZE, width);
      ObjectSetInteger(0, name, OBJPROP_YSIZE, height);

      // draw text
      TextOut(text, width / 2, height / 2, TA_CENTER | TA_VCENTER, data, width, heigh
         ColorToARGB(clrBlue), COLOR_FORMAT_ARGB_RAW);

      // update resource and chart
      ResourceCreate(name, data, width, height, 0, 0, width, COLOR_FORMAT_ARGB_RAW);
      ChartRedraw();

      // change angle
      angle += 90;

      Sleep(100);
   }
   ...
```

Note that if the text is vertical, the dimensions need to be swapped. More generally, with text rotated to an arbitrary angle, it took more math to get the buffer size to fit the entire text.

At the end, we also delete the object and resource.

```
   ObjectDelete(0, name);
   ResourceFree("::" + name);
}
```

One of the moments of the script execution is shown in the following screenshot.

Inscription with custom font

As a final example, let's take a look at the script *ResourceTextAnchOrientation.mq5* showing various rotations and anchor points of the text.

The script generates the specified number of labels (*ExampleCount*) using the specified font.

```
input string Font = "Arial";              // Font Name
input int    Size = -150;                 // Size
input int    ExampleCount = 11;           // Number of examples
```

Anchor points and rotations are chosen randomly.

To specify the names of anchor points in labels, there is the ENUM_TEXT_ANCHOR enumeration with all valid options declared. So, we can simply call *EnumToString* any randomly selected element.

```
enum ENUM_TEXT_ANCHOR
{
   LEFT_TOP = TA_LEFT | TA_TOP,
   LEFT_VCENTER = TA_LEFT | TA_VCENTER,
   LEFT_BOTTOM = TA_LEFT | TA_BOTTOM,
   CENTER_TOP = TA_CENTER | TA_TOP,
   CENTER_VCENTER = TA_CENTER | TA_VCENTER,
   CENTER_BOTTOM = TA_CENTER | TA_BOTTOM,
   RIGHT_TOP = TA_RIGHT | TA_TOP,
   RIGHT_VCENTER = TA_RIGHT | TA_VCENTER,
   RIGHT_BOTTOM = TA_RIGHT | TA_BOTTOM,
};
```

An array of these new constants is declared in the *OnStart* handler.

```
void OnStart()
{
   const ENUM_TEXT_ANCHOR anchors[] =
   {
      LEFT_TOP,
      LEFT_VCENTER,
      LEFT_BOTTOM,
      CENTER_TOP,
      CENTER_VCENTER,
      CENTER_BOTTOM,
      RIGHT_TOP,
      RIGHT_VCENTER,
      RIGHT_BOTTOM,
   };
   const int na = sizeof(anchors) / sizeof(uint);
   ...
```

Initial object and resource creation are similar to the example with *ResourceText.mq5*, so let's leave them out here. The most interesting thing happens in the loop.

```
   for(int i = 0; i < ExampleCount; ++i)
   {
      // apply a random angle
      const int angle = Random(360);
      TextSetFont(Font, Size, 0, angle * 10);

      // take random coordinates and an anchor point
      const ENUM_TEXT_ANCHOR anchor = anchors[Random(na)];
      const int x = Random(w / 2) + w / 4;
      const int y = Random(h / 2) + h / 4;
      const color clr = ColorMix::HSVtoRGB(angle);

     // draw a circle directly in that place of the image,
     // where the anchor point goes
      TextOut(ShortToString(0x2022), x, y, TA_CENTER | TA_VCENTER, data, w, h,
         ColorToARGB(clr), COLOR_FORMAT_ARGB_NORMALIZE);

      // form the text describing the anchor type and angle
      const string text =  EnumToString(anchor) +
         "(" + (string)angle + CharToString(0xB0) + ")";

      // draw text
      TextOut(text, x, y, anchor, data, w, h,
         ColorToARGB(clr), COLOR_FORMAT_ARGB_NORMALIZE);
   }
   ...
```

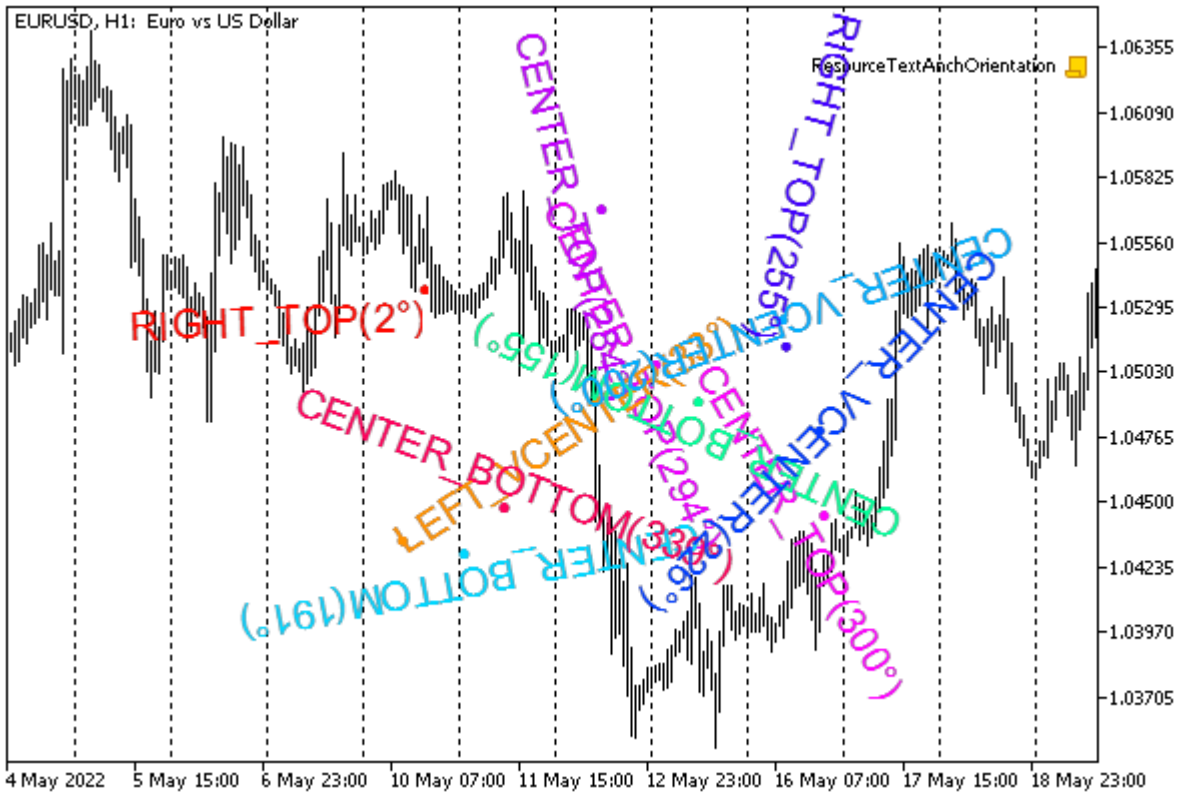
It remains only to update the picture and chart, and then wait for the user's command and free up resources.

```
      ResourceCreate(name, data, w, h, 0, 0, w, COLOR_FORMAT_ARGB_NORMALIZE);
      ChartRedraw();

      const uint timeout = GetTickCount() + Seconds * 1000;
      while(!IsStopped() && GetTickCount() < timeout)
      {
         Sleep(1000);
      }

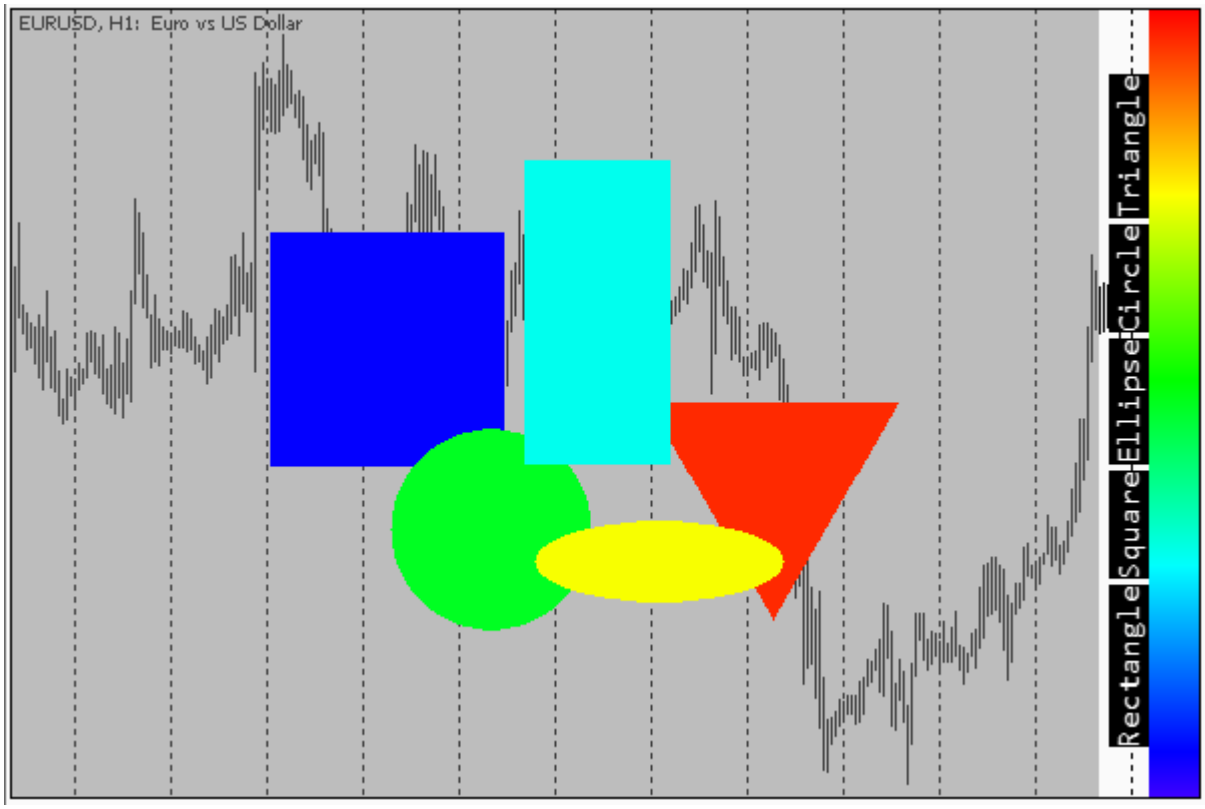
      ObjectDelete(0, name);
      ResourceFree("::" + name);
   }
```

Here's what we get as a result.



Text output with random coordinates, anchor points, and angles

Additionally, for an independent study, the book provides a toy graphics editor *SimpleDrawing.mq5*. It is designed as a bufferless indicator and uses in its work the classes of shapes considered earlier (see the example with *ResourceShapesDraw.mq5*). They are put in the header file *ShapesDrawing.mqh* almost unchanged. Previously, the shapes were randomly generated by the script. Now the user can select and plot them on the chart. For this purpose, an interface with a color palette and a button bar has been implemented according to the number of registered shape classes. The interface is implemented by the *SimpleDrawing* class (*SimpleDrawing.mqh*).



Simple graphic editor

The panel and palette can be positioned along any border of the chart, demonstrating the ability to rotate labels.

Selecting the next shape to draw is done by pressing the button in the panel: the button "sticks" in the pressed state, and its background color indicates the selected drawing color. To change the color, click anywhere on the palette.

When one of the shape types is selected in the panel (one of the buttons is "active"), clicking in the drawing area (the rest of the chart, indicated by shading) draws a shape of predefined size at that location. At this point, the button "switches off". In this state, when all buttons are inactive, you can move the shapes around the workspace using the mouse. If we keep the key *Ctrl* pressed, instead of moving, the shape gets resized. The "hot spot" is located in the center of each shape (the size of the sensitive area is set by a macro in the source code and will probably need to be increased for very high DPI displays).

Note that the editor includes the plot ID (*ChartID*) in the names of the generated resources. This allows to run the editor in parallel on several charts.

7.1.10 Application of graphic resources in trading

Of course, beautifying is not the primary purpose of the resources. Let's see how to create a useful tool based on them. We will also eliminate one more omission: so far we have used resources only inside OBJ_BITMAP_LABEL objects, which are positioned in screen coordinates. However, graphic resources can also be embedded in OBJ_BITMAP objects with reference to quote coordinates: prices and time.

Earlier in the book, we have seen the *IndDeltaVolume.mq5* indicator which calculates the delta volume (tick or real) for each bar. In addition to this representation of the delta volume, there is another one that is no less popular with users: the market profile. This is the distribution of volumes in the context

of price levels. Such a histogram can be built for the entire window, for a given depth (for example, within a day), or for a single bar.

It is the last option that we implement in the form of a new indicator *DeltaVolumeProfile.mq5*. We have already considered the main technical details of the tick history request within the framework of the above indicator, so now we will focus mainly on the graphical component.

Flag *ShowSplittedDelta* in the input variable will control how volumes are displayed: broken down by buy/sell directions or collapsed.

```
input bool ShowSplittedDelta = true;
```

There will be no buffers in the indicator. It will calculate and display a histogram for a specific bar at the user's request, and specifically, by clicking on this bar. Thus, we will use the *OnChartEvent* handler. In this handler, we get screen coordinates, recalculate them into price and time, and call some helper function *RequestData*, which starts the calculation.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_CLICK)
   {
      datetime time;
      double price;
      int window;
      ChartXYToTimePrice(0, (int)lparam, (int)dparam, window, time, price);
      time += PeriodSeconds() / 2;
      const int b = iBarShift(_Symbol, _Period, time, true);
      if(b != -1 && window == 0)
      {
         RequestData(b, iTime(_Symbol, _Period, b));
      }
   }
   ...
}
```

To fill it, we need the *DeltaVolumeProfile* class, which is built to be similar to the class *CalcDeltaVolume* from *IndDeltaVolume.mq5*.

The new class describes variables that take into account the volume calculation method (*tickType*), the type of price on which the chart is built (*barType*), mode from the *ShowSplittedDelta* input variable (will be placed in a member variable *delta*), as well as a prefix for generated objects on the chart.

```
class DeltaVolumeProfile
{
   const COPY_TICKS tickType;
   const ENUM_SYMBOL_CHART_MODE barType;
   const bool delta;

   static const string prefix;
   ...
public:
   DeltaVolumeProfile(const COPY_TICKS type, const bool d) :
      tickType(type), delta(d),
      barType((ENUM_SYMBOL_CHART_MODE)SymbolInfoInteger(_Symbol, SYMBOL_CHART_MODE))
   {
   }

   ~DeltaVolumeProfile()
   {
      ObjectsDeleteAll(0, prefix, 0); // TODO: delete resources
   }
   ...
};

static const string DeltaVolumeProfile::prefix = "DVP";

DeltaVolumeProfile deltas(TickType, ShowSplittedDelta);
```

The *tick type* can be changed to the TRADE_TICKS value only for trading instruments for which real volumes are available. By default, the INFO_TICKS mode is enabled, which works on all instruments.

Ticks for a particular bar are requested by the *createProfileBar* method.

```
int createProfileBar(const int i)
{
   MqlTick ticks[];
   const datetime time = iTime(_Symbol, _Period, i);
   // prev and next - time limits of the bar
   const datetime prev = time;
   const datetime next = prev + PeriodSeconds();
   ResetLastError();
   const int n = CopyTicksRange(_Symbol, ticks, COPY_TICKS_ALL,
      prev * 1000, next * 1000 - 1);
   if(n > -1 && _LastError == 0)
   {
      calcProfile(i, time, ticks);
   }
   else
   {
      return -_LastError;
   }
   return n;
}
```

Direct analysis of ticks and calculation of volumes is performed in the protected method *calcProfile*. In it, first of all, we find out the price range of the bar and its size in pixels.

```
void calcProfile(const int b, const datetime time, const MqlTick &ticks[])
{
   const string name = prefix + (string)(ulong)time;
   const double high = iHigh(_Symbol, _Period, b);
   const double low = iLow(_Symbol, _Period, b);
   const double range = high - low;

   ObjectCreate(0, name, OBJ_BITMAP, 0, time, high);

   int x1, y1, x2, y2;
   ChartTimePriceToXY(0, 0, time, high, x1, y1);
   ChartTimePriceToXY(0, 0, time, low, x2, y2);

   const int h = y2 - y1 + 1;
   const int w = (int)(ChartGetInteger(0, CHART_WIDTH_IN_PIXELS)
      / ChartGetInteger(0, CHART_WIDTH_IN_BARS));
   ...
```

Based on this information, we create an OBJ_BITMAP object, allocate an array for the image, and create a resource. The background of the whole picture is empty (transparent). Each object is anchored by the upper midpoint to the *High* price of its bar and has a width of one bar.

```
uint data[];
ArrayResize(data, w * h);
ArrayInitialize(data, 0);
ResourceCreate(name + (string)ChartID(), data, w, h, 0, 0, w, COLOR_FORMAT_ARGB

ObjectSetString(0, name, OBJPROP_BMPFILE, "::" + name + (string)ChartID());
ObjectSetInteger(0, name, OBJPROP_XSIZE, w);
ObjectSetInteger(0, name, OBJPROP_YSIZE, h);
ObjectSetInteger(0, name, OBJPROP_ANCHOR, ANCHOR_UPPER);
...
```

This is followed by the calculation of volumes in ticks of the passed array. The number of price levels is equal to the height of the bar in pixels (*h*). Usually, it is less than the price range in points, and therefore the pixels act as a kind of basket for calculating statistics. If on a small timeframe, the range of points is smaller than the size in pixels, the histogram will be visually sparse. Volumes of purchases and sales are accumulated separately in *plus* and *minus* arrays.

```
long plus[], minus[], max = 0;
ArrayResize(plus, h);
ArrayResize(minus, h);
ArrayInitialize(plus, 0);
ArrayInitialize(minus, 0);

const int n = ArraySize(ticks);
for(int j = 0; j < n; ++j)
{
   const double p1 = price(ticks[j]); // returns Bid or Last
   const int index = (int)((high - p1) / range * (h - 1));
   if(tickType == TRADE_TICKS)
   {
      // if real volumes are available, we can take them into account
      if((ticks[j].flags & TICK_FLAG_BUY) != 0)
      {
         plus[index] += (long)ticks[j].volume;
      }
      if((ticks[j].flags & TICK_FLAG_SELL) != 0)
      {
         minus[index] += (long)ticks[j].volume;
      }
   }
   else // tickType == INFO_TICKS or tickType == ALL_TICKS
   if(j > 0)
   {
     // if there are no real volumes,
     // price movement up/down is an estimate of the volume type
      if((ticks[j].flags & (TICK_FLAG_ASK | TICK_FLAG_BID)) != 0)
      {
         const double d = (((ticks[j].ask + ticks[j].bid)
                        - (ticks[j - 1].ask + ticks[j - 1].bid)) / _Point);
         if(d > 0) plus[index] += (long)d;
         else minus[index] -= (long)d;
      }
   }
   ...
```

To normalize the histogram, we find the maximum value.

```
            if(delta)
            {
               if(plus[index] > max) max = plus[index];
               if(minus[index] > max) max = minus[index];
            }
            else
            {
               if(fabs(plus[index] - minus[index]) > max)
                  max = fabs(plus[index] - minus[index]);
            }
         }
         ...
```

Finally, the resulting statistics are output to the graphics buffer *data* and sent to the resource. Buy volumes are displayed in blue, and sell volumes are shown in red. If the net mode is enabled, then the amount is displayed in green.

```
         for(int i = 0; i < h; i++)
         {
            if(delta)
            {
               const int dp = (int)(plus[i] * w / 2 / max);
               const int dm = (int)(minus[i] * w / 2 / max);
               for(int j = 0; j < dp; j++)
               {
                  data[i * w + w / 2 + j] = ColorToARGB(clrBlue);
               }
               for(int j = 0; j < dm; j++)
               {
                  data[i * w + w / 2 - j] = ColorToARGB(clrRed);
               }
            }
            else
            {
               const int d = (int)((plus[i] - minus[i]) * w / 2 / max);
               const int sign = d > 0 ? +1 : -1;
               for(int j = 0; j < fabs(d); j++)
               {
                  data[i * w + w / 2 + j * sign] = ColorToARGB(clrGreen);
               }
            }
         }
         ResourceCreate(name + (string)ChartID(), data, w, h, 0, 0, w, COLOR_FORMAT_ARGB
      }
```

Now we can return to the *RequestData* function: its task is to call the *createProfileBar* method and handle errors (if any).

```
void RequestData(const int b, const datetime time, const int count = 0)
{
   Comment("Requesting ticks for ", time);
   if(deltas.createProfileBar(b) <= 0)
   {
      Print("No data on bar ", b, ", at ", TimeToString(time),
         ". Sending event for refresh...");
      ChartSetSymbolPeriod(0, _Symbol, _Period); // request to update the chart
      EventChartCustom(0, TRY_AGAIN, b, count + 1, NULL);
   }
   Comment("");
}
```

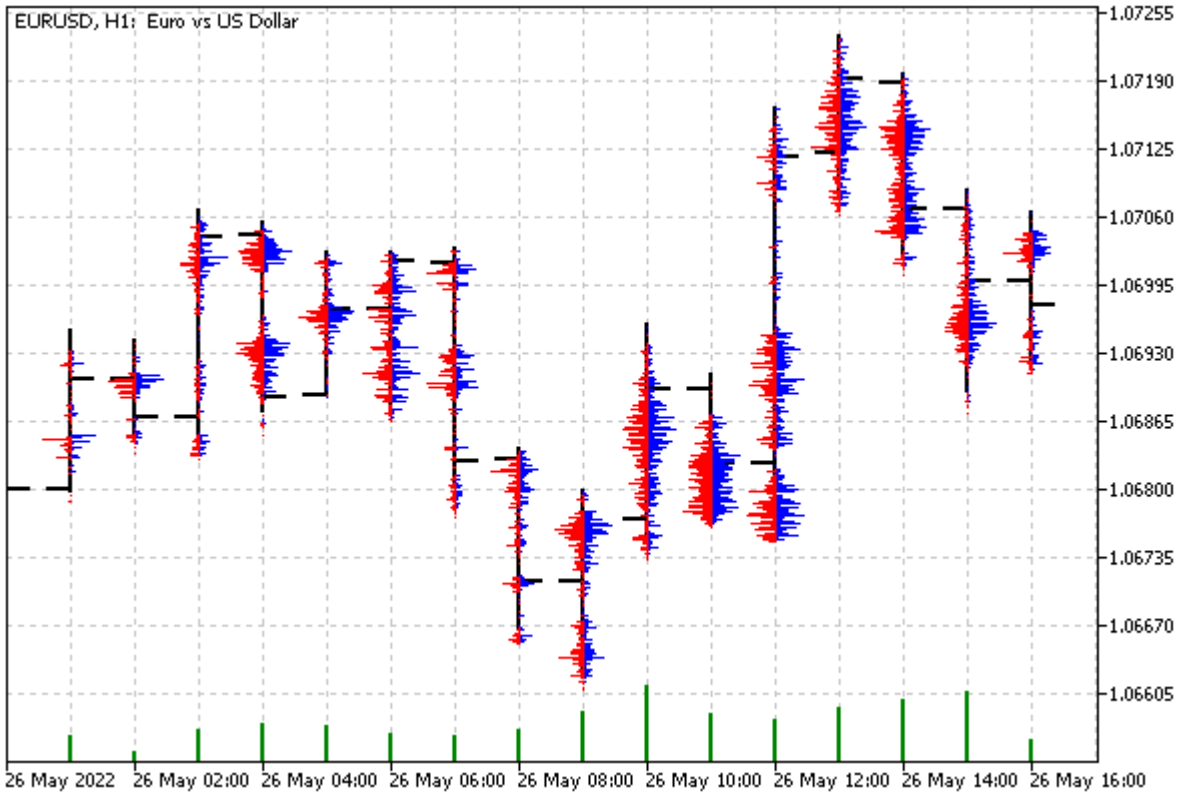
The only error-handling strategy is to try requesting the ticks again because they might not have had time to load. For this purpose, the function sends a custom TRY_AGAIN message to the chart and processes it itself.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   ...
   else if(id == CHARTEVENT_CUSTOM + TRY_AGAIN)
   {
      Print("Refreshing... ", (int)dparam);
      const int b = (int)lparam;
      if((int)dparam < 5)
      {
         RequestData(b, iTime(_Symbol, _Period, b), (int)dparam);
      }
      else
      {
         Print("Give up. Check tick history manually, please, then click the bar agai
      }
   }
}
```

We repeat this process no more than 5 times, because the tick history can have a limited depth, and it makes no sense to load the computer for no reason.

The *DeltaVolumeProfile* class also has the mechanism for processing the message CHARTEVENT_CHART_CHANGE in order to redraw existing objects in case of changing the size or scale of the chart. Details can be found in the source code.

The result of the indicator is shown in the following image.



Displaying per-bar histograms of separate volumes in graphic resources

Note that the histograms are not displayed immediately after drawing the indicator: you have to click on the bar to calculate its histogram.

7.2 Custom symbols

One of the interesting technical features of MetaTrader 5 is the support for custom financial instruments. These are the symbols that are defined not by the broker on the server side but by the trader directly in the terminal.

Custom symbols can be added to the *Market Watch* list along with standard symbols. The charts of such symbols with them can be used in a usual way.

The easiest way to create a custom symbol is to specify its calculation formula in the corresponding property. To do this, from the terminal interface, call the context menu in the *Market Watch* window, execute the *Symbols* command, go to the symbol hierarchy and its *Custom* branch, and press the *Create symbol* button. As a result, a dialog for setting the properties of the new symbol will open. At the same place, you can import external tick history (tab *Ticks*) or quotes (tab *Bars*) into similar tools, from files. This is discussed in detail in the MetaTrader 5 documentation.

However, the MQL5 API provides the most complete control over custom symbols.

For custom symbols, the API provides a group of functions working with Financial instruments and Market Watch. In particular, such symbols can be listed from the program using standard functions such as *SymbolsTotal*, *SymbolName*, and *SymbolInfo*. We have already briefly touched on this possibility and provided an example in the section on Custom symbol properties. A distinctive feature of a custom symbol is the enabled flag (property) SYMBOL_CUSTOM.

Using the built-in functions, you can splice Futures, generate random time series with specified characteristics, emulate renko, equal-range bars, equivolume, and other non-standard types of charts (for example, second timeframes). Also, unlike importing static files, software-controlled custom symbols can be generated in realt-time based on the data from web services such as cryptocurrency exchanges. The conversation on integrating MQL programs with the web is still ahead, but this possibility cannot be ignored.

A custom symbol can be easily used to test strategies in the tester or as an additional method of technical analysis. However, this technology has its limitations.

Due to the fact that custom symbols are defined in the terminal and not on the server, they cannot be traded online. In particular, if you create a renko chart, trading strategies based on it will need to be adapted in one way or another so that trading signals and trades are actually separated by different symbols: artificial user and real brokerage. We will look at a couple of solutions to the problem.

In addition, since the duration of all bars of one timeframe is the same in the platform, any emulation of bars with different periods (Renko, equivolume, etc.) is usually based on the smaller of the available M1 timeframes and does not provide a full time synchronization with reality. In other words, ticks belonging to such a bar are forced to have an artificial time within 60 seconds, even if a renko "brick" or a bar of a given volume actually required much more time to form. Otherwise, if we put ticks in real time, they would form the next M1 bars, violating the rules of renko or equivolume. Moreover, there are situations when a renko "brick" or other artificial bar should be created with a time interval smaller than 1 minute from the previous bar (for example, when there is increased fast volatility). In such cases, it will be necessary to change the time of historical bars in quotes of the custom instrument (shift them to the left "retroactively") or put future times on new bars (which is highly undesirable). This problem cannot be solved in a general way within the framework of user-defined symbols technology.

7.2.1 Creating and deleting custom symbols

The first two functions you need in order to work with custom symbols are *CustomSymbolCreate* and *CustomSymbolDelete*.

bool CustomSymbolCreate(const string name, const string path = "", const string origin = NULL)

The function creates a custom symbol with the specified name (*name*) in the specified group (*path*) and, if necessary, with the properties of an exemplary symbol – its name can be specified in the parameter *origin*.

The *name* parameter should be a simple identifier, without hierarchy. If necessary, one or more required levels of groups (subfolders) should be specified in the parameter *path*, with the delimiter character being a backslash '\' (the forward slash is not supported here, unlike the file system). The backslash must be doubled in literal strings ("\\").

By default, if the *path* string is empty ("" or NULL), the symbol is created directly in the *Custom* folder, which is allocated in the general hierarchy of symbols for user symbols. If the path is filled, it is created inside the *Custom* folder to the full depth (if there are no corresponding folders yet).

The name of a symbol, as well as the name of a group of any level, can contain Latin letters and numbers, without punctuation marks, spaces, and special characters. Additionally, only '.', '_', '&', and '#' are allowed.

The name must be unique in the entire symbol hierarchy, regardless of which group the symbol is supposed to be created in. If a symbol with the same name already exists, the function will return *false*

and will set the error code 5300 (ERR_NOT_CUSTOM_SYMBOL) or 5304 (ERR_CUSTOM_SYMBOL_EXIST) in *_LastError*.

Note that if the last (or even the only) element of the hierarchy in the *path* string exactly matches the *name* (case sensitive), then it is treated as a symbol name that is part of the path and not as a folder. For example, if the name and path contain the strings "Example" and "MQL5Book\\Example", respectively, then the symbol "Example" will be created in the "Custom\\MQL5Book\\" folder. At the same time, if we change the name to "example", we will get the "example" symbol in the "Custom\\MQL5Book\\Example" folder.

This feature has another consequence. The SYMBOL_PATH property returns the path along with the symbol name at the end. Therefore, if we transfer its value without changes from some exemplary symbol to a newly created one, we will get the following effect: a folder with the name of the old symbol will be created, inside which a new symbol will appear. Thus, if you want to create a custom symbol in the same group as the original symbol, you must strip the name of the original symbol from the string obtained from the SYMBOL_PATH property.

We will demonstrate the side effect of copying the SYMBOL_PATH property in an example in the next section. However, this effect can also be used as a positive one. In particular, by creating several of its symbols based on one original symbol, copying SYMBOL_PATH will ensure that all new symbols are placed in the folder with the name of the original, i.e., it will group the symbols according to their prototype symbol.

The SYMBOL_PATH property for custom symbols always starts with the "Custom\\" folder (this prefix is added automatically).

Name length is limited to 31 characters. When the limit is exceeded, *CustomSymbolCreate* will return *false* and set error code 5302 (ERR_CUSTOM_SYMBOL_NAME_LONG).

The maximum length of the parameter path is 127 characters, including "Custom\\", group separators "\\", and the symbol name, if it is specified at the end.

The *origin* parameter allows you to optionally specify the name of the symbol from which the properties of the created custom symbol will be copied. After creating a custom symbol, you can change any of its properties to the desired value using the appropriate functions (see *CustomSymbolSet* functions).

If a non-existent symbol is given as the *origin* parameter, then the custom symbol will be created "empty", as if the parameter *origin* was not specified. This will raise error 4301 (ERR_MARKET_UNKNOWN_SYMBOL).

In a new symbol created "blank", all properties are set to their default values. For example, the contract size is 100000, the number of digits in the price is 4, the margin calculation is carried out according to Forex rules, and charting is based on the *Bid* prices.

When you specify *origin*, only settings are transferred from this symbol to the new symbol but not quotes or ticks as they should be generated separately. This will be discussed in the following sections.

Creating a symbol does not automatically add it to *Market Watch*. So, this must be done explicitly (manually or programmatically). Without quotes, the chart window will be empty.

bool CustomSymbolDelete(const string name)

The function deletes a custom symbol with the specified name. Not only settings are deleted, but also all data on the symbol (quotes and ticks). It is worth noting, that the history is not deleted immediately, but only after some delay, which can be a source of problems if you intend to recreate a

symbol with the same name (we will touch on this point in the example of the section Adding, replacing, and deleting quotes).

Only a custom symbol can be deleted. Also, you cannot delete a symbol selected in *Market Watch* or a symbol having an open chart. Please note that a symbol can also be selected implicitly, without displaying in the visible list (in such cases, the SYMBOL_VISIBLE property is *false*, and the SYMBOL_SELECT property is *true*). Such a symbol first must be "hidden" by calling *SymbolSelect("name", false)* before attempting to delete: otherwise, we get a CUSTOM_SYMBOL_SELECTED (5306) error.

If deleting a symbol leaves an empty folder (or folder hierarchy), it is also deleted.

For example, let's create a simple script *CustomSymbolCreateDelete.mq5*. In the input parameters, you can specify a name, a path, and an exemplary symbol.

```
input string CustomSymbol = "Dummy";          // Custom Symbol Name
input string CustomPath = "MQL5Book\\Part7"; // Custom Symbol Folder
input string Origin;
```

In the *OnStart* handler, let's check if there is already a symbol with the given name. If not, then after the confirmation from the user, we will create such a symbol. If the symbol is already there and it's a custom symbol, let's delete it with the user's permission (this will make it easier to clean up after the experiment is over).

```
void OnStart()
{
   bool custom = false;
   if(!PRTF(SymbolExist(CustomSymbol, custom)))
   {
      if(IDYES == MessageBox("Create new custom symbol?", "Please, confirm", MB_YESNC
      {
         PRTF(CustomSymbolCreate(CustomSymbol, CustomPath, Origin));
      }
   }
   else
   {
      if(custom)
      {
         if(IDYES == MessageBox("Delete existing custom symbol?", "Please, confirm",
         {
            PRTF(CustomSymbolDelete(CustomSymbol));
         }
      }
      else
      {
         Print("Can't delete non-custom symbol");
      }
   }
}
```

Two consecutive runs with default options should result in the following log entries.

```
SymbolExist(CustomSymbol,custom)=false / ok
Create new custom symbol?
CustomSymbolCreate(CustomSymbol,CustomPath,Origin)=true / ok

SymbolExist(CustomSymbol,custom)=true / ok
Delete existing custom symbol?
CustomSymbolDelete(CustomSymbol)=true / ok
```

Between runs, you can open the symbol dialog in the terminal and check that the corresponding custom symbol has appeared in the symbol hierarchy.

7.2.2 Custom symbol properties

Custom symbols have the same properties as broker-provided symbols. The properties are read by the standard functions discussed in the chapter on financial instruments.

The properties of custom symbols can be set by a special group of *CustomSymbolSet* functions, one function for each fundamental type (integer, real, string).

bool CustomSymbolSetInteger(const string name, ENUM_SYMBOL_INFO_INTEGER property, long value)

bool CustomSymbolSetDouble(const string name, ENUM_SYMBOL_INFO_DOUBLE property, double value)

bool CustomSymbolSetString(const string name, ENUM_SYMBOL_INFO_STRING property, string value)

The functions set for a custom symbol named *name* a value of *property* to *value*. All existing properties are grouped into enumerations ENUM_SYMBOL_INFO_INTEGER, ENUM_SYMBOL_INFO_DOUBLE, ENUM_SYMBOL_INFO_STRING, which were considered element by element in the sections of the aforementioned chapter.

The functions return an indication of success (*true*) or error (*false*). One possible problem for errors is that not all properties are allowed to change. When trying to set a read-only property, we get the error CUSTOM_SYMBOL_PROPERTY_WRONG (5307). If you try to write an invalid value to the property, you will get a CUSTOM_SYMBOL_PARAMETER_ERROR (5308) error.

Please note that the minute and tick history of a custom symbol is completely deleted if any of the following properties are changed in the symbol specification:

- SYMBOL_CHART_MODE – price type used to build bars (*Bid* or *Last*)
- SYMBOL_DIGITS – number of decimal places in price values
- SYMBOL_POINT – value of one point
- SYMBOL_TRADE_TICK_SIZE – the value of one tick, the minimum allowable price change
- SYMBOL_TRADE_TICK_VALUE – price change cost per tick (see also SYMBOL_TRADE_TICK_VALUE_PROFIT, SYMBOL_TRADE_TICK_VALUE_LOSS)
- SYMBOL_FORMULA – formula for price calculation

If a custom symbol is calculated by a formula, then after deleting its history, the terminal will automatically try to create a new history using the updated properties. However, for programmatically generated symbols, the MQL program itself must take care of the recalculation.

Editing individual properties is most in demand for modifying custom symbols created earlier (after specifying the third parameter *origin* in the *CustomSymbolCreate* function).

In other cases, changing properties in bulk can cause subtle effects. The point is that properties are internally linked and changing one of them may require a certain state of other properties in order for the operation to complete successfully. Moreover, setting some properties leads to automatic changes in others.

In the simplest example, after setting the SYMBOL_DIGITS property, you will find that the SYMBOL_POINT property has changed as well. Here is the less obvious case: assigning SYMBOL_CURRENCY_MARGIN or SYMBOL_CURRENCY_PROFIT has no effect on Forex symbols, since the system assumes currency names to occupy the first 3 and next 3 letters of the name ("XXXYYY[suffix]"), respectively. Please note that immediately after the creation of an "empty" symbol, it is by default considered a Forex symbol, and therefore these properties cannot be set for it without first changing the market.

When copying or setting symbol properties, be aware that the platform implies some specifics. In particular, the property SYMBOL_TRADE_CALC_MODE has a default value of 0 (immediately after the symbol is created, but before any property is set), while 0 in the ENUM_SYMBOL_CALC_MODE enumeration corresponds to the SYMBOL_CALC_MODE_FOREX member. At the same time, special naming rules are implied for Forex symbols in the form XXXYYY (where XXX and YYY are currency codes) plus an optional suffix. Therefore, if you do not change SYMBOL_TRADE_CALC_MODE to another required mode in advance, substrings of the specified symbol name (the first and second triple of symbols) will automatically fall into the properties of the base currency (SYMBOL_CURRENCY_BASE) and profit currency (SYMBOL_CURRENCY_PROFIT). For example, if you specify the name "Dummy", it will be split into 2 pseudo-currencies "Dum" and "my".

Another nuance is that before setting the value of SYMBOL_POINT with an accuracy of N decimal places, you need to ensure that SYMBOL_DIGITS is at least N.

The book comes with the script *CustomSymbolProperties.mq5*, which allows you to experiment with creating copies of the symbol of the current chart and study the resulting effects in practice. In particular, you can choose the name of the symbol, its path, and the direction of bypassing (setting) all supported properties, direct or reverse in terms of property numbering in the language. The script uses a special class *CustomSymbolMonitor*, which is a wrapper for the above built-in functions: we will describe it *later*.

7.2.3 Setting margin rates

Previously, we studied the *SymbolInfoMarginRate* function, which returns the margin rates per symbol set by the broker. For a custom symbol, we are free to set these rates using the function *CustomSymbolSetMarginRate*.

bool CustomSymbolSetMarginRate(const string name, ENUM_ORDER_TYPE orderType, double initial, double maintenance)

The function sets margin rates depending on the type and direction of the order (according to the *orderType* value from the ENUM_ORDER_TYPE enumeration). The rates for calculating the initial and maintenance margin (collateral for each lot of an opened or existing position) are transmitted, respectively, in the *initial* and *maintenance* parameters.

The final margin amounts are determined based on several symbol properties (SYMBOL_TRADE_CALC_MODE, SYMBOL_MARGIN_INITIAL, SYMBOL_MARGIN_MAINTENANCE, and

others) described in the section Margin requirements, so they should also be set on the custom symbol if needed.

The function will return an indicator of success (*true*) or error (*false*).

With the help of this function and the properties related to margin calculation, you can emulate trading conditions of servers that are unavailable for one reason or another, and debug your MQL programs in the tester.

7.2.4 Configuring quoting and trading sessions

Two API functions allow setting quoting and trading sessions of a custom instrument. These two concepts were discussed in the section Schedules of trading and quoting sessions.

```
bool CustomSymbolSetSessionQuote(const string name, ENUM_DAY_OF_WEEK dayOfWeek,
   uint sessionIndex, datetime from, datetime to)

bool CustomSymbolSetSessionTrade(const string name, ENUM_DAY_OF_WEEK dayOfWeek,
   uint sessionIndex, datetime from, datetime to)
```

CustomSymbolSetSessionQuote sets the start and end time of the quoting session specified by number (*sessionIndex*) for a specific day of the week (*dayOfWeek*). *CustomSymbolSetSessionTrade* does the same for trading sessions.

Session numbering starts from 0.

Sessions can only be added sequentially, that is, a session with index 1 can only be added if there already exists a session with index 0. If this rule is violated, a new session will not be created, and the function will return *false*.

Date values in the *from* and *to* parameters are measured in seconds, and *from* should be less than *to*. The range is limited to two days, from 0 (00 hours 00 minutes 00 seconds) to 172800 (23 hours 59 minutes 59 seconds the next day). The day change was required in order to be able to specify sessions that begin before midnight and end after midnight. This situation often occurs when the exchange is located on the other side of the world relative to the broker (dealer) servers.

If zero start and end parameters (*from = 0* and *to = 0*) are passed for the *sessionIndex* session, then it is deleted, and the numbering of the next sessions (if any) is shifted down.

Trading sessions cannot go beyond quoting ones.

For example, we can create a copy of an instrument for a different time zone by shifting the intraday quote time and session schedule for debugging the robot in different conditions, like with any exotic brokers.

7.2.5 Adding, replacing, and deleting quotes

A custom symbol is populated quotes by two built-in functions: *CustomRatesUpdate* and *CustomRatesReplace*. At the input, in addition to the name of the symbol, both expect an array of structures *MqlRates* for the M1 timeframe (higher timeframes are completed automatically from M1). *CustomRatesReplace* has an additional pair of parameters (*from* and *to*) that define the time range to which history editing is limited.

int CustomRatesUpdate(const string symbol, const MqlRates &rates[], uint count = WHOLE_ARRAY)

int CustomRatesReplace(const string symbol, datetime from, datetime to, const MqlRates &rates[], uint count = WHOLE_ARRAY)

CustomRatesUpdate adds missing bars to the history and replaces existing matching bars with data from the array.

CustomRatesReplace completely replaces the history in the specified time interval with the data from the array.

The difference between the functions is due to different scenarios of the intended application. The differences are listed in more detail in the following table.

CustomRatesUpdate	**CustomRatesReplace**
Applies the elements of the passed MqlRates array to the history, regardless of their timestamps	Applies only those elements of the passed MqlRates array that fall within the specified range
Leaves untouched in the history those M1 bars that were already there before the function call and do not coincide in time with the bars in the array	Leaves untouched all history out of range
Replaces existing history bars with the bars from the array when timestamps match	Completely deletes existing history bars in the specified range
Inserts elements from the array as "new" bars if there are no matches with the old bars	Inserts the bars from the array that fall within the relevant range into the specified history range

Data in the *rates* array must be represented by valid OHLC prices, and bar opening times must not contain seconds.

An interval within *from* and *to* is set inclusive: *from* is equal to the time of the first bar to be processed and *to* is equal to the time of the last.

The following diagram illustrates these rules more clearly. Each unique timestamp for a bar is designated by its own Latin letter. Available bars in the history are shown in capital letters, while bars in the array are shown in lowercase. The character '-' is a gap in the history or in the array for the corresponding time.

```
History                       ABC-EFGHIJKLMN-PQRST------    B
Array                         -------hijk--nopqrstuvwxyz    A
Result of CustomRatesUpdate   ABC-EFGhijkLMnopqrstuvwxyz    R
Result of CustomRatesReplace  ABC-E--hijk--nopqrstuvw---    S
                                   ^               ^
                                   |from         to|    TIME
```

The optional parameter *count* sets the number of elements in the *rates* array that should be used (others will be ignored). This allows you to partially process the passed array. The default value WHOLE_ARRAY means the entire array.

The quotes history of a custom symbol can be deleted entirely or partially using the *CustomRatesDelete* function.

int CustomRatesDelete(const string symbol, datetime from, datetime to)

Here, the parameters *from* and *to* also set the time range of removed bars. To cover the entire history, specify 0 and LONG_MAX.

All three functions return the number of processed bars: updated or deleted. In case of an error, the result is -1.

It should be noted that quotes of a custom symbol can be formed not only by adding ready-made bars but also by arrays of ticks or even a sequence of individual ticks. The relevant functions will be presented in the next section. When adding ticks, the terminal will automatically calculate bars based on them. The difference between these methods is that the custom tick history allows you to test MQL programs in the "real" ticks mode, while the history of bars only will force you to either limit yourself to the OHLC M1 or open price modes or rely on the tick emulation implemented by the tester.

In addition, adding ticks one at a time allows you to simulate standard events *OnTick* and *OnCalculate* on the chart of a custom symbol, which "animates" the chart similar to tools available online, and launches the corresponding handler functions in MQL programs if they are plotted on the chart. But we will talk about this in the next section.

As an example of using new functions, let's consider the script *CustomSymbolRandomRates.mq5*. It is designed to generate random quotes on the principle of "random walk" or noise existing quotes. The latter can be used to assess the stability of an Expert Advisor.

To check the correctness of the formation of quotes, we will also support the mode in which a complete copy of the original instrument is created, on the chart of which the script was launched.

All modes are collected in the RANDOMIZATION enumeration.

```
enum RANDOMIZATION
{
   ORIGINAL,
   RANDOM_WALK,
   FUZZY_WEAK,
   FUZZY_STRONG,
};
```

We implement quotes noise with two levels of intensity: weak and strong.

In the input parameters, you can choose, in addition to the mode, a folder in the symbol hierarchy, a date range, and a number to initialize the random generator (to be able to reproduce the results).

```
input string CustomPath = "MQL5Book\\Part7";    // Custom Symbol Folder
input RANDOMIZATION RandomFactor = RANDOM_WALK;
input datetime _From;                           // From (default: 120 days ago)
input datetime _To;                             // To (default: current time)
input uint RandomSeed = 0;
```

By default, when no dates are specified, the script generates quotes for the last 120 days. The value 0 in the *RandomSeed* parameter means random initialization.

The name of the symbol is generated based on the symbol of the current chart and the selected settings.

```
const string CustomSymbol = _Symbol + "." + EnumToString(RandomFactor)
   + (RandomSeed ? "_" + (string)RandomSeed : "");
```

At the beginning of *OnStart* we will prepare and check the data.

```
datetime From;
datetime To;

void OnStart()
{
   From = _From == 0 ? TimeCurrent() - 60 * 60 * 24 * 120 : _From;
   To = _To == 0 ? TimeCurrent() / 60 * 60 : _To;
   if(From > To)
   {
      Alert("Date range must include From <= To");
      return;
   }

   if(RandomSeed != 0) MathSrand(RandomSeed);
   ...
```

Since the script will most likely need to be run several times, we will provide the ability to delete the custom symbol created earlier, with a preliminary confirmation request from the user.

```
   bool custom = false;
   if(PRTF(SymbolExist(CustomSymbol, custom)) && custom)
   {
      if(IDYES == MessageBox(StringFormat("Delete custom symbol '%s'?", CustomSymbol)
         "Please, confirm", MB_YESNO))
      {
         if(CloseChartsForSymbol(CustomSymbol))
         {
            Sleep(500); // wait for the changes to take effect (opportunistically)
            PRTF(CustomRatesDelete(CustomSymbol, 0, LONG_MAX));
            PRTF(SymbolSelect(CustomSymbol, false));
            PRTF(CustomSymbolDelete(CustomSymbol));
         }
      }
   }
   ...
```

The helper function *CloseChartsForSymbol* is not shown here (those who wish can look at the attached source code): its purpose is to view the list of open charts and close those where the working symbol is the custom symbol being deleted (without this, the deletion will not work).

More important is to pay attention to calling *CustomRatesDelete* with a full range of dates. If it is not done, the data of the previous user symbol will remain on the disk for a while in the history database (folder *bases/Custom/history/<symbol-name>*). In other words, the *CustomSymbolDelete* call, which is shown in the last line above, is not enough to actually clear the custom symbol from the terminal.

If the user decides to immediately create a symbol with the same name again (and we provide such an opportunity in the code below), then the old quotes can be mixed into the new ones.

Further, upon the user's confirmation, the process of generating quotes is launched. This is done by the *GenerateQuotes* function (see further).

```
   if(IDYES == MessageBox(StringFormat("Create new custom symbol '%s'?", CustomSymbol
      "Please, confirm", MB_YESNO))
   {
      if(PRTF(CustomSymbolCreate(CustomSymbol, CustomPath, _Symbol)))
      {
         if(RandomFactor == RANDOM_WALK)
         {
            CustomSymbolSetInteger(CustomSymbol, SYMBOL_DIGITS, 8);
         }

         CustomSymbolSetString(CustomSymbol, SYMBOL_DESCRIPTION, "Randomized quotes")

         const int n = GenerateQuotes();
         Print("Bars M1 generated: ", n);
         if(n > 0)
         {
            SymbolSelect(CustomSymbol, true);
            ChartOpen(CustomSymbol, PERIOD_M1);
         }
      }
   }
```

If successful, the newly created symbol is selected in *Market Watch* and a chart opens for it. Along the way, setting a pair of properties is demonstrated here: SYMBOL_DIGITS and SYMBOL_DESCRIPTION.

In the function *GenerateQuotes* it is required to request quotes of the original symbol for all modes except RANDOM_WALK.

```
int GenerateQuotes()
{
   MqlRates rates[];
   MqlRates zero = {};
   datetime start;     // time of the current bar
   double price;       // last closing price

   if(RandomFactor != RANDOM_WALK)
   {
      if(PRTF(CopyRates(_Symbol, PERIOD_M1, From, To, rates)) <= 0)
      {
         return 0; // error
      }
      if(RandomFactor == ORIGINAL)
      {
         return PRTF(CustomRatesReplace(CustomSymbol, From, To, rates));
      }
      ...
```

It is important to recall that *CopyRates* is affected by the limit on the number of bars on the chart, which is set in the terminal settings, affects.

In the case of ORIGINAL mode, we simply forward the resulting array *rates* into the *CustomRatesReplace* function. For noise modes, we set the specially selected *price* and *start* variables to the initial values of price and time from the first bar.

```
      price = rates[0].open;
      start = rates[0].time;
   }
   ...
```

In random walk mode, quotes are not needed, so we just allocate the *rates* array for future random M1 bars.

```
   else
   {
      ArrayResize(rates, (int)((To - From) / 60) + 1);
      price = 1.0;
      start = From;
   }
   ...
```

Further in the loop through the *rates* array, random values are added either to the noisy prices of the original symbol or "as is". In the RANDOM_WALK mode, we ourselves are responsible for increasing the time in the variable *start*. In other modes, the time is already in the initial quotes.

```
      const int size = ArraySize(rates);

      double hlc[3]; // future High Low Close (in unknown order)
      for(int i = 0; i < size; ++i)
      {
         if(RandomFactor == RANDOM_WALK)
         {
            rates[i] = zero;             // zeroing the structure
            rates[i].time = start += 60; // plus a minute to the last bar
            rates[i].open = price;       // start from the last price
            hlc[0] = RandomWalk(price);
            hlc[1] = RandomWalk(price);
            hlc[2] = RandomWalk(price);
         }
         else
         {
            double delta = 0;
            if(i > 0)
            {
               delta = rates[i].open - price; // cumulative correction
            }
            rates[i].open = price;
            hlc[0] = RandomWalk(rates[i].high - delta);
            hlc[1] = RandomWalk(rates[i].low - delta);
            hlc[2] = RandomWalk(rates[i].close - delta);
         }
         ArraySort(hlc);

         rates[i].high = fmax(hlc[2], rates[i].open);
         rates[i].low = fmin(hlc[0], rates[i].open);
         rates[i].close = price = hlc[1];
         rates[i].tick_volume = 4;
      }
      ...
```

Based on the closing price of the last bar, 3 random values are generated (using the *RandomWalk* function). The maximum and minimum of them become, respectively, the prices *High* and *Low* of a new bar. The average is the price *Close*.

At the end of the loop, we pass the array to *CustomRatesReplace*.

```
      return PRTF(CustomRatesReplace(CustomSymbol, From, To, rates));
   }
```

In the *RandomWalk* function, an attempt was made to simulate a distribution with wide tails, which is typical for real quotes.

```
double RandomWalk(const double p)
{
   const static double factor[] = {0.0, 0.1, 0.01, 0.05};
   const static double f = factor[RandomFactor] / 100;
   const double r = (rand() - 16383.0) / 16384.0; // [-1,+1]
   const int sign = r >= 0 ? +1 : -1;
   if(r != 0)
   {
      return p + p * sign * f * sqrt(-log(sqrt(fabs(r))));
   }
   return p;
}
```

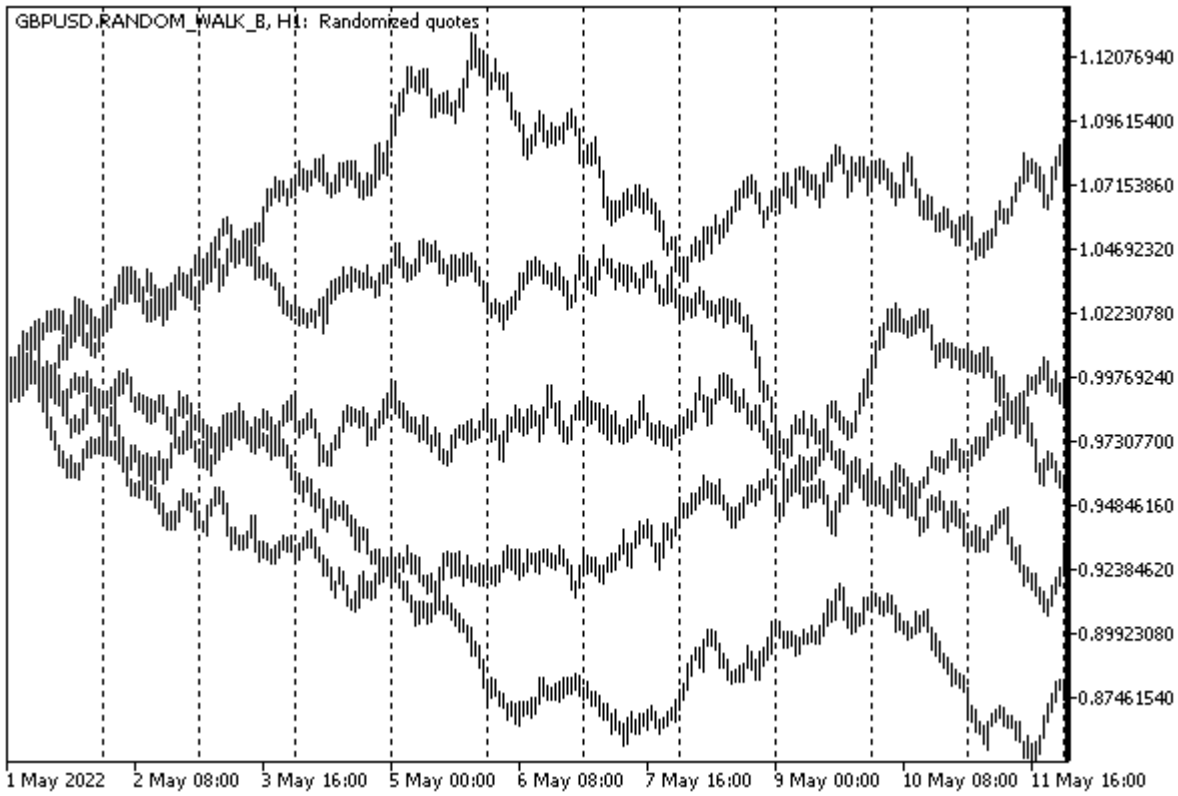
The scatter coefficients of random variables depend on the mode. For example, weak noise adds (or subtracts) a maximum of 1 hundredth of a percent, and strong noise adds 5 hundredths of a percent of the price.

While running, the script outputs a detailed log like this one:

```
Create new custom symbol 'GBPUSD.RANDOM_WALK'?
CustomSymbolCreate(CustomSymbol,CustomPath,_Symbol)=true / ok
CustomRatesReplace(CustomSymbol,From,To,rates)=171416 / ok
Bars M1 generated: 171416
```

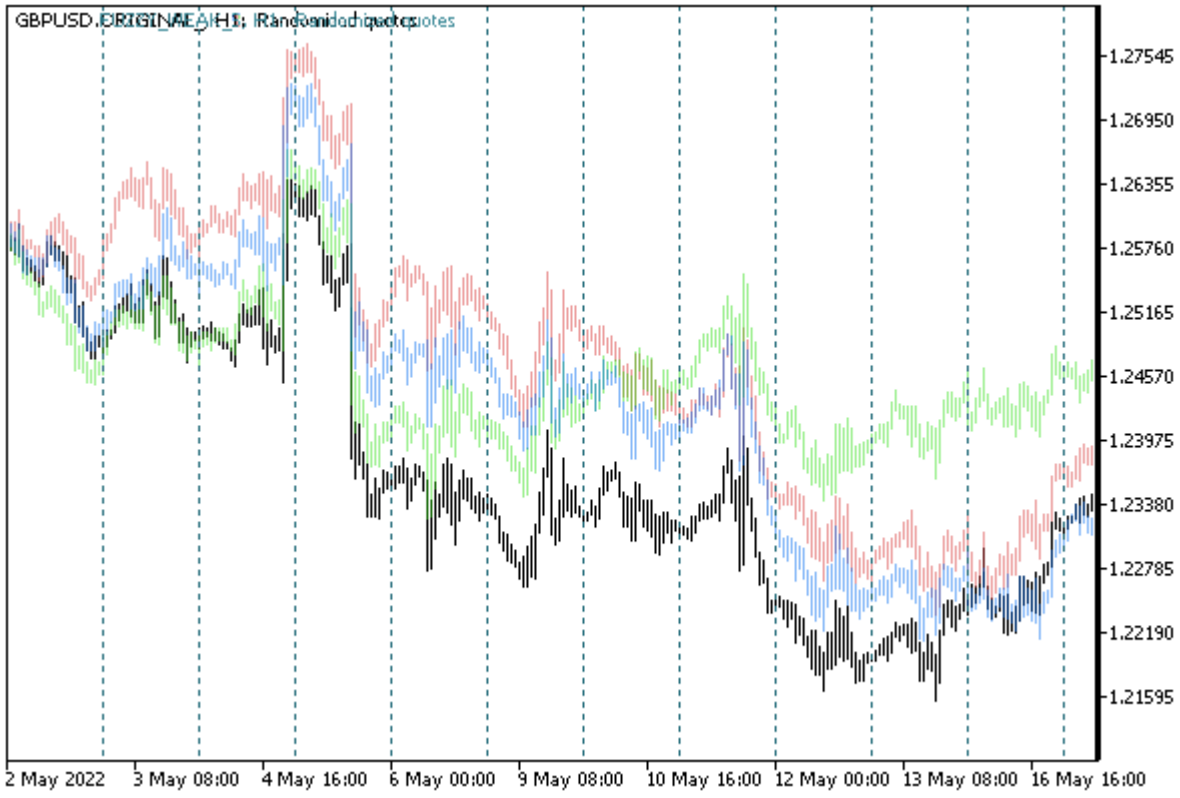
Let's see what we get as a result.

The following image shows several implementations of a random walk (the visual overlay is done in a graphical editor, in reality, each custom symbol opens in a separate window as usual).



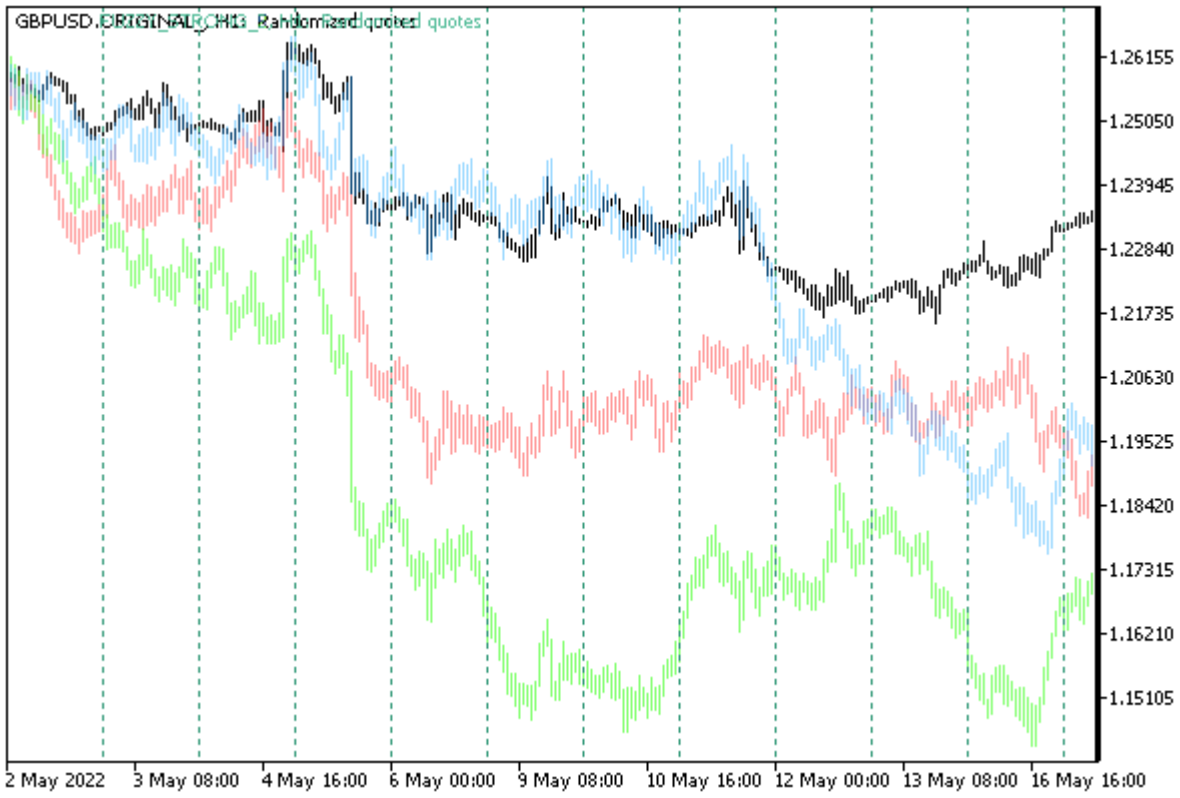
Quote options for custom symbols with random walk

And here is how noisy GBPUSD quotes look like (original in black, color with noise). First, in a weak version.



GBPUSD quotes with low noise

And then with strong noise.



GBPUSD quotes with strong noise

Larger discrepancies are obvious, though with the preservation of local features.

7.2.6 Adding, replacing, and removing ticks

The MQL5 API allows you to generate the history of a custom symbol not only at the bar level but also at the tick level. Thus, it is possible to achieve greater realism when testing and optimizing Expert Advisors, as well as to emulate real-time updating of charts of custom symbols, broadcasting your ticks to them. The set of ticks transferred to the system is automatically taken into account when forming bars. In other words, there is no need to call the functions from the previous section that operate on structures *MqlRates*, if more detailed information about price changes for the same period is provided in the form of ticks, namely the *MqlTick* arrays of structures. The only advantage of per-bar *MqlRates* quotes is the performance and memory efficiency.

There are two functions for adding ticks: *CustomTicksAdd* and *CustomTicksReplace*. The first one adds interactive ticks that arrive at the *Market Watch* window (from which they are automatically transferred by the terminal to the tick database) and that generate corresponding events in MQL programs. The second one writes ticks directly to the tick database.

int CustomTicksAdd(const string symbol, const MqlTick &ticks[], uint count = WHOLE_ARRAY)

The *CustomTicksAdd* function adds data from the *ticks* array to the price history of a custom symbol specified in *symbol*. By default, if the *count* setting is equal to WHOLE_ARRAY, the entire array is added. If necessary, you can specify a smaller number and download only a part of the ticks.

Please note that the custom symbol must be selected in the *Market Watch* window by the time of the function call. For symbols not selected in *Market Watch*, you need to use the *CustomTicksReplace* function (see further).

The array of tick data must be sorted by time in ascending order, i.e. it is required that the following conditions are met: *ticks[i].time_msc <= ticks[j].time_msc* for all *i < j*.

The function returns the number of added ticks or -1 in case of an error.

The *CustomTicksAdd* function broadcasts ticks to the chart in the same way as if they came from the broker's server. Usually, the function is applied for one or more ticks. In this case, they are "played" in the *Market Watch* window, from which they are saved in the tick database.

However, when a large amount of data is transferred in one call, the function changes its behavior to save resources. If more than 256 ticks are transmitted, they are divided into two parts. The first part (large) is immediately written directly to the tick database (as does *CustomTicksReplace*). The second part, consisting of the last (most recent) 128 ticks, is passed to the *Market Watch* window, and after that is saved by the terminal in the database.

The *MqlTick* structure has two fields with time values: *time* (tick time in seconds) and *time_msc* (tick time in milliseconds). Both values are dated starting from 01/01/1970. The filled (non-null) *time_msc* field takes precedence over *time*. Note that *time* is filled in seconds as a result of recalculation based on the formula *time_msc / 1000*. If the *time_msc* field is zero, the value from the *time* field is used, and the *time_msc* field in turn gets the value in milliseconds from the formula *time * 1000*. If both fields are equal to zero, the current server time (accurate to milliseconds) is put into a tick.

Of the two fields describing the volume, *volume_real* has a higher priority than *volume*.

Depending on what other fields are filled in a particular array element (structure *MqlTick*), the system sets flags for the saved tick in the *flags* field:

- ticks[i].bid – TICK_FLAG_BID (the tick changed the Bid price)
- ticks[i].ask – TICK_FLAG_ASK (the tick changed the Ask price)
- ticks[i].last – TICK_FLAG_LAST (the tick changed the price of the last trade)
- ticks[i].volume or ticks[i].volume_real – TICK_FLAG_VOLUME (the tick changed volume)

If the value of some field is less than or equal to zero, the corresponding flag is not written to the *flags* field.

The TICK_FLAG_BUY and TICK_FLAG_SELL flags are not added to the history of a custom symbol.

The *CustomTicksReplace* function completely replaces the price history of the custom symbol in the specified time interval with the data from the passed array.

```
int CustomTicksReplace(const string symbol, long from_msc, long to_msc,
  const MqlTick &ticks[], uint count = WHOLE_ARRAY)
```

The interval is set by the parameters *from_msc* and *to_msc*, in milliseconds since 01/01/1970. Both values are included in the interval.

The array *ticks* must be ordered in chronological order of ticks' arrival, which corresponds to increasing, or rather, non-decreasing time since ticks with the same time often occur in a row in a stream with millisecond accuracy.

The *count* parameter can be used to process a part of the array.

The ticks are replaced sequentially day by day before the time specified in *to_msc*, or until an error occurs in the tick order. The first day in the specified range is processed first, then goes the next day, and so on. As soon as a discrepancy between the tick time and the ascending (non-decreasing) order is detected, the tick replacement process stops on the current day. In this case, the ticks for the previous days will be successfully replaced, while the current day (at the time of the wrong tick) and all remaining days in the specified interval will remain unchanged. The function will return -1, with the error code in *_LastError* being 0 ("no error").

If the *ticks* array does not have data for some period within the general interval between *from_msc* and *to_msc* (inclusive), then after executing the function, the history of the custom symbol will have a gap corresponding to the missing data.

If there is no data in the tick database in the specified time interval, *CustomTicksReplace* will add ticks to it from the array *ticks*.

The *CustomTicksDelete* function can be used to delete all ticks in the specified time interval.

```
int CustomTicksDelete(const string symbol, long from_msc, long to_msc)
```

The name of the custom symbol being edited is set in the *symbol* parameter, and the interval to be cleared is set by the parameters *from_msc* and *to_msc* (inclusive), in milliseconds.

The function returns the number of ticks removed or -1 in case of an error.

> Attention! Deleting ticks with *CustomTicksDelete* leads to the automatic removal of the corresponding bars! However, calling *CustomRatesDelete*, i.e., removing bars, does not remove ticks!

To master the material in practice, we will solve several applied problems using the newly considered functions.

To begin with, let's touch on such an interesting task as creating a custom symbol based on a real symbol but with a reduced tick density. This will speed up testing and optimization, as well as reduce resource consumption (primarily RAM) compared to the mode based on real ticks while maintaining an acceptable, close to ideal, quality of the process.

Speeding up testing and optimization

Traders often seek ways to speed up Expert Advisor optimization and testing processes. Among the possible solutions, there are obvious ones, for which you can simply change the settings (when it is allowed), and there are more time-consuming ones that require the adaptation of an Expert Advisor or a test environment.

Among the first type of solutions are:

· Reducing the optimization space by eliminating some parameters or reducing their step;
· Reducing the optimization period;
· Switching to the tick simulation mode of lower quality (for example, from real ones to OHLC M1);
· Enabling profit calculation in points instead of money;
· Upgrading the computer;
· Using MQL Cloud or additional local network computers.

Among the second type of development-related solutions are:

· Code profiling, on the basis of which you can eliminate "bottlenecks" in the code;
· If possible, use the resource-efficient calculation of indicators, that is, without the *#property tester_everytick_calculate* directive;
· Transferring indicator algorithms (if they are used) directly into the Expert Advisor code: indicator calls impose certain overhead costs;
· Eliminating graphics and objects;
· Caching calculations, if possible;
· Reducing the number of simultaneously open positions and placed orders (their calculation on each tick can become noticeable with a large number);
· Full virtualization of settlements, orders, deals, and positions: the built-in accounting mechanism, due to its versatility, multicurrency support, and other features, has its own overheads, which can be eliminated by performing similar actions in the MQL5 code (although this option is the most time-consuming).

Tick density reduction belongs to an intermediate type of solution: it requires the programmatic creation of a custom symbol but does not affect the source code of the Expert Advisor.

A custom symbol with reduced ticks will be generated by the script *CustomSymbolFilterTicks.mq5*. The initial instrument will be the working symbol of the chart on which the script is launched. In the input parameters, you can specify the folder for the custom symbol and the start date for history processing. By default, if no date is given, the calculation is made for the last 120 days.

```
input string CustomPath = "MQL5Book\\Part7"; // Custom Symbol Folder
input datetime _Start;                       // Start (default: 120 days back)
```

The name of the symbol is formed from the name of the source instrument and the ".TckFltr" suffix. Later we will add to it the designation of the tick reducing method.

```
string CustomSymbol = _Symbol + ".TckFltr";
const uint DailySeconds = 60 * 60 * 24;
datetime Start = _Start == 0 ? TimeCurrent() - DailySeconds * 120 : _Start;
```

For convenience, in the *OnStart* handler, it is possible to delete a previous copy of a symbol if it already exists.

```
void OnStart()
{
   bool custom = false;
   if(PRTF(SymbolExist(CustomSymbol, custom)) && custom)
   {
      if(IDYES == MessageBox(StringFormat("Delete existing custom symbol '%s'?", Cust
         "Please, confirm", MB_YESNO))
      {
         SymbolSelect(CustomSymbol, false);
         CustomRatesDelete(CustomSymbol, 0, LONG_MAX);
         CustomTicksDelete(CustomSymbol, 0, LONG_MAX);
         CustomSymbolDelete(CustomSymbol);
      }
      else
      {
         return;
      }
   }
```

Next, upon the consent of the user, a symbol is created. The history is filled with tick data in the auxiliary function *GenerateTickData*. If successful, the script adds a new symbol to *Market Watch* and opens the chart.

```
   if(IDYES == MessageBox(StringFormat("Create new custom symbol '%s'?", CustomSymbol
      "Please, confirm", MB_YESNO))
   {
      if(PRTF(CustomSymbolCreate(CustomSymbol, CustomPath, _Symbol)))
      {
         CustomSymbolSetString(CustomSymbol, SYMBOL_DESCRIPTION, "Prunned ticks by "
         if(GenerateTickData())
         {
            SymbolSelect(CustomSymbol, true);
            ChartOpen(CustomSymbol, PERIOD_H1);
         }
      }
   }
}
```

The *GenerateTickData* function processes ticks in a loop in portions, per day. Ticks per day are requested by calling *CopyTicksRange*. Then they need to be reduced in one way or another, which is implemented by the *TickFilter* class which we will show below. Finally, the tick array is added to the custom symbol history using *CustomTicksReplace*.

```
bool GenerateTickData()
{
   bool result = true;
   datetime from = Start / DailySeconds * DailySeconds; // round up to the beginning
   ulong read = 0, written = 0;
   uint day = 0;
   const uint total = (uint)((TimeCurrent() - from) / DailySeconds + 1);
   MqlTick array[];

   while(!IsStopped() && from < TimeCurrent())
   {
      Comment(TimeToString(from, TIME_DATE), " ", day++, "/", total);

      const int r = CopyTicksRange(_Symbol, array, COPY_TICKS_ALL,
         from * 1000L, (from + DailySeconds) * 1000L - 1);
      if(r < 0)
      {
         Alert("Error reading ticks at ", TimeToString(from, TIME_DATE));
         result = false;
         break;
      }
      read += r;

      if(r > 0)
      {
         const int t = TickFilter::filter(Mode, array);
         const int w = CustomTicksReplace(CustomSymbol,
            from * 1000L, (from + DailySeconds) * 1000L - 1, array);
         if(w <= 0)
         {
            Alert("Error writing custom ticks at ", TimeToString(from, TIME_DATE));
            result = false;
            break;
         }
         written += w;
      }
      from += DailySeconds;
   }

   if(read > 0)
   {
      PrintFormat("Done ticks - read: %lld, written: %lld, ratio: %.1f%%",
         read, written, written * 100.0 / read);
   }
   Comment("");
   return result;
}
```

Error control and counting of processed ticks are implemented at all stages. It the end, we output to the log the number of initial and remaining ticks, as well as the "compression" factor.

Now let's turn directly to the tick reducing technique. Obviously, there can be many approaches, with each of them being better or worse suited to a specific trading strategy. We will offer 3 basic versions combined in the class *TickFilter* (*TickFilter.mqh*). Also, to complete the picture, the mode of copying ticks without reduction is also supported.

Thus, the following modes are implemented in the class:

- No reduction
- Skipping sequences of ticks with a monotonous price change without a reversal (a la "zig-zag")
- Skipping price fluctuations within the spread
- Recording only ticks with a fractal configuration when the *Bid* or *Ask* price represents an extremum between two adjacent ticks

These modes are described as elements of the FILTER_MODE enumeration.

```
class TickFilter
{
public:
   enum FILTER_MODE
   {
      NONE,
      SEQUENCE,
      FLUTTER,
      FRACTALS,
   };
   ...
```

Each of the modes is implemented by a separate static method that accepts as input an array of ticks that needs to be thinned out. Editing an array is performed in place (without allocating a new output array).

```
   static int filterBySequences(MqlTick &data[]);
   static int filterBySpreadFlutter(MqlTick &data[]);
   static int filterByFractals(MqlTick &data[]);
```

All methods return the number of ticks left (reduced array size).

To unify the execution of the procedure in different modes, the *filter* method is provided. For the mode NONE the *data* array stays the same.

```
   static int filter(FILTER_MODE mode, MqlTick &data[])
   {
      switch(mode)
      {
      case SEQUENCE: return filterBySequences(data);
      case FLUTTER: return filterBySpreadFlutter(data);
      case FRACTALS: return filterByFractals(data);
      }
      return ArraySize(data);
   }
```

For example, here is how filtering by monotonous sequences of ticks is implemented in the *filterBySequences* method.

```
static int filterBySequences(MqlTick &data[])
{
   const int size = ArraySize(data);
   if(size < 3) return size;

   int index = 2;
   bool dirUp = data[1].bid - data[0].bid + data[1].ask - data[0].ask > 0;

   for(int i = 2; i < size; i++)
   {
      if(dirUp)
      {
         if(data[i].bid - data[i - 1].bid + data[i].ask - data[i - 1].ask < 0)
         {
            dirUp = false;
            data[index++] = data[i];
         }
      }
      else
      {
         if(data[i].bid - data[i - 1].bid + data[i].ask - data[i - 1].ask > 0)
         {
            dirUp = true;
            data[index++] = data[i];
         }
      }
   }
   return ArrayResize(data, index);
}
```

And here is what fractal thinning looks like.

```
static int filterByFractals(MqlTick &data[])
{
   int index = 1;
   const int size = ArraySize(data);
   if(size < 3) return size;

   for(int i = 1; i < size - 2; i++)
   {
      if((data[i].bid < data[i - 1].bid && data[i].bid < data[i + 1].bid)
      || (data[i].ask > data[i - 1].ask && data[i].ask > data[i + 1].ask))
      {
         data[index++] = data[i];
      }
   }

   return ArrayResize(data, index);
}
```

Let's sequentially create a custom symbol for EURUSD in several tick density reduction modes and compare their performance, i.e., the degree of "compression", how fast the testing will be, and how the trading performance of the Expert Advisor will change.

For example, thinning out sequences of ticks gives the following results (for a one-and-a-half-year history on MQ Demo).

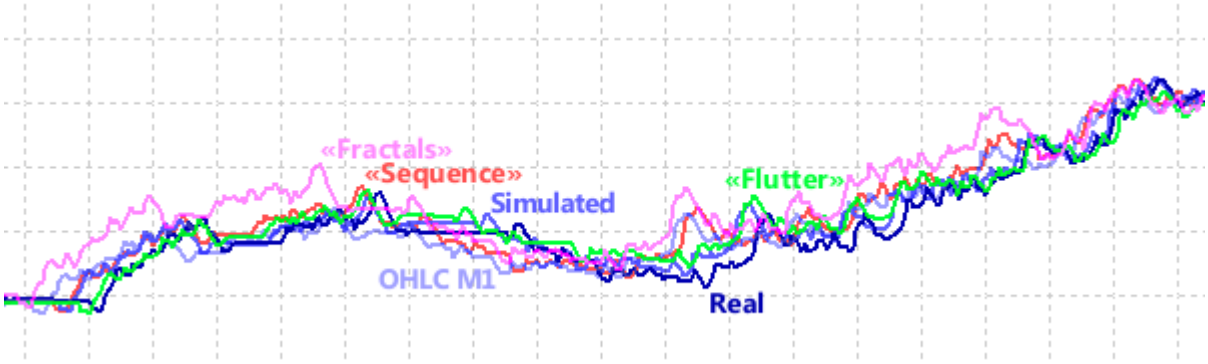
```
Create new custom symbol 'EURUSD.TckFltr-SE'?
Fixing SYMBOL_TRADE_TICK_VALUE: 0.0 <<< 1.0
true  SYMBOL_TRADE_TICK_VALUE 1.0 -> SUCCESS (0)
Fixing SYMBOL_TRADE_TICK_SIZE: 0.0 <<< 1e-05
true  SYMBOL_TRADE_TICK_SIZE 1e-05 -> SUCCESS (0)
Number of found discrepancies: 2
Fixed
Done ticks - read: 31553509, written: 16927376, ratio: 53.6%
```

For modes of smoothing fluctuations and for fractals, the indicators are different:

```
EURUSD.TckFltr-FL will be updated
Done ticks - read: 31568782, written: 22205879, ratio: 70.3%
...
Create new custom symbol 'EURUSD.TckFltr-FR'?
...
Done ticks - read: 31569519, written: 12732777, ratio: 40.3%
```

For practical trading experiments based on compressed ticks, we need an Expert Advisor. Let's take the adapted version of *BandOsMATicks.mq5*, in which, compared to the original, trading on each tick is enabled (in the method *SimpleStrategy::trade* the line*if(lastBar == iTime(_Symbol, _Period, 0)) return false;* is disabled), and the values of signal indicators are taken from bars 0 and 1 (previously there were only completed bars 1 and 2).

Let's run the Expert Advisor using the dates range from the beginning of 2021 to June 1, 2022. The settings are attached in the file *MQL5/Presets/MQL5Book/BandOsMAticks.set*. The general behavior of the balance curve in all modes is quite similar.



Combined charts of test balances in different modes by ticks

The shift of equivalent extremums of different curves horizontally is caused by the fact that the standard report chart uses not the time but the number of trades for the horizontal coordinate, which, of course, differs due to the accuracy of triggering trading signals for different tick bases.

The differences in performance metrics are shown in the following table (N - number of trades, $ - profit, PF - profit factor, RF - recovery factor, DD - drawdown):

Mode	Ticks	Time mm:ss.msec	Memory	N	$	PF	RF	DD
Real	31002919	02:45.251	835 Mb	962	166.24	1.32	2.88	54.99
Emulation	25808139	01:58.131	687 Mb	928	171.94	1.34	3.44	47.64
OHLC M1	2084820	00:11.094	224 Mb	856	193.52	1.39	3.97	46.55
Sequence	16310236	01:24.784	559 Mb	860	168.95	1.34	2.92	55.16
Flutter	21362616	01:52.172	623 Mb	920	179.75	1.37	3.60	47.28
Fractal	12270854	01:04.756	430 Mb	866	142.19	1.27	2.47	54.80

We will consider the test based on real ticks to be the most reliable and evaluate the rest by how close it is to this test. Obviously, the OHLC M1 mode showed the highest speed and lower resource costs due to a significant loss of accuracy (the mode at opening prices was not considered). It exhibits over-optimistic financial results.

Among the three modes with artificially compressed ticks, "Sequence" is the closest to the real one in terms of a set of indicators. It is 2 times faster than the real one in terms of time and is 1.5 times more efficient in terms of memory consumption. The "Flutter" mode seems to better preserve the original number of trades. The fastest and least memory-demanding fractal mode, of course, takes more time and resources than OHLC M1, but it does not overestimate trading scores.

Keep in mind that tick reduction algorithms may work differently or, conversely, give poor results with different trading strategies, financial instruments, and even the tick history of a particular broker. Conduct research with your Expert Advisors and in your work environment.

As part of the second example of working with custom symbols, let's consider an interesting feature provided by tick translation using *CustomTicksAdd*.

Many traders use trading panels – programs with interactive controls for performing arbitrary trading actions manually. You have to practice working with them mainly online because the tester imposes

some restrictions. First of all, the tester does not support on-chart events and objects. This causes the controls to stop functioning. Also, in the tester, you cannot apply arbitrary objects for graphics markup.

Let's try to solve these problems.

We can generate a custom symbol based on historical ticks in slow motion. Then the chart of such a symbol will become an analog of a visual tester.

This approach has several advantages:

- Standard behavior of all chart events
- Interactive application and setting of indicators
- Interactive application and adjustment of objects
- Timeframe switching on the go
- Test on history up to the current time, including today (the standard tester does not allow testing today)

Regarding the last point, we note that the developers of MetaTrader 5 deliberately prohibited checking trading on the last (current) day, although it is sometimes needed to quickly find errors (in the code or in the trading strategy).

It is also potentially interesting to modify prices on the go (increasing the spread, for example).

Based on the chart of such a custom symbol, later we can implement a manual trading emulator on historical data.

The symbol generator will be the non-trading Expert Advisor *CustomTester.mq5*. In its input parameters, we will provide an indication of the placement of a new custom symbol in the symbol hierarchy, the start date in the past for tick translation (and building custom symbol quotes), as well as a timeframe for the chart, which will be automatically opened for visual testing.

```
input string CustomPath = "MQL5Book\\Part7"; // Custom Symbol Folder
input datetime _Start;                       // Start (120-day indent by default)
input ENUM_TIMEFRAMES Timeframe = PERIOD_H1;
```

The name of the new symbol is constructed from the symbol name of the current chart and the ".Tester" suffix.

```
string CustomSymbol = _Symbol + ".Tester";
```

If the start date is not specified in the parameters, the Expert Advisor will indent back by 120 days from the current date.

```
const uint DailySeconds = 60 * 60 * 24;
datetime Start = _Start == 0 ? TimeCurrent() - DailySeconds * 120 : _Start;
```

Ticks will be read from the history of real ticks of the working symbol in batches for the whole day at once. The pointer to the day being read is stored in the *Cursor* variable.

```
bool FirstCopy = true;
// additionally 1 day ago, because otherwise, the chart will not update immediately
datetime Cursor = (Start / DailySeconds - 1) * DailySeconds; // round off at the border c
```

The ticks of one day to be reproduced will be requested in the *Ticks* array, from where they will be translated in small batches of size *step* to the chart of a custom symbol.

```
MqlTick Ticks[];       // ticks for the "current" day in the past
int Index = 0;         // position in ticks within a day
int Step = 32;         // fast forward 32 ticks at a time (default)
int StepRestore = 0;   // remember the speed for the duration of the pause
long Chart = 0;        // created custom symbol chart
bool InitDone = false; // sign of completed initialization
```

To play ticks at a constant rate, let's start the timer in *OnInit*.

```
void OnInit()
{
   EventSetMillisecondTimer(100);
}

void OnTimer()
{
   if(!GenerateData())
   {
      EventKillTimer();
   }
}
```

The ticks will be generated by the *GenerateData* function. Immediately after launching, when the *InitDone* flag is reset, we will try to create a new symbol or clear the old quotes and ticks if the custom symbol already exists.

```
bool GenerateData()
{
   if(!InitDone)
   {
      bool custom = false;
      if(PRTF(SymbolExist(CustomSymbol, custom)) && custom)
      {
         if(IDYES == MessageBox(StringFormat("Clean up existing custom symbol '%s'?",
            CustomSymbol), "Please, confirm", MB_YESNO))
         {
            PRTF(CustomRatesDelete(CustomSymbol, 0, LONG_MAX));
            PRTF(CustomTicksDelete(CustomSymbol, 0, LONG_MAX));
            Sleep(1000);
            MqlRates rates[1];
            MqlTick tcks[];
            if(PRTF(CopyRates(CustomSymbol, PERIOD_M1, 0, 1, rates)) == 1
            || PRTF(CopyTicks(CustomSymbol, tcks) > 0))
            {
               Alert("Can't delete rates and Ticks, internal error");
               ExpertRemove();
            }
         }
         else
         {
            return false;
         }
      }
      else
      if(!PRTF(CustomSymbolCreate(CustomSymbol, CustomPath, _Symbol)))
      {
         return false;
      }
      ... // (A)
```

At this point, we'll omit something at (A) and come back to this point later.

After creating the symbol, we select it in *Market Watch* and open a chart for it.

```
   SymbolSelect(CustomSymbol, true);
      Chart = ChartOpen(CustomSymbol, Timeframe);
      ... // (B)
      ChartSetString(Chart, CHART_COMMENT, "Custom Tester");
      ChartSetInteger(Chart, CHART_SHOW_OBJECT_DESCR, true);
      ChartRedraw(Chart);
      InitDone = true;
   }
   ...
```

A couple of lines (B) are missing here too; they are related to future improvements, but not required yet.

If the symbol has already been created, we start broadcasting ticks in batches of *Step* ticks, but no more than 256. This limitation is related to the specifics of the *CustomTicksAdd* function.

```
   else
   {
      for(int i = 0; i <= (Step - 1) / 256; ++i)
      if(Step > 0 && !GenerateTicks())
      {
         return false;
      }
   }
   return true;
}
```

The helper function *GenerateTicks* broadcasts ticks in batches of *Step* ticks (but not more than 256), reading them from the daily array *Ticks* by offset *Index*. When the array is empty or we have read it to the end, we request the next day's ticks by calling *FillTickBuffer*.

```
bool GenerateTicks()
{
   if(Index >= ArraySize(Ticks)) // daily array is empty or read to the end
   {
      if(!FillTickBuffer()) return false; // fill the array with ticks per day
   }

   const int m = ArraySize(Ticks);
   MqlTick array[];
   const int n = ArrayCopy(array, Ticks, 0, Index, fmin(fmin(Step, 256), m));
   if(n <= 0) return false;

   ResetLastError();
   if(CustomTicksAdd(CustomSymbol, array) != ArraySize(array) || _LastError != 0)
   {
      Print(_LastError); // in case of ERR_CUSTOM_TICKS_WRONG_ORDER (5310)
      ExpertRemove();
   }
   Comment("Speed: ", (string)Step, " / ", STR_TIME_MSC(array[n - 1].time_msc));
   Index += Step; // move forward by 'Step' ticks
   return true;
}
```

The *FillTickBuffer* function uses *CopyTicksRange* for operation.

```
bool FillTickBuffer()
{
   int r;
   ArrayResize(Ticks, 0);
   do
   {
      r = PRTF(CopyTicksRange(_Symbol, Ticks, COPY_TICKS_ALL, Cursor * 1000L,
         (Cursor + DailySeconds) * 1000L - 1));
      if(r > 0 && FirstCopy)
      {
         // NB: this pre-call is only needed to display the chart
        // from "Waiting for update" state
         PRTF(CustomTicksReplace(CustomSymbol, Cursor * 1000L,
            (Cursor + DailySeconds) * 1000L - 1, Ticks));
         FirstCopy = false;
         r = 0;
      }
      Cursor += DailySeconds;
   }
   while(r == 0 && Cursor < TimeCurrent()); // skip non-trading days
   Index = 0;
   return r > 0;
}
```

When the Expert Advisor is stopped, we will also close the dependent chart (so that it is not duplicated at the next start).

```
void OnDeinit(const int)
{
   if(Chart != 0)
   {
      ChartClose(Chart);
   }
   Comment("");
}
```

At this point, the Expert Advisor could be considered complete, but there is a problem. The thing is that, for one reason or another, the properties of a custom symbol are not copied "as is" from the original working symbol, at least in the current implementation of the MQL5 API. This applies even to very important properties, such as SYMBOL_TRADE_TICK_VALUE, SYMBOL_TRADE_TICK_SIZE. If we print the values of these properties immediately after calling *CustomSymbolCreate(CustomSymbol, CustomPath,_Symbol)*, we will see zeros there.

To organize the checking of properties, their comparison and, if necessary, correction, we have written a special class *CustomSymbolMonitor* (*CustomSymbolMonitor.mqh*) derived from *SymbolMonitor*. You can study its internal structure on your own, while here we will only present the public interface.

Constructors allow you to create a custom symbol monitor, specifying an exemplary working symbol (by name in a string, or from The *SymbolMonitor* object) which serves as a source of settings.

```
class CustomSymbolMonitor: public SymbolMonitor
{
public:
   CustomSymbolMonitor(); // sample - _Symbol
   CustomSymbolMonitor(const string s, const SymbolMonitor *m = NULL);
   CustomSymbolMonitor(const string s, const string other);

   //set/replace sample symbol
   void inherit(const SymbolMonitor &m);

   // copy all properties from the sample symbol in forward or reverse order
   bool setAll(const bool reverseOrder = true, const int limit = UCHAR_MAX);

   // check all properties against the sample, return the number of corrections
   int verifyAll(const int limit = UCHAR_MAX);

   // check the specified properties with the sample, return the number of correction
   int verify(const int &properties[]);

   // copy the given properties from the sample, return true if they all applied
   bool set(const int &properties[]);

   // copy the specific property from the sample, return true if applied
   template<typename E>
   bool set(const E e);

   bool set(const ENUM_SYMBOL_INFO_INTEGER property, const long value) const
   {
      return CustomSymbolSetInteger(name, property, value);
   }

   bool set(const ENUM_SYMBOL_INFO_DOUBLE property, const double value) const
   {
      return CustomSymbolSetDouble(name, property, value);
   }

   bool set(const ENUM_SYMBOL_INFO_STRING property, const string value) const
   {
      return CustomSymbolSetString(name, property, value);
   }
};
```

Since custom symbols, unlike standard symbols, allow you to set your own properties, a triple of *set* methods has been added to the class. In particular, they are used to batch transfer the properties of a sample and check the success of these actions in other class methods.

We can now return to the custom symbol generator and its source code snippet, as indicated earlier by the comment (A).

```
   // (A) check important properties and set them in "manual" mode
   SymbolMonitor sm; // _Symbol
   CustomSymbolMonitor csm(CustomSymbol, &sm);
   int props[] = {SYMBOL_TRADE_TICK_VALUE, SYMBOL_TRADE_TICK_SIZE};
   const int d1 = csm.verify(props); // check and try to fix
   if(d1)
   {
      Print("Number of found discrepancies: ", d1); // number of edits
      if(csm.verify(props)) // check again
      {
         Alert("Custom symbol can not be created, internal error!");
         return false; // symbol cannot be used without successful edits
      }
      Print("Fixed");
   }
```

Now you can run the *CustomTester.mq5* Expert Advisor and observe how quotes are dynamically formed in the automatically opened chart as well as how ticks are forwarded from history in the *Market Watch* window.

However, this is done at a constant rate of 32 ticks per 0.1 second. It is desirable to change the playback speed on the go at the request of the user, both up and down. Such control can be organized, for example, from the keyboard.

Therefore, you need to add the *OnChartEvent* handler. As we know, for the CHARTEVENT_KEYDOWN event, the program receives the code of the pressed key in the *lparam* parameter, and we pass it to the *CheckKeys* function (see below). A fragment (C), closely related to (B), had to be postponed for the time being and we will return to it shortly.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   ... // (C)
   if(id == CHARTEVENT_KEYDOWN) // these events only arrive while the chart is active
   {
      CheckKeys(lparam);
   }
}
```

In the *CheckKeys* function, we are processing the "up arrow" and "down arrow" keys to increase and decrease the playback speed. In addition, the "pause" key allows you to completely suspend the process of "testing" (transmission of ticks). Pressing "pause" again resumes work at the same speed.

```
void CheckKeys(const long key)
{
   if(key == VK_DOWN)
   {
      Step /= 2;
      if(Step > 0)
      {
         Print("Slow down: ", Step);
         ChartSetString(Chart, CHART_COMMENT, "Speed: " + (string)Step);
      }
      else
      {
         Print("Paused");
         ChartSetString(Chart, CHART_COMMENT, "Paused");
         ChartRedraw(Chart);
      }
   }
   else if(key == VK_UP)
   {
      if(Step == 0)
      {
         Step = 1;
         Print("Resumed");
         ChartSetString(Chart, CHART_COMMENT, "Resumed");
      }
      else
      {
         Step *= 2;
         Print("Speed up: ", Step);
         ChartSetString(Chart, CHART_COMMENT, "Speed: " + (string)Step);
      }
   }
   else if(key == VK_PAUSE)
   {
      if(Step > 0)
      {
         StepRestore = Step;
         Step = 0;
         Print("Paused");
         ChartSetString(Chart, CHART_COMMENT, "Paused");
         ChartRedraw(Chart);
      }
      else
      {
         Step = StepRestore;
         Print("Resumed");
         ChartSetString(Chart, CHART_COMMENT, "Speed: " + (string)Step);
      }
   }
}
```

The new code can be tested in action after first making sure that the chart on which the Expert Advisor works is active. Recall that keyboard events only go to the active window. This is another problem of our tester.

Since the user must perform trading actions on the custom symbol chart, the generator window will almost always be in the background. Switching to the generator window to temporarily stop the flow of ticks and then resume it is not practical. Therefore, it is required in some way to organize interactive control from the keyboard directly from the custom symbol window.

For this purpose, a special indicator is suitable, which we can automatically add to the custom symbol window that opens. The indicator will intercept keyboard events in its own window (window with a custom symbol) and send them to the generator window.

The source code of the indicator is attached in the file *KeyboardSpy.mq5*. Of course, the indicator does not have charts. A pair of input parameters is dedicated to getting the chart ID *HostID*, where messages should be send and custom event code *EventID*, in which interactive events will be packed.

```
#property indicator_chart_window
#property indicator_plots 0

input long HostID;
input ushort EventID;
```

The main work is done in the *OnChartEvent* handler.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      EventChartCustom(HostID, EventID, lparam,
         // this is always 0 when inside iCustom
         (double)(ushort)TerminalInfoInteger(TERMINAL_KEYSTATE_CONTROL),
         sparam);
   }
}
```

Note that all of the "hotkeys" we have chosen are simple, that is, they do not use shortcuts with keyboard status keys, such as *Ctrl* or *Shift*. This was done by force because inside the indicators created programmatically (in particular, through *iCustom*), the keyboard state is not read. In other words, calling *TerminalInfoInteger(TERMINAL_KEYSTATE_XYZ)* always returns 0. In the handler above, we've added it just for demonstration purposes, so that you can verify this limitation if you wish, by displaying the incoming parameters on the "receiving side".

However, single arrow and pause clicks will be transferred to the parent chart normally, and that's enough for us. The only thing left to do is to integrate the indicator with the Expert Advisor.

In the previously skipped fragment (B), during the initialization of the generator, we will create an indicator and add it to the custom symbol chart.

```
#define EVENT_KEY 0xDED // custom event
      ...
      // (B)
      const int handle = iCustom(CustomSymbol, Timeframe, "MQL5Book/p7/KeyboardSpy",
         ChartID(), EVENT_KEY);
      ChartIndicatorAdd(Chart, 0, handle);
```

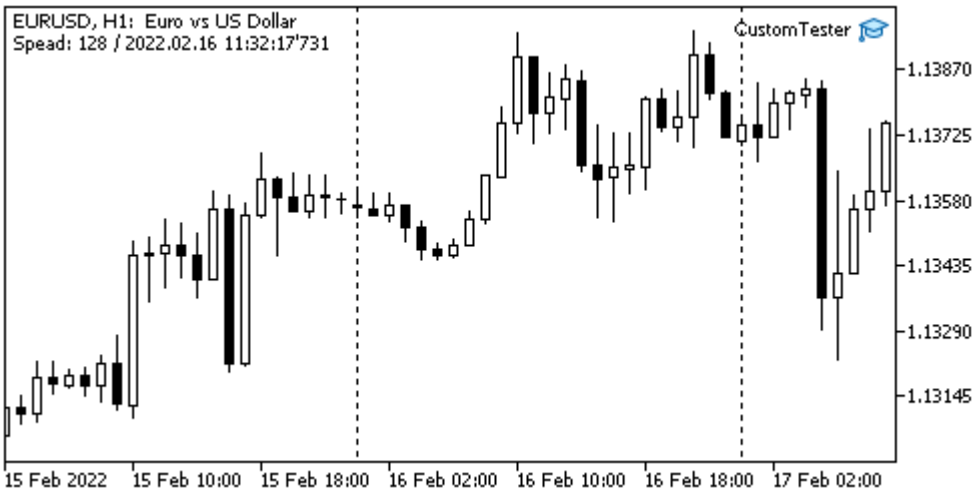
Further along, in fragment (C), we will ensure the receipt of user messages from the indicator and their transfer to the already known *CheckKeys* function.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   // (C)
   if(id == CHARTEVENT_CUSTOM + EVENT_KEY) // notifications from the dependent chart
   {
      CheckKeys(lparam); // "remote" processing of key presses
   }
   else if(id == CHARTEVENT_KEYDOWN) // these events are only fired while the chart i
   {
      CheckKeys(lparam); // standard processing
   }
}
```

Thus, the playback speed can now be controlled both on the chart with the Expert Advisor and on the chart of the custom symbol generated by it.

With the new toolkit, you can try interactive work with a chart that "lives in the past". A comment with the current playback speed or a pause mark is displayed on the graph.

On the chart with the Expert Advisor, the time of the "current" broadcast ticks is displayed in the comment.



An Expert Advisor that reproduces the history of ticks (and quotes) of a real symbol

There is basically nothing for the user to do in this window (if only the Expert Advisor is deleted and custom symbol generation is stopped). The tick translation process itself is not visible here. Moreover, since the Expert Advisor automatically opens a custom symbol chart (where historical quotes are updated), it is this one that becomes active. To get the above screenshot, we specifically needed to briefly switch to the original chart.

Therefore, let's return to the chart of the custom symbol. The way it is smoothly and progressively updated in the past is already great, but you can't conduct trading experiments on it. For example, if you run your usual trading panel on it, its controls, although they will formally work, will not execute deals since the custom symbol does not exist on the server, and thus you will get errors. This feature is observed in any programs that are not specially adapted for custom symbols. Let's show an example of how trading with a custom symbol can be virtualized.

Instead of a trading panel (in order to simplify the example, but without loss of generality), we will take as a basis the simplest Expert Advisor, *CustomOrderSend.mq5*, which can perform several trading actions on keystrokes:

- 'B' – market buy
- 'S' – market sell
- 'U' – placing a limit buy order
- 'L' – placing a limit sell order
- 'C' – close all positions
- 'D' – delete all orders
- 'R' – output a trading report to the journal

In the Expert Advisor input parameters, we will set the volume of one trade (by default, the minimum lot) and the distance to the stop loss and take profit levels in points.

```
input double Volume;           // Volume (0 = minimal lot)
input int Distance2SLTP = 0;   // Distance to SL/TP in points (0 = no)

const double Lot = Volume == 0 ? SymbolInfoDouble(_Symbol, SYMBOL_VOLUME_MIN) : Volum
```

If *Distance2SLTP* is left equal to zero, no protective levels are placed in market orders, and pending orders are not formed. When *Distance2SLTP* has a non-zero value, it is used as the distance from the current price when placing a pending order (either up or down, depending on the command).

Taking into account the previously presented classes from *MqlTradeSync.mqh*, the above logic is converted to the following source code.

```
#include <MQL5Book/MqlTradeSync.mqh>

#define KEY_B 66
#define KEY_C 67
#define KEY_D 68
#define KEY_L 76
#define KEY_R 82
#define KEY_S 83
#define KEY_U 85

void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      MqlTradeRequestSync request;
      const double ask = SymbolInfoDouble(_Symbol, SYMBOL_ASK);
      const double bid = SymbolInfoDouble(_Symbol, SYMBOL_BID);
      const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);

      switch((int)lparam)
      {
      case KEY_B:
         request.buy(Lot, 0,
            Distance2SLTP ? ask - point * Distance2SLTP : Distance2SLTP,
            Distance2SLTP ? ask + point * Distance2SLTP : Distance2SLTP);
         break;
      case KEY_S:
         request.sell(Lot, 0,
            Distance2SLTP ? bid + point * Distance2SLTP : Distance2SLTP,
            Distance2SLTP ? bid - point * Distance2SLTP : Distance2SLTP);
         break;
      case KEY_U:
         if(Distance2SLTP)
         {
            request.buyLimit(Lot, ask - point * Distance2SLTP);
         }
         break;
      case KEY_L:
         if(Distance2SLTP)
         {
            request.sellLimit(Lot, bid + point * Distance2SLTP);
         }
         break;
      case KEY_C:
         for(int i = PositionsTotal() - 1; i >= 0; i--)
         {
            request.close(PositionGetTicket(i));
         }
         break;
      case KEY_D:
         for(int i = OrdersTotal() - 1; i >= 0; i--)
```

```
            {
               request.remove(OrderGetTicket(i));
            }
            break;
         case KEY_R:
   // there should be something here...
            break;
         }
      }
   }
```

As we can see, both standard trading API functions and *MqlTradeRequestSync* methods are used here. The latter, indirectly, also ends up calling a lot of built-in functions. We need to make this Expert Advisor trade with a custom symbol.

The simplest, albeit time-consuming idea is to replace all standard functions with their own analogs that would count orders, deals, positions, and financial statistics in some structures. Of course, this is possible only in cases where we have the source code of the Expert Advisor, which should be adapted.

An experimental implementation of the approach is demonstrated in the attached file *CustomTrade.mqh*. You can familiarize yourself with the full code on your own, since within the framework of the book we will list only the main points.

First of all, we note that many calculations are made in a simplified form, many modes are not supported, and a complete check of the data for correctness is not performed. Use the source code as a starting point for your own developments.

The entire code is wrapped in the *CustomTrade* namespace to avoid conflicts.

The order, deal, and position entities are formalized as the corresponding classes *CustomOrder*, *CustomDeal*, and *CustomPosition*. All of them are inheritors of the class *MonitorInterface<I,D,S>::TradeState*. Recall that this class already automatically supports the formation of arrays of integer, real, and string properties for each type of object and its specific triples of enumerations. For example, *CustomOrder* looks like that:

```
class CustomOrder: public MonitorInterface<ENUM_ORDER_PROPERTY_INTEGER,
   ENUM_ORDER_PROPERTY_DOUBLE,ENUM_ORDER_PROPERTY_STRING>::TradeState
{
   static long ticket; // order counter and ticket provider
   static int done;    // counter of executed (historical) orders
public:
   CustomOrder(const ENUM_ORDER_TYPE type, const double volume, const string symbol)
   {
      _set(ORDER_TYPE, type);
      _set(ORDER_TICKET, ++ticket);
      _set(ORDER_TIME_SETUP, SymbolInfoInteger(symbol, SYMBOL_TIME));
      _set(ORDER_TIME_SETUP_MSC, SymbolInfoInteger(symbol, SYMBOL_TIME_MSC));
      if(type <= ORDER_TYPE_SELL)
      {
         // TODO: no deferred execution yet
         setDone(ORDER_STATE_FILLED);
      }
      else
      {
         _set(ORDER_STATE, ORDER_STATE_PLACED);
      }

      _set(ORDER_VOLUME_INITIAL, volume);
      _set(ORDER_VOLUME_CURRENT, volume);

      _set(ORDER_SYMBOL, symbol);
   }

   void setDone(const ENUM_ORDER_STATE state)
   {
      const string symbol = _get<string>(ORDER_SYMBOL);
      _set(ORDER_TIME_DONE, SymbolInfoInteger(symbol, SYMBOL_TIME));
      _set(ORDER_TIME_DONE_MSC, SymbolInfoInteger(symbol, SYMBOL_TIME_MSC));
      _set(ORDER_STATE, state);
      ++done;
   }

   bool isActive() const
   {
      return _get<long>(ORDER_TIME_DONE) == 0;
   }

   static int getDoneCount()
   {
      return done;
   }
};
```

Note that in the virtual environment of the old "current" time, you cannot use the *TimeCurrent* function and the last known time of the custom symbol *SymbolInfoInteger(symbol, SYMBOL_TIME)* is taken instead.

During virtual trading, current objects and their history are accumulated in arrays of the corresponding classes.

```
AutoPtr<CustomOrder> orders[];
CustomOrder *selectedOrders[];
CustomOrder *selectedOrder = NULL;
AutoPtr<CustomDeal> deals[];
CustomDeal *selectedDeals[];
CustomDeal *selectedDeal = NULL;
AutoPtr<CustomPosition> positions[];
CustomPosition *selectedPosition = NULL;
```

The metaphor for selecting orders, deals, and positions was required to simulate a similar approach in built-in functions. For them, there are duplicates in the *CustomTrade* namespace that replace the originals using macro substitution directives.

```
#define HistorySelect CustomTrade::MT5HistorySelect
#define HistorySelectByPosition CustomTrade::MT5HistorySelectByPosition
#define PositionGetInteger CustomTrade::MT5PositionGetInteger
#define PositionGetDouble CustomTrade::MT5PositionGetDouble
#define PositionGetString CustomTrade::MT5PositionGetString
#define PositionSelect CustomTrade::MT5PositionSelect
#define PositionSelectByTicket CustomTrade::MT5PositionSelectByTicket
#define PositionsTotal CustomTrade::MT5PositionsTotal
#define OrdersTotal CustomTrade::MT5OrdersTotal
#define PositionGetSymbol CustomTrade::MT5PositionGetSymbol
#define PositionGetTicket CustomTrade::MT5PositionGetTicket
#define HistoryDealsTotal CustomTrade::MT5HistoryDealsTotal
#define HistoryOrdersTotal CustomTrade::MT5HistoryOrdersTotal
#define HistoryDealGetTicket CustomTrade::MT5HistoryDealGetTicket
#define HistoryOrderGetTicket CustomTrade::MT5HistoryOrderGetTicket
#define HistoryDealGetInteger CustomTrade::MT5HistoryDealGetInteger
#define HistoryDealGetDouble CustomTrade::MT5HistoryDealGetDouble
#define HistoryDealGetString CustomTrade::MT5HistoryDealGetString
#define HistoryOrderGetDouble CustomTrade::MT5HistoryOrderGetDouble
#define HistoryOrderGetInteger CustomTrade::MT5HistoryOrderGetInteger
#define HistoryOrderGetString CustomTrade::MT5HistoryOrderGetString
#define OrderSend CustomTrade::MT5OrderSend
#define OrderSelect CustomTrade::MT5OrderSelect
#define HistoryOrderSelect CustomTrade::MT5HistoryOrderSelect
#define HistoryDealSelect CustomTrade::MT5HistoryDealSelect
```

For example, this is how the *MT5HistorySelectByPosition* function is implemented.

```
bool MT5HistorySelectByPosition(long id)
{
   ArrayResize(selectedOrders, 0);
   ArrayResize(selectedDeals, 0);

   for(int i = 0; i < ArraySize(orders); i++)
   {
      CustomOrder *ptr = orders[i][];
      if(!ptr.isActive())
      {
         if(ptr._get<long>(ORDER_POSITION_ID) == id)
         {
            PUSH(selectedOrders, ptr);
         }
      }
   }

   for(int i = 0; i < ArraySize(deals); i++)
   {
      CustomDeal *ptr = deals[i][];
      if(ptr._get<long>(DEAL_POSITION_ID) == id)
      {
         PUSH(selectedDeals, ptr);
      }
   }
   return true;
}
```

As you can see, all the functions of this group have the MT5 prefix, so that their dual purpose is immediately clear and it is easy to distinguish them from the functions of the second group.

The second group of functions in the *CustomTrade* namespace performs utilitarian actions: checks and updates the states of orders, deals and positions, creates new and deletes old objects in accordance with the situation. In particular, they include the *CheckPositions* and *CheckOrders* functions, which can be called on a timer or in response to user actions. But you can not do this if you use a couple of other functions designed to display the current and historical state of the virtual trading account:

- *string ReportTradeState()* returns a multiline text with a list of open positions and placed orders
- *void PrintTradeHistory()* displays the history of orders and deals in the log

These functions independently call *CheckPositions* and *CheckOrders* to provide you with up-to-date information.

In addition, there is a function for visualizing positions and active orders on the chart in the form of objects: *DisplayTrades*.

The header file *CustomTrade.mqh* should be included in the Expert Advisor before other headers so that macro substitution has an effect on all subsequent lines of source codes.

```
#include <MQL5Book/CustomTrade.mqh>
#include <MQL5Book/MqlTradeSync.mqh>
```

Now, the above algorithm *CustomOrderSend.mq5* can start "trading" in the virtual environment based on the current custom symbol (which does not require a server or a standard tester) without any extra changes.

To quickly display the state, we will start a second timer and periodically change the comment, as well as display graphical objects.

```
int OnInit()
{
   EventSetTimer(1);
   return INIT_SUCCEEDED;
}

void OnTimer()
{
   Comment(CustomTrade::ReportTradeState());
   CustomTrade::DisplayTrades();
}
```

To build a report by pressing 'R', we add the *OnChartEvent* handler.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam, const strin
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      switch((int)lparam)
      {
      ...
      case KEY_R:
         CustomTrade::PrintTradeHistory();
         break;
      }
   }
}
```

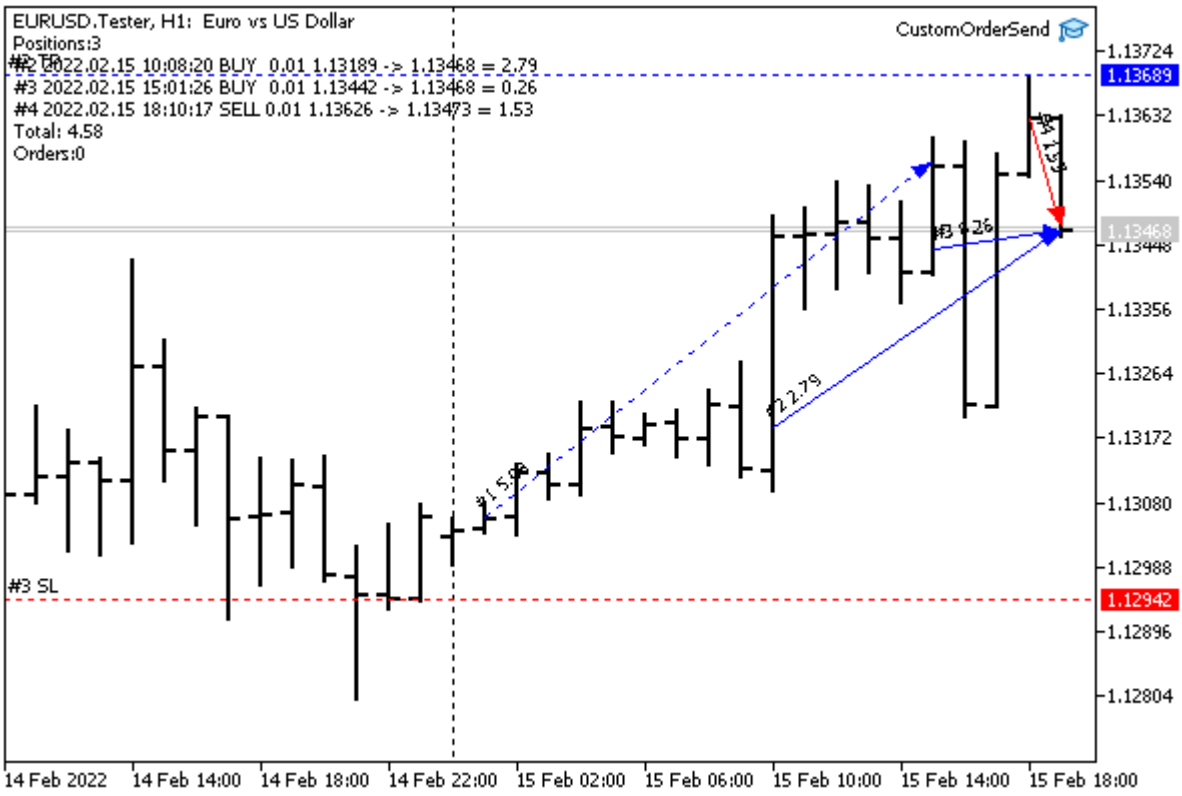
Finally, everything is ready to test the new software package in action.

Run the custom symbol generator *CustomTester.mq5* on EURUSD. On the "EURUSD.Tester" chart that opens, run *CustomOrderSend.mq5* and start trading. Below is a picture of the testing process.

Virtual trading on a custom symbol chart

Here you can see two open long positions (with protective levels) and a pending sell limit order.

After some time, one of the positions is closed (indicated below by a dotted blue line with an arrow), and a pending sell order is triggered (red line with an arrow), resulting in the following picture.



Virtual trading on a custom symbol chart

After closing all positions (some by take profit, and the rest by the user's command), a report was ordered by pressing 'R'.

```
History Orders:
(1) #1 ORDER_TYPE_BUY 2022.02.15 01:20:50 -> 2022.02.15 01:20:50 L=0.01 @ 1.1306
(4) #2 ORDER_TYPE_SELL_LIMIT 2022.02.15 02:34:29 -> 2022.02.15 18:10:17 L=0.01 @ 1.13
(2) #3 ORDER_TYPE_BUY 2022.02.15 10:08:20 -> 2022.02.15 10:08:20 L=0.01 @ 1.13189
(3) #4 ORDER_TYPE_BUY 2022.02.15 15:01:26 -> 2022.02.15 15:01:26 L=0.01 @ 1.13442

```

Parentheses indicate position identifiers and square brackets indicate tickets of orders for the corresponding deals (tickets of both types are preceded by a "hash" '#').

Swaps and commissions are not taken into account here. Their calculation can be added.

We will consider another example of working with custom symbol ticks in the section on custom symbol trading specifics. We will talk about creating equivolume charts.

7.2.7 Translation of order book changes

If necessary, an MQL program can generate an order book for a custom symbol using the *CustomBookAdd* function. This, in particular, can be useful for instruments from external exchanges, such as cryptocurrencies.

int CustomBookAdd(const string symbol, const MqlBookInfo &books[], uint count = WHOLE_ARRAY)

The function broadcasts the state of the order book to the signed MQL programs for the custom *symbol* using data from the *books* array. The array describes the full state of the order book, that is, all buy and sell orders. The translated state completely replaces the previous one and becomes available through the *MarketBookGet* function.

Using the *count* parameter, you can specify the number of elements of the *books* array to be passed to the function. The entire array is used by default.

The function returns an indicator of success (*true*) or error (*false*).

To obtain order books generated by the *CustomBookAdd* function, an MQL program that requires them must, as usual, subscribe to the events using *MarketBookAdd*.

The update of an order book does not update the *Bid* and *Ask* prices of the instrument. To update the required prices, add ticks using *CustomTicksAdd*.

The transmitted data is checked for correctness: prices and volumes must be greater than zero, and for each element, its type, price, and volume must be specified (fields *volume* and/or *volume_real*). If at least one element of the order book is described incorrectly, the function will return an error.

The Book Depth parameter (SYMBOL_TICKS_BOOKDEPTH) of the custom instrument is also checked. If the number of sell or buy levels in the translated order book exceeds this value, the extra levels are discarded.

Volume with increased accuracy *volume_real* takes precedence over normal *volume*. If both values are specified for the order book element, *volume_real* will be used.

> Attention! In the current implementation, *CustomBookAdd* automatically locks the custom symbol as if it were subscribed to it made by *MarketBookAdd*, but at the same time, the *OnBookEvent* events do not arrive (in theory, the program that generates order books can subscribe to them by calling *MarketBookAdd* explicitly and controlling what other programs receive). You can remove this lock by calling *MarketBookRelease*.
>
> This may be required due to the fact that the symbols for which there are subscriptions to the order book cannot be hidden from *Market Watch* by any means (until all explicit or implicit subscriptions are canceled from the programs, and the order book window is closed). As a consequence, such symbols cannot be deleted.

As an example, let's create a non-trading Expert Advisor *PseudoMarketBook.mq5*, which will generate a pseudo-state of the order book from the nearest tick history. This can be useful for symbols for which the order book is not translated, in particular for Forex. If you wish, you can use such custom symbols for formal debugging of your own trading algorithms using the order book.

Among the input parameters, we indicate the maximum depth of the order book.

```
input uint CustomBookDepth = 20;
```

The name of the custom symbol will be formed by adding the suffix ".Pseudo" to the name of the current chart symbol.

```
string CustomSymbol = _Symbol + ".Pseudo";
```

In the *OnInit* handler, we create a custom symbol and set its formula to the name of the original symbol. Thus, we will get a copy of the original symbol automatically updated by the terminal, and we will not need to trouble ourselves with copying quotes or ticks.

```
int OnInit()
{
   bool custom = false;
   if(!PRTF(SymbolExist(CustomSymbol, custom)))
   {
      if(PRTF(CustomSymbolCreate(CustomSymbol, CustomPath, _Symbol)))
      {
         CustomSymbolSetString(CustomSymbol, SYMBOL_DESCRIPTION, "Pseudo book generat
         CustomSymbolSetString(CustomSymbol, SYMBOL_FORMULA, "\"" + _Symbol + "\"");
      }
   }
   ...
```

If the custom symbol already exists, the Expert Advisor can offer the user to delete it and complete the work there (the user should first close all charts with this symbol).

```
   else
   {
      if(IDYES == MessageBox(StringFormat("Delete existing custom symbol '%s'?",
         CustomSymbol), "Please, confirm", MB_YESNO))
      {
         PRTF(MarketBookRelease(CustomSymbol));
         PRTF(SymbolSelect(CustomSymbol, false));
         PRTF(CustomRatesDelete(CustomSymbol, 0, LONG_MAX));
         PRTF(CustomTicksDelete(CustomSymbol, 0, LONG_MAX));
         if(!PRTF(CustomSymbolDelete(CustomSymbol)))
         {
            Alert("Can't delete ", CustomSymbol, ", please, check up and delete manua
         }
         return INIT_PARAMETERS_INCORRECT;
      }
   }
   ...
```

A special feature of this symbol is setting the SYMBOL_TICKS_BOOKDEPTH property, as well as reading the contract size SYMBOL_TRADE_CONTRACT_SIZE, which will be required when generating volumes.

```
   if(SymbolInfoInteger(_Symbol, SYMBOL_TICKS_BOOKDEPTH) != CustomBookDepth
   && SymbolInfoInteger(CustomSymbol, SYMBOL_TICKS_BOOKDEPTH) != CustomBookDepth)
   {
      Print("Adjusting custom market book depth");
      CustomSymbolSetInteger(CustomSymbol, SYMBOL_TICKS_BOOKDEPTH, CustomBookDepth);
   }

   depth = (int)PRTF(SymbolInfoInteger(CustomSymbol, SYMBOL_TICKS_BOOKDEPTH));
   contract = PRTF(SymbolInfoDouble(CustomSymbol, SYMBOL_TRADE_CONTRACT_SIZE));

   return INIT_SUCCEEDED;
}
```

The algorithm is launched in the *OnTick* handler. Here we call the *GenerateMarketBook* function which is yet to be written. It will fill the array of structures *MqlBookInfo* passed by reference, and we'll send it to a custom symbol using *CustomBookAdd*.

```
void OnTick()
{
   MqlBookInfo book[];
   if(GenerateMarketBook(2000, book))
   {
      ResetLastError();
      if(!CustomBookAdd(CustomSymbol, book))
      {
         Print("Can't add market books, ", E2S(_LastError));
         ExpertRemove();
      }
   }
}
```

The *GenerateMarketBook* function analyzes the latest *count* ticks and, based on them, emulates the possible state of the order book, guided by the following hypotheses:

- What has been bought is likely to be sold
- What has been sold is likely to be bought

The division of ticks into those that correspond to purchases and sales, in the general case (in the absence of exchange flags) can be estimated by the movement of the price itself:

- The movement of the *Ask* price upwards is treated as a purchase
- The movement of the *Bid* price downwards is treated as a sale

As a result, we get the following algorithm.

```
bool GenerateMarketBook(const int count, MqlBookInfo &book[])
{
   MqlTick tick; // order book centre
   if(!SymbolInfoTick(_Symbol, tick)) return false;

   double buys[];  // buy volumes by price levels
   double sells[]; // sell volumes by price levels

   MqlTick ticks[];
   CopyTicks(_Symbol, ticks, COPY_TICKS_ALL, 0, count); // request tick history
   for(int i = 1; i < ArraySize(ticks); ++i)
   {
      // we believe that ask was pushed up by buys
      int k = (int)MathRound((tick.ask - ticks[i].ask) / _Point);
      if(ticks[i].ask > ticks[i - 1].ask)
      {
         // already bought, probably will take profit by selling
         if(k <= 0)
         {
            Place(sells, -k, contract / sqrt(sqrt(ArraySize(ticks) - i)));
         }
      }

      // believe that the bid was pushed down by sells
      k = (int)MathRound((tick.bid - ticks[i].bid) / _Point);
      if(ticks[i].bid < ticks[i - 1].bid)
      {
         // already sold, probably will take profit by buying
         if(k >= 0)
         {
            Place(buys, k, contract / sqrt(sqrt(ArraySize(ticks) - i)));
         }
      }
   }
   ...
```

The helper function *Place* fills *buys* and *sells* arrays, accumulating volumes in them by price levels. We will show this below. Indexes in arrays are defined as the distance in points from the current best prices (*Bid* or *Ask*). The size of the volume is inversely proportional to the age of the tick, i.e. ticks that are more distant in the past have less effect.

After the arrays are filled, an array of structures *MqlBookInfo* is formed based on them.

```
      for(int i = 0, k = 0; i < ArraySize(sells) && k < depth; ++i) // top half of the c
      {
         if(sells[i] > 0)
         {
            MqlBookInfo info = {};
            info.type = BOOK_TYPE_SELL;
            info.price = tick.ask + i * _Point;
            info.volume = (long)sells[i];
            info.volume_real = (double)(long)sells[i];
            PUSH(book, info);
            ++k;
         }
      }

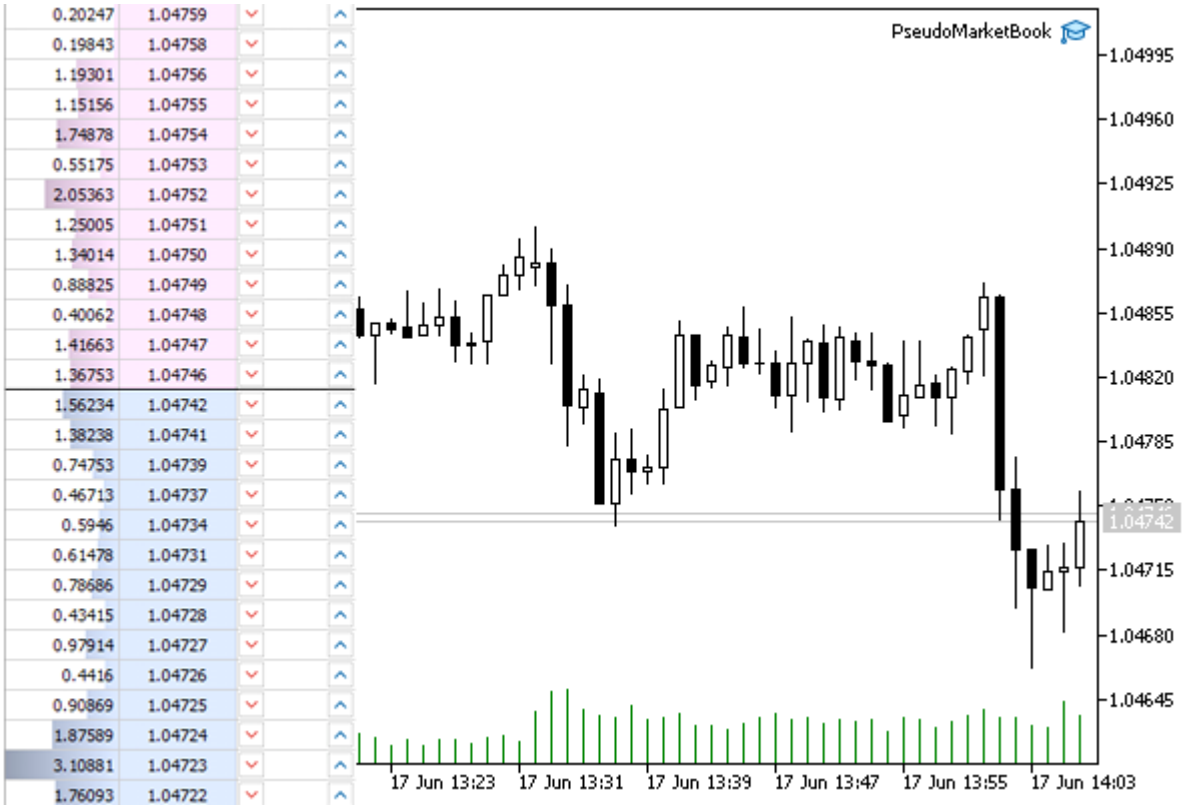
      for(int i = 0, k = 0; i < ArraySize(buys) && k < depth; ++i) // bottom half of the
      {
         if(buys[i] > 0)
         {
            MqlBookInfo info = {};
            info.type = BOOK_TYPE_BUY;
            info.price = tick.bid - i * _Point;
            info.volume = (long)buys[i];
            info.volume_real = (double)(long)buys[i];
            PUSH(book, info);
            ++k;
         }
      }

      return ArraySize(book) > 0;
   }
```

The *Place* function is simple.

```
   void Place(double &array[], const int index, const double value = 1)
   {
      const int size = ArraySize(array);
      if(index >= size)
      {
         ArrayResize(array, index + 1);
         for(int i = size; i <= index; ++i)
         {
            array[i] = 0;
         }
      }
      array[index] += value;
   }
```

The following screenshot shows a EURUSD chart with the *PseudoMarketBook.mq5* Expert Advisor running on it, and the resulting version of the order book.



Synthetic order book of a custom symbol based on EURUSD

7.2.8 Custom symbol trading specifics

The custom symbol is known only to the client terminal and is not available on the trade server. Therefore, if a custom symbol is built on the basis of some real symbol, then any Expert Advisor placed on the chart of such a custom symbol should generate trade orders for the original symbol.

As the simplest solution to this problem, you can place an Expert Advisor on the chart of the original symbol but receive signals (for example, from indicators) from the custom symbol. Another obvious approach is to replace the names of the symbols when performing trading operations. To test both approaches, we need a custom symbol and an Expert Advisor.

As an interesting practical example of custom symbols, let's take several different equivolume charts.

An equivolume (equal volume) chart is a chart of bars built on the principle of equality of the volume contained in them. On a regular chart, each new bar is formed at a specified frequency, coinciding with the timeframe size. On an equivolume chart, each bar is considered formed when the sum of ticks or real volumes reaches a preset value. At this moment, the program starts calculating the amount for the next bar. Of course, in the process of calculating volumes, price movements are controlled, and we get the usual sets of prices on the chart: *Open*, *High*, *Low*, and *Close*.

The equal-range bars are built in a similar way: a new bar opens there when the price passes a given number of points in any direction.

Thus, the *EqualVolumeBars.mq5* Expert Advisor will support three modes, i.e., three chart types:

- EqualTickVolumes – equivolume bars by ticks
- EqualRealVolumes – equivolume bars by real volumes (if they are broadcast)
- RangeBars – equal range bars

They are selected using the input parameter *WorkMode*.

The bar size and history depth for calculation are specified in the parameters *TicksInBar* and *StartDate*.

```
input int TicksInBar = 1000;
input datetime StartDate = 0;
```

Depending on the mode, the custom symbol will receive the suffix "_Eqv", "_Qrv" or "_Rng", respectively, with the addition of the bar size.

Although the horizontal axis on an Equivolume/Equal-Range chart still represents chronology, the timestamps of each bar are arbitrary and depend on the volatility (number or size of trades) in each time frame. In this regard, the timeframe of the custom symbol chart should be chosen equal to the minimum M1.

> The limitation of the platform is that all bars have the same nominal duration, but in the case of our "artificial" charts, it should be remembered that the real duration of each bar is different and can significantly exceed 1 minute or, on the contrary, be less. So, with a sufficiently small given volume for one bar, a situation may arise that new bars are formed much more often than once a minute, and then the virtual time of the custom symbol bars will run ahead of real time, into the future. To prevent this from happening, you should increase the volume of the bar (the *TicksInBar* parameter) or move old bars to the left.

Initialization and other auxiliary tasks for managing custom symbols (in particular, resetting an existing history, and opening a chart with a new symbol) are performed in a similar way as in other examples, and we will omit them. Let's turn to the specifics of an applied nature.

We will read the history of real ticks using built-in functions *CopyTicks*/*CopyTicksRange*: the first one is for swapping the history in batches of 10,000 ticks, and the second one is for requesting new ticks since the previous processing. All this functionality is packaged in the class *TicksBuffer* (full source code attached).

```
class TicksBuffer
{
private:
   MqlTick array[]; // internal array of ticks
   int tick;        // incremental index of the next tick for reading
public:
   bool fill(ulong &cursor, const bool history = false);
   bool read(MqlTick &t);
};
```

Public method *fill* is designed to fill the internal array with the next portion of ticks, starting from the *cursor* time (in milliseconds). At the same time, the time in *cursor* on each call moves forward based on the time of the last tick read into the buffer (note that the parameter is passed by reference).

Parameter *history* determines whether to use *CopyTicks* or *CopyTicksRange*. As a rule, online we will read one or more new ticks from the *OnTick* handler.

Method *read* returns one tick from the internal array and shifts the internal pointer (*tick*) to the next tick. If the end of the array is reached while reading, the method will return *false*, which means it's time to call the method *fill*.

Using these methods, the tick history bypass algorithm is implemented as follows (this code is indirectly called from *OnInit* via timer).

```
ulong cursor = StartDate * 1000;
TicksBuffer tb;

while(tb.fill(cursor, true) && !IsStopped())
{
   MqlTick t;
   while(tb.read(t))
   {
      HandleTick(t, true);
   }
}
```

In the *HandleTick* function, it is required to take into account the properties of tick *t* in some global variables that control the number of ticks, the total trading volume (real, if any), as well as the price movement distance. Depending on the mode of operation, these variables should be analyzed differently for the condition of the formation of a new bar. So if in the equivolume mode, the number of ticks exceeded *TicksInBar*, we should start a new bar by resetting the counter to 1. In this case, the time of a new bar is taken as the tick time rounded to the nearest minute.

This group of global variables provides for storing the virtual time of the last ("current") bar on a custom symbol (*now_time*), its OHLC prices, and volumes.

```
datetime now_time;
double now_close, now_open, now_low, now_high;
long now_volume, now_real;
```

Variables are constantly updated both during history reading and later when the Expert Advisor starts processing online ticks in real-time (we will return to this a bit later).

In a somewhat simplified form, the algorithm inside *HandleTick* looks like this:

```
void HandleTick(const MqlTick &t, const bool history = false)
{
   now_volume++;               // count the number of ticks
   now_real += (long)t.volume; // sum up all real volumes

   if(!IsNewBar()) // continue the current bar
   {
      if(t.bid < now_low) now_low = t.bid;   // monitor price fluctuations downward
      if(t.bid > now_high) now_high = t.bid; // and upwards
      now_close = t.bid;                     // update the closing price

      if(!history)
      {
         // update the current bar if we are not in the history
         WriteToChart(now_time, now_open, now_low, now_high, now_close,
            now_volume - !history, now_real);
      }
   }
   else // new bar
   {
      do
      {
         // save the closed bar with all attributes
         WriteToChart(now_time, now_open, now_low, now_high, now_close,
            WorkMode == EqualTickVolumes ? TicksInBar : now_volume,
            WorkMode == EqualRealVolumes ? TicksInBar : now_real);

         // round up the time to the minute for the new bar
         datetime time = t.time / 60 * 60;

         // prevent bars with old or same time
         // if gone to the "future", we should just take the next count M1
         if(time <= now_time) time = now_time + 60;

         // start a new bar from the current price
         now_time = time;
         now_open = t.bid;
         now_low = t.bid;
         now_high = t.bid;
         now_close = t.bid;
         now_volume = 1;             // first tick in the new bar
         if(WorkMode == EqualRealVolumes) now_real -= TicksInBar;
         now_real += (long)t.volume; // initial real volume in the new bar

         // save new bar 0
         WriteToChart(now_time, now_open, now_low, now_high, now_close,
            now_volume - !history, now_real);
      }
      while(IsNewBar() && WorkMode == EqualRealVolumes);
   }
}
```

Parameter *history* determines whether the calculation is based on history or already in real-time (on incoming online ticks). If based on history, it is enough to form each bar once, while online, the current bar is updated with each tick. This allows you to speed up the processing of history.

The helper function *IsNewBar* returns *true* when the condition for closing the next bar according to the mode is met.

```
bool IsNewBar()
{
   if(WorkMode == EqualTickVolumes)
   {
      if(now_volume > TicksInBar) return true;
   }
   else if(WorkMode == EqualRealVolumes)
   {
      if(now_real > TicksInBar) return true;
   }
   else if(WorkMode == RangeBars)
   {
      if((now_high - now_low) / _Point > TicksInBar) return true;
   }

   return false;
}
```

The function *WriteToChart* creates a bar with the given characteristics by calling *CustomRatesUpdate*.

```
void WriteToChart(datetime t, double o, double l, double h, double c, long v, long m
{
   MqlRates r[1];

   r[0].time = t;
   r[0].open = o;
   r[0].low = l;
   r[0].high = h;
   r[0].close = c;
   r[0].tick_volume = v;
   r[0].spread = 0;
   r[0].real_volume = m;

   if(CustomRatesUpdate(SymbolName, r) < 1)
   {
      Print("CustomRatesUpdate failed: ", _LastError);
   }
}
```

The aforementioned loop of reading and processing ticks is performed during the initial access to the history, after the creation or complete recalculation of an already existing user symbol. When it comes to new ticks, the *OnTick* function uses a similar code but without the "historicity" flags.

```
void OnTick()
{
   static ulong cursor = 0;
   MqlTick t;

   if(cursor == 0)
   {
      if(SymbolInfoTick(_Symbol, t))
      {
         HandleTick(t);
         cursor = t.time_msc + 1;
      }
   }
   else
   {
      TicksBuffer tb;
      while(tb.fill(cursor))
      {
         while(tb.read(t))
         {
            HandleTick(t);
         }
      }
   }

   RefreshWindow(now_time);
}
```

The *RefreshWindow* function adds a custom symbol tick in the *Market Watch*.

Please note that tick forwarding increases the tick counter in the bar by 1, and therefore, when writing the tick counter to the 0th bar, we previously subtracted one (see the expression *now_volume - !history* when calling *WriteToChart*).

Tick generation is important because it triggers the *OnTick* event on custom instrument charts, which potentially allows Expert Advisors placed on such charts to trade. However, this technology requires some additional tricks, which we will consider later.

```
void RefreshWindow(const datetime t)
{
   MqlTick ta[1];
   SymbolInfoTick(_Symbol, ta[0]);
   ta[0].time = t;
   ta[0].time_msc = t * 1000;
   if(CustomTicksAdd(SymbolName, ta) == -1)
   {
      Print("CustomTicksAdd failed:", _LastError, " ", (long) ta[0].time);
      ArrayPrint(ta);
   }
}
```

We emphasize that the time of the generated custom tick is always set equal to the label of the current bar since we cannot leave the real tick time: if it has gone ahead by more than 1 minute and we will

send such a tick to *Market Watch*, the terminal will create the next bar M1, which will violate our "equivolume" structure because our bars are formed not by time, but by volume filling (and we ourselves control this process).

In theory, we could add one millisecond to each tick, but we have no guarantee that the bar will not need to store more than 60,000 ticks (for example, if the user orders a chart with a certain price range that is unpredictable in terms of how many ticks will be required for such movement).

In modes by volume, it is theoretically possible to interpolate the second and millisecond components of the tick time using linear formulas:

- EqualTickVolumes – (now_volume - 1) * 60000 / TicksInBar;
- EqualRealVolumes – (now_real - 1) * 60000 / TicksInBar;

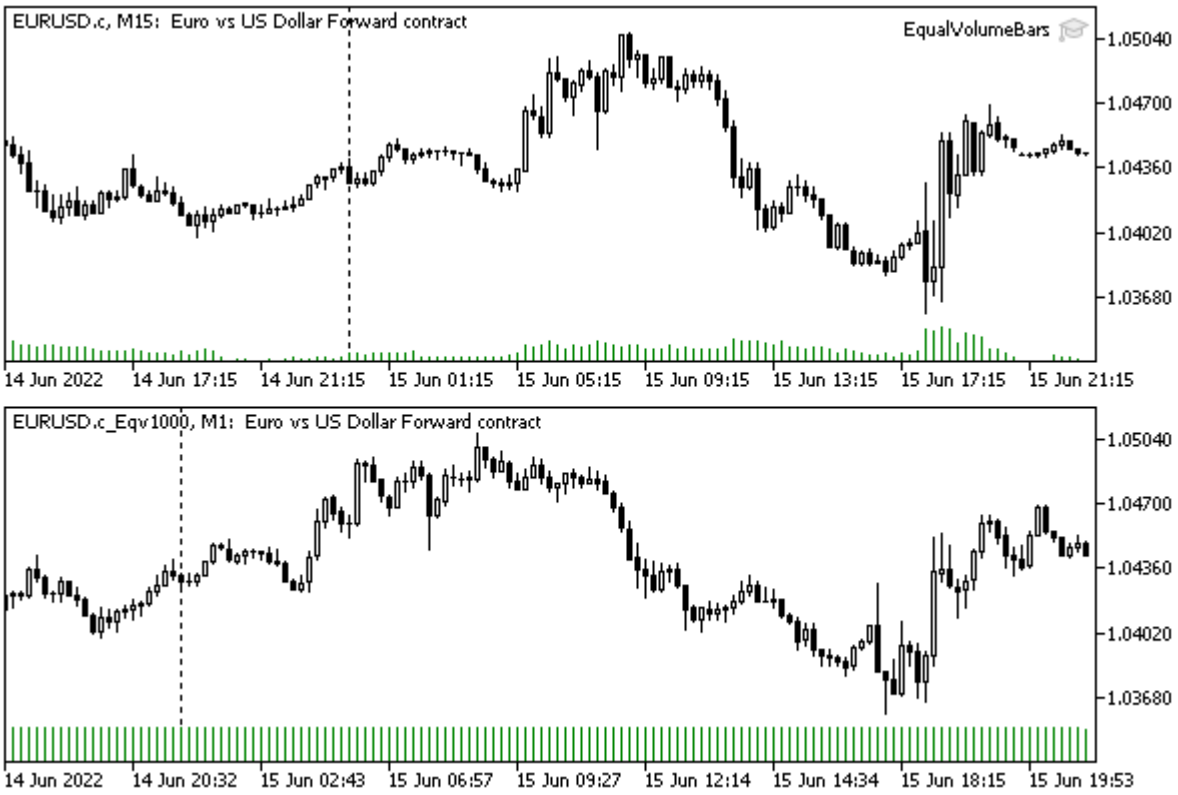
However, this is nothing more than a means of identifying ticks, and not an attempt to make the time of "artificial" ticks closer to the time of real ones. This is not only about the loss of unevenness of the real flow of ticks, which in itself will already lead to differences in price between the original symbol and the custom symbol generated on its basis.

The main problem is the need to round off the tick time along the border of the M1 bar and "pack" them within one minute (see the sidebar about special types of charts). For example, the next tick with real-time 12:37:05'123 becomes the 1001st tick and should form a new equivolume bar. However, bar M1 can only be timestamped to the minute, i.e. 12:37. As a result, the real price of the instrument at 12:37 will not match the price in the tick that provided the *Open* price for the equivolume bar 12:37. Also, if the next 1000 ticks stretch over several minutes, we will still be forced to "compress" their time so as not to reach the 12:38 mark.

The problem is of a systemic nature due to time quantization when special charts are emulated by a standard M1 timeframe chart. This problem cannot be completely solved on such charts. But when generating custom symbols with ticks in continuous time (for example, with synthetic quotes or based on streaming data from external services), this problem does not arise.

> It is important to note that tick forwarding is done online only in this version of the generator, while custom ticks are not generated on history! This is done in order to speed up the creation of quotes. If you need to generate a tick history despite the slower process, the Expert Advisor *EqualVolumeBars.mq5* should be adapted: exclude the *WriteToChart* function and perform the entire generation using *CustomTicksReplace/CustomTicksAdd*. At the same time, it should be remembered that the original time of ticks should be replaced by another one, within a minute bar, so as not to disturb the structure of the formed equivolume chart.

Let's see how *EqualVolumeBars.mq5* works. Here is the working chart of EURUSD M15 with the Expert Advisor running in it. It has the equivolume chart, in which 1000 ticks are allotted for each bar.



Equivolume EURUSD chart with 1000 ticks per bar generated by the EqualVolumeBars Expert Advisor

Note that the tick volumes on all bars are equal, except for the last one, which is still forming (tick counting continues).

Statistics are displayed in the log.

```
Creating "EURUSD.c_Eqv1000"
Processing tick history...
End of CopyTicks at 2022.06.15 12:47:51
Bar 0: 2022.06.15 12:40:00 866 0
2119 bars written in 10 sec
Open "EURUSD.c_Eqv1000" chart to view results
```

Let's check another mode of operation: equal range. Below is a chart where the range of each bar is 250 points.

EURUSD equal range chart with 250 pips bars generated by EqualVolumeBars

For exchange instruments, the Expert Advisor allows the use of the real volume mode, for example, as follows:

Ethereum raw and equivolume chart with real volume of 10000 per bar

The timeframe of the working symbol when placing the Expert Advisor generator is not important, since the tick history is always used for calculations.

At the same time, the timeframe of the custom symbol chart must be equal to M1 (the smallest available in the terminal). Thus, the time of the bars, as a rule, corresponds as closely as possible (as far as possible) to the moments of their formation. However, during strong movements in the market, when the number of ticks or the size of volumes forms several bars per minute, the time of the bars will run ahead of the real one. When the market calms down, the situation with the time marks of the equi-volume bars will normalize. This does not affect the flow of online prices, so it is probably not particularly critical, since the whole point of using equal-volume or equal-range bars is to decouple from absolute time.

Unfortunately, the name of the original symbol and the custom symbol created on its basis cannot be linked in any way by means of the platform itself. It would be convenient to have a string field "origin" (source) among the properties of the custom symbol, in which we could write the name of the real working tool. By default, it would be empty, but if filled in, the platform could replace the symbol in all trade orders and history requests, and do it automatically and transparently for the user. In theory, among the properties of user-defined symbols, there is a SYMBOL_BASIS field that is suitable in terms of its meaning, but since we cannot guarantee that arbitrary generators of user-defined symbols (any MQL programs) will correctly fill it in or use it exactly for this purpose, we cannot rely on its use.

Since this mechanism is not in the platform, we will need to implement it ourselves. You will have to set the correspondence between the names of the source and user symbols using parameters.

To solve the problem, we developed the class *CustomOrder* (see the attached file *CustomOrder.mqh*). It contains wrapper methods for all MQL API functions related to sending trading orders and requesting history, which have a string parameter with the symbol name. In these methods, the custom symbol is replaced with the current working one or vice versa. Other API functions do not require "hooking". Below is a snippet.

```
class CustomOrder
{
private:
   static string workSymbol;

   static void replaceRequest(MqlTradeRequest &request)
   {
      if(request.symbol == _Symbol && workSymbol != NULL)
      {
         request.symbol = workSymbol;
         if(MQLInfoInteger(MQL_TESTER)
            && (request.type == ORDER_TYPE_BUY
            || request.type == ORDER_TYPE_SELL))
         {
            if(TU::Equal(request.price, SymbolInfoDouble(_Symbol, SYMBOL_ASK)))
               request.price = SymbolInfoDouble(workSymbol, SYMBOL_ASK);
            if(TU::Equal(request.price, SymbolInfoDouble(_Symbol, SYMBOL_BID)))
               request.price = SymbolInfoDouble(workSymbol, SYMBOL_BID);
         }
      }
   }

public:
   static void setReplacementSymbol(const string replacementSymbol)
   {
      workSymbol = replacementSymbol;
   }

   static bool OrderSend(MqlTradeRequest &request, MqlTradeResult &result)
   {
      replaceRequest(request);
      return ::OrderSend(request, result);
   }
   ...
```

Please note that the main working method *replaceRequest* replaces not only the symbol but also the current *Ask* and *Bid* prices. This is due to the fact that many custom tools, such as our Equivolume plot, have a virtual time that is different from the time of the real prototype symbol. Therefore, the prices of the custom instrument emulated by the tester are out of sync with the corresponding prices of the real instrument.

This artifact occurs only in the tester. When trading online, the custom symbol chart will be updated (at prices) synchronously with the real one, although the bar labels will differ (one "artificial" M1 bar has a real duration of more or less than a minute, and its countdown time is not a multiple of a minute). Thus, this price conversion is more of a precaution to avoid getting requotes in the tester. However, in the tester, we usually do not need to do symbol substitution, since the tester can trade with a custom symbol (unlike the broker's server). Further, just for the sake of interest, we will compare the results of tests run both with and without character substitution.

To minimize edits to the client source code, global functions and macros of the following form are provided (for all *CustomOrder* methods):

```
bool CustomOrderSend(const MqlTradeRequest &request, MqlTradeResult &result)
{
  return CustomOrder::OrderSend((MqlTradeRequest)request, result);
}

#define OrderSend CustomOrderSend
```

They allow the automatic redirection of all standard API function calls to the *CustomOrder* class methods. To do this, simply include *CustomOrder.mqh* into the Expert Advisor and set the working symbol, for example, in the *WorkSymbol* parameter:

```
#include <CustomOrder.mqh>
#include <Expert/Expert.mqh>
...
input string WorkSymbol = "";

int OnInit()
{
  if(WorkSymbol != "")
  {
    CustomOrder::setReplacementSymbol(WorkSymbol);

    // initiate the opening of the chart tab of the working symbol (in the visual m
    MqlRates rates[1];
    CopyRates(WorkSymbol, PERIOD_CURRENT, 0, 1, rates);
  }
  ...
}
```

It is important that the directive *#include<CustomOrder.mqh>* was the very first, before the others. Thus, it affects all source codes, including the standard libraries from the MetaTrader 5 distribution. If no substitution symbol is specified, the connected *CustomOrder.mqh* has no effect on the Expert Advisor and "transparently" transfers control to the standard API functions.

Now we have everything ready to test the idea of trading on a custom symbol, including the custom symbol itself.

Applying the technique shown above we modify the already familiar Expert Advisor *BandOsMaPro*, renaming it to *BandOsMaCustom.mq5*. Let's test it on the EURUSD equivolume chart with a bar size of 1000 ticks obtained using *EqualVolumeBars.mq5*.

Optimization or testing mode is set to OHLC M1 prices (more accurate methods do not make sense because we did not generate ticks and also because this version trades at the prices of formed bars). The date range is the entire 2021 and the first half of 2022. The file with the settings *BandOsMACustom.set* is attached.

In the tester settings, you should not forget to select the custom symbol EURUSD_Eqv1000 and the M1 timeframe, since it is on it that equi-volume bars are emulated.

When the *WorkSymbol* parameter is empty, the Expert Advisor trades a custom symbol. Here are the results:

Bars	32533	Ticks	130132	Symbols	1

Tester's report when trading EURUSD from the EURUSD_Eqv1000 equivolume chart

However, as it was already mentioned at the beginning of the section, there is an easier way for Expert Advisors which trade on indicator signals to support custom symbols. To do this, it is enough to create indicators on a custom symbol and place the Expert Advisor on the chart of a working symbol.

We can easily implement this option. Let's call it *BandOsMACustomSignal.mq5*.

The header file *CustomOrder.mqh* is no longer needed. Instead of the *WorkSymbol* input parameter, we add two new ones:

```
input string SignalSymbol = "";
input ENUM_TIMEFRAMES SignalTimeframe = PERIOD_M1;
```

They should be passed to the constructor of the *BandOsMaSignal* class which manages the indicators. Previously, *_Symbol* and *_Period* were used everywhere.

```
interface TradingSignal
{
   virtual int signal(void);
   virtual string symbol();
   virtual ENUM_TIMEFRAMES timeframe();
};

class BandOsMaSignal: public TradingSignal
{
   int hOsMA, hBands, hMA;
   int direction;
   const string _symbol;
   const ENUM_TIMEFRAMES _timeframe;
public:
   BandOsMaSignal(const string s, const ENUM_TIMEFRAMES tf,
      const int fast, const int slow, const int signal, const ENUM_APPLIED_PRICE pric
      const int bands, const int shift, const double deviation,
      const int period, const int x, ENUM_MA_METHOD method): _symbol(s), _timeframe(t
   {
      hOsMA = iOsMA(s, tf, fast, slow, signal, price);
      hBands = iBands(s, tf, bands, shift, deviation, hOsMA);
      hMA = iMA(s, tf, period, x, method, hOsMA);
      direction = 0;
   }
   ...
   virtual string symbol() override
   {
      return _symbol;
   }

   virtual ENUM_TIMEFRAMES timeframe() override
   {
      return _timeframe;
   }
}
```

Since the symbol and timeframe for signals can now differ from the symbol and period of the chart, we have expanded the *TradingSignal* interface by adding read methods. The actual values are passed to the constructor in *OnInit*.

```
int OnInit()
{
   ...
   strategy = new SimpleStrategy(
      new BandOsMaSignal(SignalSymbol != "" ? SignalSymbol : _Symbol,
         SignalSymbol != "" ? SignalTimeframe : _Period,
         p.fast, p.slow, SignalOsMA, PriceOsMA,
         BandsMA, BandsShift, BandsDeviation,
         PeriodMA, ShiftMA, MethodMA),
         Magic, StopLoss, Lots);
   return INIT_SUCCEEDED;
}
```

In the *SimpleStrategy* class, the *trade* method now checks for the occurrence of a new bar not according to the current chart, but according to the properties of the signal.

```
   virtual bool trade() override
   {
      // looking for a signal once at the opening of the bar of the desired symbol an
      if(lastBar == iTime(command[].symbol(), command[].timeframe(), 0)) return false

      int s = command[].signal(); // get signal
      ...
   }
```

For a comparative experiment with the same settings, the Expert Advisor *BandOsMACustomSignal.mq5* should be launched on EURUSD (you can use M1 or another timeframe), and EURUSD_Eqv1000 should be specified in the *SignalSymbol* parameter. *SignalTimeframe* should be left equal to PERIOD_M1 by default. As a result, we will get a similar report.

Bars	545621	Ticks	2159010	Symbols	1

Tester's report when trading on the EURUSD chart based on signals from the EURUSD_Eqv1000 equivolume symbol

The number of bars and ticks is different here because EURUSD was chosen as the tested instrument and not the custom EURUSD_Eqv1000.

All three test results are slightly different. This is due to the "packing" of quotes into minute bars and a slight desynchronization of the price movements of the original and custom instruments. Which of the results is more accurate? This, most likely, depends on the specific trading system and the features of its implementation. In the case of our Expert Advisor *BandOsMa* with control over bar opening, the version with direct trading on EURUSD_Eqv1000 should have the most realistic results. In theory, the rule of thumb stating that of several alternative checks, the most reliable is the least profitable, is almost always satisfied.

So, we have analyzed a couple of techniques for adapting Expert Advisors for trading on custom symbols that have a prototype among the broker's working symbols. However, this situation is not mandatory. In many cases, custom symbols are generated based on data from external systems such as crypto exchanges. Trading on them must be done using their public API with MQL5 network functions.

Emulating special types of charts with custom symbols

Many traders use special types of charts, in which continuous real-time is excluded from consideration. This includes not only equivolume and equal range bars, but also Renko, Point-And-Figure (PAF), Kagi, and others. Custom symbols allow these kinds of charts to be emulated in MetaTrader 5 using M1 timeframe charts but should be treated with caution when it comes to testing trading systems rather than technical analysis.

For special types of charts, the actual bar opening time (accurate to milliseconds) almost always does not coincide exactly with the minute with which the M1 bar will be marked. Thus, the opening price of a custom bar differs from the opening price of the M1 bar of a standard symbol.

Moreover, other OHLC prices will also differ because the real duration of the formation of the M1 bar on a special chart is not equal to one minute. For example, 1000 ticks for an equivolume chart can accumulate for longer than 5 minutes.

The closing price of a custom bar also does not correspond to the real closing time because a custom bar is, technically, an M1 bar, i.e. it has a nominal duration of 1 minute.

Special care should be taken when working with such types of charts as the classic Renko or PAF. The fact is that their reversal bars have an opening price with a gap from the closing of the previous bar. Thus, the opening price becomes a predictor of future price movement.

The analysis of such charts is supposed to be carried out according to the formed bars, that is, their characteristic price is the closing price, however, when working by bar, the tester provides only the opening price for the current (last) bar (there is no mode by closing prices). Even if we take indicator signals from closed bars (usually from the 1st one), deals are made at the current price of the 0th bar anyway. And even if we turn to tick modes, the tester always generates ticks according to the usual rules, guided by reference points based on the configuration of each bar. The tester does not take into account the structure and behavior of special charts, which we are trying to visually emulate with M1 bars.

Trading in the tester using such symbols in any mode (by opening prices, M1 OHLC, or by ticks) affects the accuracy of the results: they are too optimistic and can serve as a source of too high

expectations. In this regard, it is essential to check the trading system not on a separate Renko or PAF chart, but in conjunction with the execution of orders on a real symbol.

Custom symbols can also be used for second timeframes or tick charts. In this case, virtual time is also generated for bars and ticks, decoupled from real-time. Therefore, such charts are well suited for operational analysis but require additional attention when developing and testing trading strategies, especially multi-symbol ones.

An alternative for any custom symbols is the independent calculation of arrays of bars and ticks inside an Expert Advisor or indicator. However, debugging and visualizing such structures requires additional effort.

7.3 Economic calendar

When developing trading strategies, it is desirable to take into account the fundamental factors that affect the market. MetaTrader 5 has a built-in economic calendar, which is available in the program interface as a separate tab in the toolbar, as well as labels, optionally displayed directly on the chart. The calendar can be enabled by a separate flag on the Community tab in the terminal settings dialog (login to the community is not necessary).

Since MetaTrader 5 supports algorithmic trading, economic calendar events can also be accessed programmatically from the MQL5 API. In this chapter, we will introduce the functions and data structures that enable reading, filtering, and monitoring changes in economic events.

The economic calendar contains a description, release schedule, and historical values of macroeconomic indicators for many countries. For each event, the exact time of the planned release, the degree of importance, the impact on specific currencies, forecast values, and other attributes are known. Actual values of macroeconomic indicators arrive at MetaTrader 5 immediately at the time of publication.

The availability of the calendar allows you to automatically analyze incoming events and react to them in Expert Advisors in a variety of ways, for example, trading as part of a breakout strategy or volatility fluctuations within the corridor. On the other hand, knowing the upcoming fluctuations in the market allows you to find quiet hours in the schedule and temporarily turn off those robots for which strong price movements are dangerous due to possible losses.

Values of *datetime* type used by all functions and structures that work with the economic calendar are equal to the trade server time (*TimeTradeServer*) including its time zone and DST (Daylight Saving Time) settings. In other words, for correct testing of news-trading Expert Advisors, their developer must independently change the times of historical news in those periods (about half a year within each year) when the DST mode differs from the current one.

Calendar functions cannot be used in the tester: when trying to call any of them, we get the FUNCTION_NOT_ALLOWED (4014) error. In this regard, testing calendar-based strategies involves first saving calendar entries in external storages (for example, in files) when running the MQL program on the online chart, and then loading and reading them from the MQL program running in the tester.

7.3.1 Basic concepts of the calendar

When working with the calendar, we will operate with several concepts, for the formal description of which MQL5 defines special types of structures.

First of all, the events are related to specific countries, and each country is described using the *MqlCalendarCountry* structure.

```
struct MqlCalendarCountry
{
   ulong  id;              //country identifier according to ISO 3166-1
   string name;            // text name of the country (in the current terminal encod
   string code;            // two-letter country designation according to ISO 3166-1
   string currency;        // international country currency code
   string currency_symbol; // symbol/sign of the country's currency
   string url_name;        // country name used in the URL on the mql5.com website
};
```

How to get a list of countries available in the calendar and their attributes as an array of *MqlCalendarCountry* structures, we will find out in the next section.

For now, we just pay attention to the *id* field. It is important because it is the key to determining whether calendar events belong to a particular country. In each country (or a registered association of countries, such as the European Union) there is a specific, internationally known list of types of economic indicators and informational events that affect the market and are therefore included in the calendar.

Each event type is defined by the *MqlCalendarEvent* structure, in which the field *country_id* uniquely links the event to the country. We will consider the types of enumerations used below.

```
struct MqlCalendarEvent
{
   ulong                          id;         // event ID
   ENUM_CALENDAR_EVENT_TYPE       type;       // event type
   ENUM_CALENDAR_EVENT_SECTOR     sector;     // sector to which the event belongs
   ENUM_CALENDAR_EVENT_FREQUENCY  frequency;  // frequency (periodicity) of the event
   ENUM_CALENDAR_EVENT_TIMEMODE   time_mode;  // event time mode
   ulong                          country_id; // country identifier
   ENUM_CALENDAR_EVENT_UNIT       unit;       // indicator unit
   ENUM_CALENDAR_EVENT_IMPORTANCE importance; // importance of the event
   ENUM_CALENDAR_EVENT_MULTIPLIER multiplier; // indicator multiplier
   uint                           digits;     // number of decimal places
   string                         source_url; // URL of the event publication source
   string                         event_code; // event code
   string                         name;       // text name of the event in the termin
};
```

It is important to understand that the *MqlCalendarEvent* structure describes exactly the type of event (for example, the publication of the Consumer Price Index, CPI) but not a specific event that may occur once a quarter, once a month, or according to another schedule. It contains the general characteristics of the event, including importance, frequency, relation to the sector of the economy, units of measurement, name, and source of information. As for the actual and forecast indicators, these will be provided in the calendar entries for each specific event of this type: these entries are stored as *MqlCalendarValue* structures, which will be discussed later. Functions for querying the supported types of events will be introduced in later sections.

The event type in the *type* field is specified as one of the ENUM_CALENDAR_EVENT_TYPE enumeration values.

Identifier	Description
CALENDAR_TYPE_EVENT	Event (meeting, speech, etc.)
CALENDAR_TYPE_INDICATOR	Economic indicator
CALENDAR_TYPE_HOLIDAY	Holiday (weekend)

The sector of the economy to which the event belongs is selected from the ENUM_CALENDAR_EVENT_SECTOR enumeration.

Identifier	Description
CALENDAR_SECTOR_NONE	Sector is not set
CALENDAR_SECTOR_MARKET	Market, exchange
CALENDAR_SECTOR_GDP	Gross Domestic Product (GDP)
CALENDAR_SECTOR_JOBS	Labor market
CALENDAR_SECTOR_PRICES	Prices
CALENDAR_SECTOR_MONEY	Money
CALENDAR_SECTOR_TRADE	Trade
CALENDAR_SECTOR_GOVERNMENT	Government
CALENDAR_SECTOR_BUSINESS	Business
CALENDAR_SECTOR_CONSUMER	Consumption
CALENDAR_SECTOR_HOUSING	Housing
CALENDAR_SECTOR_TAXES	Taxes
CALENDAR_SECTOR_HOLIDAYS	Holidays

The frequency of the event is indicated in the *frequency* field using the ENUM_CALENDAR_EVENT_FREQUENCY enumeration.

Identifier	Description
CALENDAR_FREQUENCY_NONE	Publication frequency is not set
CALENDAR_FREQUENCY_WEEK	Weekly
CALENDAR_FREQUENCY_MONTH	Monthly
CALENDAR_FREQUENCY_QUARTER	Quarterly
CALENDAR_FREQUENCY_YEAR	Yearly
CALENDAR_FREQUENCY_DAY	Daily

Event duration (*time_mode*) can be described by one of the elements of the ENUM_CALENDAR_EVENT_TIMEMODE enumeration.

Identifier	Description
CALENDAR_TIMEMODE_DATETIME	The exact time of the event is known
CALENDAR_TIMEMODE_DATE	The event takes all day
CALENDAR_TIMEMODE_NOTIME	Time is not published
CALENDAR_TIMEMODE_TENTATIVE	Only the day is known in advance, but not the exact time of the event (the time is specified after the fact)

The importance of the event is specified in the *importance* field using the ENUM_CALENDAR_EVENT_IMPORTANCE enumeration.

Identifier	Description
CALENDAR_IMPORTANCE_NONE	Not set
CALENDAR_IMPORTANCE_LOW	Low
CALENDAR_IMPORTANCE_MODERATE	Moderate
CALENDAR_IMPORTANCE_HIGH	High

The units of measurement in which event values are given are defined in the *unit* field as a member of the ENUM_CALENDAR_EVENT_UNIT enumeration.

Identifier	Description
CALENDAR_UNIT_NONE	Unit is not set
CALENDAR_UNIT_PERCENT	Interest (%)
CALENDAR_UNIT_CURRENCY	National currency
CALENDAR_UNIT_HOUR	Number of hours
CALENDAR_UNIT_JOB	Number of workplaces
CALENDAR_UNIT_RIG	Drilling rigs
CALENDAR_UNIT_USD	U.S. dollars
CALENDAR_UNIT_PEOPLE	Number of people
CALENDAR_UNIT_MORTGAGE	Number of mortgage loans
CALENDAR_UNIT_VOTE	Number of votes
CALENDAR_UNIT_BARREL	Amount in barrels

Identifier	Description
CALENDAR_UNIT_CUBICFEET	Volume in cubic feet
CALENDAR_UNIT_POSITION	Net volume of speculative positions in contracts
CALENDAR_UNIT_BUILDING	Number of buildings

In some cases, the values of an economic indicator require a *multiplier* according to one of the elements of the ENUM_CALENDAR_EVENT_MULTIPLIER enumeration.

Identifier	Description
CALENDAR_MULTIPLIER_NONE	Multiplier is not set
CALENDAR_MULTIPLIER_THOUSANDS	Thousands
CALENDAR_MULTIPLIER_MILLIONS	Millions
CALENDAR_MULTIPLIER_BILLIONS	Billions
CALENDAR_MULTIPLIER_TRILLIONS	Trillions

So, we have considered all the special data types used to describe the types of events in the *MqlCalendarEvent* structure.

A separate calendar entry is formed as a *MqlCalendarValue* structure. Its detailed description is given below, but for now, it is important to pay attention to the following nuance. *MqlCalendarValue* has the *event_id* field which points to the identifier of the event type, i.e., contains one of the existing *id* in *MqlCalendarEvent* structures.

As we saw above, the *MqlCalendarEvent* structure in turn is related to *MqlCalendarCountry* via the *country_id* field. Thus, having once entered information about a specific country or type of event into the calendar database, it is possible to register an arbitrary number of similar events for them. Of course, the information provider is responsible for filling the database, not the developers.

Let's summarize the subtotal: the system stores three internal tables separately:

- The *MqlCalendarCountry* structure table to describe countries
- The *MqlCalendarEvent* structure table with descriptions of types of events
- The *MqlCalendarValue* structure table with indicators of specific events of various types

By referencing event type identifiers, duplication of information is eliminated from records of specific events. For example, monthly publications of CPI values only refer to the same *MqlCalendarEvent* structure with the general characteristics of this event type. If it were not for the different tables, it would be necessary to repeat the same properties in each CPI calendar entry. This approach to establishing relationships between tables with data using identifier fields is called *relational*, and we will return to it in the chapter on SQLite. All this is illustrated in the following diagram.

Diagram of links between structures by fields with identifiers

All tables are stored in the internal calendar database, which is constantly kept up to date while the terminal is connected to the server.

Calendar entries (specific events) are *MqlCalendarValue* structures. They are also identified by their own unique number in the *id* field (each of the three tables has its own *id* field).

```
struct MqlCalendarValue
{
   ulong      id;                // entry ID
   ulong      event_id;          // event type ID
   datetime   time;              // time and date of the event
   datetime   period;            // reporting period of the event
   int        revision;          // revision of the published indicator in relation
   long       actual_value;      // actual value in ppm or LONG_MIN
   long       prev_value;        // previous value in ppm or LONG_MIN
   long       revised_prev_value; // revised previous value in ppm or LONG_MIN
   long       forecast_value;    // forecast value in ppm or LONG_MIN
   ENUM_CALENDAR_EVENT_IMPACT impact_type;  // potential impact on the exchange rate

  // functions for checking values
   bool HasActualValue(void) const;     // true if the actual_value field is filled
   bool HasPreviousValue(void) const;   // true if the prev_value field is filled
   bool HasRevisedValue(void) const;    // true if the revised_prev_value field is fi
   bool HasForecastValue(void) const;   // true if the forecast_value field is filled

   // functions for getting values
   double GetActualValue(void) const;   // actual_value or nan if value is not set
   double GetPreviousValue(void) const; // prev_value or nan if value is not set
   double GetRevisedValue(void) const;  // revised_prev_value or nan if value is not
   double GetForecastValue(void) const; // forecast_value or nan if value is not set
};
```

For each event, in addition to the time of its publication (*time*), the following four values are also stored:

- Actual value (*actual_value*), which becomes known immediately after the publication of the news
- Previous value (*prev_value*), which became known in the last release of the same news
- Revised value of the previous indicator, *revised_prev_value* (if it has been modified since the last publication)
- Forecast value (*forecast_value*)

Obviously, not all the fields must be necessarily filled. So, the current value is absent (not yet known) for future events, and the revision of past values also does not always occur. In addition, all four fields make sense only for quantitative indicators, while the calendar also reflects regulators' speeches, meetings and holidays.

An empty field (no value) is indicated by the constant LONG_MIN (-9223372036854775808). If the value in the field is specified (not equal to LONG_MIN), then it corresponds to the real value of the indicator increased by a million times, that is, to obtain the indicator in the usual (real) form, it is necessary to divide the field value by 1,000,000.

For the convenience of the programmer, the structure defines 4 *Has* methods for checking the field is filled, as well as 4 *Get* methods that return the value of the corresponding field already converted to a real number, and in the case when it is not filled, the method will return NaN (Not A Number).

Sometimes, in order to obtain absolute values (if they are required for the algorithm), it is important to additionally analyze the *multiplier* property in the *MqlCalendarEvent* structure since some values are specified in multiple units according to the ENUM_CALENDAR_EVENT_MULTIPLIER enumeration.

Besides, *MqlCalendarEvent* has the *digits* field, which specifies the number of significant digits in the received values for subsequent correct formatting (for example, in a call to *NormalizeDouble*).

The reporting period (for which the published indicator is calculated) is set in the *period* field as its first day. For example, if the indicator is calculated monthly, then the date '2022.05.01 00:00:00' means the month of May. The duration of the period (for example, month, quarter, year) is defined in the *frequency* field of the related structure *MqlCalendarEvent*: the type of this field is the special ENUM_CALENDAR_EVENT_FREQUENCY enumeration described above, along with other enumerations.

Of particular interest is the *impact_type* field, in which, after the release of the news, the direction of influence of the corresponding currency on the exchange rate is automatically set by comparing the current and forecast values. This influence can be positive (the currency is expected to appreciate) or negative (the currency is expected to depreciate). For example, a larger drop in sales than expected would be labeled as having a negative impact, and a larger drop in unemployment as positive. But this characteristic is interpreted unambiguously not for all events (some economic indicators are considered contradictory), and besides, one should pay attention to the relative numbers of changes.

The potential impact of an event on the national currency rate is indicated using the ENUM_CALENDAR_EVENT_IMPACT enumeration.

Identifier	Description
CALENDAR_IMPACT_NA	Influence is not stated
CALENDAR_IMPACT_POSITIVE	Positive influence
CALENDAR_IMPACT_NEGATIVE	Negative influence

Another important concept of the calendar is the fact of its change. Unfortunately, there is no special structure for change. The only property a change has is its unique ID, which is an integer assigned by the system each time the internal calendar base is changed.

As you know, the calendar is constantly modified by information providers: new upcoming events are added to it, and already published indicators and forecasts are corrected. Therefore, it is very important to keep track of any edits, the occurrence of which makes it possible to detect periodically increasing change numbers.

The edit time with a specific identifier and its essence are not available in MQL5. If necessary, MQL programs should implement periodic calendar state queries and record analysis themselves.

A set of MQL5 functions allows getting information about countries, types of events and specific calendar entries, as well as their changes. We will consider this in the following sections.

> Attention! When accessing the calendar for the first time (if the Calendar tab in the terminal toolbar has not been opened before), it may take several seconds to synchronize the internal calendar database with the server.

7.3.2 Getting the list and descriptions of available countries

You can get a complete list of countries for which events are broadcast on the calendar using the *CalendarCountries* function.

int CalendarCountries(MqlCalendarCountry &countries[])

The function fills the *countries* array passed by reference with *MqlCalendarCountry* structures. The array can be dynamic or fixed, of sufficient size.

On success, the function returns the number of country descriptions received from the server or 0 on error. Among the possible error codes in *_LastError* we may find, in particular, 5401 (ERR_CALENDAR_TIMEOUT, request time limit exceeded) or 5400 (ERR_CALENDAR_MORE_DATA, if the size of the fixed array is insufficient to obtain descriptions of all countries). In the latter case, the system will copy only what fits.

Let's write a simple script *CalendarCountries.mq5*, which gets the full list of countries and logs it out.

```
void OnStart()
{
   MqlCalendarCountry countries[];
   PRTF(CalendarCountries(countries));
   ArrayPrint(countries);
}
```

Here is an example result.

```
CalendarCountries(countries)=23 / ok
      [id]           [name] [code] [currency] [currency_symbol]       [url_name] [rese
[ 0]  554 "New Zealand"    "NZ"   "NZD"      "$"               "new-zealand"

[10]   76 "Brazil"         "BR"   "BRL"      "R$"              "brazil"
[11]  484 "Mexico"         "MX"   "MXN"      "Mex$"            "mexico"
[12]  710 "South Africa"   "ZA"   "ZAR"      "R"               "south-africa"
[13]  344 "Hong Kong"      "HK"   "HKD"      "HK$"             "hong-kong"
[14]  356 "India"          "IN"   "INR"      "₹"               "india"
[15]  578 "Norway"         "NO"   "NOK"      "Kr"              "norway"
[16]    0 "Worldwide"      "WW"   "ALL"      ""                "worldwide"
[17]  840 "United States"  "US"   "USD"      "$"               "united-states"
[18]  826 "United Kingdom" "GB"   "GBP"      "£"               "united-kingdom"
[19]  756 "Switzerland"    "CH"   "CHF"      "₣"               "switzerland"
[20]  410 "South Korea"    "KR"   "KRW"      "₩"               "south-korea"
[21]  724 "Spain"          "ES"   "EUR"      "€"               "spain"
[22]  752 "Sweden"         "SE"   "SEK"      "Kr"              "sweden"
```

It is important to note that the identifier 0 (code "WW" and pseudo-currency "ALL") corresponds to global events (concerning many countries, for example, the G7, G20 meetings), and the currency "EUR" is associated with several EU countries available in the calendar (as you can see, not the entire Eurozone is presented). Also, the European Union itself has a generic identifier 999.

If you are interested in a particular country, you can check its availability by a numerical code according to the ISO 3166-1 standard. In particular, in the log above, these codes are displayed in the first column (field *id*).

To get a description of one country by its ID specified in the *id* parameter, you can use the *CalendarCountryById* function.

bool CalendarCountryById(const long id, MqlCalendarCountry &country)

If successful, the function will return *true* and fill in the fields of the *country* structure.

If the country is not found, we get *false*, and in *_LastError* we will get an error code 5402 (ERR_CALENDAR_NO_DATA).

For an example of using this function, see Getting event records by country or currency.

7.3.3 Querying event types by country and currency

The calendar of economic events and holidays has its own specifics in each country. An MQL program can query the types of events within a particular country, as well as the types of events associated with a particular currency. The latter is relevant in cases where several countries use the same currency, as, for example, most members of the European Union.

int CalendarEventByCountry(const string country, MqlCalendarEvent &events[])

The *CalendarEventByCountry* function fills an array of *MqlCalendarEvent* structures passed by reference with descriptions of all types of events available in the calendar for the country specified by the two-letter country code (according to the ISO 3166-1 alpha-2 standard). We saw examples of such codes in the previous section, in the log: EU for the European Union, US for the USA, DE for Germany, CN for China, and so on.

The receiving array can be dynamic or fixed of sufficient size.

The function returns the number of received descriptions and 0 in case of an error. In particular, if the fixed array is not able to contain all events, the function will fill it with the fit part of the available data and set the code *_LastError*, equal to CALENDAR_MORE_DATA (5400). Memory allocation errors (4004, ERR_NOT_ENOUGH_MEMORY) or calendar request timeout from the server (5401, ERR_CALENDAR_TIMEOUT) are also possible.

If the country with the given code does not exist, an INTERNAL_ERROR (4001) will occur.

By specifying NULL or an empty string "" instead of *country*, you can get a complete list of events for all countries.

Let's test the performance of the function using the simple script *CalendarEventKindsByCountry.mq5*. It has a single input parameter which is the code of the country we are interested in.

```
input string CountryCode = "HK";
```

Next, a request for event types is made by calling *CalendarEventByCountry*, and if successful, the resulting arrays are logged.

```
void OnStart()
{
   MqlCalendarEvent events[];
   if(PRTF(CalendarEventByCountry(CountryCode, events)))
   {
      Print("Event kinds for country: ", CountryCode);
      ArrayPrint(events);
   }
}
```

Here is an example of the result (due to the fact that the lines are long, they are artificially divided into 2 blocks for publication in the book: the first block contains the numeric fields of the structures *MqlCalendarEvent*, and the second block contains string fields).

```
CalendarEventByCountry(CountryCode,events)=26 / ok
Event kinds for country: HK
          [id] [type] [sector] [frequency] [time_mode] [country_id] [unit] [importanc
[ 0] 344010001      1        5           2           0          344      6

```

int CalendarEventByCurrency(const string currency, MqlCalendarEvent &events[])

The *CalendarEventByCurrency* function fills the passed *events* array with descriptions of all kinds of events in the calendar that are associated with the specified *currency*. The three-letter designation of currencies is known to all Forex traders.

If an invalid currency code is specified, the function will return 0 (no error) and an empty array.

Specifying NULL or an empty string "" instead of *currency*, you can get a complete list of calendar events.

Let's test the function using the script *CalendarEventKindsByCurrency.mq5*. The input parameter specifies the currency code.

```
input string Currency = "CNY";
```

In the handler *OnStart* we request events and output them to the log.

```
void OnStart()
{
   MqlCalendarEvent events[];
   if(PRTF(CalendarEventByCurrency(Currency, events)))
   {
      Print("Event kinds for currency: ", Currency);
      ArrayPrint(events);
   }
}
```

Here is an example of the result (given with abbreviations).

```
CalendarEventByCurrency(Currency,events)=40 / ok
Event kinds for currency: CNY

```

An attentive reader will notice that the event type identifier contains the country code, the number of the news source and the serial number within the source (numbering starts from 1). So, the general format of the event type identifier is: CCCSSNNNN, where CCC is the country code, SS is the source, NNNN is the number. For example, 156020001 is the first news from the second source for China and 344030010 is the tenth news from the third source for Hong Kong. The only exception is global news, for which the "country" code is not 000 but 1000.

7.3.4 Getting event descriptions by ID

Real MQL programs, as a rule, request current or upcoming calendar events, filtering by time range, countries, currencies, or other criteria. The API functions intended for this, which we have yet to consider, return *MqlCalendarValue* structures, which store only the event identifier instead of its description. Therefore, the *CalendarEventById* function can be useful if you need to extract complete information.

bool CalendarEventById(ulong id, MqlCalendarEvent &event)

The *CalendarEventById* function gets the description of the event by its ID. The function returns a success or error indication.

An example of how to use this function will be given in the next section.

7.3.5 Getting event records by country or currency

Specific events of various kinds are queried in the calendar for a given range of dates and filtered by country or currency.

```
int CalendarValueHistory(MqlCalendarValue &values[], datetime from, datetime to = 0,
  const string country = NULL, const string currency = NULL)
```

The *CalendarValueHistory* function fills the *values* array passed by reference with calendar entries in the time range between *from* and *to*. Both parameters may include date and time. Value *from* is included in the interval, but value *to* is not. In other words, the function selects calendar entries (structures*MqlCalendarValue*), in which the following compound condition is met for the *time* property: *from* <= *time* < *to*.

The start time *from* must be specified, while the end time *to* is optional: if it is omitted or equal to 0, all future events are copied to the array.

Time *to* there should be larger than *from*, except when it is 0. A special combination for querying all available events (both past and future) is when *from* and *to* are both 0.

If the receiving array is dynamic, memory will be automatically allocated for it. If the array is of a fixed size, the number of entries copied will be no more than the size of the array.

The *country* and *currency* parameters allow you to set an additional filtering of records by country or currency. The *country* parameter accepts a two-letter ISO 3166-1 alpha-2 country code (for example. "DE", "FR", "EU"), and the *currency* parameter accepts a three-letter currency designation (for example, "EUR", "CNY").

The default value NULL or an empty string "" in any of the parameters is equivalent to the absence of the corresponding filter.

If both filters are specified, only the values of those events are selected for which both conditions – country and currency – are satisfied simultaneously. This can come in handy if the calendar includes countries with multiple currencies, each of which also has circulation in several countries. There are no such events in the calendar at the moment. To get the events in the Eurozone countries, it is enough to specify the code of a particular country or "EU", and the currency "EUR" will be assumed.

The function returns the number of elements copied and can set an error code. In particular, if the request timeout from the server is exceeded, in *_LastError* we get error 5401 (ERR_CALENDAR_TIMEOUT). If the fixed array does not fit all the records, the code will be equal to 5400 (ERR_CALENDAR_MORE_DATA), but the array will be filled. When allocating memory for a dynamic array, error 4004 (ERR_NOT_ENOUGH_MEMORY) is potentially possible.

> Attention! The order of the elements in an array can be different from chronological. You have to sort records by time.

Using the *CalendarValueHistory* function, we could query upcoming events like this:

```
MqlCalendarValue values[];
if(CalendarValueHistory(values, TimeCurrent()))
{
   ArrayPrint(values);
}
```

However, with this code, we will get a table with insufficient information, where the event names, importance, and currency codes will be hidden behind the event ID in the *MqlCalendarValue::event_id* field and, indirectly, behind the country identifier in the *MqlCalendarEvent::country_id* field. To make the output of information more user-friendly, you should request a description of the event by the event code, take the country code from this description, and get its attributes. Let's show it in the example script *CalendarForDates.mq5*.

In the input parameters, we will provide the ability to enter the country code and currency for filtering. By default, events for the European Union are requested.

```
input string CountryCode = "EU";
input string Currency = "";
```

The date range of the events will automatically count for some time back and forth. This "some time" will also be left to the user to choose from three options: a day, a week, or a month.

```
#define DAY_LONG   60 * 60 * 24
#define WEEK_LONG  DAY_LONG * 7
#define MONTH_LONG DAY_LONG * 30
#define YEAR_LONG  MONTH_LONG * 12

enum ENUM_CALENDAR_SCOPE
{
   SCOPE_DAY = DAY_LONG,
   SCOPE_WEEK = WEEK_LONG,
   SCOPE_MONTH = MONTH_LONG,
   SCOPE_YEAR = YEAR_LONG,
};

input ENUM_CALENDAR_SCOPE Scope = SCOPE_DAY;
```

Let's define our structure *MqlCalendarRecord*, derivative of *MqlCalendarValue*, and add fields to it for a convenient presentation of attributes that will be filled in by links (identifiers) from dependent structures.

```
struct MqlCalendarRecord: public MqlCalendarValue
{
   static const string importances[];

   string importance;
   string name;
   string currency;
   string code;
   double actual, previous, revised, forecast;
   ...
};

static const string MqlCalendarRecord::importances[] = {"None", "Low", "Medium", "Hig
```

Among the added fields there are lines with importance (one of the values of the static array *importances*), the name of the event, country, and currency, as well as four values in the *double* format. This actually means duplication of information for the sake of visual presentation when printing. Later we will prepare a more advanced "wrapper" for the calendar.

To fill the object, we will need a parametric constructor that takes the original structure *MqlCalendarValue*. After all the inherited fields are implicitly copied into the new object by the operator '=', we call the specially prepared *extend* method.

```
MqlCalendarRecord() { }

MqlCalendarRecord(const MqlCalendarValue &value)
{
   this = value;
   extend();
}
```

In the *extend* method, we get the description of the event by its identifier. Then, based on the country identifier from the event description, we get a structure with country attributes. After that, we can fill in the first half of the added fields from the received structures *MqlCalendarEvent* and *MqlCalendarCountry*.

```
void extend()
{
   MqlCalendarEvent event;
   CalendarEventById(event_id, event);

   MqlCalendarCountry country;
   CalendarCountryById(event.country_id, country);

   importance = importances[event.importance];
   name = event.name;
   currency = country.currency;
   code = country.code;

   MqlCalendarValue value = this;

   actual = value.GetActualValue();
   previous = value.GetPreviousValue();
   revised = value.GetRevisedValue();
   forecast = value.GetForecastValue();
}
```

Next, we called the built-in *Get* methods for filling four fields of type *double* with financial indicators.

Now we can use the new structure in the main *OnStart* handler.

```
void OnStart()
{
   MqlCalendarValue values[];
   MqlCalendarRecord records[];
   datetime from = TimeCurrent() - Scope;
   datetime to = TimeCurrent() + Scope;
   if(PRTF(CalendarValueHistory(values, from, to, CountryCode, Currency)))
   {
      for(int i = 0; i < ArraySize(values); ++i)
      {
         PUSH(records, MqlCalendarRecord(values[i]));
      }
      Print("Near past and future calendar records (extended): ");
      ArrayPrint(records);
   }
}
```

Here the array of standard *MqlCalendarValue* structures is filled by calling *CalendarValueHistory* for the current conditions set in the input parameters. Next, all elements are transferred to the *MqlCalendarRecord* array. Moreover, while objects are being created, they are expanded with additional information. Finally, the array of events is output to the log.

The log entries are coming quite long. First, let's show the left half, which is exactly what we would see if we printed an array of standard *MqlCalendarValue* structures.

```
CalendarValueHistory(values,from,to,CountryCode,Currency)=6 / ok
Near past and future calendar records (extended):
      [id] [event_id]              [time]            [period] [revision] [actual_valu
[0] 162723  999020003 2022.06.23 03:00:00 1970.01.01 00:00:00    0 -92233720368547758
[1] 162724  999020003 2022.06.24 03:00:00 1970.01.01 00:00:00    0 -92233720368547758
[2] 168518  999010034 2022.06.24 11:00:00 1970.01.01 00:00:00    0 -92233720368547758
[3] 168515  999010031 2022.06.24 13:10:00 1970.01.01 00:00:00    0 -92233720368547758
[4] 168509  999010014 2022.06.24 14:30:00 1970.01.01 00:00:00    0 -92233720368547758
[5] 161014  999520001 2022.06.24 22:30:00 2022.06.21 00:00:00    0 -92233720368547758
```

Here is the second half with the "decoding" of names, importance, and meanings.

```
CalendarValueHistory(values,from,to,CountryCode,Currency)=6 / ok
Near past and future calendar records (extended):
     [importance]                                                [name] [currency] [c
[0]  "High"       "EU Leaders Summit"                                  "EUR"      "E
[1]  "High"       "EU Leaders Summit"                                  "EUR"      "E
[2]  "Medium"     "ECB Supervisory Board Member McCaul Speech"         "EUR"      "E
[3]  "Medium"     "ECB Supervisory Board Member Fernandez-Bollo Speech" "EUR"      "E
[4]  "Medium"     "ECB Vice President de Guindos Speech"               "EUR"      "E
[5]  "Low"        "CFTC EUR Non-Commercial Net Positions"              "EUR"      "E
```

7.3.6 Getting event records of a specific type

If necessary, an MQL program has the ability to request events of a specific type: to do this, it is enough to know the event identifier in advance, for example, using the *CalendarEventByCountry* or

CalendarEventByCurrency functions which were presented in the section Querying event types by country and currency.

int CalendarValueHistoryByEvent(ulong id, MqlCalendarValue &values[], datetime from, datetime to = 0)

The *CalendarValueHistoryByEvent* function fills the array passed by reference with records of events of a specific type indicated by the *id* identifier. Parameters *from* and *to* allow you to limit the range of dates in which events are searched.

If an optional parameter *to* is not specified, all calendar entries will be placed in the array, starting from the *from* time and further into the future. To query all the past events, set *from* to 0. If both *from* and *to* parameters are 0, all history and scheduled events will be returned. In all other cases, when *to* is not equal to 0, it must be greater than *from*.

The *values* array can be dynamic (then the function will automatically expand or reduce it according to the amount of data) or of fixed size (then only a part that fits will be copied into the array).

The function returns the number of copied elements.

As an example, consider the script *CalendarStatsByEvent.mq5*, which calculates the statistics (frequency of occurrence) of events of different types for a given country or currency in a given time range.

The analysis conditions are specified in the input variables.

```
input string CountryOrCurrency = "EU";
input ENUM_CALENDAR_SCOPE Scope = SCOPE_YEAR;
```

Depending on the length of the *CountryOrCurrency* string, it is interpreted as a country code (2 characters) or currency code (3 characters).

To collect statistics, we will declare a structure; its fields will store the identifier and name of the event type, its importance, and the counter of such events.

```
struct CalendarEventStats
{
   static const string importances[];
   ulong id;
   string name;
   string importance;
   int count;
};

static const string CalendarEventStats::importances[] = {"None", "Low", "Medium", "Hi
```

In the *OnStart* function, we first request all kinds of events using the *CalendarEventByCountry* or *CalendarEventByCurrency* function to the specified depth of history and into the future, and then, in a loop through the event descriptions received in the *events* array, we call *CalendarValueHistoryByEvent* for each event ID. In this application, we are not interested in the contents of the *values* array, as we just need to know their count.

```
void OnStart()
{
   MqlCalendarEvent events[];
   MqlCalendarValue values[];
   CalendarEventStats stats[];

   const datetime from = TimeCurrent() - Scope;
   const datetime to = TimeCurrent() + Scope;

   if(StringLen(CountryOrCurrency) == 2)
   {
      PRTF(CalendarEventByCountry(CountryOrCurrency, events));
   }
   else
   {
      PRTF(CalendarEventByCurrency(CountryOrCurrency, events));
   }

   for(int i = 0; i < ArraySize(events); ++i)
   {
      if(CalendarValueHistoryByEvent(events[i].id, values, from, to))
      {
         CalendarEventStats event = {events[i].id, events[i].name,
            CalendarEventStats::importances[events[i].importance], ArraySize(values)};
         PUSH(stats, event);
      }
   }

   SORT_STRUCT(CalendarEventStats, stats, count);
   ArrayReverse(stats);
   ArrayPrint(stats);
}
```

Upon successful function call, we fill the *CalendarEventStats* structure and add it to the array of structures *stats*. Next, we sort the structure in the way we already know (the SORT_STRUCT macro is described in the section Comparing, sorting, and searching in arrays).

Running the script with default settings generates something like this in the log (abbreviated).

```
CalendarEventByCountry(CountryOrCurrency,events)=82 / ok
          [id]                                                [name] [importance] [cc

```

Please note that a total of 82 types of events were received, however, in the statistics array, we had only 74. This is because the *CalendarValueHistoryByEvent* function returns *false* (failure) and zero error code in *_LastError* if there were no events of any kind in the specified date range. In the above test, there are 8 such entries that theoretically exist but were never encountered within the year.

7.3.7 Reading event records by ID

Knowing the events schedule for the near future, traders can adjust their robots accordingly. There are no functions or events in the calendar API ("events" in the sense of functions for processing new financial information like *OnCalendar*, by analogy with *OnTick*) to automatically track news releases. The algorithm must do this itself at any chosen frequency. In particular, you can find out the identifier of the desired event using one of the previously discussed functions (for example, *CalendarValueHistoryByEvent*, *CalendarValueHistory*) and then call *CalendarValueById* to get the current state of the fields in the *MqlCalendarValue* structure.

bool CalendarValueById(ulong id, MqlCalendarValue &value)

The function fills the structure passed by reference with current information about a specific event.

The result of the function denotes a sign of success (*true*) or error (*false*).

Let's create a simple bufferless indicator *CalendarRecordById.mq5*, which will find in the future the nearest event with the type of "financial indicator" (i.e., a numerical indicator) and will poll its status on timer. When the news is published, the data will change (the "actual" value of the indicator will become known), and the indicator will display an alert.

The frequency of polling the calendar is set in the input variable.

```
input uint TimerSeconds = 5;
```

We run the timer in *OnInit*.

```
void OnInit()
{
   EventSetTimer(TimerSeconds);
}
```

For the convenient output to the event description log, we use the *MqlCalendarRecord* structure which we already know from the example with the script *CalendarForDates.mq5*.

To store the initial state of news information, we describe the *track* structure.

```
MqlCalendarValue track;
```

When the structure is empty (and there is "0" in the field *id*), the program must query the upcoming events and find among them the closest one with the CALENDAR_TYPE_INDICATOR type and for which the current value is not yet known.

```
void OnTimer()
{
   if(!track.id)
   {
      MqlCalendarValue values[];
      if(PRTF(CalendarValueHistory(values, TimeCurrent(), TimeCurrent() + DAY_LONG *
      {
         for(int i = 0; i < ArraySize(values); ++i)
         {
            MqlCalendarEvent event;
            CalendarEventById(values[i].event_id, event);
            if(event.type == CALENDAR_TYPE_INDICATOR && !values[i].HasActualValue())
            {
               track = values[i];
               PrintFormat("Started monitoring %lld", track.id);
               StructPrint(MqlCalendarRecord(track), ARRAYPRINT_HEADER);
               return;
            }
         }
      }
   }
   ...
```

The found event is copied to *track* and output to the log. After that, every call to *OnTimer* comes down to getting updated information about the event into the *update* structure, which is transferred to *CalendarValueById* with the *track.id* identifier. Next, the original and new structures are compared using the auxiliary function *StructCompare* (based on *StructToCharArray* and *ArrayCompare*, see the complete source code). Any difference causes a new state to be printed (the forecast may have changed), and if the current value appears, the timer stops. To start waiting for the next news, this indicator needs to be reinitialized: this one is for demonstration, and to control the situation according to the list of news, we will later develop a more practical filter class.

```
      else
      {
         MqlCalendarValue update;
         if(CalendarValueById(track.id, update))
         {
            if(fabs(StructCompare(track, update)) == 1)
            {
               Alert(StringFormat("News %lld changed", track.id));
               PrintFormat("New state of %lld", track.id);
               StructPrint(MqlCalendarRecord(update), ARRAYPRINT_HEADER);
               if(update.HasActualValue())
               {
                  Print("Timer stopped");
                  EventKillTimer();
               }
               else
               {
                  track = update;
               }
            }
         }

         if(TimeCurrent() <= track.time)
         {
            Comment("Forthcoming event time: ", track.time,
               ", remaining: ", Timing::stringify((uint)(track.time - TimeCurrent())));
         }
         else
         {
            Comment("Forthcoming event time: ", track.time,
               ", late for: ", Timing::stringify((uint)(TimeCurrent() - track.time)));
         }
      }
   }
```

While waiting for the event, the indicator displays a comment with the expected time of the news release and how much time is left before it (or what is the delay).

Comment about waiting or being late for the next news

It is important to note that the news may come out a little earlier or a little later than the scheduled date. This creates some problems when testing news strategies on history, since the time of updating calendar entries in the terminal and through the MQL5 API is not provided. We will try to partially solve this problem in the next section.

Here are fragments of the log output produced by the indicator with a gap:

```
CalendarValueHistory(values,TimeCurrent(),TimeCurrent()+(60*60*24)*3)=186 / ok

```

The updated news has the *actual_value* value.

In order not to wait too long during the test, it is advisable to run this indicator during the working hours of the main markets, when the density of news releases is high.

The *CalendarValueById* function is not the only one, and probably not the most flexible, with which you can monitor changes in the calendar. We will look at a couple of other approaches in the following sections.

7.3.8 Tracking event changes by country or currency

As mentioned in the section on basic concepts of the calendar, the platform registers all event changes by some internal means. Each state is characterized by a change identifier (*change_id*). Among the MQL5 functions, there are two that allow you to find this identifier (at an arbitrary point in time) and then request calendar entries changed later. One of these functions is *CalendarValueLast*, which will be discussed in this section. The second one, *CalendarValueLastByEvent*, will be discussed in the next section.

```
int CalendarValueLast(ulong &change_id, MqlCalendarValue &values[],
  const string country = NULL, const string currency = NULL)
```

The *CalendarValueLast* function is designed for two purposes: getting the last known calendar change identifier *change_id* and filling the *values* array with modified records since the previous modification given by the passed ID in the same *change_id*. In other words, the *change_id* parameter works as both input and output. That is why it is a reference and requires a variable to be specified.

If we input *change_id* equal to 0 into the function, then the function will fill the variable with the current identifier but will not fill the array.

Optionally, using parameters *country* and *currency*, you can set filtering records by country and currency.

The function returns the number of copied calendar items. Since the array is not populated in the first operation mode (*change_id = 0*), returning 0 is not an error. We can also get 0 if the calendar has not been modified since the specified change. Therefore, to check for an error, you should analyze *_LastError*.

So the usual way to use the function is to loop through the calendar for changes.

```
ulong change = 0;
MqlCalendarValue values[];
while(!IsStopped())
{
 // pass the last identifier known to us and get a new one if it appeared
   if(CalendarValueLast(change, values))
   {
 // analysis of added and changed records
      ArrayPrint(values);
      ...
   }
   Sleep(1000);
}
```

This can be done in a loop, on a timer, or on other events.

Identifiers are constantly increasing, but they can go out of order, that is, jump over several values.

> It is important to note that each calendar entry is always available in only one last state: the history of changes is not provided in MQL5. As a rule, this is not a problem, since the life cycle of each news is standard: adding to the database in advance for a sufficiently long time and supplementing with relevant data at the time of the event. However, in practice, various deviations can occur: editing the forecast, transferring time, or revising the values. It is impossible to find out exactly what time and what was changed in the record through the MQL5 API from the calendar history. Therefore, those trading systems that make decisions based on the momentary situation

will require independent saving of the history of changes and its integration into an Expert Advisor for running in the tester.

Using the *CalendarValueLast* function, we can create a useful service, *CalendarChangeSaver.mq5*, which will check the calendar for changes at the specified intervals and, if any, save the change identifiers to the file along with the current server time. This will allow further use of the file information for more realistic testing of Expert Advisors on the history of the calendar. Of course, this will require organizing the export/import of the entire calendar database, which we will deal with over time.

Let's provide input variables for specifying the file name and the period between polls (in milliseconds).

```
input string Filename = "calendar.chn";
input int PeriodMsc = 1000;
```

At the beginning of the *OnStart* handler, we open the binary file for writing, or rather for appending (if it already exists). The format of an existing file is not checked here and thus you should add protection when embedding in a real application.

```
void OnStart()
{
   ulong change = 0, last = 0;
   int count = 0;
   int handle = FileOpen(Filename,
      FILE_WRITE | FILE_READ | FILE_SHARE_WRITE | FILE_SHARE_READ | FILE_BIN);
   if(handle == INVALID_HANDLE)
   {
      PrintFormat("Can't open file '%s' for writing", Filename);
      return;
   }

   const ulong p = FileSize(handle);
   if(p > 0)
   {
      PrintFormat("Resuming file %lld bytes", p);
      FileSeek(handle, 0, SEEK_END);
   }

   Print("Requesting start ID...");
   ...
```

Here we should make a small digression.

Each time the calendar is changed, at least a pair of integer 8-byte numbers must be written to the file: the current time (*datetime*) and news ID (*ulong*), but there can be more than one record changed at the same time. Therefore, in addition to the date, the number of changed records is packed into the first number. This takes into account that dates fit in 0x7FFFFFFF and therefore the upper 3 bytes are left unused. It is in the two most significant bytes (at a left offset of 48 bits) that the number of identifiers that the service will write after the corresponding timestamp is placed. The PACK_DATETIME_COUNTER macro creates an "extended" date, and the other two, DATETIME and COUNTER, we will need later when the archive of changes is read (by another program).

```
#define PACK_DATETIME_COUNTER(D,C) (D | (((ulong)(C)) << 48))
#define DATETIME(A) ((datetime)((A) & 0x7FFFFFFF))
#define COUNTER(A)  ((ushort)((A) >> 48))
```

Now let's go back to the main service code. In a loop that is activated every *PeriodMsc* milliseconds, we request changes using *CalendarValueLast*. If there are changes, we write the current server time and the array of received identifiers to a file.

```
      while(!IsStopped())
      {
         if(!TerminalInfoInteger(TERMINAL_CONNECTED))
         {
            Print("Waiting for connection...");
            Sleep(PeriodMsc);
            continue;
         }

         MqlCalendarValue values[];
         const int n = CalendarValueLast(change, values);
         if(n > 0)
         {
            string records = "[" + Description(values[0]);
            for(int i = 1; i < n; ++i)
            {
               records += "," + Description(values[i]);
            }
            records += "]";
            Print("New change ID: ", change, " ",
               TimeToString(TimeTradeServer(), TIME_DATE | TIME_SECONDS), "\n", records)
            FileWriteLong(handle, PACK_DATETIME_COUNTER(TimeTradeServer(), n));
            for(int i = 0; i < n; ++i)
            {
               FileWriteLong(handle, values[i].id);
            }
            FileFlush(handle);
            ++count;
         }
         else if(_LastError == 0)
         {
            if(!last && change)
            {
               Print("Start change ID obtained: ", change);
            }
         }

         last = change;
         Sleep(PeriodMsc);
      }
      PrintFormat("%d records added", count);
      FileClose(handle);
   }
```

For a convenient presentation of information about each news event, we have written a helper function *Description*.

```
string Description(const MqlCalendarValue &value)
{
   MqlCalendarEvent event;
   MqlCalendarCountry country;
   CalendarEventById(value.event_id, event);
   CalendarCountryById(event.country_id, country);
   return StringFormat("%lld (%s/%s @ %s)",
      value.id, country.code, event.name, TimeToString(value.time));
}
```

Thus, the log will display not only the identifier but also the country code, title, and scheduled time of the news.

> It is assumed that the service should work for quite a long time in order to collect information for a period sufficient for testing (days, weeks, months). Unfortunately, just like with the order book, the platform does not provide a ready-made history of the order book or calendar edits, so their collection is left entirely to the developer of MQL programs.

Let's see the service in action. In the next fragment of the log (for the time period of 2022.06.28, 15:30 - 16:00), some news events relate to the distant future (they contain the values of the prev_value field, which is also the *actual_value* field of the current event of the same name). However, something else is more important: the actual time of a news release can differ significantly, sometimes by several minutes, from the planned one.

```

Of course, this is important not for all classes of trading strategies, but only for those that trade quickly in the market. For them, the created archive of calendar edits can provide more accurate testing of news Expert Advisors. We will discuss how you can "connect" the calendar to the tester in the future, but for now, we will show how to read the received file.

We will use the script *CalendarChangeReader.mq5* to demonstrate the discussed functionality. In practice, the given source code should be placed in the Expert Advisor.

The input variables allow you to set the name of the file to be read and the start date of the scan. If the service continues to work (write the file), you need to copy the file under a different name or to another folder (in the example script, the file is renamed). If the *Start* parameter is blank, the reading of news changes will start from the beginning of the current day.

```
input string Filename = "calendar2.chn";
input datetime Start;
```

The *ChangeState* structure is described to store information about individual edits.

```
struct ChangeState
{
   datetime dt;
   ulong ids[];

   ChangeState(): dt(LONG_MAX) {}
   ChangeState(const datetime at, ulong &_ids[])
   {
      dt = at;
      ArraySwap(ids, _ids);
   }

   void operator=(const ChangeState &other)
   {
      dt = other.dt;
      ArrayCopy(ids, other.ids);
   }
};
```

It is used in the *ChangeFileReader* class, which does the bulk of the work of reading the file and providing the caller with the changes that are appropriate for a particular point in time.

The file handle is passed as a parameter to the constructor, as is the start time of the test. Reading a file and populating the *ChangeState* structure for one calendar edit is performed in the *readState* method.

```
class ChangeFileReader
{
   const int handle;
   ChangeState current;
   const ChangeState zero;

public:
   ChangeFileReader(const int h, const datetime start = 0): handle(h)
   {
      if(readState())
      {
         if(start)
         {
            ulong dummy[];
            check(start, dummy, true); // find the first edit after start
         }
      }
   }

   bool readState()
   {
      if(FileIsEnding(handle)) return false;
      ResetLastError();
      const ulong v = FileReadLong(handle);
      current.dt = DATETIME(v);
      ArrayFree(current.ids);
      const int n = COUNTER(v);
      for(int i = 0; i < n; ++i)
      {
         PUSH(current.ids, FileReadLong(handle));
      }
      return _LastError == 0;
   }
   ...
```

Method *check* reads the file until the next edit appears in the future. In this case, all previous (by timestamps) edits since the previous method call are placed in the output array *records*.

```
      bool check(datetime now, ulong &records[], const bool fastforward = false)
      {
         if(current.dt > now) return false;

         ArrayFree(records);

         if(!fastforward)
         {
            ArrayCopy(records, current.ids);
            current = zero;
         }

         while(readState() && current.dt <= now)
         {
            if(!fastforward) ArrayInsert(records, current.ids, ArraySize(records));
         }

         return true;
      }
   };
```

Here is how the class is used in *OnStart*.

```
void OnStart()
{
   const long day = 60 * 60 * 24;
   datetime now = Start ? Start : (datetime)(TimeCurrent() / day * day);

   int handle = FileOpen(Filename,
      FILE_READ | FILE_SHARE_WRITE | FILE_SHARE_READ | FILE_BIN);
   if(handle == INVALID_HANDLE)
   {
      PrintFormat("Can't open file '%s' for reading", Filename);
      return;
   }

   ChangeFileReader reader(handle, now);

   // reading step by step, time now artificially increased in this demo
   while(!FileIsEnding(handle))
   {
      // in a real application, a call to reader.check can be made on every tick
      ulong records[];
      if(reader.check(now, records))
      {
         Print(now);          // output time
         ArrayPrint(records); // array of IDs of changed news
      }
      now += 60; // add 1 minute at a time, can be per second
   }

   FileClose(handle);
}
```

Here are the results of the script for the same calendar changes that were saved by the service in the context of the previous log fragment.

```
2022.06.28 15:31:00
155955 155956 156117 156118 156231 156232 156255

154532 154544 154571
```

The same identifiers are reproduced in virtual time with the same delay as online, although here you can see the rounding to 1 minute, which happened because we set an artificial step of this size in the loop. In theory, for reasons of efficiency, we can postpone checks until the time stored in the *ChangeState current* structure. The attached source code defines the *getState* method to get this time.

7.3.9 Tracking event changes by type

The MQL5 API allows you to request recent changes not only in general for the entire calendar or by country or currency, but also in a narrower range, or rather, for a specific type of event.

In theory, we can say that the built-in functions provide filtering of events according to several basic conditions: time, country, currency, or type of event. For other attributes, such as importance or economic sector, you need to implement your own filtering, and we will deal with this later. For now, let's introduce the *CalendarValueLastByEvent* function.

int CalendarValueLastByEvent(ulong id, ulong &change_id, MqlCalendarValue &values[])

The function fills the *values* array passed by reference with event records of a specific type with the *id* identifier that have occurred since *change_id*. This *change_id* parameter is both input and output: the calling code passes in it the label of the past state of the calendar, after which changes are requested, and when control returns, the function writes the current label of the calendar database state to *change_id*. It should be used the next time the function is called.

If you pass null in *change_id*, then the function does not fill the array but simply sends the current state of the database through the parameter *change_id*.

The array can be dynamic (then it will be automatically adjusted to the amount of data) or fixed size (if its size is insufficient, only data that fit will be copied).

The output value of the function is equal to the number of elements copied into the *values* array. If there are no changes or *change_id = 0* is specified, the function will return 0.

To check for an error, analyze the built-in *_LastError* variable. Some of the possible error codes are:

- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory to complete the request),
- 5401 - ERR_CALENDAR_TIMEOUT (request timed out),
- 5400 - ERR_CALENDAR_MORE_DATA (the size of the fixed array is not enough to get all the values).

We will not give a separate example for *CalendarValueLastByEvent*. Instead, let's turn to a more complex, but in-demand task of querying and filtering calendar entries with arbitrary conditions on news attributes, where all the "calendar" API functions will be involved. This will be the subject of the next section.

7.3.10 Filtering events by multiple conditions

As we know from the previous sections of this chapter, the MQL5 API allows you to request calendar events based on several conditions:

- by countries (*CalendarValueHistory*, *CalendarValueLast*)
- by frequencies (*CalendarValueHistory*, *CalendarValueLast*)
- by event type IDs (*CalendarValueHistoryByEvent*, *CalendarValueLastByEvent*)
- by time range (*CalendarValueHistory*, *CalendarValueHistoryByEvent*)
- by changes since the previous calendar poll (*CalendarValueLast*, *CalendarValueLastByEvent*)
- by ID of specific news (*CalendarValueById*)

This can be summarized as the following table of functions (of all *CalendarValue* functions, only *CalendarValueById* for getting one specific value is missing here).

Conditions	Time range	Last changes
Countries	CalendarValueHistory	CalendarValueLast
Currencies	CalendarValueHistory	CalendarValueLast
Events	CalendarValueHistoryByEvent	CalendarValueLastByEvent

Such a toolkit covers main, but not all, popular calendar analysis scenarios. Therefore, in practice, it is often necessary to implement custom filtering mechanisms in MQL5, including, in particular, event requests by:

- several countries
- several currencies
- several types of events
- values of arbitrary properties of events (importance, sector of the economy, reporting period, type, presence of a forecast, estimated impact on the rate, substring in the name of the event, etc.)

To solve these problems, we have created the *CalendarFilter* class (*CalendarFilter.mqh*).

Due to the specifics of the built-in API functions, some of the news attributes are given higher priority than the rest. This includes country, currency, and date range. They can be specified in the class constructor, and then the corresponding property cannot be dynamically changed in the filter conditions.

This is because the filter class will subsequently be extended with the news caching capabilities to enable reading from the tester, and the initial conditions of the constructor actually define the caching context within which further filtering is possible. For example, if we specify the country code "EU" when creating an object, then obviously it makes no sense to request news about the USA or Brazil through it. It is similar to the date range: specifying it in the constructor will make it impossible to receive news outside the range.

We can also create an object without initial conditions (because all constructor parameters are optional), and then it will be able to cache and filter news across the entire calendar database (as of the moment of saving).

In addition, since countries and currencies are now almost uniquely displayed (with the exception of the European Union and EUR), they are passed to the constructor through a single parameter *context*: if you specify a string with the length of 2 characters, the country code (or a combination of countries) is implied, and if the length is 3 characters, the currency code is implied. For the codes "EU" and "EUR", the euro area is a subset of "EU" (within countries with formal treaties). In special cases, where non-euro area EU countries are of interest, they can also be described by "EU" context. If necessary, narrower conditions for news on the currencies of these countries (BGN, HUF, DKK, ISK, PLN, RON, HRK, CZK, SEK) can be added to the filter dynamically using methods that we will present later. However, due to exotics, there are no guarantees that such news will get into the calendar.

Let's start studying the class.

```
class CalendarFilter
{
protected:
   // initial (optional) conditions set in the constructor, invariants
   string context;    // country and currency
   datetime from, to; // date range
   bool fixedDates;   // if 'from'/'to' are passed in the constructor, they cannot be

   // dedicated selectors (countries/currencies/event type identifiers)
   string country[], currency[];
   ulong ids[];

   MqlCalendarValue values[]; // filtered results

   virtual void init()
   {
      fixedDates = from != 0 || to != 0;
      if(StringLen(context) == 3)
      {
         PUSH(currency, context);
      }
      else
      {
         // even if context is NULL, we take it to poll the entire calendar base
         PUSH(country, context);
      }
   }
   ...
public:
   CalendarFilter(const string _context = NULL,
      const datetime _from = 0, const datetime _to = 0):
      context(_context), from(_from), to(_to)
   {
      init();
   }
   ...
```

Two arrays are allocated for countries and currencies: *country* and *currency*. If they are not filled from *context* during object creation, then the MQL program will be able to add conditions for several countries or currencies in order to perform a combined news query on them.

To store conditions on all other news attributes, the *selectors* array is described in the *CalendarFilter* object, with the second dimension equal to 3. We can say that this is a kind of table in which each row has 3 columns.

```
long selectors[][3];   // [0] - property, [1] - value, [2] - condition
```

At the 0th index, the news property identifiers will be located. Since the attributes are spread across three base tables (*MqlCalendarCountry*, *MqlCalendarEvent*, *MqlCalendarValue*) they are described using the elements of the generalized enumeration ENUM_CALENDAR_PROPERTY (*CalendarDefines.mqh*).

```
enum ENUM_CALENDAR_PROPERTY
{                                    // +/- means support for field filtering
   CALENDAR_PROPERTY_COUNTRY_ID,       // -ulong
   CALENDAR_PROPERTY_COUNTRY_NAME,     // -string
   CALENDAR_PROPERTY_COUNTRY_CODE,     // +string (2 characters)
   CALENDAR_PROPERTY_COUNTRY_CURRENCY, // +string (3 characters)
   CALENDAR_PROPERTY_COUNTRY_GLYPH,    // -string (1 characters)
   CALENDAR_PROPERTY_COUNTRY_URL,      // -string

   CALENDAR_PROPERTY_EVENT_ID,         // +ulong (event type ID)
   CALENDAR_PROPERTY_EVENT_TYPE,       // +ENUM_CALENDAR_EVENT_TYPE
   CALENDAR_PROPERTY_EVENT_SECTOR,     // +ENUM_CALENDAR_EVENT_SECTOR
   CALENDAR_PROPERTY_EVENT_FREQUENCY,  // +ENUM_CALENDAR_EVENT_FREQUENCY
   CALENDAR_PROPERTY_EVENT_TIMEMODE,   // +ENUM_CALENDAR_EVENT_TIMEMODE
   CALENDAR_PROPERTY_EVENT_UNIT,       // +ENUM_CALENDAR_EVENT_UNIT
   CALENDAR_PROPERTY_EVENT_IMPORTANCE, // +ENUM_CALENDAR_EVENT_IMPORTANCE
   CALENDAR_PROPERTY_EVENT_MULTIPLIER, // +ENUM_CALENDAR_EVENT_MULTIPLIER
   CALENDAR_PROPERTY_EVENT_DIGITS,     // -uint
   CALENDAR_PROPERTY_EVENT_SOURCE,     // +string ("http[s]://")
   CALENDAR_PROPERTY_EVENT_CODE,       // -string
   CALENDAR_PROPERTY_EVENT_NAME,       // +string (4+ characters or wildcard '*')

   CALENDAR_PROPERTY_RECORD_ID,        // -ulong
   CALENDAR_PROPERTY_RECORD_TIME,      // +datetime
   CALENDAR_PROPERTY_RECORD_PERIOD,    // +datetime (like long)
   CALENDAR_PROPERTY_RECORD_REVISION,  // +int
   CALENDAR_PROPERTY_RECORD_ACTUAL,    // +long
   CALENDAR_PROPERTY_RECORD_PREVIOUS,  // +long
   CALENDAR_PROPERTY_RECORD_REVISED,   // +long
   CALENDAR_PROPERTY_RECORD_FORECAST,  // +long
   CALENDAR_PROPERTY_RECORD_IMPACT,    // +ENUM_CALENDAR_EVENT_IMPACT

   CALENDAR_PROPERTY_RECORD_PREVISED,  // +non-standard (previous or revised if any)

   CALENDAR_PROPERTY_CHANGE_ID,        // -ulong (reserved)
};
```

Index 1 will store values for comparison with them in the conditions for selecting news records. For example, if you want to set a filter by sector of the economy, then we write CALENDAR_PROPERTY_EVENT_SECTOR in *selectors[i][0]* and one of the values of the standard enumeration ENUM_CALENDAR_EVENT_SECTOR in *selectors[i][1]*.

Finally, the last column (under the 2nd index) is reserved for the operation of comparing the selector value with the attribute value in the news: all supported operations are summarized in the IS enumeration.

```
enum IS
{
   EQUAL,
   NOT_EQUAL,
   GREATER,
   LESS,
   OR_EQUAL,
   ...
};
```

We saw a similar approach in *TradeFilter.mqh*. Thus, we will be able to arrange conditions not only for equality of values but also for inequality or more/less relations. For example, it is easy to imagine a filter on the CALENDAR_PROPERTY_EVENT_IMPORTANCE field, which should be GREATER than CALENDAR_IMPORTANCE_LOW (this is an element of the standard ENUM_CALENDAR_EVENT_IMPORTANCE enumeration), which means a selection of news of medium and high importance.

The next enumeration defined specifically for the calendar is ENUM_CALENDAR_SCOPE. Since calendar filtering is often associated with time spans, the most requested ones are listed here.

```
#define DAY_LONG     (60 * 60 * 24)
#define WEEK_LONG    (DAY_LONG * 7)
#define MONTH_LONG   (DAY_LONG * 30)
#define QUARTER_LONG (MONTH_LONG * 3)
#define YEAR_LONG    (MONTH_LONG * 12)

enum ENUM_CALENDAR_SCOPE
{
   SCOPE_DAY = DAY_LONG,          // Day
   SCOPE_WEEK = WEEK_LONG,        // Week
   SCOPE_MONTH = MONTH_LONG,      // Month
   SCOPE_QUARTER = QUARTER_LONG, // Quarter
   SCOPE_YEAR = YEAR_LONG,        // Year
};
```

All enumerations are placed in a separate header file *CalendarDefines.mqh*.

But let's go back to the class *CalendarFilter*. The type of the *selectors* array is *long*, which is suitable for storing values of almost all involved types: enumerations, dates and times, identifiers, integers, and even economic indicators values because they are stored in the calendar in the form of *long* numbers (in millionths of real values). However, what to do with string properties?

This problem is solved by using the array of strings *stringCache*, to which all the lines mentioned in the filter conditions will be added.

```
class CalendarFilter
{
protected:
   ...
   string stringCache[];  // cache of all rows in 'selectors'
   ...
```

Then, instead of the string value in *selectors[i][1]*, we can easily save the index of an element in the *stringCache* array.

To populate the *selectors* array with filter conditions, there are several *let* methods provided, in particular, for enumerations:

```
class CalendarFilter
{
...
public:
   // all fields of enum types are processed here
   template<typename E>
   CalendarFilter *let(const E e, const IS c = EQUAL)
   {
      const int n = EXPAND(selectors);
      selectors[n][0] = resolve(e); // by type E, returning the element ENUM_CALENDAR
      selectors[n][1] = e;
      selectors[n][2] = c;
      return &this;
   }
   ...
```

For actual values of indicators:

```
   // the following fields are processed here:
   // CALENDAR_PROPERTY_RECORD_ACTUAL, CALENDAR_PROPERTY_RECORD_PREVIOUS,
   // CALENDAR_PROPERTY_RECORD_REVISED, CALENDAR_PROPERTY_RECORD_FORECAST,
   // and CALENDAR_PROPERTY_RECORD_PERIOD (as long)
   CalendarFilter *let(const long value, const ENUM_CALENDAR_PROPERTY property, const
   {
      const int n = EXPAND(selectors);
      selectors[n][0] = property;
      selectors[n][1] = value;
      selectors[n][2] = c;
      return &this;
   }
   ...
```

And for strings:

```
// conditions for all string properties can be found here (abbreviated)
CalendarFilter *let(const string find, const IS c = EQUAL)
{
   const int wildcard = (StringFind(find, "*") + 1) * 10;
   switch(StringLen(find) + wildcard)
   {
   case 2:
      // if the initial context is different from the country, we can supplement i
      // otherwise the filter is ignored
      if(StringLen(context) != 2)
      {
         if(ArraySize(country) == 1 && StringLen(country[0]) == 0)
         {
            country[0] = find; // narrow down "all countries" to one (may add more
         }
         else
         {
            PUSH(country, find);
         }
      }
      break;
   case 3:
      // we can set a filter for a currency only if it was not in the initial cont
      if(StringLen(context) != 3)
      {
         PUSH(currency, find);
      }
      break;
   default:
      {
         const int n = EXPAND(selectors);
         PUSH(stringCache, find);
         if(StringFind(find, "http://") == 0 || StringFind(find, "https://") == 0)
         {
            selectors[n][0] = CALENDAR_PROPERTY_EVENT_SOURCE;
         }
         else
         {
            selectors[n][0] = CALENDAR_PROPERTY_EVENT_NAME;
         }
         selectors[n][1] = ArraySize(stringCache) - 1;
         selectors[n][2] = c;
         break;
      }
   }

   return &this;
}
```

In the method overload for strings, note that 2 or 3-character long strings (if they are without the template asterisk '*', which is a replacement for an arbitrary sequence of characters) fall into the

arrays of countries and symbols, respectively, and all other strings are treated as fragments of the name or news source, and both of these fields involve *stringCache* and *selectors*.

In a special way, the class also supports filtering by type (identifier) of events.

```
protected:
   ulong ids[];           // filtered event types
   ...
public:
   CalendarFilter *let(const ulong event)
   {
      PUSH(ids, event);
      return &this;
   }
   ...
```

Thus, the number of priority filters (which are processed outside the selectors array) includes not only countries, currencies, and date ranges, but also event type identifiers. Such a constructive decision is due to the fact that these parameters can be passed to certain calendar API functions as input. We get all other news attributes as output field values in arrays of structures (*MqlCalendarValue*, *MqlCalendarEvent*, *MqlCalendarCountry*). It is by them that we will perform additional filtering, according to the rules in the selectors array.

All *let* methods return a pointer to an object, which allows their calls to be chained. For example, like this:

```
CalendarFilter f;
f.let(CALENDAR_IMPORTANCE_LOW, GREATER) // important and moderately important news
  .let(CALENDAR_TIMEMODE_DATETIME) // only events with exact time
  .let("DE").let("FR") // a couple of countries, or, to choose from...
  .let("USD").let("GBP") // ...a couple of currencies (but both conditions won't work
  .let(TimeCurrent() - MONTH_LONG, TimeCurrent() + WEEK_LONG) // date range "around"
  .let(LONG_MIN, CALENDAR_PROPERTY_RECORD_FORECAST, NOT_EQUAL) // there is a forecast
  .let("farm"); // full text search by news titles
```

Country and currency conditions can, in theory, be combined. However, please note that multiple values can only be set for either countries or currencies but not both. One of these two aspects of the context (either of the two) in the current implementation supports only one or none of the values (i.e., no filter on it). For example, if the currency EUR is selected, it is possible to narrow the search context for news only in Germany and France (country codes "DE" and "FR"). As a result, ECB and Eurostat news will be discarded, as well as, specifically, Italy and Spain news. However, the indication of EUR in this case is redundant since there are no other currencies in Germany and France.

Since the class uses built-in functions in which the parameters *country* and *currency* are applied to the news using the logical AND operation, check the consistency of the filter conditions.

After the calling code sets up the filtering conditions, it is necessary to select news based on them. This is what the public method *select* does (given with simplifications).

```
public:
   bool select(MqlCalendarValue &result[])
   {
      int count = 0;
      ArrayFree(result);
      if(ArraySize(ids)) // identifiers of event types
      {
         for(int i = 0; i < ArraySize(ids); ++i)
         {
            MqlCalendarValue temp[];
            if(PRTF(CalendarValueHistoryByEvent(ids[i], temp, from, to)))
            {
               ArrayCopy(result, temp, ArraySize(result));
               ++count;
            }
         }
      }
      else
      {
         // several countries or currencies, choose whichever is more as a basis,
         // only the first element from the smaller array is used
         if(ArraySize(country) > ArraySize(currency))
         {
            const string c = ArraySize(currency) > 0 ? currency[0] : NULL;
            for(int i = 0; i < ArraySize(country); ++i)
            {
               MqlCalendarValue temp[];
               if(PRTF(CalendarValueHistory(temp, from, to, country[i], c)))
               {
                  ArrayCopy(result, temp, ArraySize(result));
                  ++count;
               }
            }
         }
         else
         {
            const string c = ArraySize(country) > 0 ? country[0] : NULL;
            for(int i = 0; i < ArraySize(currency); ++i)
            {
               MqlCalendarValue temp[];
               if(PRTF(CalendarValueHistory(temp, from, to, c, currency[i])))
               {
                  ArrayCopy(result, temp, ArraySize(result));
                  ++count;
               }
            }
         }
      }

      if(ArraySize(result) > 0)
      {
```

```
         filter(result);
      }

      if(count > 1 && ArraySize(result) > 1)
      {
         SORT_STRUCT(MqlCalendarValue, result, time);
      }

      return ArraySize(result) > 0;
   }
```

Depending on which of the priority attribute arrays are filled, the method calls different API functions to poll the calendar:

- If the *ids* array is filled, *CalendarValueHistoryByEvent* is called in a loop for all identifiers
- If the *country* array is filled and it's larger than the array of currencies, call *CalendarValueHistory* and loop through the countries
- If the *currency* array is filled and it is greater than or equal to the size of the array of countries, call *CalendarValueHistory* and loop through the currencies

Each function call populates a temporary array of structures *MqlCalendarValue temp[]*, which is sequentially accumulated in the *result* parameter array. After writing all relevant news into it according to the main conditions (dates, countries, currencies, identifiers), if any, an auxiliary method *filter* comes into play, which filters the array based on the conditions in *selectors*. At the end of the *select* method, the news items are sorted in chronological order, which can be broken by combining the results of multiple queries of "calendar" functions. Sorting is implemented using the SORT_STRUCT macro, which was discussed in the section Comparing, sorting, and searching in arrays.

For each element of the news array, the *filter* method calls the worker method *match*, which returns a boolean indicator of whether the news matches the filter conditions. If not, the element is removed from the array.

```
protected:
   void filter(MqlCalendarValue &result[])
   {
      for(int i = ArraySize(result) - 1; i >= 0; --i)
      {
         if(!match(result[i]))
         {
            ArrayRemove(result, i, 1);
         }
      }
   }
   ...
```

Finally, the *match* method analyzes our *selectors* array and compares it with the fields of the passed structure *MqlCalendarValue*. Here the code is provided in an abbreviated form.

```
bool match(const MqlCalendarValue &v)
  {
     MqlCalendarEvent event;
     if(!CalendarEventById(v.event_id, event)) return false;

     // loop through all filter conditions, except for countries, currencies, dates,
     // which have already been previously used when calling Calendar functions
     for(int j = 0; j < ArrayRange(selectors, 0); ++j)
     {
        long field = 0;
        string text = NULL;

        // get the field value from the news or its description
        switch((int)selectors[j][0])
        {
        case CALENDAR_PROPERTY_EVENT_TYPE:
           field = event.type;
           break;
        case CALENDAR_PROPERTY_EVENT_SECTOR:
           field = event.sector;
           break;
        case CALENDAR_PROPERTY_EVENT_TIMEMODE:
           field = event.time_mode;
           break;
        case CALENDAR_PROPERTY_EVENT_IMPORTANCE:
           field = event.importance;
           break;
        case CALENDAR_PROPERTY_EVENT_SOURCE:
           text = event.source_url;
           break;
        case CALENDAR_PROPERTY_EVENT_NAME:
           text = event.name;
           break;
        case CALENDAR_PROPERTY_RECORD_IMPACT:
           field = v.impact_type;
           break;
        case CALENDAR_PROPERTY_RECORD_ACTUAL:
           field = v.actual_value;
           break;
        case CALENDAR_PROPERTY_RECORD_PREVIOUS:
           field = v.prev_value;
           break;
        case CALENDAR_PROPERTY_RECORD_REVISED:
           field = v.revised_prev_value;
           break;
        case CALENDAR_PROPERTY_RECORD_PREVISED: // previous or revised (if any)
           field = v.revised_prev_value != LONG_MIN ? v.revised_prev_value : v.prev_
           break;
        case CALENDAR_PROPERTY_RECORD_FORECAST:
           field = v.forecast_value;
           break;
```

```
      ...
      }

      // compare value with filter condition
      if(text == NULL) // numeric fields
      {
         switch((IS)selectors[j][2])
         {
         case EQUAL:
            if(!equal(field, selectors[j][1])) return false;
            break;
         case NOT_EQUAL:
            if(equal(field, selectors[j][1])) return false;
            break;
         case GREATER:
            if(!greater(field, selectors[j][1])) return false;
            break;
         case LESS:
            if(greater(field, selectors[j][1])) return false;
            break;
         }
      }
      else // string fields
      {
         const string find = stringCache[(int)selectors[j][1]];
         switch((IS)selectors[j][2])
         {
         case EQUAL:
            if(!equal(text, find)) return false;
            break;
         case NOT_EQUAL:
            if(equal(text, find)) return false;
            break;
         case GREATER:
            if(!greater(text, find)) return false;
            break;
         case LESS:
            if(greater(text, find)) return false;
            break;
         }
      }
   }

   return true;
}
```

The *equal* and *greater* methods almost completely copy those used in our previous developments with filter classes.

On this, the filtering problem is generally solved, i.e., the MQL program can use the object *CalendarFilter* in the following way:

```
CalendarFilter f;
f.let()... // a series of calls to the let method to set filtering conditions
MqlCalendarValue records[];
if(f.select(records))
{
   ArrayPrint(records);
}
```

In fact, the *select* method can do something else important that we left for an independent elective study.

First, in the resulting list of news, it is desirable to somehow insert a separator (*delimiter*) between the past and the future, so that the eye can catch on to it. In theory, this feature is extremely important for calendars, but for some reason, it is not available in the MetaTrader 5 user interface and on the mql5.com website. Our implementation is able to insert an empty structure between the past and the future, which we should visually display (which we will deal with below).

Second, the size of the resulting array can be quite large (especially at the first stages of selecting settings), and therefore the *select* method additionally provides the ability to limit the size of the array (*limit*). This is done by removing the elements furthest from the current time.

So, the full method prototype looks like this:

```
bool select(MqlCalendarValue &result[],
   const bool delimiter = false, const int limit = -1);
```

By default, no delimiter is inserted and the array is not truncated.

A couple of paragraphs above, we mentioned an additional subtask of filtering which is the visualization of the resulting array. The *CalendarFilter* class has a special method *format*, which turns the passed array of structures *MqlCalendarValue &data[]* into an array of human-readable strings *string &result[]*. The code of the method can be found in the attached file *CalendarFilter.mqh*.

```
bool format(const MqlCalendarValue &data[],
   const ENUM_CALENDAR_PROPERTY &props[], string &result[],
   const bool padding = false, const bool header = false);
```

The fields of the *MqlCalendarValue* that we want to display are specified in the *props* array. Recall that the ENUM_CALENDAR_PROPERTY enumeration contains fields from all three dependent calendar structures so that an MQL program can automatically display not only economic indicators from a specific event record but also its name, characteristics, country, or currency code. All this is implemented by the *format* method.

Each row in the output *result* array contains a text representation of the value of one of the fields (number, description, enumeration element). The size of the *result* array is equal to the product of the number of structures at the input (in *data*) and the number of displayed fields (in *props*). The optional parameter *header* allows you to add a row with the names of fields (columns) to the beginning of the output array. The *padding* parameter controls the generation of additional spaces in the text so that it is convenient to display the table in a monospaced font (for example, in a magazine).

The *CalendarFilter* class has another important public method: *update*.

```
bool update(MqlCalendarValue &result[]);
```

Its structure almost completely repeats *select*. However, instead of calling the *CalendarValueHistoryByEvent* and *CalendarValueHistory* functions, the method calls *CalendarValueLastByEvent* and *CalendarValueLast*. The purpose of the method is obvious: it queries the calendar for recent changes that match the filtering conditions. But for its operation, it requires an ID of changes. Such a field is indeed defined in the class: the first time it is filled inside the *select* method.

```
class CalendarFilter
{
protected:
   ...
   ulong change;
   ...
public:
   bool select(MqlCalendarValue &result[],
      const bool delimiter = false, const int limit = -1)
   {
      ...
      change = 0;
      MqlCalendarValue dummy[];
      CalendarValueLast(change, dummy);
      ...
   }
```

Some nuances of the *CalendarFilter* class are still "behind the scenes", but we will address some of them in the following sections.

Let's test the filter in action: first in a simple script *CalendarFilterPrint.mq5* and then in a more practical indicator *CalendarMonitor.mq5*.

In the input parameters of the script, you can set the context (country code or currency), time range, and string for full-text search by event names, as well as limit the size of the resulting news table.

```
input string Context; // Context (country - 2 characters, currency - 3 characters, em
input ENUM_CALENDAR_SCOPE Scope = SCOPE_MONTH;
input string Text = "farm";
input int Limit = -1;
```

Given the parameters, a global filter object is created.

```
CalendarFilter f(Context, TimeCurrent() - Scope, TimeCurrent() + Scope);
```

Then, in *OnStart*, we configure a couple of additional constant conditions (medium and high importance of events) and the presence of a forecast (the field is not equal to LONG_MIN), as well as pass and a search string to the object.

```
void OnStart()
{
   f.let(CALENDAR_IMPORTANCE_LOW, GREATER)
      .let(LONG_MIN, CALENDAR_PROPERTY_RECORD_FORECAST, NOT_EQUAL)
      .let(Text); // with '*' replacement support
      // NB: strings with the character length of 2 or 3 without '*' will be treated
      // as a country or currency code, respectively
```

Next, the *select* method is called and the resulting array of *MqlCalendarValue* structures is formatted into a table with 9 columns using the *format* method.

```
   MqlCalendarValue records[];
     // apply the filter conditions and get the result
     if(f.select(records, true, Limit))
     {
        static const ENUM_CALENDAR_PROPERTY props[] =
        {
           CALENDAR_PROPERTY_RECORD_TIME,
           CALENDAR_PROPERTY_COUNTRY_CURRENCY,
           CALENDAR_PROPERTY_EVENT_NAME,
           CALENDAR_PROPERTY_EVENT_IMPORTANCE,
           CALENDAR_PROPERTY_RECORD_ACTUAL,
           CALENDAR_PROPERTY_RECORD_FORECAST,
           CALENDAR_PROPERTY_RECORD_PREVISED,
           CALENDAR_PROPERTY_RECORD_IMPACT,
           CALENDAR_PROPERTY_EVENT_SECTOR,
        };
        static const int p = ArraySize(props);

        // output the formatted result
        string result[];
        if(f.format(records, props, result, true, true))
        {
           for(int i = 0; i < ArraySize(result) / p; ++i)
           {
              Print(SubArrayCombine(result, " | ", i * p, p));
           }
        }
     }
}
```

The cells of the table are joined into rows and output to the log.

With the default settings (i.e., for all countries and currencies, with the "farm" part in the name of events of medium and high importance), you can get something like this schedule.

```
Selecting calendar records...
country[i]= / ok
calendarValueHistory(temp,from,to,country[i],c)=2372 / ok
Filtering 2372 records
Got 9 records
            TIME | CUR⊠ |                          NAME | IMPORTAN⊠ | ACTU⊠ | FORE⊠ |
2022.06.02 15:15 |  USD | ADP Nonfarm Employment Change |      HIGH |  +128 |  -225 |

2022.07.08 15:30 |  USD |      Private Nonfarm Payrolls |  MODERATE |  +nan |   +51 |
```

Now let's take a look at the indicator *CalendarMonitor.mq5*. Its purpose is to display the current selection of events on the chart to the user in accordance with the specified filters. To visualize the table, we will use the already familiar scoreboard class (*Tableau.mqh*, see section Margin calculation for a future order). The indicator has no buffers and charts.

The input parameters allow you to set the range of the time window (*scope*), as well as the global context for the object *CalendarFilter*, which is either the currency or country code in *Context* (empty by default, i.e. without restrictions) or using a boolean flag *UseChartCurrencies*. It is enabled by default, and it is recommended to use it in order to automatically receive news of those currencies that make up the working tool of the chart.

```
input string Context; // Context (country - 2 chars, currency - 3 chars, empty - all)
input ENUM_CALENDAR_SCOPE Scope = SCOPE_WEEK;
input bool UseChartCurrencies = true;
```

Additional filters can be applied for event type, sector, and severity.

```
input ENUM_CALENDAR_EVENT_TYPE_EXT Type = TYPE_ANY;
input ENUM_CALENDAR_EVENT_SECTOR_EXT Sector = SECTOR_ANY;
input ENUM_CALENDAR_EVENT_IMPORTANCE_EXT Importance = IMPORTANCE_MODERATE; // Importa
```

Importance sets the lower limit of the selection, not the exact match. Thus, the default value of IMPORTANCE_MODERATE will capture not only moderate but also high importance.

An attentive reader will notice that unknown enumerations are used here: ENUM_CALENDAR_EVENT_TYPE_EXT, ENUM_CALENDAR_EVENT_SECTOR_EXT, ENUM_CALENDAR_EVENT_IMPORTANCE_EXT. They are in the already mentioned file *CalendarDefines.mqh*, and they coincide (almost one-to-one) with similar built-in enumerations. The only difference is that they have added an element meaning "any" value. We need to describe such enumerations in order to simplify the input of conditions: now the filter for each field is configured using a drop-down list where you can select either one of the values or turn off the filter. If it weren't for the added enumeration element, we would have to enter a logical "on/off" flag into the interface for each field.

In addition, the input parameters allow you to query events by the presence of actual, forecast, and previous indicators in them, as well as by searching for a text string (*Text*).

```
input string Text;
input ENUM_CALENDAR_HAS_VALUE HasActual = HAS_ANY;
input ENUM_CALENDAR_HAS_VALUE HasForecast = HAS_ANY;
input ENUM_CALENDAR_HAS_VALUE HasPrevious = HAS_ANY;
input ENUM_CALENDAR_HAS_VALUE HasRevised = HAS_ANY;
input int Limit = 30;
```

Objects *CalendarFilter* and *tableau* are described at the global level.

```
CalendarFilter f(Context);
AutoPtr<Tableau> t;
```

Please note that the filter is created once, while the table is represented by an autoselector and will be recreated dynamically depending on the size of the received data.

Filter settings are made in *OnInit* via consecutive calls of *let* methods according to the input parameters.

```
int OnInit()
{
   if(!f.isLoaded()) return INIT_FAILED;

   if(UseChartCurrencies)
   {
      const string base = SymbolInfoString(_Symbol, SYMBOL_CURRENCY_BASE);
      const string profit = SymbolInfoString(_Symbol, SYMBOL_CURRENCY_PROFIT);
      f.let(base);
      if(base != profit)
      {
         f.let(profit);
      }
   }

   if(Type != TYPE_ANY)
   {
      f.let((ENUM_CALENDAR_EVENT_TYPE)Type);
   }

   if(Sector != SECTOR_ANY)
   {
      f.let((ENUM_CALENDAR_EVENT_SECTOR)Sector);
   }

   if(Importance != IMPORTANCE_ANY)
   {
      f.let((ENUM_CALENDAR_EVENT_IMPORTANCE)(Importance - 1), GREATER);
   }

   if(StringLen(Text))
   {
      f.let(Text);
   }

   if(HasActual != HAS_ANY)
   {
      f.let(LONG_MIN, CALENDAR_PROPERTY_RECORD_ACTUAL,
         HasActual == HAS_SET ? NOT_EQUAL : EQUAL);
   }
   ...

   EventSetTimer(1);

   return INIT_SUCCEEDED;
}
```

At the end, a second timer starts. All work is implemented in *OnTimer*.

```
void OnTimer()
{
   static const ENUM_CALENDAR_PROPERTY props[] = // table columns
   {
      CALENDAR_PROPERTY_RECORD_TIME,
      CALENDAR_PROPERTY_COUNTRY_CURRENCY,
      CALENDAR_PROPERTY_EVENT_NAME,
      CALENDAR_PROPERTY_EVENT_IMPORTANCE,
      CALENDAR_PROPERTY_RECORD_ACTUAL,
      CALENDAR_PROPERTY_RECORD_FORECAST,
      CALENDAR_PROPERTY_RECORD_PREVISED,
      CALENDAR_PROPERTY_RECORD_IMPACT,
      CALENDAR_PROPERTY_EVENT_SECTOR,
   };
   static const int p = ArraySize(props);

   MqlCalendarValue records[];

almost one to one   f.let(TimeCurrent() - Scope, TimeCurrent() + Scope); // shift the

   const ulong trackID = f.getChangeID();
   if(trackID) // if the state has already been removed, check for changes
   {
      if(f.update(records)) // request changes by filters
      {
         // if there are changes, notify the user
         string result[];
         f.format(records, props, result);
         for(int i = 0; i < ArraySize(result) / p; ++i)
         {
            Alert(SubArrayCombine(result, " | ", i * p, p));
         }
      // "fall through" further to update the table
      }
      else if(trackID == f.getChangeID())
      {
         return; // calendar without changes
      }
   }

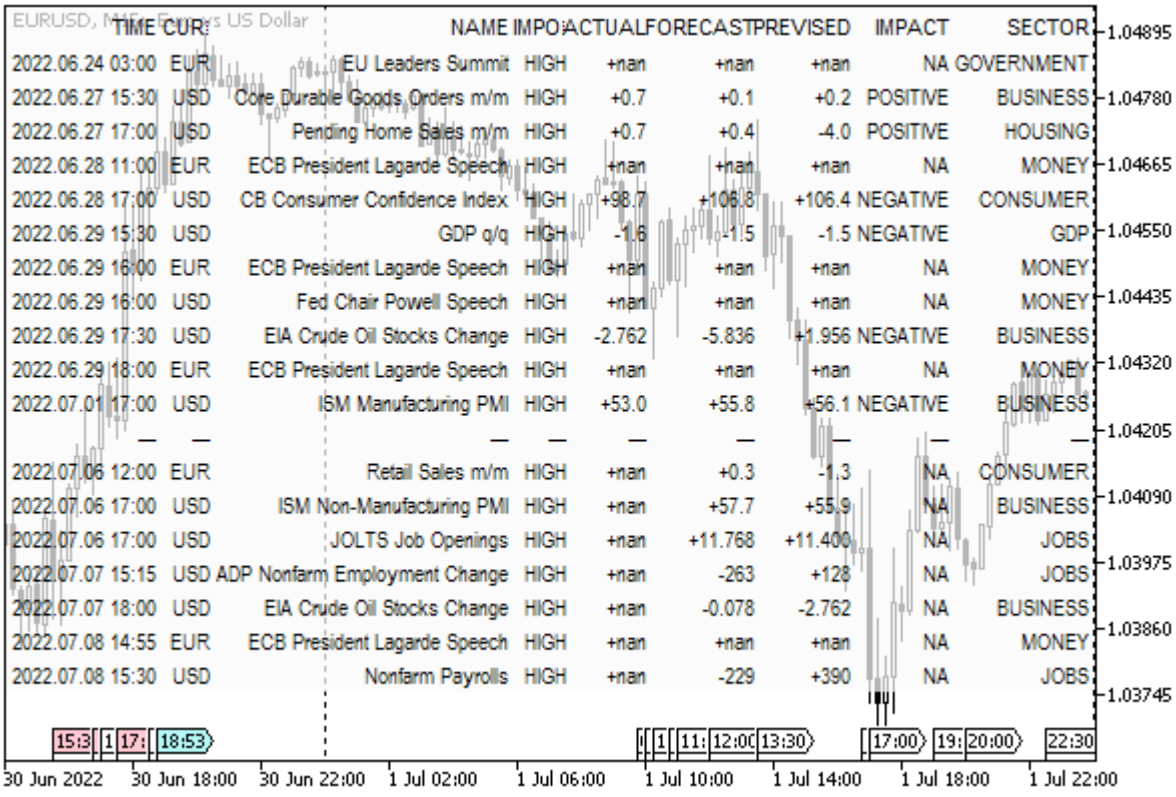
   // request a complete set of news by filters
   f.select(records, true, Limit);

   // display the news table on the chart
   string result[];
   f.format(records, props, result, true, true);

   if(t[] == NULL || t[].getRows() != ArraySize(records) + 1)
   {
      t = new Tableau("CALT", ArraySize(records) + 1, p,
         TBL_CELL_HEIGHT_AUTO, TBL_CELL_WIDTH_AUTO,
```

```
            Corner, Margins, FontSize, FontName, FontName + " Bold",
            TBL_FLAG_ROW_0_HEADER,
            BackgroundColor, BackgroundTransparency);
      }
      const string hints[] = {};
      t[].fill(result, hints);
   }
```

If we run the indicator on the EURUSD chart with default settings, we can get the following picture.



Filtered and formatted set of news on the chart

7.3.11 Transferring calendar database to tester

The calendar is available for MQL programs only online, and therefore testing news trading strategies poses some difficulties. One of the solutions is to independently create a certain image of the calendar, that is, the cache, and then use it inside the tester. Cache storage technologies can be different, such as files or an embedded SQLite database. In this section, we will show an implementation using a file.

In any case, when using the calendar cache, remember that it corresponds to a specific point in time X. In all "old" events (financial reports) that happened before X, actual values are already set, and in later ones (in "future", relative to X) there are no actual values, and will not be until a new, more recent copy of the cache appears. In other words, it makes no sense to test indicators and Expert Advisors to the right of X. As for those to the left of X, you should avoid looking ahead, that is, do not read the current indicators until the time of publication of each specific news.

> Attention! When requesting calendar data in the terminal, the time of all events is reported taking into account the current time zone of the server, including a possible correction for "daylight saving" time (as a rule, this means increasing the timestamps by 1 hour). This synchronizes news releases with online quote times. However, past clock changes (half a year, a year ago, or more)

are displayed only in quotes, but not in calendar events. The entire calendar database is read through MQL5 according to the server's current time zone. Because of this, any created calendar archive will contain the correct timestamps for those events that occurred with the same DST mode (on or off) that was active at the time of storing. For events in "opposite" half-years, it is required to independently make an adjustment for an hour after reading the archive. In the examples below, this situation is omitted.

Let's call the cache class *CalendarCache* and put it in a file named *CalendarCache.mqh*. We will need to save all 3 tables of the calendar base in the file (*MqlCalendarCountry*, *MqlCalendarEvent*, *MqlCalendarValue*). MQL5 provides functions *FileWriteArray* and *FileReadArray* (see Writing and reading arrays) that can directly write and read arrays of simple structures to files. However, 2 out of 3 structures in our case are not simple, because they have string fields. Therefore, we need a mechanism for separately storing strings, similar to the one we already used in the *CalendarFilter* class (there was an array of strings *stringCache*, and the index of the desired string from this array was indicated in the filters).

In order to avoid missing strings from different "calendar" structures in one "dictionary", we will prepare a template class *StringRef*: the type parameter T will be any of *MqlCalendar* structures. This will give us a separate string cache for countries, and a separate string cache for event types.

```
template<typename T>
struct StringRef
{
   static string cache[];
   int index;
   StringRef(): index(-1) { }

   void operator=(const string s)
   {
      if(index == -1)
      {
         PUSH(cache, s);
         index = ArraySize(cache) - 1;
      }
      else
      {
         cache[index] = s;
      }
   }

   string operator[](int x = 0) const
   {
      if(index != -1)
      {
         return cache[index];
      }
      return NULL;
   }

   static bool save(const int handle)
   {
      FileWriteInteger(handle, ArraySize(cache));
      for(int i = 0; i < ArraySize(cache); ++i)
      {
         FileWriteInteger(handle, StringLen(cache[i]));
         FileWriteString(handle, cache[i]);
      }
      return true;
   }

   static bool load(const int handle)
   {
      const int n = FileReadInteger(handle);
      for(int i = 0; i < n; ++i)
      {
         PUSH(cache, FileReadString(handle, FileReadInteger(handle)));
      }
      return true;
   }
};
```

```
template<typename T>
static string StringRef::cache[];
```

The strings are stored in the *cache* array by using *operator=*, and extracted from it using *operator[]* (with a dummy index that is always omitted). Each object stores only the index of the string in the array. The *cache* array is declared static, so it will accumulate all string fields of one T structure. Those who wish can change the method of caching in such a way that each field of the structure has its own array, but this is not important for us.

Writing an array to a file and reading from a file are performed by a pair of static methods *save* and *load*: both take a file handle as a parameter.

Taking into account the *StringRef* class, let's describe structures that duplicate the standard calendar structures which use *StringRef* objects instead of string fields. For example, for *MqlCalendarCountry* we get *MqlCalendarCountryRef*. Standard and modified structures are copied into each other in a similar way by overloaded operators '=' and '[]'.

```
struct MqlCalendarCountryRef
{
   ulong id;
   StringRef<MqlCalendarCountry> name;
   StringRef<MqlCalendarCountry> code;
   StringRef<MqlCalendarCountry> currency;
   StringRef<MqlCalendarCountry> currency_symbol;
   StringRef<MqlCalendarCountry> url_name;

   void operator=(const MqlCalendarCountry &c)
   {
      id = c.id;
      name = c.name;
      code = c.code;
      currency = c.currency;
      currency_symbol = c.currency_symbol;
      url_name = c.url_name;
   }

   MqlCalendarCountry operator[](int x = 0) const
   {
      MqlCalendarCountry r;
      r.id = id;
      r.name = name[];
      r.code = code[];
      r.currency = currency[];
      r.currency_symbol = currency_symbol[];
      r.url_name = url_name[];
      return r;
   }
};
```

Note that the assignment operators of the first method have the overload '=' from *StringRef*, due to which all the lines fall into the array *StringRef<MqlCalendarCountry>::cache*. In the second method, the '[]' operator calls invisibly get the address of the string and return from *StringRef* directly the string stored at that address in the *cache* array.

The *MqlCalendarEventRef* structure is defined in a similar way, but only 3 fields in it (*source_url*, *event_code*, *name*) require replacing type *string* by *StringRef<MqlCalendarEvent>*. The *MqlCalendarValue* structure does not require such transformations, since there are no string fields in it.

This concludes the preparatory stages, and you can proceed to the main cache class *CalendarCache*.

From general considerations, as well as for compatibility with the already developed *CalendarFilter* class, let's describe the fields in the cache that specify the context (country or currency), the range of dates for stored events, and the moment of cache generation (time X, variable t).

```
class CalendarCache
{
   string context;
   datetime from, to;
   datetime t;
   ...

public:
   CalendarCache(const string _context = NULL,
      const datetime _from = 0, const datetime _to = 0):
      context(_context), from(_from), to(_to), t(0)
   {
      ...
   }
```

Actually, it does not make much sense to set restrictions when creating a cache from a calendar. A full cache is probably more practical since its size is not critical as it is about two dozens of megabytes till the middle of 2022 (this include historical data from 2007 with events planned until 2024). However, restrictions can be useful for demo programs with artificially reduced functionality.

It is obvious that arrays of calendar structures should be provided in the cache to store all the data.

```
   MqlCalendarValue values[];
   MqlCalendarEvent events[];
   MqlCalendarCountry countries[];
   ...
```

Initially, they are filled from the calendar database by the *update* method.

```
bool update()
{
   string country = NULL, currency = NULL;
   if(StringLen(context) == 3)
   {
      currency = context;
   }
   else if(StringLen(context) == 2)
   {
      country = context;
   }

   Print("Reading online calendar base...");

   if(!PRTF(CalendarValueHistory(values, from, to, country, currency))
      || (currency != NULL ?
         !PRTF(CalendarEventByCurrency(currency, events)) :
         !PRTF(CalendarEventByCountry(country, events)))
      || !PRTF(CalendarCountries(countries)))
   {
      // object is not ready, t = 0
   }
   else
   {
      t = TimeTradeServer();
   }
   return (bool)t;
}
```

The *t* field is a sign of cache health, with the time of filling arrays.

The filled cache object can be written to a file using the *save* method. At the beginning of the file, there is a header CALENDAR_CACHE_HEADER – this is the string "MQL5 Calendar Cache\r\nv.1.0\r\n", which allows you to make sure that the format is correct when reading. Next, the method saves the *context*, *from*, *to*, and *t* variables, as well as the *values* array, "as is". Before the array itself, we write down its size in order to restore it when reading.

```
bool save(string filename = NULL)
{
   if(!t) return false;

   MqlDateTime mdt;
   TimeToStruct(t, mdt);
   if(filename == NULL) filename = "calendar-" +
      StringFormat("%04d-%02d-%02d-%02d-%02d.cal",
      mdt.year, mdt.mon, mdt.day, mdt.hour, mdt.min);
   int handle = PRTF(FileOpen(filename, FILE_WRITE | FILE_BIN));
   if(handle == INVALID_HANDLE) return false;

   FileWriteString(handle, CALENDAR_CACHE_HEADER);
   FileWriteString(handle, context, 4);
   FileWriteLong(handle, from);
   FileWriteLong(handle, to);
   FileWriteLong(handle, t);
   FileWriteInteger(handle, ArraySize(values));
   FileWriteArray(handle, values);
   ...
```

With arrays *events* and *countries* come our wrapper structures with the "Ref" suffix. The helper method *store* converts the *events* array into an array of simple structures *erefs*, in which strings are replaced by numbers in the dictionary of strings *StringRef<MqlCalendarEvent>*. Such simple structures can already be written to a file in the usual way, but for their subsequent reading, it is also necessary to save all the lines of the dictionary (calling *StringRef<MqlCalendarEvent> ::save(handle)*). Country structures are converted and saved to file in the same way.

```
   MqlCalendarEventRef erefs[];
   store(erefs, events);
   FileWriteInteger(handle, ArraySize(erefs));
   FileWriteArray(handle, erefs);
   StringRef<MqlCalendarEvent>::save(handle);

   MqlCalendarCountryRef crefs[];
   store(crefs, countries);
   FileWriteInteger(handle, ArraySize(crefs));
   FileWriteArray(handle, crefs);
   StringRef<MqlCalendarCountry>::save(handle);

   FileClose(handle);
   return true;
}
```

The aforementioned *store* method is quite simple: in it, in a loop over the elements, an overloaded assignment operator is executed in the *MqlCalendarEventRef* or *MqlCalendarCountryRef* structures.

```
template<typename T1,typename T2>
void static store(T1 &array[], T2 &origin[])
{
   ArrayResize(array, ArraySize(origin));
   for(int i = 0; i < ArraySize(origin); ++i)
   {
      array[i] = origin[i];
   }
}
```

To load the received file into the cache object, a mirror method *load* is written. It reads data from the file into variables and arrays in the same order, simultaneously performing reverse transformations of string fields for event types and countries.

```
bool load(const string filename)
{
   Print("Loading calendar cache ", filename);
   t = 0;
   int handle = PRTF(FileOpen(filename, FILE_READ | FILE_BIN));
   if(handle == INVALID_HANDLE) return false;

   const string header = FileReadString(handle, StringLen(CALENDAR_CACHE_HEADER));
   if(header != CALENDAR_CACHE_HEADER) return false; // not our format

   context = FileReadString(handle, 4);
   if(!StringLen(context)) context = NULL;
   from = (datetime)FileReadLong(handle);
   to = (datetime)FileReadLong(handle);
   t = (datetime)FileReadLong(handle);
   Print("Calendar cache interval: ", from, "-", to);
   Print("Calendar cache saved at: ", t);
   int n = FileReadInteger(handle);
   FileReadArray(handle, values, 0, n);

   MqlCalendarEventRef erefs[];
   n = FileReadInteger(handle);
   FileReadArray(handle, erefs, 0, n);
   StringRef<MqlCalendarEvent>::load(handle);
   restore(events, erefs);

   MqlCalendarCountryRef crefs[];
   n = FileReadInteger(handle);
   FileReadArray(handle, crefs, 0, n);
   StringRef<MqlCalendarCountry>::load(handle);
   restore(countries, crefs);

   FileClose(handle);
   ... // something else will be here
}
```

Helper method *restore* uses the overload of the '[]' operator in a loop over elements in the *MqlCalendarEventRef* or *MqlCalendarCountryRef* structures to get the line itself by line number and assign it to a standard *MqlCalendarEvent* or *MqlCalendarCountry* structure.

```
template<typename T1,typename T2>
void static restore(T1 &array[], T2 &origin[])
{
   ArrayResize(array, ArraySize(origin));
   for(int i = 0; i < ArraySize(origin); ++i)
   {
      array[i] = origin[i][];
   }
}
```

At this stage, we already could write a simple test indicator based on the *CalendarCache* class, run it on an online chart, and save it to a file with the calendar cache. Then the file could be loaded from the

copy of the indicator in the tester, and the full set of events could be received. However, this is not enough for practical developments.

The fact is that for quick access to data, it is required to provide *indexing*, a well-known concept in programming, which we will touch on later, in the chapter on databases. In theory, we could use the built-in SQLite engine to store the cache, and then we would get indexes "for free", but more on that later.

The point of indexing is easy to understand if we imagine how to effectively implement analogs of standard calendar functions in our cache. For example, the event ID is passed in the *CalendarValueById* function. Direct enumeration of records in the array *values* would be very time-consuming. Therefore, it is required to supplement the array with some "data structure" that would allow us to optimize the search. "Data structure" is in quotation marks, because it is not about the meaning of the programming language (*struct*), but in general about the architecture of data construction. It can consist of different parts and be based on different organizational principles. Of course, the extra data will require memory, but exchanging memory for speed is a common approach in programming.

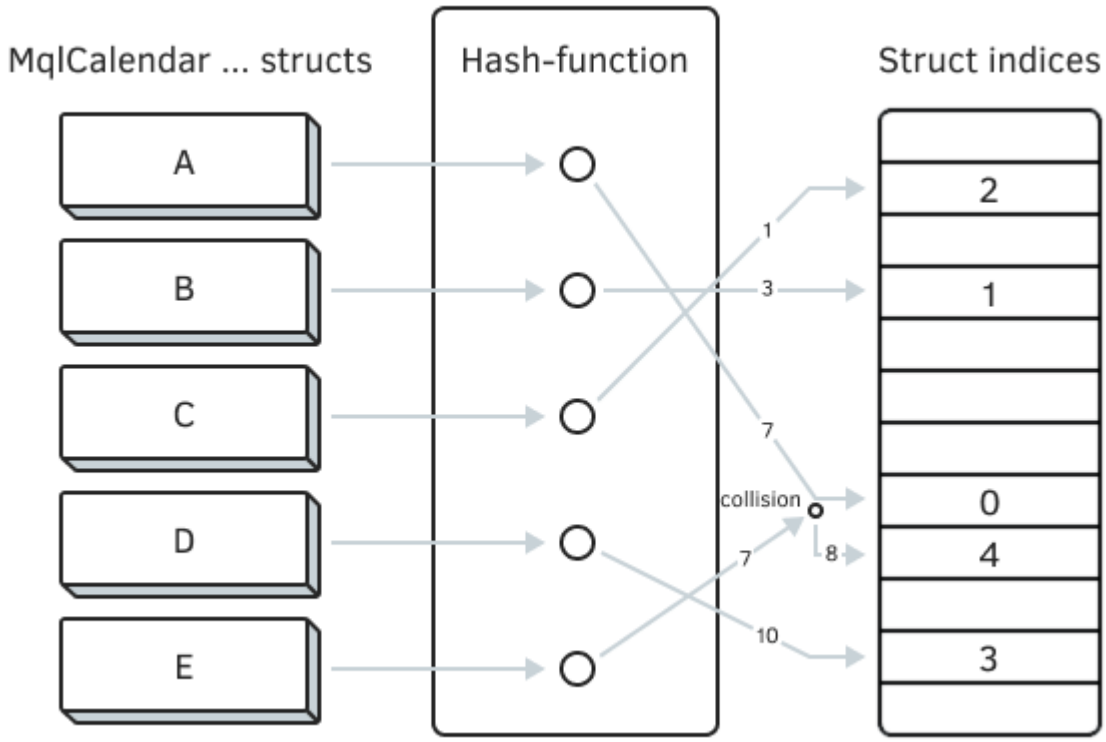
The simplest solution for indexing is a separate two-dimensional array, sorted in ascending order so that it can be quickly searched using the *ArrayBsearch* function. Two elements are enough for the second dimension: values with indices *[i][0]*, by which sorting is performed, contain identifiers, and values *[i][1]* contain the ordinal positions in the array of structures.

Another frequently used concept is *hashing* which is a transformation of the initial values into some keys (hashes, integers) in such a way that it provides the minimum number of collisions (matches of keys for different initial data). The fundamental property of keys is a close to uniform random distribution of their values, due to which they can be used as indexes in pre-allocated arrays. Computing a hash function for a single element of the original data is a fast process that actually yields the address of the element itself. For example, the well-known hash map data structures follow this principle.

If the two original values do get the same hash (although this is rare), they are lined up in a list for their key, and a sequential search will be performed within the list. However, since the hash functions are chosen so that the number of matches is small, the search usually hits the target as soon as the hash is computed.

For demonstration, we will use both approaches in the *CalendarCache* class: hashing and binary search.

The MetaTrader 5 package includes a set of classes for creating hash maps (MQL5/Include/Generic/HashMap.mqh), but we will manage with our own simpler implementation, in which only the principle of using the hash function remains.



Scheme for indexing data by hashing

In our case, it is enough to hash only the identifiers of the calendar objects. The hashing function that we choose will have to convert the identifier to an index inside a special array: the position of the identifier in the array of "calendar" structures will be stored in a cell with this index. For countries, types of events, and specific news, it is allocated according to its own array.

```
int id4country[];
int id4event[];
int id4value[];
```

Their elements will store the sequence number of the entry in the relevant array (*countries*, *events*, *values*).

For each of the "redirect" arrays, at least 2 times more elements should be allocated than the number of corresponding structures in the database (and in the cache) of the calendar. Due to this redundancy, we minimize the number of hash collisions. It is believed that the greatest efficiency is achieved when choosing a size equal to a prime number. Therefore, the class has a static method *size2prime* which returns the recommended size of the array of hash "baskets" (one of *id4* -arrays) according to the number of elements in the source data.

```
static int size2prime(const int size)
{
   static int primes[] =
   {
     17, 53, 97, 193, 389,
     769, 1543, 3079, 6151,
     12289, 24593, 49157, 98317,
     196613, 393241, 786433, 1572869,
     3145739, 6291469, 12582917, 25165843,
     50331653, 100663319, 201326611, 402653189,
     805306457, 1610612741
   };

   const int pmax = ArraySize(primes);
   for(int p = 0; p < pmax; ++p)
   {
      if(primes[p] >= 2 * size)
      {
         return primes[p];
      }
   }
   return size;
}
```

The whole process of calendar hashing is described in the *hash* method. Let's look at its beginning using the example of an array of structures *countries*, and the other two arrays are treated similarly.

So we get the recommended "plain" index size *id4country* from the size of the *countries* array by calling *size2prime*. Initially, the index array is filled with the value -1, that is, all its elements are free. Further in the loop through the countries, it is necessary to calculate the hash for each next country identifier and using it find a free index in the *id4country* array. This is the job for the helper method *place*.

```
bool hash()
{
   Print("Hashing calendar...");
   ...
   const int c = PRTF(ArraySize(countries));
   PRTF(ArrayResize(id4country, size2prime(c)));
   ArrayInitialize(id4country, -1);

   for(int i = 0; i < c; ++i)
   {
      if(place(countries[i].id, i, id4country) == -1)
      {
         return false; // failure
      }
   }
   ...
   return true; // success
}
```

The hash function inside *place* is the expression *(MathSwap(id) ^ 0xEFCDAB8967452301) % n*, where *id* is our identifier, and *n* is the size of the index array. Thus, the result of calculations is always reduced

to a valid index inside *array[]*. The principle of choosing a hash function is a separate topic that is beyond the scope of the book.

```
int place(const ulong id, const int index, int &array[])
{
   const int n = ArraySize(array);
   int p = (int)((MathSwap(id) ^ 0xEFCDAB8967452301) % n); // hash function
   int attempt = 0;
   while(array[p] != -1)
   {
      if(++attempt > n / 10) // number of collisions - no more than 1/10 of the nu
      {
         return -1; // error writing to index array
      }
      p = (p + attempt) % n;
   }
   array[p] = index;
   return p;
}
```

If the cell at the *p* positionin the index array is not occupied (equal to -1), we immediately write the location address of the calendar structure to the element *[p]*. If the cell is already occupied, we try to select the next one using the formula *p = (p + attempt) % n*, where *attempt* is a counter of attempts (this is our camouflaged version of the list of elements with a matched hash). If the number of failed attempts reaches one-tenth of the original data, indexing will fail, but this is practically impossible with our oversized index array size and the known nature of the hashed data (unique identifiers).

As a result of hashing the array of structures, we get a filled index array (there are free spaces in it, but this is how it is intended), through which we can find the location of the corresponding structure in the array of structures by the identifier of the calendar element. This is done by the *find* method which is opposite in meaning to *place*.

```
template<typename S>
int find(const ulong id, const int &array[], const S &structs[])
{
   const int n = ArraySize(array);
   if(!n) return false;
   int p = (int)((MathSwap(id) ^ 0xEFCDAB8967452301) % n); // hash function
   int attempt = 0;
   while(structs[array[p]].id != id)
   {
      if(++attempt > n / 10)
      {
         return -1; // error extracting from index array
      }
      p = (p + attempt) % n;
   }
   return array[p];
}
```

Let's show how it is used in practice. The standard calendar functions include *CalendarCountryById* and *CalendarEventById*. When you need to test an MQL program in the tester, it will not be able to directly

access them, but it will be able to load the calendar cache into the *CalendarCache* object and therefore it should have similar methods.

```
bool calendarCountryById(ulong country_id, MqlCalendarCountry &cnt)
{
   const int index = find(country_id, id4country, countries);
   if(index == -1) return false;

   cnt = countries[index];
   return true;
}

bool calendarEventById(ulong event_id, MqlCalendarEvent &event)
{
   const int index = find(event_id, id4event, events);
   if(index == -1) return false;

   event = events[index];
   return true;
}
```

They use the *find* method and index arrays *id4country* and *id4event*.

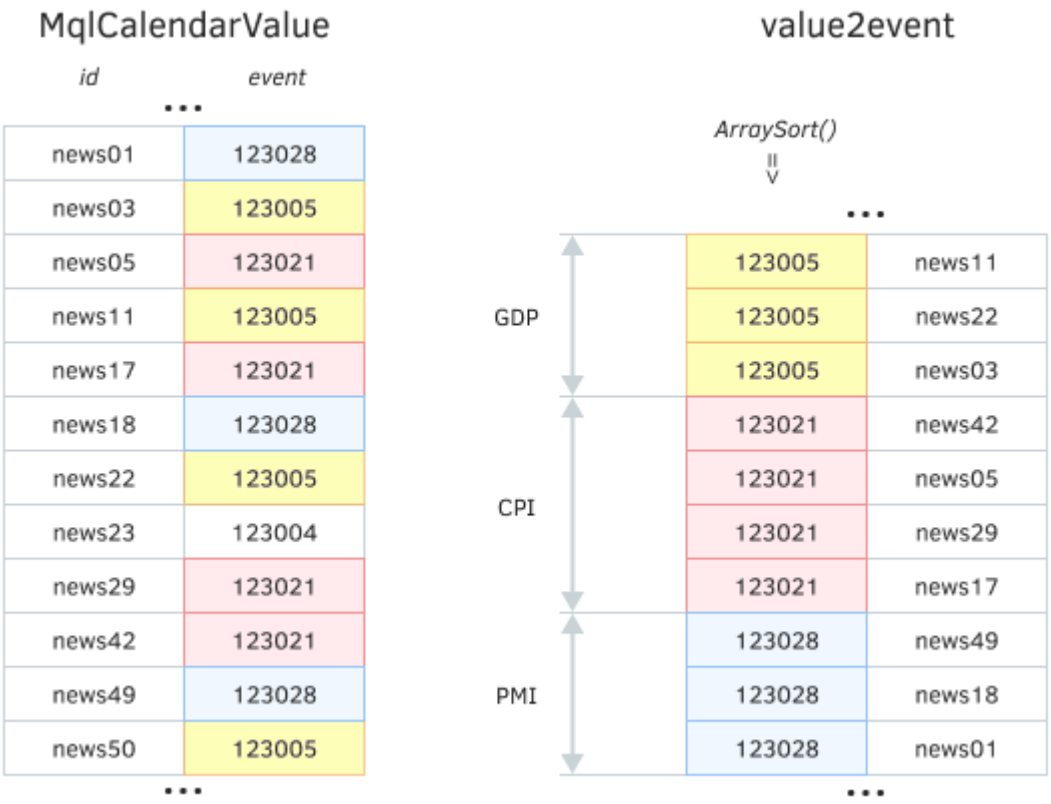
But these are not the most desired features of the calendar. Much more often, an MQL program with a news strategy needs functions *CalendarValueHistory*, *CalendarValueHistoryByEvent*, *CalendarValueLast*, or *CalendarValueLastByEvent*. They provide quick access to calendar entries by time, country, or currency.

So, the *CalendarCache* class should provide similar methods. Here we will use the second method of "indexing" – through a binary search in a sorted array.

To implement the above methods, let's add 4 more two-dimensional arrays to the class to establish a correspondence between news and event type, news and country, news, and currency, as well as news and the time of its publication.

```
ulong value2event[][2];    // [0] - event_id, [1] - value_id
ulong value2country[][2];  // [0] - country_id, [1] - value_id
ulong value2currency[][2]; // [0] - currency ushort[4]<->long, [1] - value_id
ulong value2time[][2];     // [0] - time, [1] - value_id
```

In the first element of each row, i.e., under the indices *[i][0]* an event ID, country, currency or time, respectively, will be recorded. In the second element of the series, under indices *[i][1]* IDs of specific news will be placed. After filling all the arrays once, they are sorted using *ArraySort* on values *[i][0]*. Then we can search by ID, for example, by *event_id*, for all such news in the *value2event* array: the *ArrayBsearch* function will return the number of the first matching element, followed by others with the same *event_id* until a distinct identifier is encountered. The order in the second "column" is not defined (can be any).



Quick search for related structures based on sorting

This operation of mutual binding of structures of different types is carried out in the *bind* method. The size of each "binding" array is the same as the size of the news array. Going through all the news in a loop, we use ready-made index arrays and the *find* method for fast addressing.

```
bool bind()
{
   Print("Binding calendar tables...");
   const int n = ArraySize(values);
   ArrayResize(value2event, n);
   ArrayResize(value2country, n);
   ArrayResize(value2currency, n);
   ArrayResize(value2time, n);
   for(int i = 0; i < n; ++i)
   {
      value2event[i][0] = values[i].event_id;
      value2event[i][1] = values[i].id;

      const int e = find(values[i].event_id, id4event, events);
      if(e == -1) return false;

      value2country[i][0] = events[e].country_id;
      value2country[i][1] = values[i].id;

      const int c = find(events[e].country_id, id4country, countries);
      if(c == -1) return false;

      value2currency[i][0] = currencyId(countries[c].currency);
      value2currency[i][1] = values[i].id;

      value2time[i][0] = values[i].time;
      value2time[i][1] = values[i].id;
   }
   ArraySort(value2event);
   ArraySort(value2country);
   ArraySort(value2currency);
   ArraySort(value2time);
   return true;
}
```

In the case of currencies, a special number obtained from the string using the *currencyId* function is taken as an identifier.

```
static ulong currencyId(const string s)
{
   union CRNC4
   {
      ushort word[4];
      ulong ul;
   } v;
   StringToShortArray(s, v.word);
   return v.ul;
}
```

Now we can finally present the entire constructor of the *CalendarCache* class.

```
CalendarCache(const string _context = NULL,
   const datetime _from = 0, const datetime _to = 0):
   context(_context), from(_from), to(_to), t(0), eventId(0)
{
   if(from > to) // label that context is a filename
   {
      load(_context);
   }
   else
   {
      if(!update() || !hash() || !bind())
      {
         t = 0;
      }
   }
}
```

When launched on an online chart, the created object with default parameters will collect all calendar information (*update*), index it (*hash*), and link the tables (*bind*). If something goes wrong at any of the stages, the error sign will be 0 in the variable *t*. If successful, the value from the function *TimeTradeServer* will remain there (remember, it is placed inside *update*). Such a ready-to-use object can be exported to a file using the *save* method described above.

When launched in the tester, the object should be created with a special combination of parameters *from* and *to* (*from* > *to*) – in this case, the program will consider the *context* string a filename and will load the calendar state from it. The easiest way to do it is this:

```
CalendarCache calca("filename.cal", true);
```

Inside the method *load* we will also call *hash* and *bind* to bring the object into a working state.

```
bool load(const string filename)
{
   ... // reading the file was shown earlier
   const bool result = hash() && bind();
   if(!result) t = 0;
   return result;
}
```

Using the *CalendarValueLast* function as an example, we show an equivalent implementation of the *calendarValueLast* method (with exactly the same prototype). The cache will use the current "server" time as a change identifier, in the absence of an open software API for reading the online calendar change table. Hypothetically, we could use the information about the change IDs saved by the *CalendarChangeSaver.mq5* service, but this approach requires a long-term collection of statistics before testing can begin. Therefore, the "server" time generated by the tester is accepted as a fairly adequate replacement.

When the MQL program requests changes for the first time with a null identifier, we simply return the value from *TimeTradeServer*.

```
int calendarValueLast(ulong &change, MqlCalendarValue &result[],
   const string code = NULL, const string currency = NULL)
{
   if(!change)
   {
      change = TimeTradeServer();
      return 0;
   }
   ...
```

If the change identifier is already non-zero, we continue the main branch of the algorithm.

Depending on the contents of the *code* and *currency* parameters, we find the identifiers of the country and currency. By default, it is 0, which means it searches for all changes.

```
   ulong country_id = 0;
   ulong currency_id = currency != NULL ? currencyId(currency) : 0;

   if(code != NULL)
   {
      for(int i = 0; i < ArraySize(countries); ++i)
      {
         if(countries[i].code == code)
         {
            country_id = countries[i].id;
            break;
         }
      }
   }
   ...
```

Further along, using the transmitted time count *change* as the beginning of the search, we find all the news in *value2time* up to the new, current value *TimeTradeServer*. Inside the loop, we use the *find* method to look for the index of the corresponding *MqlCalendarValue* structure in the *values* array and, if necessary, compare the country and currency of the associated event type with the desired ones. All news items that meet the criteria are written to the *result* output array.

```
      const ulong past = change;
      const int index = ArrayBsearch(value2time, past);
      if(index < 0 || index >= ArrayRange(value2time, 0)) return 0;

      int i = index;
      while(value2time[i][0] <= (ulong)past && i < ArrayRange(value2time, 0)) ++i;

      if(i >= ArrayRange(value2time, 0)) return 0;

      for(int j = i; j < ArrayRange(value2time, 0)
         && value2time[j][0] <= (ulong)TimeTradeServer(); ++j)
      {
         const int p = find(value2time[j][1], id4value, values);
         if(p != -1)
         {
            change = TimeTradeServer();
            if(country_id != 0 || currency_id != 0)
            {
               const int q = find(values[p].event_id, id4event, events);
               if(country_id != 0 && country_id != events[q].country_id) continue;
               if(currency_id != 0)
               {
                  const int m = find(events[q].country_id, id4country, countries);
                  if(countries[m].currency != currency) continue;
               }
            }

            PUSH(result, values[p]);
         }
      }

      return ArraySize(result);
   }
```

Methods *calendarValueHistory*, *calendarValueHistoryByEvent*, and *calendarValueLastByEvent* are implemented according to a similar principle (the latter actually delegates all the work to the method *calendarValueLast* discussed earlier). The complete source code can be found in the attached file *CalendarCache.mqh*.

Based on the cache class, it is logical to create a derived class *CalendarFilter*, which, when processing requests, would access the cache instead of the calendar.

The finished solution is in the file *CalendarFilterCached.mqh*. Due to the fact that the cache API was designed on the basis of the standard API, the integration is reduced to only forwarding filter calls to the cache object (autopointer *cache*).

```
class CalendarFilterCached: public CalendarFilter
{
protected:
   AutoPtr<CalendarCache> cache;

   virtual bool calendarCountryById(ulong country_id, MqlCalendarCountry &cnt) overri
   {
      return cache[].calendarCountryById(country_id, cnt);
   }

   virtual bool calendarEventById(ulong event_id, MqlCalendarEvent &event) override
   {
      return cache[].calendarEventById(event_id, event);
   }

   virtual int calendarValueHistoryByEvent(ulong event_id, MqlCalendarValue &temp[],
      datetime _from, datetime _to = 0) override
   {
      return cache[].calendarValueHistoryByEvent(event_id, temp, _from, _to);
   }

   virtual int calendarValueHistory(MqlCalendarValue &temp[],
      datetime _from, datetime _to = 0,
      const string _code = NULL, const string _coin = NULL) override
   {
      return cache[].calendarValueHistory(temp, _from, _to, _code, _coin);
   }

   virtual int calendarValueLast(ulong &_change, MqlCalendarValue &result[],
      const string _code = NULL, const string _coin = NULL) override
   {
      return cache[].calendarValueLast(_change, result, _code, _coin);
   }

   virtual int calendarValueLastByEvent(ulong event_id, ulong &_change,
      MqlCalendarValue &result[]) override
   {
      return cache[].calendarValueLastByEvent(event_id, _change, result);
   }

public:
   CalendarFilterCached(CalendarCache *_cache): cache(_cache),
      CalendarFilter(_cache.getContext(), _cache.getFrom(), _cache.getTo())
   {
   }

   virtual bool isLoaded() const override
   {
    // readiness is determined by the cache
      return cache[].isLoaded();
   }
```

```
};
```

To test the calendar in the tester, let's create a new version of the indicator *CalendarMonitor.mq5* — *CalendarMonitorCached.mq5*.

The main differences are as follows.

We assume that some cache file will be created or already created under the name "xyz.cal" (in the folder *MQL5/Files*) and therefore connect it to the MQL program with the directive *tester_file*.

```
#property tester_file "xyz.cal"
```

This directive ensures the transfer of the cache to any agents, including distributed ones (which, however, is more relevant for Expert Advisors, rather than an indicator). A cache file with this (or another name) can be created using a new input variable *CalendarCacheFile*. If the user changes the default name to something else, then to work in the tester, you will need to correct the directive (requires recompilation!), or transfer the file to the shared folder of terminals (this feature is supported in the cache class, but "left behind the scenes"), however, such a file is no longer available to remote agents.

```
input string CalendarCacheFile = "xyz.cal";
```

The *CalendarFilter* object is now described as an autopointer, because depending on where the indicator is run, it can use the original class *CalendarFilter* as well as the derived class *CalendarFilterCached*.

```
AutoPtr<CalendarFilter> fptr;
AutoPtr<CalendarCache> cache;
```

At the beginning of *OnInit*, there is a new fragment that is responsible for generating the cache and reading it.

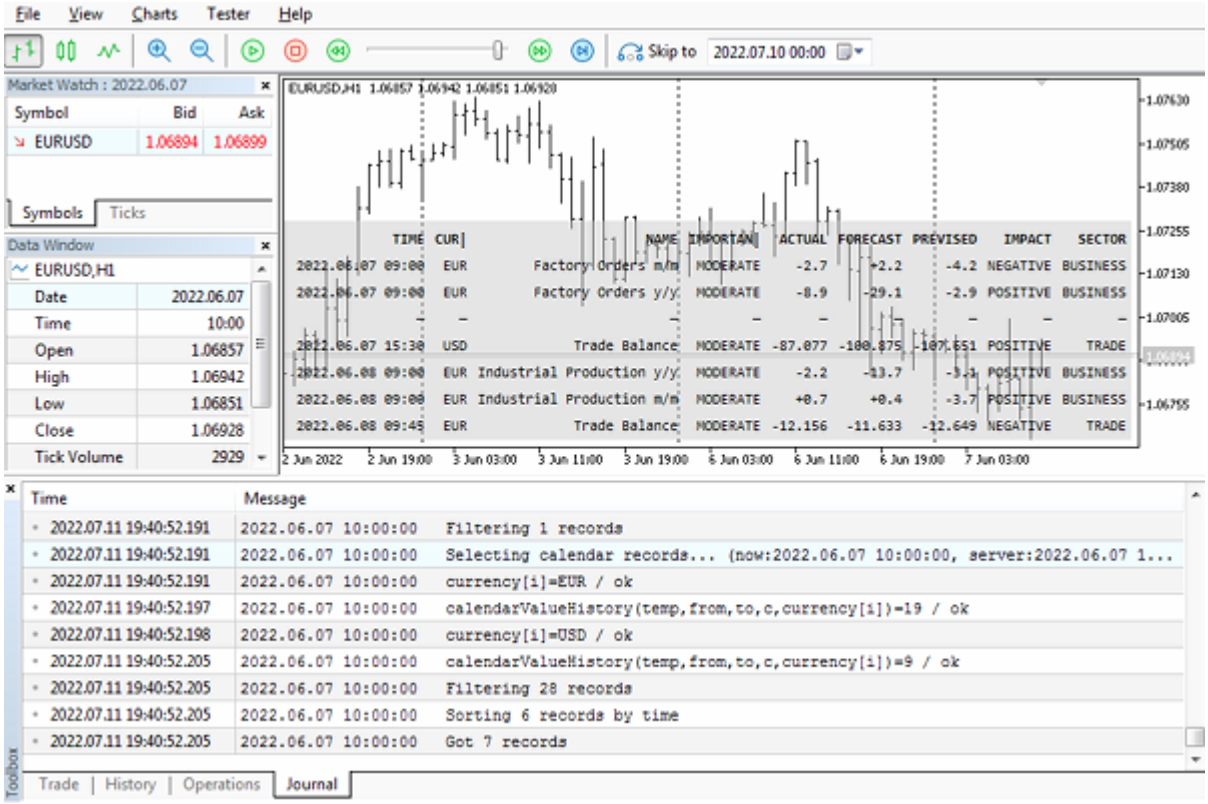
```
int OnInit()
{
   cache = new CalendarCache(CalendarCacheFile, true);
   if(cache[].isLoaded())
   {
      fptr = new CalendarFilterCached(cache[]);
   }
   else
   {
      if(MQLInfoInteger(MQL_TESTER))
      {
         Print("Can't run in the tester without calendar cache file");
         return INIT_FAILED;
      }
      else
      if(StringLen(CalendarCacheFile))
      {
         Alert("Calendar cache not found, trying to create '" + CalendarCacheFile + "
         cache = new CalendarCache();
         if(cache[].save(CalendarCacheFile))
         {
            Alert("File saved. Re-run indicator in online chart or in the tester");
         }
         else
         {
            Alert("Error: ", _LastError);
         }
         ChartIndicatorDelete(0, 0, MQLInfoString(MQL_PROGRAM_NAME));
         return INIT_PARAMETERS_INCORRECT;
      }
      Alert("Currently working in online mode (no cache)");
      fptr = new CalendarFilter(Context);
   }
   CalendarFilter *f = fptr[];
   ... // continued without changes
```

If the cache file has been read, we will get the finished object *CalendarCache*, which is passed to the *CalendarFilterCached* constructor. Otherwise, the program checks whether it is running in the tester or online. The absence of a cache in the tester is a fatal case. On a regular chart, the program creates a new object based on the built-in calendar data and saves it in the cache under the specified name. But if the file name is made empty, the indicator will work exactly as the original one – directly with the calendar.

Let's run the indicator on the EURUSD chart. The user will be warned that the specified file was not found and an attempt was made to save it. Provided that the calendar is enabled in the terminal settings, we should get approximately the following lines in the log. Below is a version with detailed diagnostic information. The details can be disabled by commenting out the directive in the source code *#define LOGGING*.

```
Loading calendar cache xyz.cal
FileOpen(filename,FILE_READ|FILE_BIN|flags)=-1 / CANNOT_OPEN_FILE(5004)
Alert: Calendar cache not found, trying to create 'xyz.cal'
Reading online calendar base...
CalendarValueHistory(values,from,to,country,currency)=157173 / ok
CalendarEventByCountry(country,events)=1493 / ok
CalendarCountries(countries)=23 / ok
Hashing calendar...
ArraySize(countries)=23 / ok
ArrayResize(id4country,size2prime(c))=53 / ok
Total collisions: 9, worse:3, average: 2.25 in 4
ArraySize(events)=1493 / ok
ArrayResize(id4event,size2prime(e))=3079 / ok
Total collisions: 495, worse:7, average: 1.43478 in 345
ArraySize(values)=157173 / ok
ArrayResize(id4value,size2prime(v))=393241 / ok
Total collisions: 3511, worse:1, average: 1.0 in 3511
Binding calendar tables...
FileOpen(filename,FILE_WRITE|FILE_BIN|flags)=1 / ok
Alert: File saved. Re-run indicator in online chart or in the tester
```

Now we can choose the indicator *CalendarMonitorCached.mq5* in the tester and see in dynamics, based on history, how the news table changes.



News indicator with calendar cache in the tester

The presence of the calendar cache allows you to test trading strategies on the news. We will show this in the next section.

7.3.12 Calendar trading

There are many news trading strategies: with market or pending orders, with analysis of financial indicators (the direction of price movement), and without it (volatility capture). In addition, it is useful to insert an anti-news filter into many other trading systems. It is difficult to optimize and debug all such programs since the MQL5 calendar is not available in the tester. However, with the help of the cache developed in the previous section, we can rectify the situation.

Let's try to create an Expert Advisor that will enter the market upon news releases, in accordance with the assessment of their impact on the price. The cache file "xyz.cal" has just been created using the indicator *CalendarMonitorCached.mq5*.

> Recall that the image of the calendar in the cache always corresponds to the moment of saving and requires caution when reading: for later events, actual indicators are unknown, and more distant events may not exist at all. You should regularly update the calendar cache file before the next optimization or testing.
>
> If necessary, also take into account the DST time settings during the year: if the DST mode of events is different from the DST at the time the calendar archive was saved, you will need to shift the time back or forward by 1 hour. You can avoid these difficulties by choosing a broker without DST or by building a strategy on timeframes greater than H1.

The Expert Advisor *CalendarTrading.mq5* will only trade the news events that:

- refer to the working symbol of the chart
- have the type of financial indicator (that is, quantitative)
- high importance
- just received the current value of the indicator

The latter is important because for indicators that have forecast and actual values, the system sets the value of the field *impact_type* accordingly: it will serve as a trading signal (indicate the direction of entering the market).

> The exact time of the release of the news, as a rule, does not coincide with the planned time entered in the field *MqlCalendarValue::time*. The calendar does not record this time, and it is not available in the cache. In this regard, the accuracy of testing news strategies may suffer. If you want to bring analysis and decision-making closer to an online process, accumulate news release statistics using a service such as *CalendarChangeSaver.mq5* and embed it in the cache.

By default, trading is carried out with a minimum lot, with take profit and stop loss levels set at a specified distance in points. All this is reflected in the input parameters.

```
input double Volume;                // Volume (0 = minimal lot)
input int Distance2SLTP = 500;      // Distance to SL/TP in points (0 = no)
input uint MultiplePositions = 25;
```

For hedging accounts, we allow the simultaneous existence of several positions, the default is 25. This is the recommended testing environment because it allows you to independently evaluate the profitability of parallel trading on news of different types (each position is created independently and does not lead to closing positions on other news). On the other hand, maintaining only one position automatically levels out conflicting signals of different news.

Optionally, the Expert Advisor supports filters for the news type identifier and text for searching by title.

```
sinput ulong EventID;
sinput string Text;
```

This can be useful for future research on specific news.

At the global level, object pointers are described by analytical processing of news and position tracking.

```
AutoPtr<CalendarFilter> fptr;
AutoPtr<CalendarCache> cache;
AutoPtr<TrailingStop> trailing[];
```

The mode of operation and the currency pair of the current working symbol are stored in the corresponding variables. To simplify the example, it is assumed to be used on Forex (on other markets, you will get trading in one currency – the quote currency of the ticker).

```
const bool Hedging =
   AccountInfoInteger(ACCOUNT_MARGIN_MODE) == ACCOUNT_MARGIN_MODE_RETAIL_HEDGING;
const string Base = SymbolInfoString(_Symbol, SYMBOL_CURRENCY_BASE);
const string Profit = SymbolInfoString(_Symbol, SYMBOL_CURRENCY_PROFIT);
```

In the *OnInit* handler, we load the calendar cache and configure the filters as described above. The absence of cache is allowed on the online chart: then the Expert Advisor works in combat mode, directly with the calendar. In the tester, the absence of a cache file will prevent the Expert Advisor from starting.

```
int OnInit()
{
   cache = new CalendarCache("xyz.cal", true);
   if(cache[].isLoaded())
   {
      fptr = new CalendarFilterCached(cache[]);
   }
   else
   {
      if(!MQLInfoInteger(MQL_TESTER))
      {
         Print("Calendar cache file not found, fall back to online mode");
         fptr = new CalendarFilter();
      }
      else
      {
         Print("Can't proceed in the tester without calendar cache file");
         return INIT_FAILED;
      }
   }
   CalendarFilter *f = fptr[];

   if(!f.isLoaded()) return INIT_FAILED;

   // if a specific type of event is set, we look only at it
   if(EventID > 0) f.let(EventID);
   else
   {
      // otherwise follow the news on the currencies of the current symbol
      f.let(Base);
      if(Base != Profit)
      {
         f.let(Profit);
      }

      // financial indicators, high importance, actual value
      f.let(CALENDAR_TYPE_INDICATOR);
      f.let(LONG_MIN, CALENDAR_PROPERTY_RECORD_FORECAST, NOT_EQUAL);
      f.let(CALENDAR_IMPORTANCE_HIGH);

      if(StringLen(Text)) f.let(Text);
   }

   f.describe();

   if(Distance2SLTP)
   {
      ArrayResize(trailing, Hedging && MultiplePositions ? MultiplePositions : 1);
   }
   // check the news filter and start trading on it by a second timer
   EventSetTimer(1);
```

```
   return INIT_SUCCEEDED;
}
```

In the *OnTimer* handler, we request changes to the news according to the configured filters.

```
void OnTimer()
{
   CalendarFilter *f = fptr[];
   MqlCalendarValue records[];

   f.let(TimeTradeServer() - SCOPE_DAY, TimeTradeServer() + SCOPE_DAY);

   if(f.update(records)) // find changes that undergo filtering
   {
      // output properties of changed news to the log
      static const ENUM_CALENDAR_PROPERTY props[] =
      {
         CALENDAR_PROPERTY_RECORD_TIME,
         CALENDAR_PROPERTY_COUNTRY_CURRENCY,
         CALENDAR_PROPERTY_COUNTRY_CODE,
         CALENDAR_PROPERTY_EVENT_NAME,
         CALENDAR_PROPERTY_EVENT_IMPORTANCE,
         CALENDAR_PROPERTY_RECORD_ACTUAL,
         CALENDAR_PROPERTY_RECORD_FORECAST,
         CALENDAR_PROPERTY_RECORD_PREVISED,
         CALENDAR_PROPERTY_RECORD_IMPACT,
      };
      static const int p = ArraySize(props);
      string result[];
      f.format(records, props, result);
      for(int i = 0; i < ArraySize(result) / p; ++i)
      {
         Print(SubArrayCombine(result, " | ", i * p, p));
      }
      ...
```

When suitable changes are detected, they are logged as follows (a fragment of the real log is below), indicating the time, currency, country, name, current and forecast values, previous value, and theoretical interpretation of the signal:

```
...
Filtering 5 records
2021.02.16 13:00 | EUR | EU | Employment Change q/q | HIGH | +0.3 | -0.4 | +1.0 | POS
2021.02.16 13:00 | EUR | EU | GDP q/q | HIGH | -0.6 | -0.7 | -0.7 | POSITIVE
instant buy 0.01 EURUSD at 1.21638 sl: 1.21138 tp: 1.22138 (1.21637 / 1.21638 / 1.216
deal #64 buy 0.01 EURUSD at 1.21638 done (based on order #64)
...
Filtering 3 records
2021.07.06 12:05 | EUR | DE | ZEW Economic Sentiment Indicator | HIGH | +63.3 | +84.1
instant sell 0.01 EURUSD at 1.18473 sl: 1.18973 tp: 1.17973 (1.18473 / 1.18474 / 1.18
deal #265 sell 0.01 EURUSD at 1.18473 done (based on order #265)
...
```

The potential impact of the news on the price should be calculated based on in-field evaluation *impact_type*. It is important to note here that we have two currencies: base and quote. When the news has a positive effect on the base currency, the rate is expected to rise, and if it is negative, the rate will fall. For the quote currency, the opposite is true: a positive effect should increase the price of the second currency in the pair, which means a decrease in the exchange rate, while a negative one leads to its increase. This normalized direction of price movement is calculated in the following fragment using the *sign* variable.

```
static const int impacts[3] = {0, +1, -1};
int impact = 0;
string about = "";
ulong lasteventid = 0;
for(int i = 0; i < ArraySize(records); ++i)
{
   int sign = result[i * p + 1] == Profit ? -1 : +1;
   impact += sign * impacts[records[i].impact_type];
   about += StringFormat("%+lld ", sign * (long)records[i].event_id);
   lasteventid = records[i].event_id;
}

if(impact == 0) return; // no signal
...
```

Often several news releases appear at the same time, so it is necessary to accumulate ratings for all of them. This is done in the variable *impact*. Since our strategy only filters the news of single, highest importance, all single signals from them are simply summed up, without weight coefficients. The *about* string variable is used to prepare the text for the comment on the upcoming deal: the identifiers of the events that caused the deal will be mentioned there.

If the robot is launched on a netting account or the maximum allowed number of positions has been reached, we will close one.

```
      PositionFilter positions;
      ulong tickets[];
      positions.let(POSITION_SYMBOL, _Symbol).select(tickets);
      const int n = ArraySize(tickets);

      if(n >= (int)(Hedging ? MultiplePositions : 1))
      {
         MqlTradeRequestSync position;
         position.close(_Symbol) && position.completed();
      }
      ...
```

Now you can open a new position on a signal. An event identifier is set as a "magic" number, which will allow us to later analyze the financial performance of trading in the context of different types of news.

```
      MqlTradeRequestSync request;
      request.magic = lasteventid;
      request.comment = about;
      const double ask = SymbolInfoDouble(_Symbol, SYMBOL_ASK);
      const double bid = SymbolInfoDouble(_Symbol, SYMBOL_BID);
      const double point = SymbolInfoDouble(_Symbol, SYMBOL_POINT);
      ulong ticket = 0;

      if(impact > 0)
      {
         ticket = request.buy(Lot, 0,
            Distance2SLTP ? ask - point * Distance2SLTP : 0,
            Distance2SLTP ? ask + point * Distance2SLTP : 0);
      }
      else if(impact < 0)
      {
         ticket = request.sell(Lot, 0,
            Distance2SLTP ? bid + point * Distance2SLTP : 0,
            Distance2SLTP ? bid - point * Distance2SLTP : 0);
      }

      if(ticket && request.completed() && Distance2SLTP)
      {
         for(int i = 0; i < ArraySize(trailing); ++i)
         {
            if(trailing[i][] == NULL) // looking for a free slot for the position tra
            {
               trailing[i] = new TrailingStop(ticket, Distance2SLTP, Distance2SLTP /
               break;
            }
         }
      }
   }
}
```

We move stop-losses for all positions upon the arrival of ticks.

```
void OnTick()
{
   for(int i = 0; i < ArraySize(trailing); ++i)
   {
      if(trailing[i][])
      {
         if(!trailing[i][].trail()) // position was closed
         {
            trailing[i] = NULL; // release object and slot
         }
      }
   }
}
```

Now comes the most interesting point. Thanks to the tester, it becomes possible to analyze the success of the news strategy not only in general but also broken down by specific news. The corresponding block is implemented in our *OnTester* handler. Data collection is performed using the deal filter. Having received from it the *trades* array of tuples, which reports on the profit, swap, commission, and magic number of each trade, we accumulate the results in three objects of *MapArray*: they calculate separately profits, losses, and the number of trades for each *magic* number.

```
double OnTester()
{
   Print("Trade profits by calendar events:");
   HistorySelect(0, LONG_MAX);
   DealFilter filter;
   int props[] = {DEAL_PROFIT, DEAL_SWAP, DEAL_COMMISSION, DEAL_MAGIC};
   filter.let(DEAL_TYPE, (1 << DEAL_TYPE_BUY) | (1 << DEAL_TYPE_SELL), IS::OR_BITWISE
      .let(DEAL_ENTRY, (1 << DEAL_ENTRY_OUT) | (1 << DEAL_ENTRY_INOUT) | (1 << DEAL_E
      IS::OR_BITWISE);
   Tuple4<double, double, double, ulong> trades[];
   MapArray<ulong,double> profits;
   MapArray<ulong,double> losses;
   MapArray<ulong,int> counts;
   if(filter.select(props, trades))
   {
      for(int i = 0; i < ArraySize(trades); ++i)
      {
         counts.inc((ulong)trades[i]._4);
         const double payout = trades[i]._1 + trades[i]._2 + trades[i]._3;
         if(payout >= 0)
         {
            profits.inc((ulong)trades[i]._4, payout);
            losses.inc((ulong)trades[i]._4, 0);
         }
         else
         {
            profits.inc((ulong)trades[i]._4, 0);
            losses.inc((ulong)trades[i]._4, payout);
         }
      }
      ...
```

As a result, we get a table that displays statistics for each type of event line by line: its identifier, country, currency, total profit or loss, number of trades (number of news), profit factor, and event name.

```
      for(int i = 0; i < profits.getSize(); ++i)
      {
         MqlCalendarEvent event;
         MqlCalendarCountry country;
         const ulong keyId = profits.getKey(i);
         if(cache[].calendarEventById(keyId, event)
            && cache[].calendarCountryById(event.country_id, country))
         {
            PrintFormat("%lld %s %s %+.2f [%d] (PF:%.2f) %s",
               event.id, country.code, country.currency,
               profits[keyId] + losses[keyId], counts[keyId],
               profits[keyId] / (losses[keyId] != 0 ? -losses[keyId] : DBL_MIN),
               event.name);
         }
         else
         {
            Print("undefined ", DoubleToString(profits.getValue(i), 2));
         }
      }
   }
   return 0;
}
```

To test the idea, let's run the Expert Advisor for the period from the beginning of 2021 (to the middle of 2022) on the EURUSD pair. Below is a snippet of a log with a printout from *OnTester*.

```
Trade profits by calendar events:
840040001 US USD -21.81 [17] (PF:0.53) ISM Manufacturing PMI
840190001 US USD -10.95 [17] (PF:0.69) ADP Nonfarm Employment Change
840200001 US USD -67.09 [78] (PF:0.60) EIA Crude Oil Stocks Change
999030003 EU EUR +14.13 [19] (PF:1.46) Retail Sales m/m
840040003 US USD -17.12 [18] (PF:0.59) ISM Non-Manufacturing PMI
840030016 US USD -1.20 [19] (PF:0.97) Nonfarm Payrolls
840030021 US USD +5.25 [14] (PF:1.21) JOLTS Job Openings
840020010 US USD -14.63 [17] (PF:0.63) Retail Sales m/m
276070001 DE EUR -22.71 [17] (PF:0.47) ZEW Economic Sentiment Indicator
840020005 US USD +10.76 [18] (PF:1.37) Building Permits
840120001 US USD -20.78 [17] (PF:0.49) Existing Home Sales
276030003 DE EUR +18.57 [17] (PF:1.87) Ifo Business Climate
840180002 US USD -3.22 [14] (PF:0.89) CB Consumer Confidence Index
840020014 US USD -8.74 [16] (PF:0.74) Core Durable Goods Orders m/m
840020008 US USD -14.54 [16] (PF:0.63) New Home Sales
250010005 FR EUR +0.66 [10] (PF:1.03) GDP q/q
840010007 US USD +0.99 [15] (PF:1.04) GDP q/q
840120003 US USD +4.53 [18] (PF:1.15) Pending Home Sales m/m
276010008 DE EUR -0.72 [10] (PF:0.97) GDP q/q
999030016 EU EUR -14.04 [14] (PF:0.59) GDP q/q
999030001 EU EUR +1.30 [2] (PF:1.35) Employment Change q/q
```

The results are not very impressive. Still, news trading is full of subjectivity. First, theoretical assessments of the impact of the actual value of the news on the course may differ from the emotional expectations of the crowd or additional information background (remaining outside the calendar and not

quantifiable). Second, we have already mentioned the inaccuracy in the actual value publication time. Third, our strategy is implemented in the simplest form, without analyzing the preliminary price movement (when there was probably a leak and the news was "played out" earlier).

Overall, this test found that traders' favorite Nonfarm Payrolls or GDP reports do not guarantee success, at least not with our default settings. Further, it is required, in the usual manner, to analyze individual transactions, find out what went wrong, select parameters, and improve the algorithm, in particular, add a time adjustment module for switching DST in the server time zone.

At the same time, the technique itself works fine, and we can just try to choose the most successful news to begin with. For example, let's take news 276030003 (Ifo Business Climate). By setting it into *EventID*, we will receive the following report, coinciding with our calculated indicators.

Bars	9494	Ticks	2250448	Symbols	1

Report on trading in the tester based on Ifo Business Climate news

You can also try trading on a group of similar events. In particular, to respond only to GDP news (of different countries), enter the string "*GDP*" in the *Text* variable. The asterisks are added because, without them, a 3-character string will be treated as a currency by the filter class. Strings of any length other than 2 (country code) or 3 (currency code) can be specified as is, for example, "farm", "Nonfarm", "Sales" – they will be searched by the filter as substrings of names, case-sensitive.

7.4 Cryptography

Algo trading appeared at the cross-section of exchange trading and information technology, allowing, on the one hand, to connect more and more new markets to work, and on the other hand, to expand the functionality of trading platforms. One technological trend that has made its way into most areas of activity, including the arsenals of traders, is cryptography, or, more generally, information security.

MQL5 provides functions for encrypting, hashing, and compressing data: *CryptEncode* and *CryptDecode*. We have already used them in some of the examples in the book: in the script *EnvSignature.mq5* (Binding a program to runtime properties) and the service *ServiceAccount.mq5* (Services).

In this chapter, we will discuss these functions in more detail. However, before proceeding directly to their description, let's review the information transformation methods: this direction of programming is very extensive, and MQL5 supports only a part of the standards. This list will probably be expanded in the future, but for now, if you don't find the required encryption method in the help, try to find a ready-made implementation on mql5.com website (in the article sections or in the source code database).

7.4.1 Overview of available information transformation methods

Information protection can be implemented for different purposes and therefore use different methods. In particular, it may be necessary to completely hide the essence of information from an outside observer or to ensure its transmission, while guaranteeing an unchanged state, but the information itself remains available. In the first case, we are talking about encryption, and the second case refers to a digital fingerprint (hash). Thus, encryption and hashing are reduced to processing the original data into a new representation using, if necessary, additional parameters.

Both encryption and hashing come in many varieties.

The most general gradation divides encryption into public-key (asymmetric) and private-key (symmetric) encryption.

> An asymmetric scheme implies the presence of 2 keys – public and private – for each participant in the data exchange. Pairs of public and private keys are pre-generated using special algorithms. Each private key is known only to the owner. Everyone's public keys are known to everyone. Public keys will need to be exchanged in one way or another before the encrypted data can be transmitted. Next, the data provider uses its private key, known only to them, in conjunction with one or more public keys of the data recipients. Those, in turn, use their private keys and the sender's public key to decrypt.

A symmetric encryption scheme uses the same secret (private) key for both encryption and decryption.

MQL5 supports the out-of-the-box private key feature (symmetric). The built-in MQL5 tools do not provide an electronic signature that uses asymmetric encryption.

Primitive algorithms without keys stand out among the encryption methods. With their help users achieve conditional hiding of information or transformation of the information type. These include, for example, ROT13 (replacement of characters with a shift of their alphanumeric codes by 13, used, in particular, in the Windows registry) or Base64 (translation of binary files to text and vice versa, usually in web projects). Another popular data transformation task is data compression. This one also can be thought of in a sense as encryption, as the data becomes unreadable by a human or application program.

There are also a lot of hashing methods on offer. And CRC (Cyclic Redundancy Check) is perhaps the most famous and simple. Unlike encryption, which allows you to restore the original message from the encrypted one, hashing only creates a fingerprint (a characteristic set of bytes) based on the original information, in such a way that its unchanged state while it is subsequently recalculated guarantees (with a high probability) the invariance of the original information. Of course, this assumes that the information is available to all participants/users of the respective software system. It is impossible to recover information by hash. As a rule, the size of the hash (the number of bytes in it) is limited and

standardized for each method, so that for a string of 80 characters long and for a file of 1 MB we will get a hash of the same size. An application of hashing that most users will find really useful is the hashing of passwords by sites and programs, i.e., the latter are stored at home and verified during login with the password hash, and not with the password in its original form.

It should be noted that we already encountered the term "hash" in the previous chapter: we used a hashing function to index economic calendar structures. That simple hash has a very weak degree of protection, which, in particular, is expressed in a high probability of collisions (coincidence of results for different data), which we specially processed in the algorithm. It is suitable for problems of uniform pseudo-random distribution of data over a limited number of "baskets". In contrast, industrial standards of hashing focus specifically on verifying the integrity of information and use much more complex calculation methods. But the length of the hash in this case is several tens of bytes and not a single number.

Information encryption and hashing methods available to MQL programs are collected in the ENUM_CRYPT_METHOD enumeration.

Constant	Description
CRYPT_BASE64	Base64 re-encoding
CRYPT_DES	DES encryption with a 56-bit (7-byte) key
CRYPT_AES128	AES encryption with a 128-bit (16-byte) key
CRYPT_AES256	AES encryption with a 256-bit (32-byte) key
CRYPT_HASH_MD5	MD5 hash calculation (16 bytes)
CRYPT_HASH_SHA1	SHA1 hash calculation (20 bytes)
CRYPT_HASH_SHA256	SHA256 hash calculation (32 bytes)
CRYPT_ARCH_ZIP	Compression using the "deflate" method

The specified enumeration is used in both cryptographic API functions – *CryptEncode* (encryption/hashing) and *CryptDecode* (decryption). They will be discussed in the following sections.

AES and DES encryption methods require, in addition to data, the encryption key – an array of bytes of a predefined length (it is indicated in brackets in the table). As already mentioned, the key must be kept secret and remain known only to the developer of the program or the owner of the information. The cryptographic strength of encryption, that is, the difficulty of selecting a key by an attacker's computer, directly depends on the size of the key: the larger it is, the more reliable the protection. Therefore, DES is considered obsolete and has been replaced in the financial sector by its improved version of Triple DES: it implies the successive applying of DES for three times with three different keys, which is easy to implement in MQL5. There is a popular version of Triple DES, which performs decryption at the second iteration instead of encryption with key number 2, that is, as it were, restores data to an intermediate, deliberately incorrect representation before the final, third round of DES. But Triple DES is also planned to be removed from industry standards after 2024.

At the same time, cryptographic strength should be commensurate with the lifetime of the secret (key and information). If a fast flow of secure messages is required, shorter keys that are updated regularly will provide better performance.

Of the hashing methods, the most modern is SHA256 (a subset of the SHA-2 standard). SHA1 and MD5 methods are considered insecure but are still widely used in order to be compatible with existing services. For hashing methods, the size of the resulting byte array with a digital fingerprint of the data is indicated in brackets. A key is not needed for hashing, but in many applications, the "salt" is attached to the hashed data – a secret component that makes it difficult for attackers to reproduce the required hashes (for example, when guessing a password).

The CRYPT_ARCH_ZIP element provides ZIP archiving and transmission/reception of data requests on the Internet (see *WebRequest*).

> Despite the fact that the name of the method includes ZIP, the compressed data is not equivalent to the usual ZIP archives, which, in addition to the "deflate" containers, always contain meta-data: special headers, a list of files, and their attributes. On the site mql5.com, in the articles and the source code library, you can find ready-made implementations of compressing files into a ZIP archive and extracting them from there. The compression and extraction are performed by the *CryptEncode*/*CryptDecode* functions, and all additional necessary ZIP format structures are described and filled in the MQL5 code.

The Base64 method is designed to convert binary data to text and back. Binary data generally contains many non-printable characters and is not supported by editing and input tools such as input variables in MQL program properties dialogs. Base64 can be useful, for example, when working with the popular JSON object data interchange text format.

Every 3 original bytes are encoded in Base64 with 4 characters, resulting in an increase of the data size by a third. The book is accompanied by test files that we will experiment with in the following examples, in particular, the web page *MQL5/Files/MQL5Book/clock10.htm* and the file used in it with the image of the clock *MQL5/Files/MQL5Book/clock10.png*. Already at this introductory stage, you can clearly see the possibilities and the difference in the internal representation of binary data and Base64 text, while maintaining an identical appearance.

Web page with embedded binary image and in Base64 format

The same image with a clock face is inserted into the page as an external file *clock10.png*, as well as its Base64 encoding in the *img* tag (in its *src* attribute: this is the "data URL"). Directly in the text of the web page itself, it looks like this (it is not necessary to wrap a long Base64 string across a width of 76 characters, but it is allowed by the standard and done here for publication):

```
<img src="
iVBORw0KGgoAAAANSUhEUgAAABIAAAASCAQAAAD8x0bcAAAAAXNSR0IArs4c6QAAAAJiS0dEAP+
Hj8y/AAABdUlEQVQoz1WSPUiVYRiGr/f4qaRwyAMOLpVnSGuvBh3SoSnLwclwqQa3CNxaWxwcrS
D/CAQH4ShF4RBnqCWQWiQwAp1C6WBi4B/5Xg7f1+fxgXd4eC5e7ue+nxAFgADABj+Bq1wGIBsRU
ihwwCMa6eE6ga+s0sgLmv5j0ahOOOqxqq98q+qeI86o0ShRfWpFHVC105uq3lOnfa5G0UXn1Ji9

IxyRFdomUgB1qlDlmtu6vbYqckES+U6SEtNFGjScMcUhz5tAmrTTAiGZupI79cv9crw8sXGM9Dw
WkgwtncQBf6CfoQ8rcpjcfkSPL/OYdSyRwkWHKSDiHBeQ+39hJs9Nb7qmTmdNpTapb9qexpPLu+
NGqqlVXVf1gxcGzgFNswQGn/OOB/9zypXd9n28Z6o/uBxU2kW4GuVJ3dKeW6inhKgZyVwAAAABJ
RU5ErkJggg==" title="Clock 10:00 Base64 built-it" />
```

Soon we will reproduce this sequence of characters using the *CryptEncode* function, but for now, just note that using a similar technique, we can generate HTML reports with embedded graphics from MQL5.

7.4.2 Encryption, hashing, and data packaging: CryptEncode

The MQL5 function responsible for data encryption, hashing, and compression is *CryptEncode*. It transforms the data of the passed source array *data* to the destination array *result* by the specified method.

int CryptEncode(ENUM_CRYPT_METHOD method, const uchar &data[], const uchar &key[], uchar &result[])

Encryption methods also require passing a byte array *key* with a private (secret) key: its length depends on the specific method and is specified in the ENUM_CRYPT_METHOD method table in the previous section. If the size of the *key* array is larger, only the first bytes in the required quantity will still be used for the key.

A key is not needed for hashing or compression, but there is one caveat for CRYPT_ARCH_ZIP. The fact is that the implementation of the "deflate" algorithm built into the terminal adds several bytes to the resulting data to control the integrity: 2 initial bytes contain the settings of the "deflate" algorithm, and 4 bytes at the end contain the Adler32 checksum. Because of this feature, the resulting packed container differs from the one generated by ZIP archives for each individual element of the archive (the ZIP standard stores CRC32, which is similar in meaning, in its headers). Therefore, in order to be able to create and read compatible ZIP archives based on data packed by the *CryptEncode* function, MQL5 allows you to disable your own integrity check and the generation of extra bytes using a special value in the *key* array.

```
uchar key[] = {1, 0, 0, 0};
CryptEncode(CRYPT_ARCH_ZIP, data, key, result);
```

Any key with a length of at least 4 bytes can be used. The obtained *result* array can be enriched with a title according to the standard ZIP format (this question is out of the scope of the book) to create an archive accessible to other programs.

The function returns the number of bytes placed in the destination array or 0 on error. The error code, as usual, will be stored in *_LastError*.

Let's check the function performance using the script *CryptEncode.mq5*. It allows the user to enter text (*Text*) or specify a file (*File*) for processing. To use the file, you need to clear the *Text* field.

You can choose a specific *Method* or loop through all the methods at once to visually see and compare different results. For such a review loop, leave the default value _CRYPT_ALL in the *Method* parameter.

By the way, to introduce such functionality, we again needed to extend the standard enumeration (this time ENUM_CRYPT_METHOD), but since enumerations in MQL5 cannot be inherited as classes, a new enumeration ENUM_CRYPT_METHOD_EXT is actually declared here. An added bonus of this is that we have added friendlier names for the elements (in the comments, with hints that will be displayed in the settings dialog).

```
enum ENUM_CRYPT_METHOD_EXT
{
   _CRYPT_ALL = 0xFF,                     // Try All in a Loop
   _CRYPT_DES = CRYPT_DES,                // DES    (key required, 7 bytes)
   _CRYPT_AES128 = CRYPT_AES128,          // AES128 (key required, 16 bytes)
   _CRYPT_AES256 = CRYPT_AES256,          // AES256 (key required, 32 bytes)
   _CRYPT_HASH_MD5 = CRYPT_HASH_MD5,      // MD5
   _CRYPT_HASH_SHA1 = CRYPT_HASH_SHA1,    // SHA1
   _CRYPT_HASH_SHA256 = CRYPT_HASH_SHA256, // SHA256
   _CRYPT_ARCH_ZIP = CRYPT_ARCH_ZIP,      // ZIP
   _CRYPT_BASE64 = CRYPT_BASE64,          // BASE64
};

input string Text = "Let's encrypt this message"; // Text (empty to process File)
input string File = "MQL5Book/clock10.htm"; // File (used only if Text is empty)
input ENUM_CRYPT_METHOD_EXT Method = _CRYPT_ALL;
```

By default, the *Text* parameter is filled with a message that is supposed to be encrypted. You can replace it with your own. If we clear *Text*, the program will process the file. At least one of the parameters (*Text* or *File*) should contain information.

Since encryption requires a key, the other two options allow you to enter it directly as text (although the key does not have to be text and can contain any binary data, but they are not supported in inputs) or generate the desired length, depending on the encryption method.

```
enum DUMMY_KEY_LENGTH
{
   DUMMY_KEY_0 = 0,   // 0 bytes (no key)
   DUMMY_KEY_7 = 7,   // 7 bytes (sufficient for DES)
   DUMMY_KEY_16 = 16, // 16 bytes (sufficient for AES128)
   DUMMY_KEY_32 = 32, // 32 bytes (sufficient for AES256)
   DUMMY_KEY_CUSTOM,  // use CustomKey
};

input DUMMY_KEY_LENGTH GenerateKey = DUMMY_KEY_CUSTOM; // GenerateKey (length, or fro
input string CustomKey = "My top secret key is very strong";
```

Finally, there is an option *DisableCRCinZIP* to enable ZIP compatibility mode, which only affects the CRYPT_ARCH_ZIP method.

```
input bool DisableCRCinZIP = false;
```

To simplify checks of whether the method requires an encryption key or a hash is calculated (an irreversible one-way conversion), 2 macros are defined.

```
#define KEY_REQUIRED(C) ((C) == CRYPT_DES || (C) == CRYPT_AES128 || (C) == CRYPT_AES2
#define IS_HASH(C) ((C) == CRYPT_HASH_MD5 || (C) == CRYPT_HASH_SHA1 || (C) == CRYPT_H
```

The beginning of *OnStart* contains a description of the required variables and arrays.

```
void OnStart()
{
   ENUM_CRYPT_METHOD method = 0;
   int methods[];           // here we will collect all the elements of ENUM_CRYPT_ME
   uchar key[] = {};        // empty by default: suitable for hashing, zip, base64
   uchar zip[], opt[] = {1, 0, 0, 0}; // "options" for zip
   uchar data[], result[];  // initial data and result
```

According to *GenerateKey* settings, we get the key from the *CustomKey* field or just populate the *key* array with monotonically increasing integer values. In reality, the key should be a secret; non-trivial, arbitrarily chosen block of values.

```
   if(GenerateKey == DUMMY_KEY_CUSTOM)
   {
      if(StringLen(CustomKey))
      {
         PRTF(CustomKey);
         StringToCharArray(CustomKey, key, 0, -1, CP_UTF8);
         ArrayResize(key, ArraySize(key) - 1);
      }
   }
   else if(GenerateKey != DUMMY_KEY_0)
   {
      ArrayResize(key, GenerateKey);
      for(int i = 0; i < GenerateKey; ++i) key[i] = (uchar)i;
   }
```

Here and below, please note the use of *ArrayResize* after *StringToCharArray*. Be sure to reduce the array by 1 element, because in case the function *StringToCharArray* converts the string to an array of bytes, including the terminal 0, this can break the expected execution of the program. In particular, in this case, we will have an extra zero byte in the secret key, and if a program with a similar artifact is not used on the receiving side, then it will not be able to decrypt the message. Such extra zeros can also affect compatibility with data exchange protocols (if one or another integration of an MQL program with the "outside world" is performed).

Next, we log a raw representation of the resulting key in hexadecimal format: this is done by the *ByteArrayPrint* function which was used in the section Writing and reading files in simplified mode.

```
if(ArraySize(key))
{
   Print("Key (bytes):");
   ByteArrayPrint(key);
}
else
{
   Print("Key is not provided");
}
```

Subject to the availability of *Text* or *File*, we populate the *data* array either with text characters or with file contents.

```
if(StringLen(Text))
{
   PRTF(Text);
   PRTF(StringToCharArray(Text, data, 0, -1, CP_UTF8));
   ArrayResize(data, ArraySize(data) - 1);
}
else if(StringLen(File))
{
   PRTF(File);
   if(PRTF(FileLoad(File, data)) <= 0)
   {
      return; // error
   }
}
```

Finally, we loop through all the methods or perform the transformation once with a specific method.

```
const int n = (Method == _CRYPT_ALL) ?
   EnumToArray(method, methods, 0, UCHAR_MAX) : 1;
ResetLastError();
for(int i = 0; i < n; ++i)
{
   method = (ENUM_CRYPT_METHOD)((Method == _CRYPT_ALL) ? methods[i] : Method);
   Print("- ", i, " ", EnumToString(method), ", key required: ",
      KEY_REQUIRED(method));

   if(method == CRYPT_ARCH_ZIP)
   {
      if(DisableCRCinZIP)
      {
         ArrayCopy(zip, opt); // array with additional option dynamic for ArraySwa
      }
      ArraySwap(key, zip); // change key to empty or option
   }

   if(PRTF(CryptEncode(method, data, key, result)))
   {
      if(StringLen(Text))
      {
         // code page Latin (Western) to unify the display for all users
         Print(CharArrayToString(result, 0, WHOLE_ARRAY, 1252));
         ByteArrayPrint(result);
         if(method != CRYPT_BASE64)
         {
            const uchar dummy[] = {};
            uchar readable[];
            if(PRTF(CryptEncode(CRYPT_BASE64, result, dummy, readable)))
            {
               PrintFormat("Try to decode this with CryptDecode.mq5 (%s):",
                  EnumToString(method));
               // to receive encoded data back for decoding
               // via string input, apply Base64 over binary result
               Print("base64:'" + CharArrayToString(readable, 0, WHOLE_ARRAY, 1252
            }
         }
      }
      else
      {
         string parts[];
         const string filename = File + "." +
            parts[StringSplit(EnumToString(method), '_', parts) - 1];
         if(PRTF(FileSave(filename, result)))
         {
            Print("File saved: ", filename);
            if(IS_HASH(method))
            {
               ByteArrayPrint(result, 1000, "");
            }
```

```
                }
            }
        }
    }
}
```

When we convert text, we log the result, but since it is almost always binary data, with the exception of the CRYPT_BASE64 method, their display will be complete gibberish (to say the truth, binary data should not be logged, but we do this for clarity). Non-printable symbols and symbols with codes greater than 128 are displayed differently on computers with different languages. Therefore, in order to unify the display of examples for all readers, when forming a line in *CharArrayToString*, we use an explicit code page (1252, Western European languages). True, the fonts used when publishing a book will most likely contribute to how certain characters will be displayed (the set of glyphs in fonts may be limited).

> It is important to note that we control the choice of code page only in the display method, and the bytes in the *result* array do not change because of this (of course, the string obtained in this way should not be sent anywhere further; it is needed only for visualization to use the bytes of the result itself for data exchange).

However, it is still desirable for us to provide the user with some opportunity to save the encrypted result in order to decode it later. The simplest way is to re-transform the binary data using the CRYPT_BASE64 method.

In the case of file encoding, we simply save the result in a new file with a name in which the extension of the last word in the method name is added to the original one. For example, by applying CRYPT_HASH_MD5 to the file *Example.txt*, we will get the output file *Example.txt.MD5* containing the MD5 hash of the source file. Please note that for the CRYPT_ARCH_ZIP method, we will get a file with a ZIP extension, but it is not a standard ZIP archive (due to the lack of headers with meta information and a table of contents).

Let's run the script with the default settings: they correspond to checking in the loop all methods for the text "Let's encrypt this message".

```
CustomKey=My top secret key is very strong / ok
Key (bytes):
[00] 4D | 79 | 20 | 74 | 6F | 70 | 20 | 73 | 65 | 63 | 72 | 65 | 74 | 20 | 6B | 65 |

```

The key in this case is of sufficient length for all three encryption methods, and other methods for which it is not needed simply ignore it. Therefore, all function calls have been completed successfully.

In the next section, we will learn how to decode encryptions and we can check if the *CryptDecode* function returns the original message. Please note this piece of the log.

The enabled *DisableCRCinZIP* option will reduce the result of the CRYPT_ARCH_ZIP method by a few overhead bytes.

```

FileSave(filename,result)=true / ok
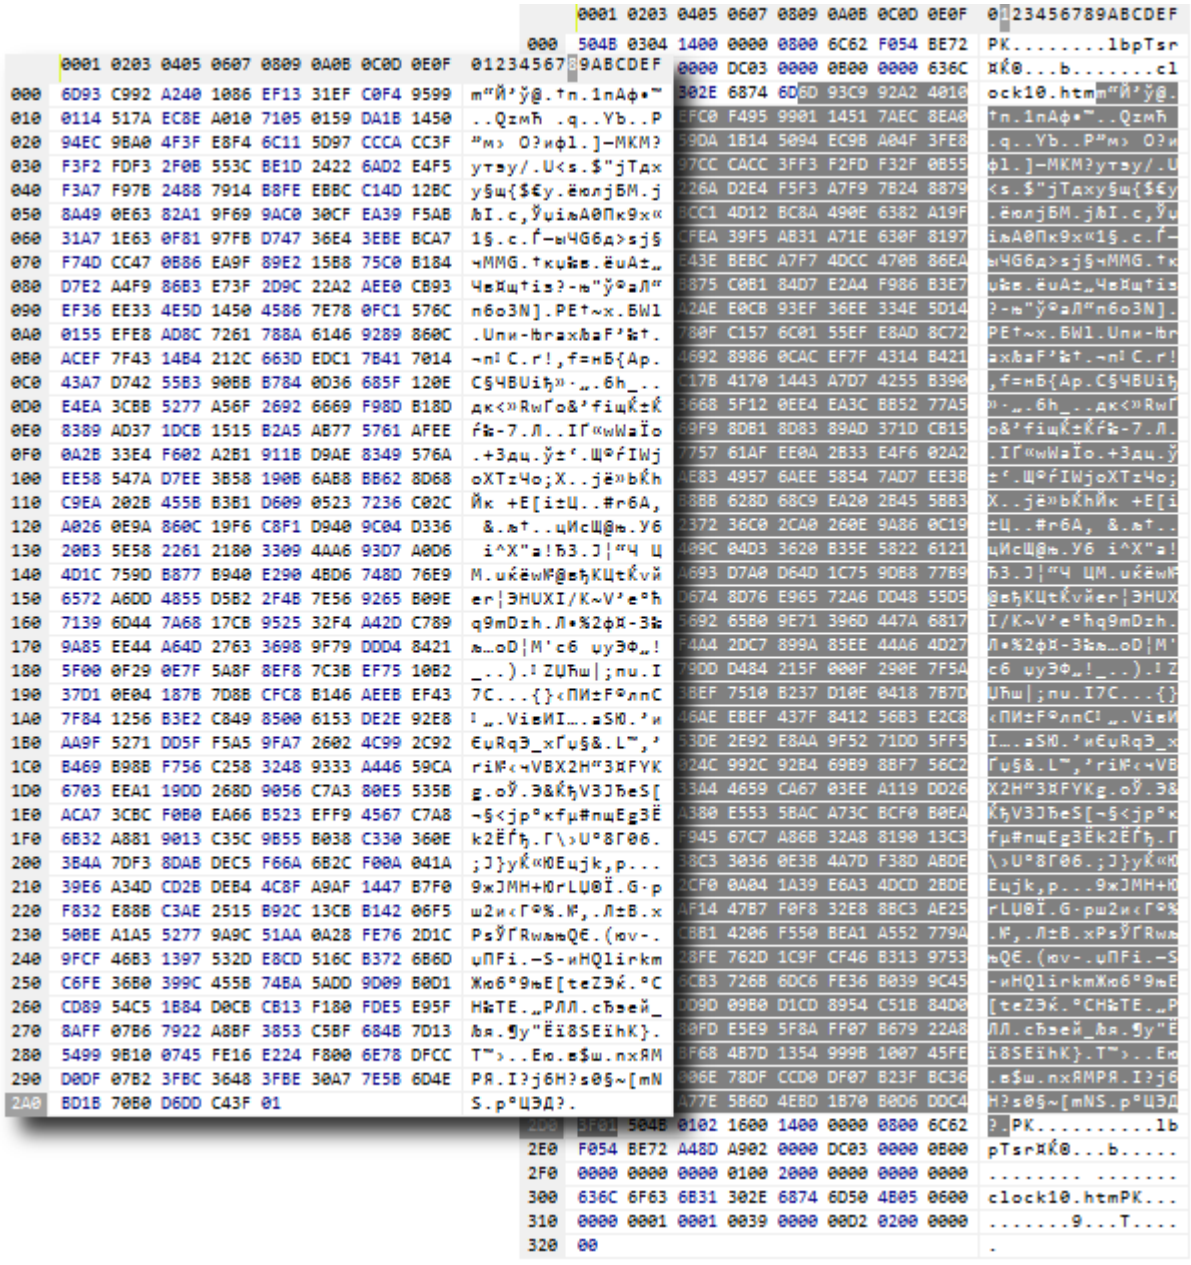
File saved: MQL5Book/clock10.htm.AES256
- 3 CRYPT_DES, key required: true
CryptEncode(method,data,key,result)=992 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.DES
- 4 CRYPT_HASH_SHA1, key required: false
CryptEncode(method,data,key,result)=20 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.SHA1
[00] 486ADFDD071CD23AB28E820B164D813A310B213F
- 5 CRYPT_HASH_SHA256, key required: false
CryptEncode(method,data,key,result)=32 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.SHA256
[00] 8990BBAC9C23B1F987952564EBCEF2078232D8C9D6F2CCC2A50784E8CDE044D0
- 6 CRYPT_HASH_MD5, key required: false
CryptEncode(method,data,key,result)=16 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.MD5
[00] 0CC4FBC899554BE0C0DBF5C18748C773
- 7 CRYPT_ARCH_ZIP, key required: false
CryptEncode(method,data,key,result)=687 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.ZIP
```

You can look inside all the files from the file manager and make sure that there is nothing left in common with the original content. Many file managers have commands or plugins to calculate hash sums so that they can be compared to MD5, SHA1, and SHA256 hex values printed out to the log.

If we try to encode a text or a file without providing a key of the correct length, we will get an INVALID_ARRAY(4006) error. For example, for a default text message, we select AES256 in the *method* parameter (requires a 32-byte key). Using the *GenerateKey* parameter, we order a key with a length of 16 bytes (or you can partially or completely remove the text from the *CustomKey* field, leaving *GenerateKey* default).

```
Key (bytes):
[00] 00 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 | 09 | 0A | 0B | 0C | 0D | 0E | 0F |
Text=Let's encrypt this message / ok
StringToCharArray(Text,data,0,-1,CP_UTF8)=26 / ok
- 0 CRYPT_AES256, key required: true
CryptEncode(method,data,key,result)=0 / INVALID_ARRAY(4006)
```

You can also compress the same file (as we did with *clock10.htm*) using the CRYPT_ARCH_ZIP method or using a regular archiver. If you later look with a binary viewer utility (which is usually built into the file manager), then both results will show a common packed block, and the differences will be only in the meta-data framing it.



Comparison of a file compressed with the CRYPT_ARCH_ZIP method (left) and a standard ZIP archive with it (right)

It shows that the middle and main part of the archive is a sequence of bytes (highlighted in dark) identical to those produced by the *CryptEncode* function.

Finally, we will show how the *Base64* text representation of a graphic file *clock10.png* was generated. To do this, clear the field *Text* and write *MQL5Book/clock10.png* in the *File* parameter. Choose *Base64* in the drop-down list *Method*.

```
File=MQL5Book/clock10.png / ok
FileLoad(File,data)=457 / ok
- 0 CRYPT_BASE64, key required: false
CryptEncode(method,data,key,result)=612 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.png.BASE64
```

The *clock10.png.BASE64* file has been created as a result. Inside it, we will see the very line that is inserted in the web page code, in the *img* tag.

By the way, the "deflate" compression method is the basis for the PNG graphics format, so we can use *CryptEncode* to save resource bitmaps to PNG files. The header file *PNG.mqh* is included with the book, with minimal support for internal structures necessary to describe the image: it is suggested to experiment with its source code independently. Using *PNG.mqh*, we have written a simple script *CryptPNG.mq5* which converts the resource from the "euro.bmp" file supplied with the terminal to the "my.png" file. Loading PNG files is not implemented.

```
#resource "\\Images\\euro.bmp"

#include <MQL5Book/PNG.mqh>

void OnStart()
{
   uchar null[];      // empty key for CRYPT_ARCH_ZIP
   uchar result[];    // receiving array
   uint data[];       // original pixels
   uchar bytes[];     // original bytes
   int width, height;
   PRTF(ResourceReadImage("::Images\\euro.bmp", data, width, height));

   ArrayResize(bytes, ArraySize(data) * 3 + width); // *3 for PNG_CTYPE_TRUECOLOR (RG
   ArrayInitialize(bytes, 0);
   int j = 0;
   for(int i = 0; i < ArraySize(data); ++i)
   {
      if(i % width == 0) bytes[j++] = 0; // each line is prepended with a filter mode
      const uint c = data[i];
      // bytes[j++] = (uchar)((c >> 24) & 0xFF); // alpha, for PNG_CTYPE_TRUECOLORALP
      bytes[j++] = (uchar)((c >> 16) & 0xFF);
      bytes[j++] = (uchar)((c >> 8) & 0xFF);
      bytes[j++] = (uchar)(c & 0xFF);
   }

   PRTF(CryptEncode(CRYPT_ARCH_ZIP, bytes, null, result));

   int h = PRTF(FileOpen("my.png", FILE_BIN | FILE_WRITE));

   PNG::Image image(width, height, result); // default PNG_CTYPE_TRUECOLOR (RGB)
   image.write(h);

   FileClose(h);
}
```

7.4.3 Data decryption and decompression: CryptDecode

To perform data decryption and decompression operations, MQL5 provides the *CryptDecode* function.

The *CryptDecode* function performs an inverse transformation of the *data* array to the receiving *result* array using the specified method.

int CryptDecode(ENUM_CRYPT_METHOD method, const uchar &data[], const uchar &key[], uchar &result[])

Please note that the obtaining of hash sums performed, in particular, by the *CryptEncode* function, is a one-way transformation: it is impossible to recover the original data from hashes.

The function returns the number of bytes placed in the destination array or 0 on error. The error code will be added to *_LastError*. This could be, for example, INVALID_PARAMETER (4003) if we try to

decode the hash (*method* equals one of the CRYPT_HASH constants) or INVALID_ARRAY (4006) if the decryption key is not long enough or is missing.

If the key is incorrect (different from the one used in encryption), we will get gibberish as a result instead of the encoded source data but the error code is zero. This is the normal behavior of the function.

Let's check the work of *CryptDecode* using the same script *CryptDecode.mq5*.

In the input parameters, you can specify the text or file to be converted. Text is always implied in encoding *Base64* since all encoded data is in binary format and is not supported in *input* parameters. The conversion method is selected from the *Method* list.

```
input string Text; // Text (base64, or empty to process File)
input string File = "MQL5Book/clock10.htm.BASE64";
input ENUM_CRYPT_METHOD_EXT Method = _CRYPT_BASE64;
```

Encryption methods require a key which can be specified as a string in the *CustomKey* field if *GenerateKey* contains the DUMMY_KEY_CUSTOM option. You can also generate a demo key of the required length from the DUMMY_KEY_LENGTH enumeration (it's the same as in the *CryptEncode.mq5* script).

```
input DUMMY_KEY_LENGTH GenerateKey = DUMMY_KEY_CUSTOM; // GenerateKey (length, or fro
input string CustomKey = "My top secret key is very strong";
input bool DisableCRCinZIP = false;
```

In *GenerateKey* and *CustomKey*, you should choose the same values as when launching *CryptEncode.mq5*.

The algorithm in *OnStart* starts with a description of the required arrays and obtaining a key from a string or by simple generation (only for a demo, use special software or algorithms to generate a working crypto-resistant key).

```
void OnStart()
{
   ENUM_CRYPT_METHOD method = 0;
   int methods[];
   uchar key[] = {};        // default empty key suitable for zip and base64
   uchar data[], result[];
   uchar zip[], opt[] = {1, 0, 0, 0};

   if(GenerateKey == DUMMY_KEY_CUSTOM)
   {
      if(StringLen(CustomKey))
      {
         PRTF(CustomKey);
         StringToCharArray(CustomKey, key, 0, -1, CP_UTF8);
         ArrayResize(key, ArraySize(key) - 1);
      }
   }
   else if(GenerateKey != DUMMY_KEY_0)
   {
      ArrayResize(key, GenerateKey);
      for(int i = 0; i < GenerateKey; ++i) key[i] = (uchar)i;
   }

   if(ArraySize(key))
   {
      Print("Key (bytes):");
      ByteArrayPrint(key);
   }
   else
   {
      Print("Key is not provided");
   }
```

Next, we read the contents of the file or decode *Base64* from the *Text* field (depending on what is filled in) to get the data to process.

```
   method = (ENUM_CRYPT_METHOD)Method;
   Print("- ", EnumToString(method), ", key required: ", KEY_REQUIRED(method));
   if(StringLen(Text))
   {
      if(method != CRYPT_BASE64)
      {
         // since all methods except Base64 produce binary results,
         // they are additionally converted to CryptEncode.mq5 using Base64 to text,
         // so here we want to recover binary data from text input
         // before decryption
         uchar base64[];
         const uchar dummy[] = {};
         PRTF(Text);
         PRTF(StringToCharArray(Text, base64, 0, -1, CP_UTF8));
         ArrayResize(base64, ArraySize(base64) - 1);
         Print("Text (bytes):");
         ByteArrayPrint(base64);
         if(!PRTF(CryptDecode(CRYPT_BASE64, base64, dummy, data)))
         {
            return; // error
         }

         Print("Raw data to decipher (after de-base64):");
         ByteArrayPrint(data);
      }
      else
      {
         PRTF(StringToCharArray(Text, data, 0, StringLen(Text), CP_UTF8));
         ArrayResize(data, ArraySize(data) - 1);
      }
   }
   else if(StringLen(File))
   {
      PRTF(File);
      if(PRTF(FileLoad(File, data)) <= 0)
      {
         return; // error
      }
   }
```

If the user tries to recover data from the hash, we will show a warning.

```
   if(IS_HASH(method))
   {
      Print("WARNING: hashes can not be used to restore data! CryptDecode will fail."
   }
```

Finally, we perform the decryption or decompression (unpacking) directly. In the case of a text, the result is simply logged. In the case of a file, we add the extension ".dec" to the name and write a new file: it can be compared with the original one, which was processed using the *CryptEncode.mq5* script.

```
   ResetLastError();
   if(PRTF(CryptDecode(method, data, key, result)))
   {
      if(StringLen(Text))
      {
         Print("Text restored:");
         Print(CharArrayToString(result, 0, WHOLE_ARRAY, CP_UTF8));
      }
      else // File
      {
         const string filename = File + ".dec";
         if(PRTF(FileSave(filename, result)))
         {
            Print("File saved: ", filename);
         }
      }
   }
```

If you run the script with default settings, it will try to decode the file *MQL5Book/clock10.htm.BASE64*. It is assumed that this was created during the experiments in the previous section, so the process should be successful.

```
- CRYPT_BASE64, key required: false
File=MQL5Book/clock10.htm.BASE64 / ok
FileLoad(File,data)=1320 / ok
CryptDecode(method,data,key,result)=988 / ok
FileSave(filename,result)=true / ok
File saved: MQL5Book/clock10.htm.BASE64.dec
```

The obtained file *clock10.htm.BASE64.dec* is completely identical to the original *clock10.htm*. The same should happen if you decrypt files with extensions AES128, AES256, or DES, provided that you specify the same key as the one used when encrypting.

For clarity, let's check the decryption of the text. Previously, encryption of a known phrase using the AES128 method produced a binary which was converted into the following *Base64* string for convenience.

```
AQuvVCoSy1szaN8Owy8tQxl9rIrRj9hOqK7KgYYGh9E=
```

Let's enter it in the *Text* field and select AES128 in the *Method* dropdown list. We will see the following logs.

```
CustomKey=My top secret key is very strong / ok
Key (bytes):
[00] 4D | 79 | 20 | 74 | 6F | 70 | 20 | 73 | 65 | 63 | 72 | 65 | 74 | 20 | 6B | 65 |

CryptDecode(method,data,key,result)=32 / ok
Text restored:
Let's encrypt this message
```

The message was successfully decrypted.

If, with the same input text, you choose to generate an arbitrary key (albeit of sufficient length), you will get gibberish instead of a message.

```
Key (bytes):
[00] 00 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 | 09 | 0A | 0B | 0C | 0D | 0E | 0F |
- CRYPT_AES128, key required: true
Text=AQuvVCoSy1szaN8Owy8tQxl9rIrRj9hOqK7KgYYGh9E= / ok
StringToCharArray(Text,base64,0,-1,CP_UTF8)=44 / ok
Text (bytes):
[00] 41 | 51 | 75 | 76 | 56 | 43 | 6F | 53 | 79 | 31 | 73 | 7A | 61 | 4E | 38 | 4F |
[16] 77 | 79 | 38 | 74 | 51 | 78 | 6C | 39 | 72 | 49 | 72 | 52 | 6A | 39 | 68 | 4F |
[32] 71 | 4B | 37 | 4B | 67 | 59 | 59 | 47 | 68 | 39 | 45 | 3D |
CryptDecode(CRYPT_BASE64,base64,dummy,data)=32 / ok
Raw data to decipher (after de-base64):
[00] 01 | 0B | AF | 54 | 2A | 12 | CB | 5B | 33 | 68 | DF | 0E | C3 | 2F | 2D | 43 |
[16] 19 | 7D | AC | 8A | D1 | 8F | D8 | 4E | A8 | AE | CA | 81 | 86 | 06 | 87 | D1 |
CryptDecode(method,data,key,result)=32 / ok
Text restored:
??? ?L?? ??J Q+?]?v?9?????n?N?Ű
```

The program will behave similarly if you confuse the encryption method.

It doesn't make sense to choose "unhashing" methods: INVALID_PARAMETER (4003).

```
- CRYPT_HASH_MD5, key required: false
File=MQL5Book/clock10.htm.MD5 / ok
FileLoad(File,data)=16 / ok
WARNING: hashes can not be used to restore data! CryptDecode will fail.
CryptDecode(method,data,key,result)=0 / INVALID_PARAMETER(4003)
```

An attempt to unpack (CRYPT_ARCH_ZIP) something that is not a compressed "deflate" block will result in INTERNAL_ERROR (4001). The same error can be obtained if you enable the skip CRC option for the "archive" without it, or, conversely, uncompress the data without the option, although packing was done with it.

7.5 Network functions

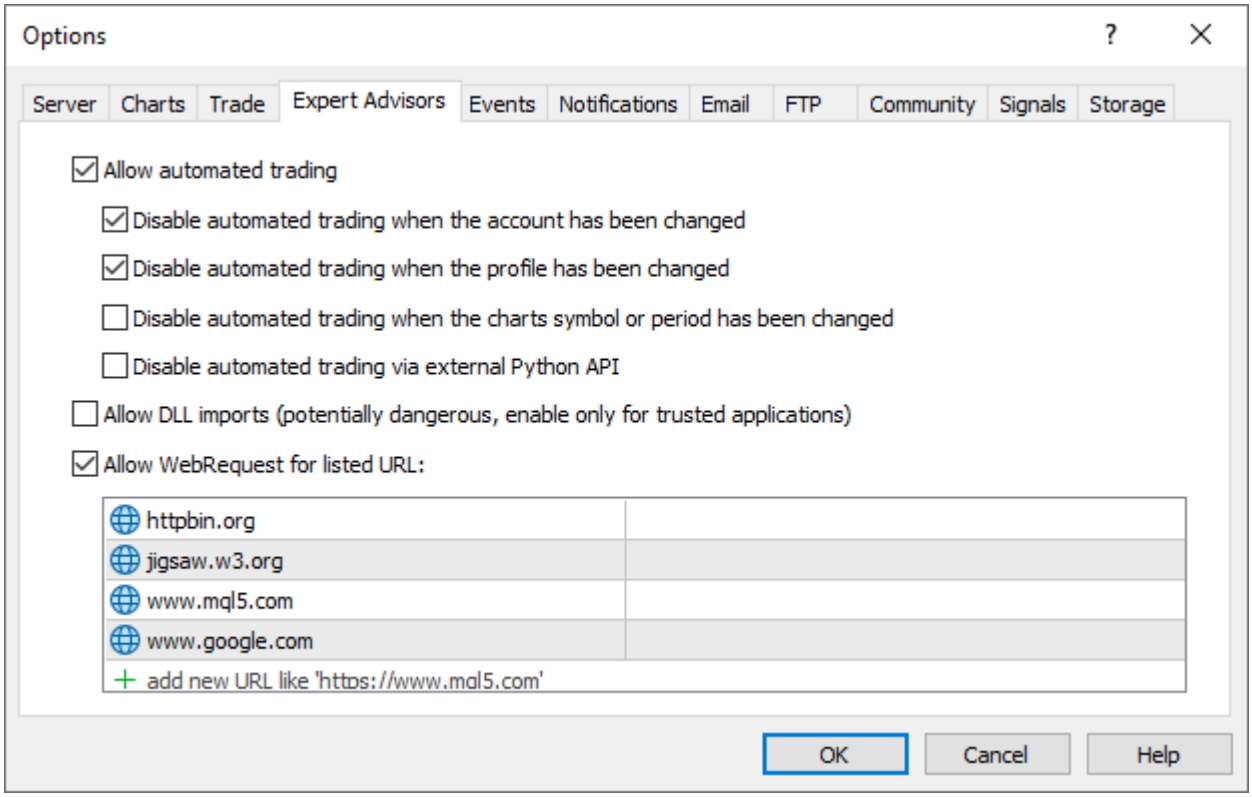
MQL programs can communicate with other computers on a distributed network or Internet servers using various protocols. The functions support operations with websites and services (HTTP/HTTPS), file transfer (FTP), email sending (SMTP), and push notifications.

Network functions can be divided into three groups:

- *SendFTP*, *SendMail*, and *SendNotification* are the most basic functions for sending files, e-mails, and mobile notifications.
- The *WebRequest* function is designed to work with web resources and allows you to easily send HTTP requests (including GET and POST).
- The set of *Socket* functions allows you to create a TCP connection (including a secure TLS connection) with a remote host via system sockets.

The sequence in which the groups are listed corresponds to the transition from high-level functions that offer ready-made mechanisms for interaction between the client and the server, to low-level ones that allow the implementation of an arbitrary application protocol according to the requirements of a particular public service (for example, a cryptocurrency exchange or a trading signal service). Of course, such an implementation requires a lot of effort.

For end-user safety, the list of allowed web addresses that an MQL program can connect to using *Socket* functions and *WebRequest* must be explicitly specified in the settings dialog on the *Expert Advisors* tab. Here you can specify domains, the full path to web pages (not only the site, but also other fragments of the URL, such as folders or a port number), or IP addresses. Below is a screenshot of the settings for some of the domains from the examples in this chapter.



Permissions to access network resources in the terminal settings

You cannot programmatically edit this list. If you try to access a network resource that is not in this list, the MQL program will receive an error and the request will be rejected.

It is important to note that all network functions provide only a client connection to a particular server, that is, it is impossible to organize a server using MQL5 to wait and process incoming requests. For this purpose, it will be necessary to integrate the terminal with an external program or an Internet service (for example, with a cloud one).

7.5.1 Sending push notifications

As you know, the terminal allows you to send push notifications from MetaQuotes services, the terminal itself, and MQL programs to a mobile device with iOS or Android operating systems. This technology uses MetaQuotes ID, a unique identifier of a user (see the note). MetaQuotes ID is allocated when installing the mobile version of the terminal on the user's device, after which the ID must be specified in the terminal settings, on the Notifications tab (several identifiers can be specified separated by commas). After that, the functionality for sending push notifications becomes available for MQL programs.

> In fact, MetaQuotes ID does not identify a user, but a specific installation of a mobile terminal; a user can have several installations. The ID is not associated with the registration in the mql5.com community by default, although such a binding can be specified on the site. Do not confuse user registration in the community with MetaQuotes ID. To work with notifications, the terminal user is not required to log into the community.

bool SendNotification(const string text)

The *SendNotification* function sends push notifications with the specified text to all mobile terminals that have a MetaQuotes ID from the terminal settings. The message length is no more than 255 characters.

If the notification is successfully sent from the terminal, the function returns *true*, and it returns *false* if an error occurs. Possible error codes in *_LastError* include:

- 4515 – ERR_NOTIFICATION_SEND_FAILED – communication problems
- 4516 – ERR_NOTIFICATION_WRONG_PARAMETER – an invalid parameter, for example, an empty string
- 4517 – ERR_NOTIFICATION_WRONG_SETTINGS – MetaQuotes ID is incorrectly configured or missing
- 4518 – ERR_NOTIFICATION_TOO_FREQUENT – too frequent function calls

If there is a connection to the server, the message is sent instantly. If the user's device is online, the message should reach the addressee, but delivery cannot be guaranteed in the general case. There is no return notification to the program about the delivery of the message. The history of push messages on the server for deferred delivery is not saved.

The function has restrictions on the frequency of use: no more than 2 calls per second and no more than 10 per minute.

The *SendNotification* function is not executed in the strategy tester.

The book includes a simple script *NetNotification.mq5* that sends a test notification when the settings are correct.

```
void OnStart()
{
   const string message = MQLInfoString(MQL_PROGRAM_NAME)
      + " runs on " + AccountInfoString(ACCOUNT_SERVER)
      + " " + (string)AccountInfoInteger(ACCOUNT_LOGIN);
   Print("Sending notification: " + message);
   PRTF(SendNotification(NULL));    // INVALID_PARAMETER(4003)
   PRTF(SendNotification(message)); // NOTIFICATION_WRONG_SETTINGS(4517) or 0 (succes
}
```

7.5.2 Sending email notifications

The terminal allows you to send emails to the email address specified on the Email tab of the settings dialog. For this, MQL5 provides the *SendMail* function.

bool SendMail(const string subject, const string text)

The function parameters set the title and text (the body of the message).

The function returns *true* if the message is queued for sending on the mail server; otherwise, it returns *false*. Errors are possible if the work with mail is disabled in the settings or the mail data (SMTP server, port, login, password) contains an error or is not specified.

The function *SendMail* is not executed in the strategy tester.

MQL5 does not support checking incoming email and reading it (ie POP, IMAP protocols).

The book includes the script *NetMail.mq5* that attempts to send a test message.

```
void OnStart()
{
   const string message = "Hello from "
      + AccountInfoString(ACCOUNT_SERVER)
      + " " + (string)AccountInfoInteger(ACCOUNT_LOGIN);
   Print("Sending email: " + message);
   PRTF(SendMail(MQLInfoString(MQL_PROGRAM_NAME),
      message)); // MAIL_SEND_FAILED(4510) or 0 (success)
}
```

7.5.3 Sending files to an FTP server

MetaTrader 5 supports sending files to an FTP server. For this feature to work, you must enter the necessary FTP details in the settings dialog on the FTP tab: FTP server address, login, password, and optionally the path for placing files on the server. If your computer is on the network of an ISP that has not allocated a public IP address for you, then you will probably need to turn on the passive mode.

Sending files directly from an MQL program is supported by the *SendFTP* function.

bool SendFTP(const string filename, const string path = NULL)

The function sends a file with the specified name to the FTP server from the terminal settings. If necessary, you can specify a different path than the one configured in advance. If the *path* parameter is not specified, the directory described in the settings is used.

The uploaded file must be located in the folder *MQL5/Files* or its subfolders.

The function returns an indicator of success (*true*) or error (*false*). Potential errors in *_LastError* include:

- 4514 – ERR_FTP_SEND_FAILED – failed to send a file via FTP
- 4519 – ERR_FTP_NOSERVER – FTP server not specified
- 4520 – ERR_FTP_NOLOGIN – FTP login was not specified
- 4521 – ERR_FTP_FILE_ERROR – the specified file was not found in the MQL5/Files directory
- 4522 – ERR_FTP_CONNECT_FAILED – an error occurred while connecting to the FTP server
- 4523 – ERR_FTP_CHANGEDIR – the directory for uploading the file was not found on the FTP server
- 4524 – ERR_FTP_CLOSED – the connection to the FTP server was closed

The function blocks the execution of the MQL program until the operation is completed. In this regard, the function is not allowed to be used in indicators.

Also, the *SendFTP* function is not executed in the strategy tester.

> The terminal only supports sending a single file to an FTP server. All other FTP commands are not available from MQL5.

The example script *NetFtp.mq5* takes a screenshot of the current chart and tries to send it via FTP.

```
void OnStart()
{
   const string filename = _Symbol + "-" + PeriodToString() + "-"
      + (string)(ulong)TimeTradeServer() + ".png";
   PRTF(ChartScreenShot(0, filename, 300, 200));
   Print("Sending file: " + filename);
   PRTF(SendFTP(filename, "/upload")); // 0 (success) or FTP_CONNECT_FAILED(4522), FT
}
```

7.5.4 Data exchange with a web server via HTTP/HTTPS

MQL5 allows you to integrate programs with web services and request data from the Internet. Data can be sent and received via HTTP/HTTPS protocols using the *WebRequest* function, which has two versions: for simplified and for advanced interaction with web servers.

```
int WebRequest(const string method, const string url, const string cookie, const string referer,
   int timeout, const char &data[], int size, char &result[], string &response)
int WebRequest(const string method, const string url, const string headers, int timeout,
   const char &data[], char &result[], string &response)
```

The main difference between the two functions is that the simplified version allows you to specify only two types of headers in the request: a *cookie* and a *referer*, i.e. the address from where the transition is made (there is no typo here – historically the word "referrer" is written in HTTP headers through one 'r'). The extended version takes a generic *headers* parameter to send an arbitrary set of headers. Request headers are of the form "name: value" and are joined by a line break "\r\n" if there is more than one.

If we assume that the *cookie* string must contain "name1=value1; name2=value2" and the *referer* link is equal to "google.com", then to call the second version of the function with the same effect as the

first one, we need to add the following in the *headers* parameter: "Cookie: name1=value1; name2=value2\r\nReferer: google.com".

The *method* parameter specifies one of the protocol methods, "HEAD", "GET", or "POST". The address of the requested resource or service is passed in the *url* parameter. According to the HTTP specification, the length of a network resource identifier is limited to 2048 bytes, but at the time of writing the book, MQL5 had a limit of 1024 bytes.

The maximum duration of a request is determined by the *timeout* in milliseconds.

Both versions of the function transfer data from the *data* array to the server. The first option additionally requires specifying the size of this array in bytes (*size*).

To send simple requests with values of several variables, you can combine them into a string like "name1=value1&name2=value2&..." and add them to the GET request address, after the delimiter character '?' or put in the *data* array for a POST request using the "Content-Type: application/x-www-form-urlencoded" header. For more complex cases, such as uploading files, use a POST request and "Content-Type: multipart/form-data".

The receiving *result* array gets the server response body (if any). The server response headers are placed in the *response* string.

The function returns the HTTP response code of the server or -1 in case of a system error (for example, communication problems or parameter errors). The potential error codes that can appear in *_LastError* include:

- 5200 – ERR_WEBREQUEST_INVALID_ADDRESS – invalid URL
- 5201 – ERR_WEBREQUEST_CONNECT_FAILED – failed to connect to the specified URL
- 5202 – ERR_WEBREQUEST_TIMEOUT – the timeout for receiving a response from the server has been exceeded
- 5203 – ERR_WEBREQUEST_REQUEST_FAILED – any other error as a result of the request

Recall that even if the request was executed without errors at the MQL5 level, an application error may be contained in the HTTP response code of the server (for example, authorization is required, invalid data format, page not found, etc.). In this case, the result will be empty, and instructions for resolving the situation, as a rule, are clarified by analyzing the received *response* headers.

To use the *WebRequest* function, the server addresses should be added to the list of allowed URLs in the *Expert Advisors* tab in terminal settings. The server port is automatically selected based on the specified protocol: 80 for "http://" and 443 for "https://".

> The f*WebRequest* unction is synchronous, i.e., it pauses program execution while waiting for a response from the server. In this regard, the function is not allowed to be called from indicators, since they work in common streams for each character. A delay in the execution of one indicator will stop updating all charts for this symbol.

When working in the strategy tester, the *WebRequest* function is not executed.

Let's start with a simple script *WebRequestTest.mq5* that executes a single request. In the input parameters, we will provide a choice for the method (by default "GET"), the address of the test web page, additional headers (optional), and the timeout as well.

```
input string Method = "GET"; // Method (GET,POST)
input string Address = "https://httpbin.org/headers";
input string Headers;
input int Timeout = 5000;
```

The address is entered as in the browser line: all characters that are forbidden by the HTTP specification to be used directly in addresses (including local alphabet characters) are automatically "masked" by the *WebRequest* function before sending according to the *urlencode* algorithm (the browser does exactly the same, but we don't see it, since this view is intended to be passed over the network infrastructure, not to humans).

We will also add the *DumpDataToFiles* option: when it equals *true*, the script will save the server's response to a separate file since it can be quite large. Value *false* instructs to output data directly to the log.

```
input bool DumpDataToFiles = true;
```

> We have to say right away that testing such scripts requires a server. Those interested can install a local web server, for example, node.js, but this requires self-preparation or installation of server-side scripts (in this case, connecting JavaScript modules). An easier way is to use public test web servers available on the Internet. You could use, for example, *httpbin.org*, *httpbingo.org*, *webhook site*, *putsreq.com*, *www.mockable.io*, or *reqbin.com*. They provide a different set of features. Choose or find the right one for you (convenient and understandable, or as flexible as possible).

In the *Address* parameter the default is the address of the *endpoint* of the server API *httpbin.org*. This dynamic "web page" returns the HTTP headers of its request (in JSON format) to the client. Thus, we will be able to see in our program what exactly came to the web server from the terminal.

> Don't forget to add the "httpbin.org" domain to the allowed list in the terminal settings.

The JSON text format is the de facto standard for web services. Ready-made implementations of classes for parsing JSON can be found on the *mql5.com* site, but for now, we'll just show the JSON "as is".

In the *OnStart* handler, we call *WebRequest* with the given parameters and process the result if the error code is non-negative. Server response headers (*response*) are always logged.

```
void OnStart()
{
   uchar data[], result[];
   string response;

   int code = PRTF(WebRequest(Method, Address, Headers, Timeout, data, result, respon
   if(code > -1)
   {
      Print(response);
      if(ArraySize(result) > 0)
      {
         PrintFormat("Got data: %d bytes", ArraySize(result));
         if(DumpDataToFiles)
         {
            string parts[];
            URL::parse(Address, parts);

            const string filename = parts[URL_HOST] +
               (StringLen(parts[URL_PATH]) > 1 ? parts[URL_PATH] : "/_index_.htm");
            Print("Saving ", filename);
            PRTF(FileSave(filename, result));
         }
         else
         {
            Print(CharArrayToString(result, 0, 80, CP_UTF8));
         }
      }
   }
}
```

To form the file name, we use the URL helper class from the header file *URL.mqh* (which will not be fully described here). Method *URL::parse* parses the passed string into URL components according to the specification as the general form of the URL is always "protocol://domain.com:port/path?query#hash"; note that many fragments are optional. The results are placed in the receiving array, the indexes in which correspond to specific parts of the URL and are described in the URL_PARTS enumeration:

```
enum URL_PARTS
{
   URL_COMPLETE,    // full address
   URL_SCHEME,      // protocol
   URL_USER,        // username/password (deprecated, not supported)
   URL_HOST,        // server
   URL_PORT,        // port number
   URL_PATH,        // path/directories
   URL_QUERY,       // query string after '?'
   URL_FRAGMENT,    // fragment after '#' (not highlighted)
   URL_ENUM_LENGTH
};
```

Thus, when the received data should be written to a file, the script creates it in a folder named after the server (*parts[URL_HOST]*) and so on, preserving the path hierarchy in the URL (*parts[URL_PATH]*):

in the simplest case, this will simply be the name of the "endpoint". When the home page of a site is requested (the path contains only a slash '/'), the file is named "_index_.htm".

Let's try to run the script with default parameters, remembering to allow this server in the terminal settings first. In the log, we will see the following lines (HTTP headers of the server response and a message about the successful saving of the file):

```
WebRequest(Method,Address,Headers,Timeout,data,result,response)=200 / ok
Date: Fri, 22 Jul 2022 08:45:03 GMT
Content-Type: application/json
Content-Length: 291
Connection: keep-alive
Server: gunicorn/19.9.0
Access-Control-Allow-Origin: *
Access-Control-Allow-Credentials: true

Got data: 291 bytes
Saving httpbin.org/headers
FileSave(filename,result)=true / ok
```

The *httpbin.org/headers* file contains the headers of our request as seen by the server (the server added the JSON formatting itself when answering us).

```
{
  "headers":
  {
    "Accept": "*/*",
    "Accept-Encoding": "gzip, deflate",
    "Accept-Language": "ru,en",
    "Host": "httpbin.org",
    "User-Agent": "MetaTrader 5 Terminal/5.3333 (Windows NT 10.0; Win64; x64)",
    "X-Amzn-Trace-Id": "Root=1-62da638f-2554..." // <- this is added by the reverse p
  }
}
```

Thus, the terminal reports that it is ready to accept data of any type, with support for compression by specific methods and a list of preferred languages. In addition, it appears in the User-Agent field as MetaTrader 5. The latter may be undesirable when working with some sites that are optimized to work exclusively with browsers. Then we can specify a fictitious name in the *headers* input parameter, for example, "User-Agent: Mozilla/5.0 (Windows NT 10.0) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/103.0.0.0 Safari/537.36".

> Some of the test sites listed above allow you to organize a temporary test environment on the server with a random name for your personal experiment: to do this, you need to go to the site from a browser and get a unique link that usually works for 24 hours. Then you will be able to use this link as an address for requests from MQL5 and monitor the behavior of requests directly from the browser. There you can also configure server responses, in particular, attempt submitting forms.

Let's make this example slightly more difficult. The server may require additional actions from the client to fulfill the request, in particular, authorize, perform a "redirect" (go to a different address), reduce the frequency of requests, etc. All such "signals" are denoted by special HTTP codes returned by the *WebRequest* function. For example, codes 301 and 302 mean redirect for different reasons, and *WebRequest* executes it internally automatically, re-requesting the page at the address specified by the server (therefore, redirect codes never end up in the MQL program code). The 401 code requires the

client to provide a username and password, and here the entire responsibility lies with us. There are many ways to send this data. A new script *WebRequestAuth.mq5* demonstrates the handling of two authorization options that the server requests using HTTP response headers: "WWW-Authenticate: Basic" or "WWW-Authenticate: Digest". In headers it might look like this:

```
WWW-Authenticate:Basic realm="DemoBasicAuth"
```

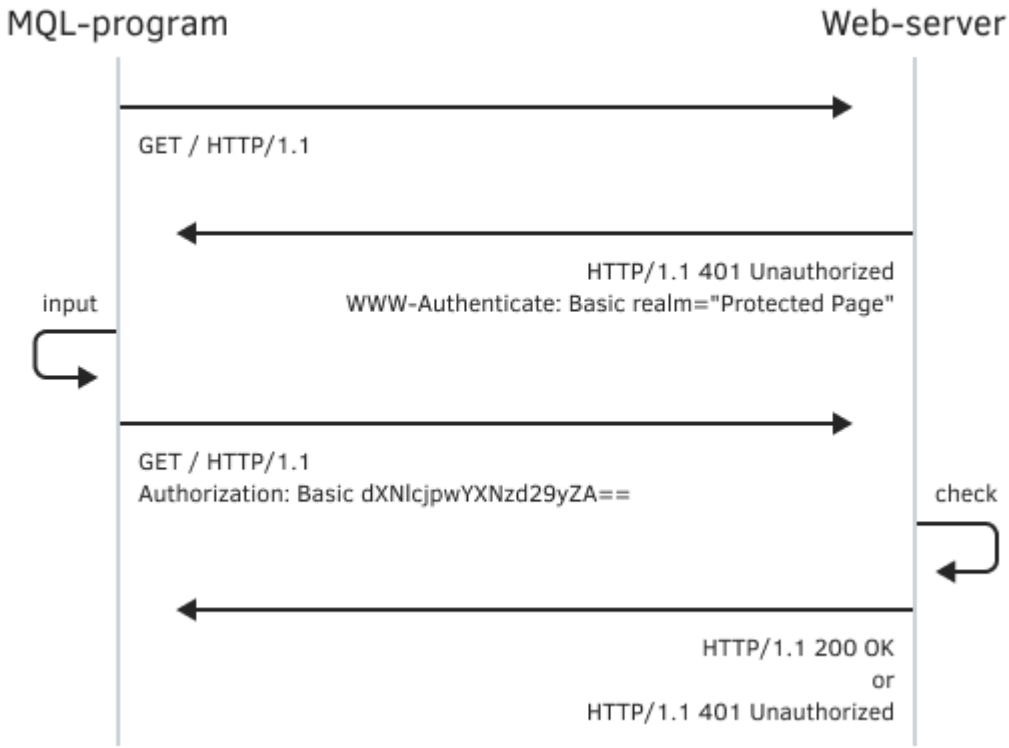
Or like this:

```
WWW-Authenticate:Digest realm="DemoDigestAuth",qop="auth", »
» nonce="cuFAuHbb5UDvtFGkZEb2mNxjqEG/DjDr",opaque="fyNjGC4x8Zgt830PpzbXRvoqExsZeQSDZ
```

The first of them is the simplest and most unsafe, and therefore is practically not used: it is given in the book because of how easy it is to learn it at the first stage. The bottom line of its work is to generate the following HTTP request in response to a server request by adding a special header:

```
Authorization: Basic dXNlcjpwYXNzd29yZA==
```

Here, the "Basic" keyword is followed by the Base64-encoded string "user:password" with the actual username and password, and the ':' character is inserted hereinafter "as is" as a linking block. More clearly, the interaction process is shown in the image.



Simple authorization scheme on a web server

The authorization scheme *Digest* is considered more advanced. In this case, the server provides some additional information in its response:

- *realms* – the name of the site (site area) where the entry is made
- *qop* – a variation of the Digest method (we will only consider "auth")
- *nonce* – a random string that will be used to generate authorization data
- *opaque* – a random string that we will pass back "as is" in our headers

- *algorithm* – an optional name of the hashing algorithm, MD5 is assumed by default

For authorization, you need to perform the following steps:

1. Generate your own random string *cnonce*
2. Initialize or increment your request counter *nc*
3. Calculate *hash1 = MD5(user:realm:password)*
4. Calculate *hash2 = MD5(method:uri)*, here *uri* is the path and name of the page
5. Calculate *response = MD5(hash1:nonce:nc:cnonce:qop:hash2)*

After that, the client can repeat the request to the server, adding a line like this to its headers:

```
Authorization: Digest username="user",realm="realm",nonce="...", »
»  uri="/path/to/page",qop=auth,nc=00000001,cnonce="...",response="...",opaque="..."
```

Since the server has the same information as the client, it will be able to repeat the calculations and check the hashes match.

Let's add variables to the script parameters to enter the username and password. By default, the *Address* parameter includes the address of the *digest-auth* endpoint, which can request authorization with parameters *qop* ("auth"), login ("test"), and password ("pass"). This is all optional in the endpoint path (you can test other methods and user credentials, like so: "https://httpbin.org/digest-auth/auth-int/mql5client/mql5password").

```
const string Method = "GET";
input string Address = "https://httpbin.org/digest-auth/auth/test/pass";
input string Headers = "User-Agent: noname";
input int Timeout = 5000;
input string User = "test";
input string Password = "pass";
input bool DumpDataToFiles = true;
```

We specified a dummy browser name in the *Headers* parameter to demonstrate the feature.

In the *OnStart* function, we add the processing of HTTP code 401. If a username and password are not provided, we will not be able to continue.

```
void OnStart()
{
   string parts[];
   URL::parse(Address, parts);
   uchar data[], result[];
   string response;
   int code = PRTF(WebRequest(Method, Address, Headers, Timeout, data, result, respon
   Print(response);
   if(code == 401)
   {
      if(StringLen(User) == 0 || StringLen(Password) == 0)
      {
         Print("Credentials required");
         return;
      }
      ...
```

The next step is to analyze the headers received from the server. For convenience, we have written the *HttpHeader* class (*HttpHeader.mqh*). The full text is passed to its constructor, as well as the element separator (in this case, the newline character '\n') and the character used between the name and value within each element (in this case, the colon ':'). During its creation, the object "parses" the text, and then the elements are made available through the overloaded operator [], with the type of its argument being a string. As a result, we can check for an authorization requirement by the name "WWW-Authenticate". If such an element exists in the text and is equal to "Basic", we form the response header "Authorization: Basic" with the login and password encoded in Base64.

```
      code = -1;
      HttpHeader header(response, '\n', ':');
      const string auth = header["WWW-Authenticate"];
      if(StringFind(auth, "Basic ") == 0)
      {
         string Header = Headers;
         if(StringLen(Header) > 0) Header += "\r\n";
         Header += "Authorization: Basic ";
         Header += HttpHeader::hash(User + ":" + Password, CRYPT_BASE64);
         PRTF(Header);
         code = PRTF(WebRequest(Method, Address, Header, Timeout, data, result, respo
         Print(response);
      }
      ...
```

For Digest authorization, everything is a little more complicated, following the algorithm outlined above.

```
else if(StringFind(auth, "Digest ") == 0)
{
   HttpHeader params(StringSubstr(auth, 7), ',', '=');
   string realm = HttpHeader::unquote(params["realm"]);
   if(realm != NULL)
   {
      string qop = HttpHeader::unquote(params["qop"]);
      if(qop == "auth")
      {
         string h1 = HttpHeader::hash(User + ":" + realm + ":" + Password);
         string h2 = HttpHeader::hash(Method + ":" + parts[URL_PATH]);
         string nonce = HttpHeader::unquote(params["nonce"]);
         string counter = StringFormat("%08x", 1);
         string cnonce = StringFormat("%08x", MathRand());
         string h3 = HttpHeader::hash(h1 + ":" + nonce + ":" + counter + ":" +
            cnonce + ":" + qop + ":" + h2);

         string Header = Headers;
         if(StringLen(Header) > 0) Header += "\r\n";
         Header += "Authorization: Digest ";
         Header += "username=\"" + User + "\",";
         Header += "realm=\"" + realm + "\",";
         Header += "nonce=\"" + nonce + "\",";
         Header += "uri=\"" + parts[URL_PATH] + "\",";
         Header += "qop=" + qop + ",";
         Header += "nc=" + counter + ",";
         Header += "cnonce=\"" + cnonce + "\",";
         Header += "response=\"" + h3 + "\",";
         Header += "opaque=" + params["opaque"] + "";
         PRTF(Header);
         code = PRTF(WebRequest(Method, Address, Header, Timeout, data, result,
         Print(response);
      }
   }
}
```

Static method *HttpHeader::hash* gets a string with a hexadecimal hash representation (default MD5) for all required compound strings. Based on this data, the header is formed for the next *WebRequest* call. The static *HttpHeader::unquote* method removes the enclosing quotes.

The rest of the script remained unchanged. A repeated HTTP request may succeed, and then we will get the content of the secure page, or authorization will be denied, and the server will write something like "Access denied".

Since the default parameters contain the correct values ("/digest-auth/auth/test/pass" corresponds to the user "test" and the password "pass"), we should get the following result of running the script (all main steps and data are logged).

```
WebRequest(Method,Address,Headers,Timeout,data,result,response)=401 / ok
Date: Fri, 22 Jul 2022 10:45:56 GMT
Content-Type: text/html; charset=utf-8
Content-Length: 0
Connection: keep-alive
Server: gunicorn/19.9.0
WWW-Authenticate: Digest realm="me@kennethreitz.com" »
»  nonce="87d28b529a7a8797f6c3b81845400370", qop="auth",
»  opaque="4cb97ad7ea915a6d24cf1ccbf6feeaba", algorithm=MD5, stale=FALSE
...
```

The first *WebRequest* call has ended with code 401, and among the response headers is an authorization request ("WWW-Authenticate") with the required parameters. Based on them, we calculated the correct answer and prepared headers for a new request.

```
Header=User-Agent: noname
Authorization: Digest username="test",realm="me@kennethreitz.com" »
»  nonce="87d28b529a7a8797f6c3b81845400370",uri="/digest-auth/auth/test/pass",
»  qop=auth,nc=00000001,cnonce="00001c74",
»  response="c09e52bca9cc90caf9a707d046b567b2",opaque="4cb97ad7ea915a6d24cf1ccbf6feea
...
```

The second request returns 200 and a payload that we write to the file.

```
WebRequest(Method,Address,Header,Timeout,data,result,response)=200 / ok
Date: Fri, 22 Jul 2022 10:45:56 GMT
Content-Type: application/json
Content-Length: 47
Connection: keep-alive
Server: gunicorn/19.9.0
...
Got data: 47 bytes
Saving httpbin.org/digest-auth/auth/test/pass
FileSave(filename,result)=true / ok
```

Inside the file *MQL5/Files/httpbin.org/digest-auth/auth/test/pass* you can find the "web page", or rather the status of successful authorization in JSON format.

```
{
  "authenticated": true,
  "user": "test"
}
```

If you specify an incorrect password when running the script, we will receive an empty response from the server, and the file will not be written.

> Using *WebRequest*, we automatically enter the field of distributed software systems, in which the correct operation depends not only on our client MQL code but also on the server (not to mention intermediate links, like a proxy). Therefore, you need to be prepared for the occurrence of other people's mistakes. In particular, at the time of writing the book in the implementation of the *digest-auth* endpoint on *httpbin.org* there was a problem: the username entered in the request did not participate in the authorization check, and therefore any login leads to successful authorization if the correct password is specified. Still, to check our script, use other services, for example,

something like *httpbingo.org/digest-auth/auth/test/pass*. You can also configure the script to the address *jigsaw.w3.org/HTTP/Digest/* – it expects login/password "guest"/"guest".

In practice, most sites implement authorization using forms embedded directly in web pages: inside the HTML code, they are essentially the *form* container tag with a set of input fields, which are filled in by the user and sent to the server using the POST method. In this regard, it makes sense to analyze the example of submitting a form. However, before getting into this in detail, it is desirable to highlight one more technique.

The thing is that the interaction between the client and the server is usually accompanied by a change in the state of both the client and the server. Using the example of authorization, this can be understood most clearly, since before authorization the user was unknown to the system, and after that, the system already knows the login and can apply the preferred settings for the site (for example, language, color, forum display method), and also allow access to those pages where unauthorized visitors cannot get into (the server stops such attempts by returning HTTP status 403, Forbidden).

Support and synchronization of the consistent state of the client and server parts of a distributed web application is provided using the cookies mechanism which implies named variables and their values in HTTP headers. The term goes back to "fortune cookies" because *cookies* also contain small messages invisible to the user.

Either side, server and client, can add *cookie* to the HTTP header. The server does this with a line like:

```
Set-Cookie: name=value; [Domain=domain; Path=path; Expires=date; Max-Age=number_of_se
```

Only the name and value are required and the rest of the attributes are optional: here are the main ones – *Domain*, *Path*, *Expires*, and *Max age*, but in real situations, there are more of them.

Having received such a header (or several headers), the client must remember the name and value of the variable and send them to the server in all requests that address to the corresponding *Domain* and *Path* inside this domain until the expiration date (*Expires* or *Max-Age*).

In an outgoing HTTP request from a client, *cookie*s are passed as a string:

```
Cookie: name(№)=value(№) [; name(i)=value(i) ...]opt
```

Here, separated by a semicolon and a space, all name=value pairs are listed; they are set by the server and known to this client, matched with the current request by the domain and path, and not expired.

The server and client exchange all the necessary cookies with each HTTP request, which is why this architectural style of distributed systems is called REST (*Representational State Transfer*). For example, after a user successfully logs in to the server, the latter sets (via the "Set-Cookie:" header) a special "cookie" with the user's identifier, after which the web browser (or, in our case, a terminal with an MQL program) will send it in subsequent requests (by adding the appropriate line to the "Cookie:" header).

The *WebRequest* function silently does all this work for us: collects cookies from incoming headers and adds appropriate cookies to outgoing HTTP requests.

Cookies are stored by the terminal and between sessions, according to their settings. To check this, it is enough to request a web page twice from a site using cookies.

Attention, cookies are stored in relation to the site and therefore are imperceptibly substituted in the outgoing headers of all MQL programs that use *WebRequest* for the same site.

To simplify sequential requests, it makes sense to formalize popular actions in a special class *HTTPRequest* (*HTTPRequest.mqh*). We will store common HTTP headers in it, which are likely to be

needed for all requests (for example, supported languages, instructions for proxies, etc.). In addition, such a setting as timeout is also common. Both settings are passed to the object's constructor.

```
class HTTPRequest: public HttpCookie
{
protected:
   string common_headers;
   int timeout;

public:
   HTTPRequest(const string h, const int t = 5000):
      common_headers(h), timeout(t) { }
   ...
```

By default, the timeout is set to 5 seconds. The main, in a sense, universal method of the class is *request*.

```
   int request(const string method, const string address,
      string headers, const uchar &data[], uchar &result[], string &response)
   {
      if(headers == NULL) headers = common_headers;

      ArrayResize(result, 0);
      response = NULL;
      Print(">>> Request:\n", method + " " + address + "\n" + headers);

      const int code = PRTF(WebRequest(method, address, headers, timeout, data, resul
      Print("<<< Response:\n", response);
      return code;
   }
};
```

Let's describe a couple more methods for queries of specific types.

GET requests use only headers and the body of the document (the term *payload* is often used) is empty.

```
   int GET(const string address, uchar &result[], string &response,
      const string custom_headers = NULL)
   {
      uchar nodata[];
      return request("GET", address, custom_headers, nodata, result, response);
   }
```

In POST requests, there is usually a payload.

```
   int POST(const string address, const uchar &payload[],
      uchar &result[], string &response, const string custom_headers = NULL)
   {
      return request("POST", address, custom_headers, payload, result, response);
   }
```

Forms can be sent in different formats. The simplest one is "application/x-www-form-urlencoded". It implies that the payload will be a string (maybe a very long one, since the specifications do not impose

restrictions, and it all depends on the settings of the web servers). For such forms, we will provide a more convenient overload of the POST method with the payload string parameter.

```
int POST(const string address, const string payload,
   uchar &result[], string &response, const string custom_headers = NULL)
{
   uchar bytes[];
   const int n = StringToCharArray(payload, bytes, 0, -1, CP_UTF8);
   ArrayResize(bytes, n - 1); // remove terminal zero
   return request("POST", address, custom_headers, bytes, result, response);
}
```

Let's write a simple script to test our client web engine *WebRequestCookie.mq5*. Its task will be to request the same web page twice: the first time the server will most likely offer to set its cookies, and then they will be automatically substituted in the second request. In the input parameters, specify the address of the page for the test: let it be the *mql5.com* website. We will also simulate the default headers by the corrected "User-Agent" string.

```
input string Address = "https://www.mql5.com";
input string Headers = "User-Agent: Mozilla/5.0 (Windows NT 10.0) Chrome/103.0.0.0";
```

In the main function of the script, we describe the *HTTPRequest* object and execute two GET requests in a loop.

> Attention! This test works under the assumption that MQL programs have not yet visited the www.mql5.com site and have not received cookies from it. After running the script once, the cookies will remain in the terminal cache, and it will become impossible to reproduce the example: on both iterations of the loop, we will get the same log entries.
>
> Don't forget to add the "www.mql5.com" domain to the allowed list in the terminal settings.

```
void OnStart()
{
   uchar result[];
   string response;
   HTTPRequest http(Headers);

   for(int i = 0; i < 2; ++i)
   {
      if(http.GET(Address, result, response) > -1)
      {
         if(ArraySize(result) > 0)
         {
            PrintFormat("Got data: %d bytes", ArraySize(result));
            if(i == 0) // show the beginning of the document only the first time
            {
               const string s = CharArrayToString(result, 0, 160, CP_UTF8);
               int j = -1, k = -1;
               while((j = StringFind(s, "\r\n", j + 1)) != -1) k = j;
               Print(StringSubstr(s, 0, k));
            }
         }
      }
   }
}
```

The first iteration of the loop will generate the following log entries (with abbreviations):

```
>>> Request:
GET https://www.mql5.com
User-Agent: Mozilla/5.0 (Windows NT 10.0) Chrome/103.0.0.0
WebRequest(method,address,headers,timeout,data,result,response)=200 / ok
<<< Response:

```

Unfortunately, here we do not see the full outgoing headers formed inside *WebRequest*, but the instance of the cookie being sent to the server using the "Cookie:" header is proven by the fact that the server in its second response no longer asks to set it.

In theory, this cookie simply identifies the visitor (as most sites do) but does not signify their authorization. Therefore, let's return to the exercise of submitting the form in a general way, meaning in the future the private task of entering a login and password.

Recall that to submit the form, we can use the POST method with a string parameter *payload*. The principle of preparing data according to the "x-www-form-urlencoded" standard is that named variables and their values are written in one continuous line (somewhat similar to cookies).

```
name(№)=value(№)[&name(i)=value(i)...]opt
```

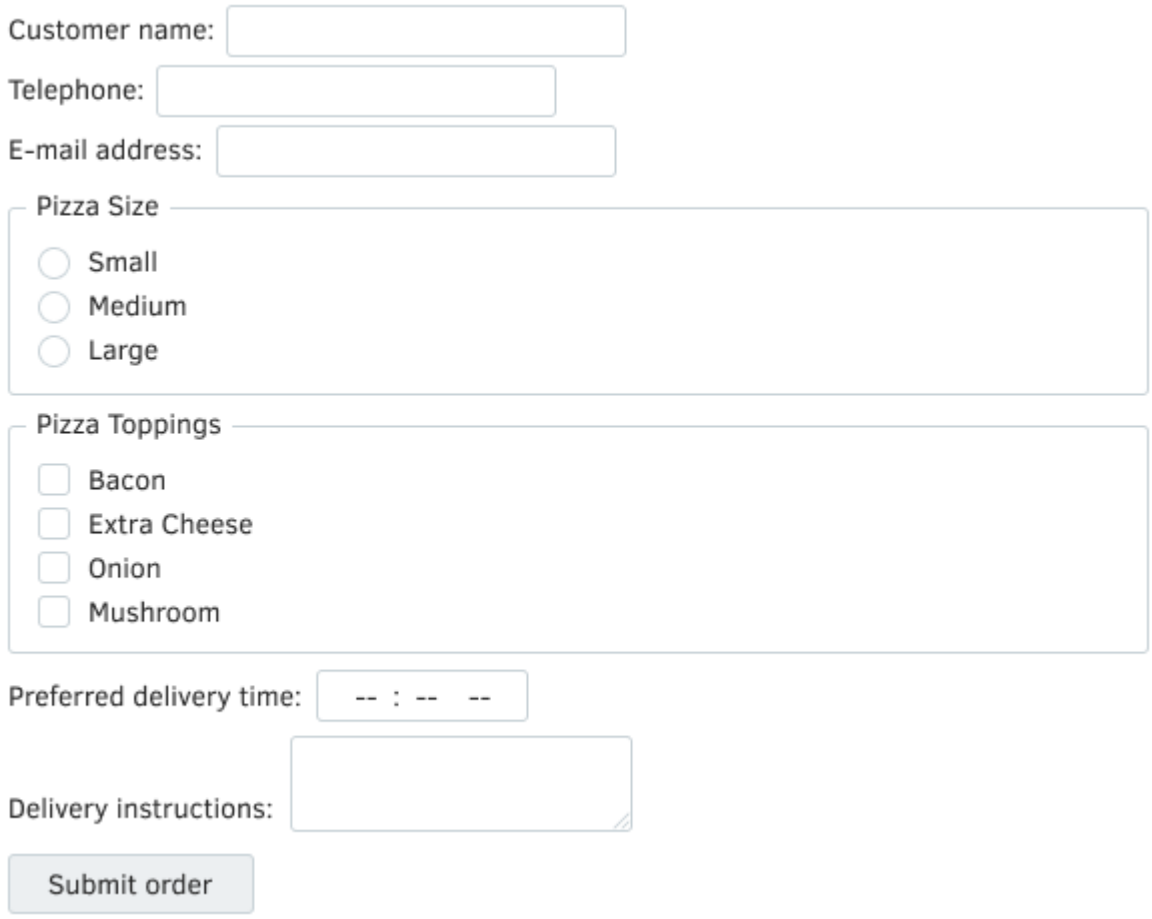
The name and value are connected with the sign '=', and the pairs are joined using the ampersand character '&'. The value may be missing. For example,

```
Name=John&Age=33&Education=&Address=
```

It is important to note that from a technical point of view, this string must be converted according to the algorithm before sending *urlencode* (this is where the name of the format comes from), however, *WebRequest* does this transformation for us.

The variable names are determined by the web form (the contents of the tag *form* in a web page) or web application logic - in any case, the web server must be able to interpret the names and values. Therefore, to get acquainted with the technology, we need a test server with a form.

The test form is available at *https://httpbin.org/forms/post*. It is a dialog for ordering pizza.



Test web form

Its internal structure and behavior are described by the following HTML code. In it, we are primarily interested in *input* tags, which set the variables expected by the server. In addition, attention should be paid to the *action* attribute in the *form* tag, since it defines the address to which the POST request should be sent, and in this case, it is "/post", which together with the domain gives the string "httpbin.org/post". This is what we will use in the MQL program.

```
<!DOCTYPE html>
<html>
  <body>
  <form method="post" action="/post">
    <p><label>Customer name: <input name="custname"></label></p>
    <p><label>Telephone: <input type=tel name="custtel"></label></p>
    <p><label>E-mail address: <input type=email name="custemail"></label></p>
    <fieldset>
      <legend> Pizza Size </legend>
      <p><label> <input type=radio name=size value="small"> Small </label></p>
      <p><label> <input type=radio name=size value="medium"> Medium </label></p>
      <p><label> <input type=radio name=size value="large"> Large </label></p>
    </fieldset>
    <fieldset>
      <legend> Pizza Toppings </legend>
      <p><label> <input type=checkbox name="topping" value="bacon"> Bacon </label></p
      <p><label> <input type=checkbox name="topping" value="cheese"> Extra Cheese </l
      <p><label> <input type=checkbox name="topping" value="onion"> Onion </label></p
      <p><label> <input type=checkbox name="topping" value="mushroom"> Mushroom </lab
    </fieldset>
    <p><label>Preferred delivery time: <input type=time min="11:00" max="21:00" step=
    <p><label>Delivery instructions: <textarea name="comments"></textarea></label></p
    <p><button>Submit order</button></p>
  </form>
  </body>
</html>
```

In the *WebRequestForm.mq5* script, we have prepared similar input variables to be specified by the user before being sent to the server.

```
input string Address = "https://httpbin.org/post";

input string Customer = "custname=Vincent Silver";
input string Telephone = "custtel=123-123-123";
input string Email = "custemail=email@address.org";
input string PizzaSize = "size=small"; // PizzaSize (small,medium,large)
input string PizzaTopping = "topping=bacon"; // PizzaTopping (bacon,cheese,onion,mush
input string DeliveryTime = "delivery=";
input string Comments = "comments=";
```

The already set strings are shown only for one-click testing: you can replace them with your own, but note that inside each string only the value to the right of '=' should be edited, and the name to the left of '=' should be kept (unknown names will be ignored by the server) .

In the *OnStart* function, we describe the HTTP header "Content-Type:" and prepare a concatenated string with all variables.

```
void OnStart()
{
   uchar result[];
   string response;
   string header = "Content-Type: application/x-www-form-urlencoded";
   string form_fields;
   StringConcatenate(form_fields,
      Customer, "&",
      Telephone, "&",
      Email, "&",
      PizzaSize, "&",
      PizzaTopping, "&",
      DeliveryTime, "&",
      Comments);
   HTTPRequest http;
   if(http.POST(Address, form_fields, result, response) > -1)
   {
      if(ArraySize(result) > 0)
      {
         PrintFormat("Got data: %d bytes", ArraySize(result));
         // NB: UTF-8 is implied for many content-types,
 // but some may be different, analyze the response headers
         Print(CharArrayToString(result, 0, WHOLE_ARRAY, CP_UTF8));
      }
   }
}
```

Then we execute the POST method and log the server response. Here is an example result.

```
>>> Request:
POST https://httpbin.org/post
Content-Type: application/x-www-form-urlencoded
WebRequest(method,address,headers,timeout,data,result,response)=200 / ok
<<< Response:
Date: Mon, 25 Jul 2022 08:41:41 GMT
Content-Type: application/json
Content-Length: 780
Connection: keep-alive
Server: gunicorn/19.9.0

  },
  "json": null,
  "url": "https://httpbin.org/post"
}
```

The test server acknowledges receipt of the data as a JSON copy. In practice, the server, of course, will not return the data itself, but simply will report a success status and possibly redirect to another web page that the data had an effect on (for example, show the order number).

With the help of such POST requests, but of smaller size, authorization is usually performed as well. But to say the truth, most web services deliberately overcomplicate this process for security purposes and require you to first calculate several hash sums from the user's details. Specially developed public APIs usually have descriptions of all necessary algorithms in the documentation. But this is not always the case. In particular, we will not be able to log in using *WebRequest* on *mql5.com* because the site does not have an open programming interface.

When sending requests to web services, always adhere to the rule about not exceeding the frequency of requests: usually, each service specifies its own limits, and violation of them will lead to the subsequent blocking of your client program, account, or IP address.

7.5.5 Establishing and breaking a network socket connection

In the previous sections, we got acquainted with the high-level MQL5 network functions: each of them provides support for a specific application protocol. For example, SMTP is used to send emails (*SendMail*), FTP is used for file transfer (*SendFTP*), and HTTP allows receiving web documents (*WebRequest*). All the mentioned standards are based on a lower, transport layer TCP (Transmission Control Protocol). It is not the last in the hierarchy as there are also lower ones, but we will not discuss them here.

The standard implementation of application protocols hides many technical nuances inside and eliminates the need for the programmer to routinely following specifications for hours. However, it does not have flexibility and does not take into account the advanced features embedded in the standards. Therefore, sometimes it is required to program network communication at the TCP level, that is, at the socket level.

A socket can be viewed as analogous to a file on a disk: a socket is also described by an integer descriptor by which data can be read or written, but this happens in a distributed network infrastructure. Unlike files, the number of sockets on a computer is limited, and therefore the socket descriptor must be requested from the system in advance before being associated with a network resource (address, URL). Let's also say in advance that access to information via a socket is streaming, that is, it is impossible to "rewind" a certain "pointer" to the beginning, as in a file.

Write and read threads do not intersect but can affect future read or write data since the transmitted information is often interpreted by servers and client programs as control commands. Protocol standards define if a stream contains commands or data.

The *SocketCreate* function allows the creation of an "empty" socket descriptor in MQL5.

```
int SocketCreate(uint flags = 0)
```

Its only parameter is reserved for the future to specify the bit pattern of the flags that determine the mode of the socket, but at the moment only one stub flag is supported: SOCKET_DEFAULT corresponds to the current mode and can be omitted. At the system level, this is equivalent to a socket in blocking mode (this may be of interest to network programmers).

If successful, the function returns the socket handle. Otherwise, it returns INVALID_HANDLE.

A maximum of 128 sockets can be created from one MQL program. When the limit is exceeded, error 5271 (ERR_NETSOCKET_TOO_MANY_OPENED) is logged into *_LastError*.

After we have opened the socket, it should be associated with a network address.

```
bool SocketConnect(int socket, const string server, uint port, uint timeout)
```

The *SocketConnect* function makes a socket connection to the server at the specified address and port (for example, web servers typically run on ports 80 or 443 for HTTP and HTTPS, respectively, and SMTP on port 25). The address can be either a domain name or an IP address.

The *timeout* parameter allows you to set a timeout in milliseconds to wait for a server response.

The function returns a sign of a successful connection (*true*) or error (*false*). The error code is written to *_LastError*, for example, 5272 (ERR_NETSOCKET_CANNOT_CONNECT).

> Please note that the connection address must be added to the list of allowed addresses in the terminal settings (dialog *Service -> Settings -> Advisors*).

After you have finished working with the network, you should release the socket with *SocketClose*.

bool SocketClose(const int socket)

The *SocketClose* function closes the socket by its handle, opened earlier using the *SocketCreate* function. If the socket was previously connected via *SocketConnect*, the connection will be broken.

The function also returns an indicator of success (*true*) or error (*false*). In particular, when passing an invalid handle to *_LastError*, error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is logged.

Let's remind you that all functions of this and subsequent sections are prohibited in indicators: there, an attempt to work with sockets will result in error 4014 (ERR_FUNCTION_NOT_ALLOWED, "The system function is not allowed to be called").

Consider an introductory example, the *SocketConnect.mq5* script. In the input parameters, you can specify the address and port of the server. We are supposed to start testing with regular web servers like mql5.com.

```
input string Server = "www.mql5.com";
input uint Port = 443;
```

In the function *OnStart* we just create a socket and bind it to a network resource.

```
void OnStart()
{
   PRTF(Server);
   PRTF(Port);
   const int socket = PRTF(SocketCreate());
   if(PRTF(SocketConnect(socket, Server, Port, 5000)))
   {
      PRTF(SocketClose(socket));
   }
}
```

If all the settings in the terminal are correct and it is connected to the Internet, we will get the following "report".

```
Server=www.mql5.com / ok
Port=443 / ok
SocketCreate()=1 / ok
SocketConnect(socket,Server,Port,5000)=true / ok
SocketClose(socket)=true / ok
```

7.5.6 Checking socket status

When working with a socket, it becomes necessary to check its status because distributed networks are not as reliable as a file system. In particular, the connection may be lost for one reason or another. The *SocketIsConnected* function allows you to find this out.

bool SocketIsConnected(const int socket)

The function checks if the socket with the specified handle (obtained from *SocketCreate*) is connected to its network resource (specified in *Socket Connect*) and returns *true* in case of success.

Another function, *SocketIsReadable*, lets you know if there is any data to read in the system buffer associated with the socket. This means that the computer, to which we connected at the network address, sent (and may continue to send) data to us.

uint SocketIsReadable(const int socket)

The function returns the number of bytes that can be read from the socket. In case of error, 0 is returned.

> Programmers familiar with the Windows/Linux socket system APIs know that a value of 0 can also be a normal state when there is no incoming data in the socket's internal buffer. However, this function behaves differently in MQL5. With an empty system socket buffer, it speculatively returns 1, deferring the actual check for data availability until the next call to one of the read functions. In particular, this situation with a dummy result of 1 byte occurs, as a rule, the first time a function is called on a socket when the receiving internal buffer is still empty.

When executing this function, an error may occur, meaning that the connection established through *SocketConnect*, was broken (in *_LastError* we will get code 5273, ERR_NETSOCKET_IO_ERROR).

The *SocketIsReadable* function is useful in programs that are designed for "non-blocking" reading of data using *SocketRead*. The point is that the *SocketRead* function when there is no data in the receive buffer, will wait for their arrival, suspending the execution of the program (by the specified timeout value).

On the other hand, a blocking read is more reliable in the sense that your program will "wake up" as soon as new data arrives, but checking for their presence with *SocketIsReadable* needs to be done periodically, according to some other events (usually, on a timer or in a loop).

Particular care should be taken when using the *SocketIsReadable* function in TLS secure mode. The function returns the amount of "raw" data, which in TLS mode is an encrypted block. If the "raw" data has not yet been accumulated in the size of the decryption block, then the subsequent call of the read function *SocketTlsRead* will block program execution, waiting for the missing fragment. If the "raw" data already contains a block ready for decryption, the read function will return fewer decrypted bytes than the number of "raw" bytes. In this regard, with TLS enabled, it is recommended to always use the *SocketIsReadable* function in conjunction with *SocketTlsReadAvailable*. Otherwise, the behavior of the program will differ from what is expected. Unfortunately, MQL5 does not provide the *SocketTlsIsReadable* function, which is compatible with the TLS mode and does not impose the described conventions.

The similar *SocketIsWritable* function checks if the given socket can be written to at the current time.

bool SocketIsWritable(const int socket)

The function returns an indication of success (*true*) or error (*false*). In the latter case, the connection established through *SocketConnect* will be broken.

Here is a simple script *SocketIsConnected.mq5* to test the functions. In the input parameters, we will provide the opportunity to enter the address and port.

```
input string Server = "www.mql5.com";
input uint Port = 443;
```

In the *OnStart* handler, we create a socket, connect to the site, and start checking the status of the socket in a loop. After the second iteration, we forcibly close the socket, and this should lead to an exit from the loop.

```
void OnStart()
{
   PRTF(Server);
   PRTF(Port);
   const int socket = PRTF(SocketCreate());
   if(PRTF(SocketConnect(socket, Server, Port, 5000)))
   {
      int i = 0;
      while(PRTF(SocketIsConnected(socket)) && !IsStopped())
      {
         PRTF(SocketIsReadable(socket));
         PRTF(SocketIsWritable(socket));
         Sleep(1000);
         if(++i >= 2)
         {
            PRTF(SocketClose(socket));
         }
      }
   }
}
```

The following entries are displayed in the log.

```
Server=www.mql5.com / ok
Port=443 / ok
SocketCreate()=1 / ok
SocketConnect(socket,Server,Port,5000)=true / ok
SocketIsConnected(socket)=true / ok
SocketIsReadable(socket)=0 / ok
SocketIsWritable(socket)=true / ok
SocketIsConnected(socket)=true / ok
SocketIsReadable(socket)=0 / ok
SocketIsWritable(socket)=true / ok
SocketClose(socket)=true / ok
SocketIsConnected(socket)=false / NETSOCKET_INVALIDHANDLE(5270)
```

7.5.7 Setting data send and receive timeouts for sockets

Since network connections are unreliable, all operations with *Socket* functions support a centralized timeout setting. If data reading or sending is not completed successfully within the specified time, the function will stop trying to perform the corresponding action.

You can set timeouts for receiving and sending data using the *SocketTimeouts* function.

bool SocketTimeouts(int socket, uint timeout_send, uint timeout_receive)

Both timeouts are given in milliseconds and affect all functions on the specified socket at the system level.

The *SocketRead* function has its own *timeout* parameter, with which you can additionally control the timeout during a particular call of the *SocketRead* function.

SocketTimeouts returns *true* if successful and *false* otherwise.

By default, there are no timeouts, which means waiting indefinitely for all data to be received or sent.

7.5.8 Reading and writing data over an insecure socket connection

Historically, sockets provide data transfer over a simple connection by default. Data transmission in an open form allows technical means to analyze all traffic. In recent years, security issues have been taken more seriously and therefore TLS (Transport Layer Security) technology has been implemented almost everywhere: it provides on-the-fly encryption of all data between the sender and the recipient. In particular, for Internet connections, the difference lies in the HTTP (simple connection) and HTTPS (secure) protocols.

MQL5 provides different sets of *Socket* functions for working with simple and secure connections. In this section, we will get acquainted with the simple mode, and later we will move to the protected one.

To read data from a socket, use the *SocketRead* function.

int SocketRead(int socket, uchar &buffer[], uint maxlen, uint timeout)

The socket descriptor is obtained from *SocketCreate* and connected to a network resource using *Socket Connect*.

The *buffer* parameter is a reference to the array into which the data will be read. If the array is dynamic, its size increases by the number of bytes read, but it cannot exceed INT_MAX (2147483647). You can limit the number of read bytes in the *maxlen* parameter. Data that does not fit will remain in the socket's internal buffer: it can be obtained by the following call *SocketRead*. The value of *maxlen* must be between 1 and INT_MAX (2147483647).

The *timeout* parameter specifies the time (in milliseconds) to wait for the read to complete. If no data is received within this time, the attempts are terminated and the function exits with the result -1.

-1 is also returned on error, while the error code in *_LastError*, for example, 5273 (ERR_NETSOCKET_IO_ERROR), means that the connection established via *SocketConnect* is now broken.

If successful, the function returns the number of bytes read.

When setting the read timeout to 0, the default value of 120000 (2 minutes) is used.

To write data to a socket, use the *SocketSend* function.

> Unfortunately, the function names *SocketRead* and *SocketSend* are not "symmetric": the reverse operation for "read" is "write", and for "send" is "receive". This may be unfamiliar to developers with experience who worked with networking APIs on other platforms.

int SocketSend(int socket, const uchar &buffer[], uint maxlen)

The first parameter is a handle to a previously created and opened socket. When passing an invalid handle, *_LastError* receives error 5270 (ERR_NETSOCKET_INVALIDHANDLE). The *buffer* array contains the data to be sent with the data size being specified in the *maxlen* parameter (the parameter was introduced for the convenience of sending part of the data from a fixed array).

The function returns the number of bytes written to the socket on success and -1 on error.

System-level errors (5273, ERR_NETSOCKET_IO_ERROR) indicate a disconnect.

The script *SocketReadWriteHTTP.mq5* demonstrates how sockets can be used to implement work over the HTTP protocol, that is, request information about a page from a web server. This is a small part of what the *WebRequest* function does for us "behind the scenes".

Let's leave the default address in the input parameters: the site "www.mql5.com". The port number was chosen to be 80 because that is the default value for non-secure HTTP connections (although some servers may use a different port: 81, 8080, etc.). Ports reserved for secure connections (in particular, the most popular 443) are not yet supported by this example. Also, in the *Server* parameter, it is important to enter the name of the domain and not a specific page because the script can only request the main page, i.e., the root path "/".

```
input string Server = "www.mql5.com";
input uint Port = 80;
```

In the main function of the script, we will create a socket and open a connection on it with the specified parameters (the timeout is 5 seconds).

```
void OnStart()
{
   PRTF(Server);
   PRTF(Port);
   const int socket = PRTF(SocketCreate());
   if(PRTF(SocketConnect(socket, Server, Port, 5000)))
   {
      ...
   }
}
```

Let's take a look at how the HTTP protocol works. The client sends requests in the form of specially designed headers (strings with predefined names and values), including, in particular, the web page address, and the server sends the entire web page or operation status in response, also using special headers for this. The client can request a web page with a GET request, send some data with a POST request, or check the status of the web page with a frugal HEAD request. In theory, there are many more HTTP methods – you can learn about them in the HTTP protocol specification.

Thus, the script must generate and send an HTTP header over the socket connection. In its simplest form, the following HEAD request allows you to get meta information about the page (we could replace HEAD with GET to request the entire page but there are some complications; we will discuss this later).

```
HEAD / HTTP/1.1
Host: _server_
User-Agent: MetaTrader 5
                                        // <- two newlines in a row \r\n\r\n
```

The forward slash after "HEAD" (or another method) is the shortest possible path on any server to the root directory, which usually results in the main page being displayed. If we wanted a specific web page, we could write something like "GET /en/forum/ HTTP/1.1" and get the table of contents of the English language forums from *mql5.com*. Specify a real domain instead of the "_server_" string.

Although the presence of "User-Agent:" is optional, it allows the program to "introduce itself" to the server, without which some servers may reject the request.

Notice the two empty lines: they mark the end of the heading. In our script, it is convenient to form the title with the following expression:

```
StringFormat("HEAD / HTTP/1.1\r\nHost: %s\r\n\r\n", Server)
```

Now we just have to send it to the server. For this purpose, we have written a simple function *HTTPSend*. It receives a socket descriptor and a header line.

```
bool HTTPSend(int socket, const string request)
{
   char req[];
   int len = StringToCharArray(request, req, 0, WHOLE_ARRAY, CP_UTF8) - 1;
   if(len < 0) return false;
   return SocketSend(socket, req, len) == len;
}
```

Internally, we convert the string to a byte array and call *SocketSend*.

Next, we need to accept the server response, for which we have written the *HTTPRecv* function. It also expects a socket descriptor and a reference to a string where the data should be placed but is more complex.

```
bool HTTPRecv(int socket, string &result, const uint timeout)
{
   char response[];
   int len;         // signed integer needed for error flag -1
   uint start = GetTickCount();
   result = "";

   do
   {
      ResetLastError();
      if(!(len = (int)SocketIsReadable(socket)))
      {
         Sleep(10); // wait for data or timeout
      }
      else          // read the data in the available volume
      if((len = SocketRead(socket, response, len, timeout)) > 0)
      {
         result += CharArrayToString(response, 0, len); // NB: without CP_UTF8 only '
         const int p = StringFind(result, "\r\n\r\n");
         if(p > 0)
         {
            // HTTP header ends with a double newline, use this
            // to make sure the entire header is received
            Print("HTTP-header found");
            StringSetLength(result, p); // cut off the body of the document (in case
            return true;
         }
      }
   }
   while(GetTickCount() - start < timeout && !IsStopped() && !_LastError);

   if(_LastError) PRTF(_LastError);

   return StringLen(result) > 0;
}
```

Here we are checking in a loop the appearance of data within the specified timeout and reading it into the *response* buffer. The occurrence of an error terminates the loop.

Buffer bytes are immediately converted to a string and concatenated into a full response in the *result* variable. It is important to note that we can only use the *CharArrayToString* function with the default encoding for the HTTP header because only Latin letters and a few special characters from ANSI are allowed in it.

To receive a complete web document, which, as a rule, has UTF-8 encoding (but potentially has another non-Latin one, which is indicated just in the HTTP header), more tricky processing will be required: first, you need to collect all the sent blocks in one common buffer and then convert the whole thing into a string indicating CP_UTF8 (otherwise, any character encoded in two bytes can be "cut" when sent, and will arrive in different blocks; that is why we cannot expect a correct UTF-8 byte stream in individual fragment). We will improve this example in the following sections.

Having functions *HTTPSend* and *HTTPRecv*, we complete the *OnStart* code.

```
void OnStart()
{
      ...
      if(PRTF(HTTPSend(socket, StringFormat("HEAD / HTTP/1.1\r\nHost: %s \r\n"
         "User-Agent: MetaTrader 5\r\n\r\n", Server))))
      {
         string response;
         if(PRTF(HTTPRecv(socket, response, 5000)))
         {
            Print(response);
         }
      }
      ...
}
```

In the HTTP header received from the server, the following lines may be of interest:

- 'Content-Length:' – the total length of the document in bytes
- 'Content-Language:' – document language (for example, "de-DE, ru")
- 'Content-Type:' – document encoding (for example, "text/html; charset=UTF-8")
- 'Last-Modified:' – the time of the last modification of the document, so as not to download what is already there (in principle, we can add the 'If-Modified-Since:' header in our HTTP request)

We will talk about finding out the document length (data size) in more detail because almost all headers are optional, that is, they are reported by the server at will, and in their absence, alternative mechanisms are used. The size is important to know when to close the connection, i.e., to make sure that all the data has been received.

Running the script with default parameters produces the following result.

```
Server=www.mql5.com / ok
Port=80 / ok
SocketCreate()=1 / ok
SocketConnect(socket,Server,Port,5000)=true / ok
HTTPSend(socket,StringFormat(HEAD / HTTP/1.1
Host: %s
,Server))=true / ok
HTTP-header found
HTTPRecv(socket,response,5000)=true / ok
HTTP/1.1 301 Moved Permanently
Server: nginx
Date: Sun, 31 Jul 2022 10:24:00 GMT
Content-Type: text/html
Content-Length: 162
Connection: keep-alive
Location: https://www.mql5.com/
Strict-Transport-Security: max-age=31536000; includeSubDomains; preload
X-Frame-Options: SAMEORIGIN
```

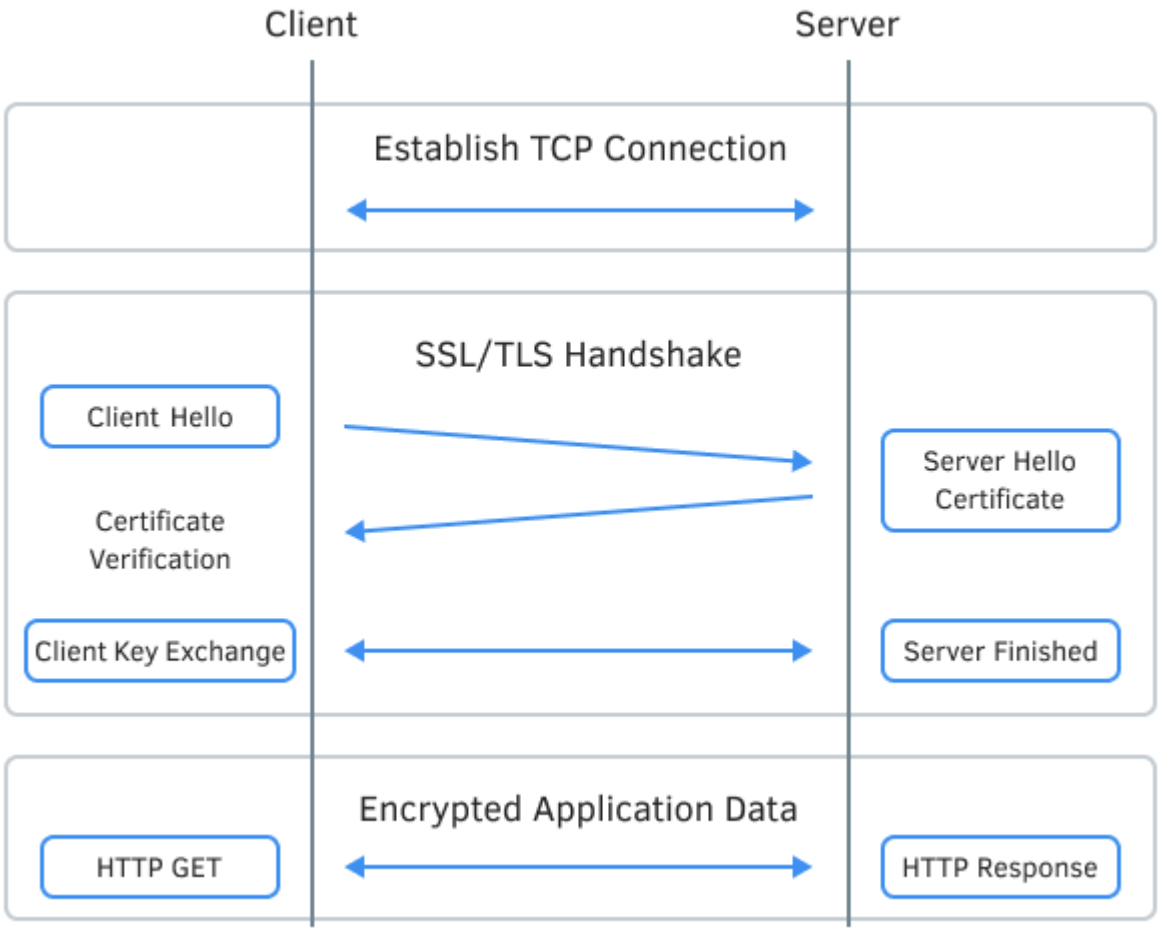
Please note that this site, like most sites today, redirects our request to a secure connection: this is achieved with the status code "301 Moved Permanently" and the new address "Location:

https://www.mql5.com/" (protocol is important here " https"). To retry a TLS-enabled request, several other functions must be used, and we will discuss them later.

7.5.9 Preparing a secure socket connection

To transfer a socket connection to a protected state and check it, MQL6 provides the following functions: *SocketTlsHandshake* and *SocketTlsCertificate*, respectively. As a rule, we do not need to "manually" enable protection by calling *SocketTlsHandshake* if the connection is established on port 443. The fact is that it is standard for HTTPS (TLS).

Protection is based on encryption of the data flow between the client and the server, for which a pair of asymmetric keys is initially used: public and private. We have already touched on this topic in the section Overview of available information transformation methods. Every decent site acquires a digital certificate from one of the certification authorities (CAs) trusted by the network community. The certificate contains the site's public key and is digitally signed by the center. Browsers and other client applications store (or can import) the public keys of CAs and therefore can verify the quality of a particular certificate.



Establishing a secure TLS connection
(picture from the internet)

Further, when preparing a secure connection, the browser or application generates a certain "secret", encrypts it with the site's public key and sends the key to it, and the site decrypts it with the private key which only the site knows. This stage looks more complicated in practice, but as a result, both the

client and the server have the encryption key for the current session (connection). This key is used by both participants in the communication to encrypt subsequent requests and responses at one end and decrypt them at the other.

The *SocketTlsHandshake* function initiates a secure TLS connection with the specified host using the TLS handshake protocol. In this case, the client and the server agree on the connection parameters: the version of the protocol used and the method of data encryption.

bool SocketTlsHandshake(int socket, const string host)

The socket handle and the address of the server with which the connection is established are passed in the function parameters (in fact, this is the same name that was specified in *SocketConnect*).

Before a secure connection, the program must first establish a regular TCP connection with the host using *SocketConnect*.

The function returns *true* if successful; otherwise, it returns *false*. In case of an error, code 5274 (ERR_NETSOCKET_HANDSHAKE_FAILED) is written in *_LastError*.

The *SocketTlsCertificate* function gets information about the certificate used to secure the network connection.

int SocketTlsCertificate(int socket, string &subject, string &issuer, string &serial, string &thumbprint, datetime &expiration)

If a secure connection is established for the socket (either after an explicit and successful *SocketTlsHandshake* call or after connecting via port 443), this function fills in all other reference variables by the socket descriptor with the corresponding information: the name of the certificate owner (*subject*), certificate issuer name (*issuer*), serial number (*serial*), digital fingerprint (*thumbprint*), and certificate validity period (*expiration*).

The function returns *true* in case of successful receipt of information about the certificate or *false* as a result of an error. The error code is 5275 (ERR_NETSOCKET_NO_CERTIFICATE). This can be used to determine whether the connection opened by the *SocketConnect* is immediately in protected mode. We will use this in an example in the next section.

7.5.10 Reading and writing data over a secure socket connection

A secure connection has its own set of data exchange functions between the client and the server. The names and concept of operation of the functions almost coincide with the previously considered functions *SocketRead* and *SocketSend*.

int SocketTlsRead(int socket, uchar &buffer[], uint maxlen)

The *SocketTlsRead* function reads data from a secure TLS connection opened on the specified socket. The data gets into the *buffer* array passed by reference. If it is dynamic, its size will be increased according to the amount of data but no more than INT_MAX (2147483647) bytes.

The *maxlen* parameter specifies the number of decrypted bytes to be received (their number is always less than the amount of "raw" encrypted data coming into the socket's internal buffer). Data that does not fit in the array remains in the socket and can be received by the next *SocketTlsRead* call.

The function is executed until it receives the specified amount of data or until the timeout specified in *SocketTimeouts* occurs.

In case of success, the function returns the number of bytes read; in case of error, it returns -1, while code 5273 (ERR_NETSOCKET_IO_ERROR) is written in *_LastError*. The presence of an error indicates that the connection was terminated.

int SocketTlsReadAvailable(int socket, uchar &buffer[], const uint maxlen)

The *SocketTlsReadAvailable* function reads all available decrypted data from a secure TLS connection but no more *maxlen* bytes. Unlike *SocketTlsRead*, *SocketTlsReadAvailable* does not wait for the mandatory presence of a given amount of data and immediately returns only what is present. Thus, if the internal buffer of the socket is "empty" (nothing has been received from the server yet, it has already been read or has not yet formed a block ready for decryption), the function will return 0 and nothing will be recorded in the receiving array *buffer*. This is a regular situation.

The value of *maxlen* must be between 1 and INT_MAX (2147483647).

int SocketTlsSend(int socket, const uchar &buffer[], uint bufferlen)

The *SocketTlsSend* function sends data from the *buffer* array over a secure connection opened on the specified socket. The principle of operation is the same as that of the previously described function *SocketSend*, while the only difference is in the type of connection.

Let's create a new script *SocketReadWriteHTTPS.mq5* based on the previously considered *SocketReadWriteHTTP.mq5* and add flexibility in terms of choosing an HTTP method (GET by default, not HEAD), setting a timeout, and supporting secure connections. The default port is 443.

```
input string Method = "GET"; // Method (HEAD,GET)
input string Server = "www.google.com";
input uint Port = 443;
input uint Timeout = 5000;
```

The default server is www.google.com. Do not forget to add it (and any other server that you enter) to the list of allowed ones in the terminal settings.

To determine whether the connection is secure or not, we will use the *SocketTlsCertificate* function: if it is successful, then the server has provided a certificate and TLS mode is active. If the function returns *false* and throws the error code NETSOCKET_NO_CERTIFICATE(5275), this means we are using a normal connection but the error can be ignored and reset since we are satisfied with an unsecured connection.

```
void OnStart()
{
   PRTF(Server);
   PRTF(Port);
   const int socket = PRTF(SocketCreate());
   if(socket == INVALID_HANDLE) return;
   SocketTimeouts(socket, Timeout, Timeout);
   if(PRTF(SocketConnect(socket, Server, Port, Timeout)))
   {
      string subject, issuer, serial, thumbprint;
      datetime expiration;
      bool TLS = false;
      if(PRTF(SocketTlsCertificate(socket, subject, issuer, serial, thumbprint, expir
      {
         PRTF(subject);
         PRTF(issuer);
         PRTF(serial);
         PRTF(thumbprint);
         PRTF(expiration);
         TLS = true;
      }
      ...
```

The rest of the *OnStart* function is implemented according to the previous plan: send a request using the *HTTPSend* function and accept the answer using *HTTPRecv*. But this time, we additionally pass the TLS flag to these functions, and they must be implemented slightly differently.

```
      if(PRTF(HTTPSend(socket, StringFormat("%s / HTTP/1.1\r\nHost: %s\r\n"
         "User-Agent: MetaTrader 5\r\n\r\n", Method, Server), TLS)))
      {
         string response;
         if(PRTF(HTTPRecv(socket, response, Timeout, TLS)))
         {
            Print("Got ", StringLen(response), " bytes");
            // for large documents, we will save to a file
            if(StringLen(response) > 1000)
            {
               int h = FileOpen(Server + ".htm", FILE_WRITE | FILE_TXT | FILE_ANSI, 0
               FileWriteString(h, response);
               FileClose(h);
            }
            else
            {
               Print(response);
            }
         }
      }
```

From the example with *HTTPSend*, you can see that depending on the TLS flag, we use either *SocketTlsSend* or *SocketSend*.

```
bool HTTPSend(int socket, const string request, const bool TLS)
{
   char req[];
   int len = StringToCharArray(request, req, 0, WHOLE_ARRAY, CP_UTF8) - 1;
   if(len < 0) return false;
   return (TLS ? SocketTlsSend(socket, req, len) : SocketSend(socket, req, len)) == l
}
```

Things are a bit more complicated with *HTTPRecv*. Since we provide the ability to download the entire page (not just the headers), we need some way to know if we have received all the data. Even after the entire document has been transmitted, the socket is usually left open to optimize future intended requests. But our program will not know if the transmission stopped normally, or maybe there was a temporary "congestion" somewhere in the network infrastructure (such relaxed, intermittent page loading can sometimes be observed in browsers). Or vice versa, in the event of a connection failure, we may wrongly believe that we have received the entire document.

The fact is that sockets themselves act only as a means of communication between programs and work with abstract blocks of data: they do not know the type of data, their meaning, and their logical conclusion. All these issues are handled by application protocols like HTTP. Therefore, we will need to delve into the specifications and implement the checks ourselves.

```
bool HTTPRecv(int socket, string &result, const uint timeout, const bool TLS)
{
   uchar response[]; // accumulate the data as a whole (headers + body of the web doc
   uchar block[];    // separate read block
   int len;          // current block size (signed integer for error flag -1)
   int lastLF = -1;  // position of the last line feed found LF(Line-Feed)
   int body = 0;     // offset where document body starts
   int size = 0;     // document size according to title
   result = "";      // set an empty result at the beginning
   int chunk_size = 0, chunk_start = 0, chunk_n = 1;
   const static string content_length = "Content-Length:";
   const static string crlf = "\r\n";
   const static int crlf_length = 2;
   ...
```

The simplest method for determining the size of the received data is based on analyzing the "Content-Length:" header. Here we need three variables: *lastLF*, *size*, and *content_length*. This header is not always present though, and we deal with "chunks" – variables *chunk_size*, *chunk_start*, *crlf*, and *crlf_length* are introduced to detect them.

To demonstrate various techniques for receiving data, we use in this example a "non-blocking" function *SocketTlsReadAvailable*. However, there is no similar function for an insecure connection, and therefore we have to write it ourselves (a little later). The general scheme of the algorithm is simple: it is a loop with attempts to receive new data blocks of 1024 (or less) bytes in size. If we manage to read something, we accumulate it in the response array. If the socket's input buffer is empty, the functions will return 0 and we pause a little. Finally, if an error or timeout occurs, the loop will break.

```
uint start = GetTickCount();
do
{
   ResetLastError();
   if((len = (TLS ? SocketTlsReadAvailable(socket, block, 1024) :
      SocketReadAvailable(socket, block, 1024))) > 0)
   {
      const int n = ArraySize(response);
      ArrayCopy(response, block, n); // put all the blocks together
      ...
      // main operation here
   }
   else
   {
      if(len == 0) Sleep(10); // wait a bit for the arrival of a portion of data
   }
}
while(GetTickCount() - start < timeout && !IsStopped() && !_LastError);
...
```

First of all, you need to wait for the completion of the HTTP header in the input data stream. As we have already seen from the previous example, headers are separated from the document by a double newline, i.e., by the character sequence "\r\n\r\n". It is easy to detect by two '\n' (LF) symbols located one after the other.

The result of the search will be the offset in bytes from the beginning of the data, where the header ends and the document begins. We will store it in the *body* variable.

```
if(body == 0) // look for the completion of the headers until we find it
{
   for(int i = n; i < ArraySize(response); ++i)
   {
      if(response[i] == '\n') // LF
      {
         if(lastLF == i - crlf_length) // found sequence "\r\n\r\n"
         {
            body = i + 1;
            string headers = CharArrayToString(response, 0, i);
            Print("* HTTP-header found, header size: ", body);
            Print(headers);
            const int p = StringFind(headers, content_length);
            if(p > -1)
            {
               size = (int)StringToInteger(StringSubstr(headers,
                  p + StringLen(content_length)));
               Print("* ", content_length, size);
            }
            ...
            break; // header/body boundary found
         }
         lastLF = i;
      }
   }
}

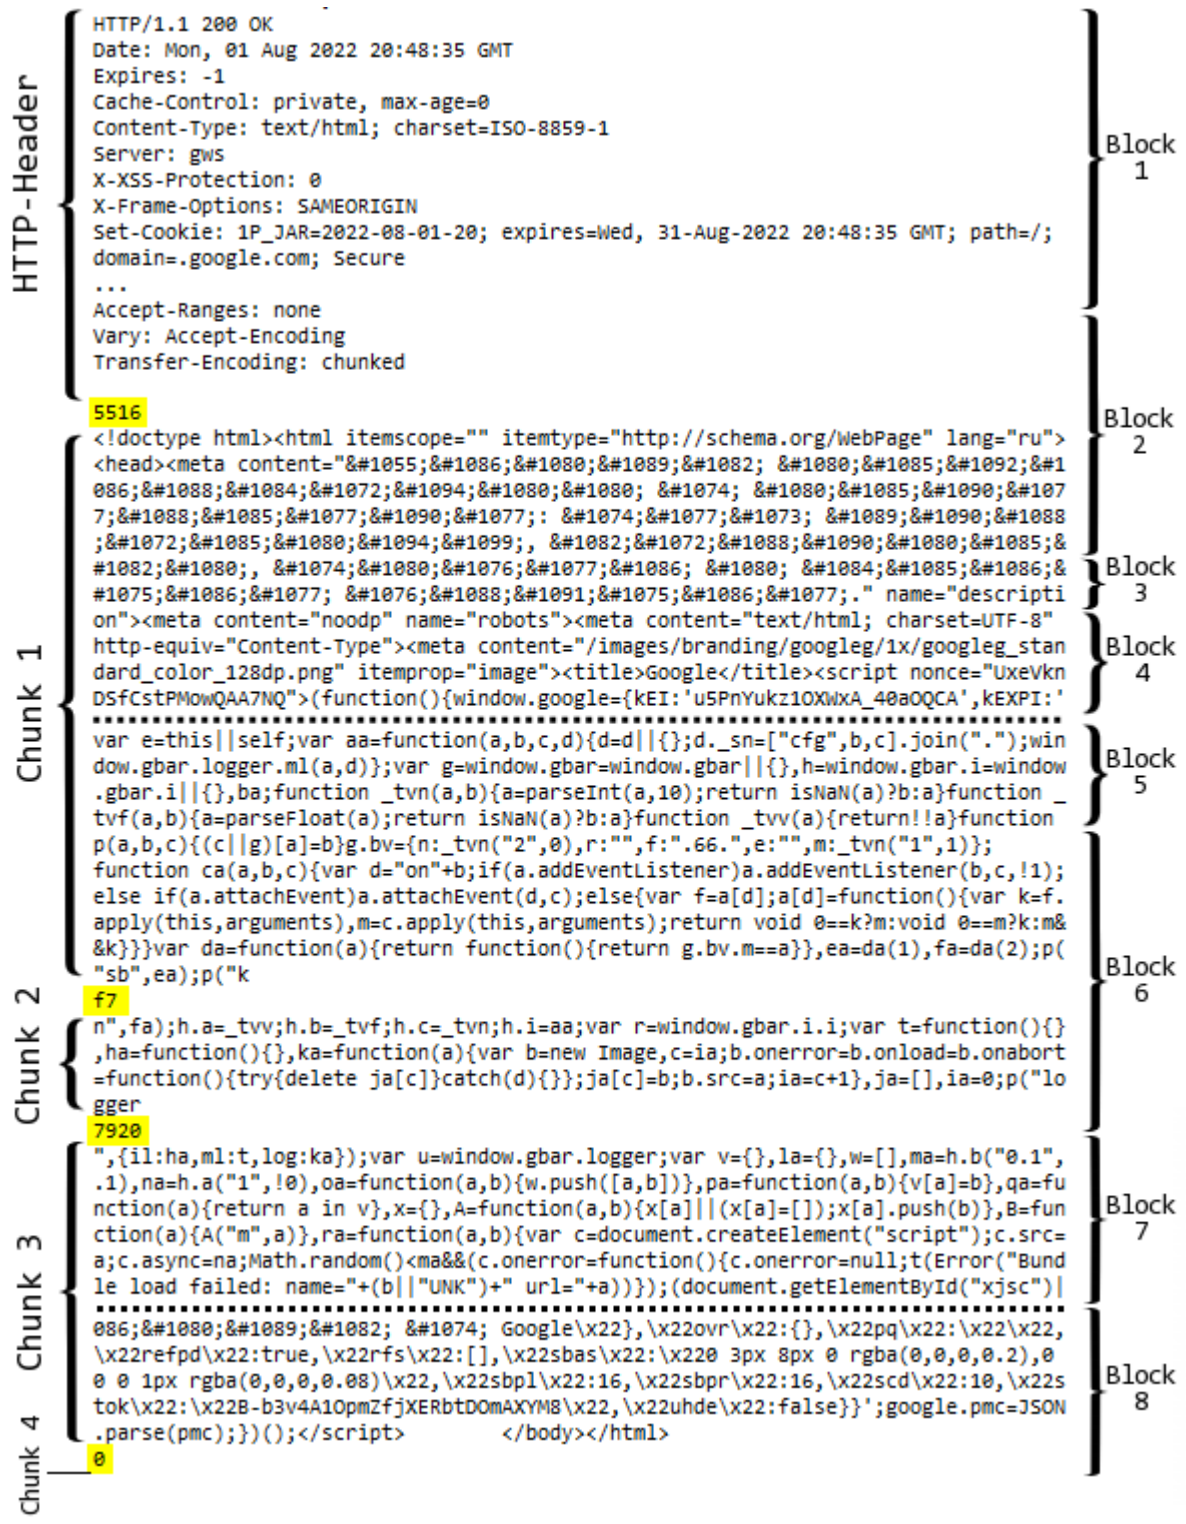
if(size == ArraySize(response) - body) // entire document
{
   Print("* Complete document");
   break;
}
...
```

This immediately searches for the "Content-Length:" header and extracts the size from it. The filled *size* variable makes it possible to write an additional conditional statement to exit the data-receiving loop when the entire document has been received.

Some servers give the content in parts called "chunks". In such cases, the "Transfer-Encoding: chunked" line is present in the HTTP header, and the "Content-Length:" line is missing. Each chunk begins with a hexadecimal number indicating the size of the chunk, followed by a newline and the specified number of data bytes. The chunk ends with another newline. The last chunk that marks the end of the document has a zero size.

Please note that the division into such segments is performed by the server, based on its own, current "preferences" for optimizing sending, and has nothing to do with blocks (packets) of data into which information is divided at the socket level for transmission over the network. In other words, chunks tend to be arbitrarily fragmented and the boundary between network packets can even occur between digits in a chunk size.

Schematically, this can be depicted as follows (on the left are chunks of the document, and on the right are data blocks from the socket buffer).



Fragmentation of a web document during transmission at the HTTP and TCP levels

In our algorithm, packages get into the *block* array at each iteration, but it makes no sense to analyze them one by one, and all the main work goes with the common response array.

So, if the HTTP header is completely received but the string "Content-Length:" is not found in it, we go to the algorithm branch with the "Transfer-Encoding: chunked" mode. By the current position of *body* in the *response* array (immediately after completion of the HTTP headers), the string fragment is selected and converted to a number assuming the hexadecimal format: this is done by the helper

function *HexStringToInteger* (see the attached source code). If there really is a number, we write it to *chunk_size*, mark the position as the beginning of the "chunk" in *chunk_start*, and remove bytes with the number and framing newlines from *response*.

```
...
if(lastLF == i - crlf_length) // found sequence "\r\n\r\n"
{
   body = i + 1;
   ...
   const int p = StringFind(headers, content_length);
   if(p > -1)
   {
      size = (int)StringToInteger(StringSubstr(headers,
         p + StringLen(content_length)));
      Print("* ", content_length, size);
   }
   else
   {
      size = -1; // server did not provide document length
      // try to find chunks and the size of the first one
      if(StringFind(headers, "Transfer-Encoding: chunked") > 0)
      {
         // chunk syntax:
         // <hex-size>\r\n<content>\r\n...
         const string preview = CharArrayToString(response, body, 2
         chunk_size = HexStringToInteger(preview);
         if(chunk_size > 0)
         {
            const int d = StringFind(preview, crlf) + crlf_length;
            chunk_start = body;
            Print("Chunk: ", chunk_size, " start at ", chunk_start,
            ArrayRemove(response, body, d);
         }
      }
   }
   break; // header/body boundary found
}
lastLF = i;
...
```

Now, to check the completeness of the document, you need to analyze not only the *size* variable (which, as we have seen, can actually be disabled by assigning -1 in the absence of "Content-Length:") but also new variables for chunks: *chunk_start* and *chunk_size*. The scheme of action is the same as after the HTTP headers: by offset in the *response* array, where the previous chunk ended, we isolate the size of the next "chunk". We continue the process until we find a chunk of size zero.

```
...
if(size == ArraySize(response) - body) // entire document
{
   Print("* Complete document");
   break;
}
else if(chunk_size > 0 && ArraySize(response) - chunk_start >= chunk_size)
{
   Print("* ", chunk_n, " chunk done: ", chunk_size, " total: ", ArraySize(r
   const int p = chunk_start + chunk_size;
   const string preview = CharArrayToString(response, p, 20);
   if(StringLen(preview) > crlf_length              // there is '\r\n...\r\n
      && StringFind(preview, crlf, crlf_length) > crlf_length)
   {
      chunk_size = HexStringToInteger(preview, crlf_length);
      if(chunk_size > 0)
      {                                 // twice '\r\n': before and after chunk
         int d = StringFind(preview, crlf, crlf_length) + crlf_length;
         chunk_start = p;
         Print("Chunk: ", chunk_size, " start at ", chunk_start, " -", d);
         ArrayRemove(response, chunk_start, d);
         ++chunk_n;
      }
      else
      {
         Print("* Final chunk");
         ArrayRemove(response, p, 5); // "\r\n0\r\n"
         break;
      }
   } // otherwise wait for more data
}
```

Thus, we provided an exit from the loop based on the results of the analysis of the incoming stream in two different ways (in addition to exiting by timeout and by error). At the regular end of the loop, we convert that part of the array into the *response* string, which starts from the *body* position and contains the whole document. Otherwise, we simply return everything that we managed to get, along with the headers, for "analysis".

```
bool HTTPRecv(int socket, string &result, const uint timeout, const bool TLS)
{
   ...
   do
   {
      ResetLastError();
      if((len = (TLS ? SocketTlsReadAvailable(socket, block, 1024) :
         SocketReadAvailable(socket, block, 1024))) > 0)
      {
         ... // main operation here - discussed above
      }
      else
      {
         if(len == 0) Sleep(10); // wait a bit for the arrival of a portion of data
      }
   }
   while(GetTickCount() - start < timeout && !IsStopped() && !_LastError);

   if(_LastError) PRTF(_LastError);

   if(ArraySize(response) > 0)
   {
      if(body != 0)
      {
         // TODO: Desirable to check 'Content-Type:' for 'charset=UTF-8'
         result = CharArrayToString(response, body, WHOLE_ARRAY, CP_UTF8);
      }
      else
      {
         // to analyze wrong cases, return incomplete headers as is
         result = CharArrayToString(response);
      }
   }

   return StringLen(result) > 0;
}
```

The only remaining function is *SocketReadAvailable* which is the analog of *SocketTlsReadAvailable* for unsecured connections.

```
int SocketReadAvailable(int socket, uchar &block[], const uint maxlen = INT_MAX)
{
   ArrayResize(block, 0);
   const uint len = SocketIsReadable(socket);
   if(len > 0)
      return SocketRead(socket, block, fmin(len, maxlen), 10);
   return 0;
}
```

The script is ready for work.

It took us quite a bit of effort to implement a simple web page request using sockets. This serves as a demonstration of how much of a chore is usually hidden in the support of network protocols at a low

level. Of course, in the case of HTTP, it is easier and more correct for us to use the built-in implementation of WebRequest, but it does not include all the features of HTTP (moreover, we touched on HTTP 1.1 in passing, but there is also HTTP / 2), and the number of other application protocols is huge. Therefore, *Socket* functions are required to integrate them in MetaTrader 5.

Let's run *SocketReadWriteHTTPS.mq5* with default settings.

```
Server=www.google.com / ok
Port=443 / ok
SocketCreate()=1 / ok
SocketConnect(socket,Server,Port,Timeout)=true / ok
SocketTlsCertificate(socket,subject,issuer,serial,thumbprint,expiration)=true / ok
subject=CN=www.google.com / ok
issuer=C=US, O=Google Trust Services LLC, CN=GTS CA 1C3 / ok
serial=00c9c57583d70aa05d12161cde9ee32578 / ok
thumbprint=1EEE9A574CC92773EF948B50E79703F1B55556BF / ok
expiration=2022.10.03 08:25:10 / ok
HTTPSend(socket,StringFormat(%s / HTTP/1.1
Host: %s
,Method,Server),TLS)=true / ok
* HTTP-header found, header size: 1080
HTTP/1.1 200 OK
Date: Mon, 01 Aug 2022 20:48:35 GMT
Expires: -1
Cache-Control: private, max-age=0
Content-Type: text/html; charset=ISO-8859-1
Server: gws
X-XSS-Protection: 0
X-Frame-Options: SAMEORIGIN
Set-Cookie: 1P_JAR=2022-08-01-20; expires=Wed, 31-Aug-2022 20:48:35 GMT;
   path=/; domain=.google.com; Secure
...
Accept-Ranges: none
Vary: Accept-Encoding
Transfer-Encoding: chunked
Chunk: 22172 start at 1080 -6
* 1 chunk done: 22172 total: 24081
Chunk: 30824 start at 23252 -8
* 2 chunk done: 30824 total: 54083
* Final chunk
HTTPRecv(socket,response,Timeout,TLS)=true / ok
Got 52998 bytes
```

As we can see, the document is transferred in chunks and has been saved to a temporary file (you can find it in *MQL5/Files/www.mql5.com.htm*).

Let's now run the script for the site "www.mql5.com" and port 80. From the previous section, we know that the site in this case issues a redirect to its protected version but this "redirect" is not empty: it has a stub document, and now we can get it in full. What matters to us here is that the "Content-Length:" header is used correctly in this case.

```
Server=www.mql5.com / ok
Port=80 / ok
SocketCreate()=1 / ok
SocketConnect(socket,Server,Port,Timeout)=true / ok
HTTPSend(socket,StringFormat(%s / HTTP/1.1
Host: %s
,Method,Server),TLS)=true / NETSOCKET_NO_CERTIFICATE(5275)
* HTTP-header found, header size: 291
HTTP/1.1 301 Moved Permanently
Server: nginx
Date: Sun, 31 Jul 2022 19:28:57 GMT
Content-Type: text/html
Content-Length: 162
Connection: keep-alive
Location: https://www.mql5.com/
Strict-Transport-Security: max-age=31536000; includeSubDomains; preload
X-Frame-Options: SAMEORIGIN
* Content-Length:162
* Complete document
HTTPRecv(socket,response,Timeout,TLS)=true / ok
<html>
<head><title>301 Moved Permanently</title></head>
<body>
<center><h1>301 Moved Permanently</h1></center>
<hr><center>nginx</center>
</body>
</html>
```

Another, large example of the use of sockets in practice, we will consider in the chapter Projects.

7.6 SQLite database

MetaTrader 5 provides native support for the SQLite database. It is a light yet fully functional database management system (DBMS). Traditionally, such systems are focused on processing data tables, where records of the same type are stored with a common set of attributes, and different correspondences (links or relations) can be established between records of different types (i.e. tables), and therefore such databases are also called relational. We have already considered examples of such connections between structures of the economic calendar, but the calendar database is stored inside the terminal, and the functions of this section will allow you to create arbitrary databases from MQL programs.

The specialization of the DBMS on these data structures allows you to optimize – speed up and simplify – many popular operations such as sorting, searching, filtering, summing up, or calculating other aggregate functions for large amounts of data.

However, there is another side to this: DBMS programming requires its own SQL (Structured Query Language), and knowledge of pure MQL5 will not be enough. Unlike MQL5, which refers to *imperative* languages (those using operators indicating what, how, in what sequence to do), SQL is *declarative*, that is, it describes the initial data and the desired result, without specifying how and in what sequence to perform calculations. The meaning of the algorithm in SQL is described in the form of SQL queries. A query is an analog of a separate MQL5 operator, formed as a string using a special syntax.

Instead of programming complex loops and comparisons, we can simply call SQLite functions (for example, *DatabaseExecute* or *Database Prepare*) by passing SQL queries to them. To get query results into a ready-made MQL5 structure, you can use the *DatabaseReadBind* function. This will allow you to read all the fields of the record (structure) at once in one call.

With the help of database functions, it is easy to create tables, add records to them, make modifications, and make selections according to complex conditions, for example, for tasks such as:

- Obtaining trading history and quotes
- Saving optimization and testing results
- Preparing and exchanging data with other analysis packages
- Analyzing economic calendar data
- Storing settings and states of MQL5 programs

In addition, a wide range of common, statistical, and mathematical functions can be used in SQL queries. Moreover, expressions with their participation can be calculated even without creating a table.

SQLite does not require a separate application, configuration, and administration, is not resource-demanding, and supports most commands of the popular SQL92 standard. An added convenience is that the entire database resides in a single file on the hard drive on the user's computer and can be easily transferred or backed up. However, to speed up read, write, and modification operations, the database can also be opened/created in RAM with the flag DATABASE_OPEN_MEMORY, however, in this case, such a database will be available only to this particular program and cannot be used for joint work of several programs.

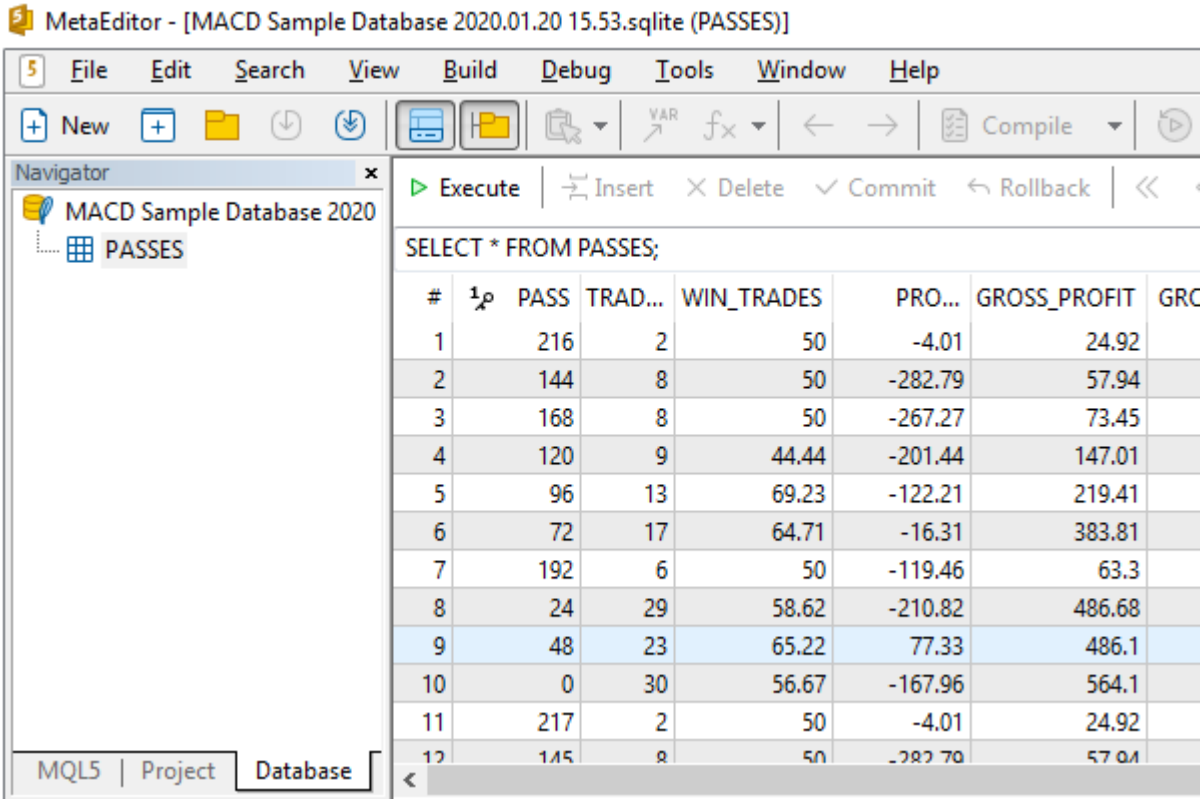
> It is important to note that the relative simplicity of SQLite, compared to full-featured DBMSs, comes with some limitations. In particular, SQLite does not have a dedicated process (system service or application) that would provide centralized access to the database and table management API, which is why parallel, shared access to the same database (file) from different processes is not guaranteed. So, if you need to simultaneously read and write to the database from optimization agents that execute instances of the same Expert Advisor, you will need to write code in it to synchronize access (otherwise, the data being written and read will be in an inconsistent state: after all, the order of writing, modifying, deleting, and reading from concurrent unsynchronized processes are random). Moreover, attempts to change the database at the same time may result in the MQL program receiving "database busy" errors (and the requested operation is not performed). The only scenario that does not require synchronization of parallel operations with SQLite is when only read operations are involved.

We will present only the basics of SQL to the extent necessary to start applying it. A complete description of the syntax and how SQL works is beyond the scope of this book. Check out the documentation on the SQLite site. However, please note that MQL5 and MetaEditor support a limited subset of commands and SQL syntax constructions.

MQL Wizard in MetaEditor has an embedded option to create a database, which immediately offers to create the first table by defining a list of its fields. Also, the *Navigator* provides a separate tab for working with databases.

Using the *Wizard* or the context menu of the *Navigator*, you can create an empty database (a file on disk, placed by default, in the directory *MQL5/Files*) of supported formats (*.db, *.sql, *.sqlite and others). In addition, in the context menu, you can import the entire database from an sql file or individual tables from csv files.

An existing or created database can be easily opened through the same menu. After that, its tables will appear in the *Navigator*, and the right, main area of the window will display a panel with tools for debugging SQL queries and a table with the results. For example, double-clicking on a table name performs a quick query of all record fields, which corresponds to the "SELECT * FROM 'table'" statement that appears in the input field at the top.



#	PASS	TRAD...	WIN_TRADES	PRO...	GROSS_PROFIT	GRC
1	216	2	50	-4.01	24.92	
2	144	8	50	-282.79	57.94	
3	168	8	50	-267.27	73.45

Viewing SQLite Database in MetaEditor

You can edit the request and click the *Execute* button to activate it. Potential SQL syntax errors are output in the log.

For further details about the *Wizard*, the import/export of databases, and the interactive work with them, please see MetaEditor documentation.

7.6.0 Principles of database operations in MQL5

Databases store information in the form of tables. Getting, modifying, and adding new data to them is done using queries in the SQL language. We will describe its specifics in the following sections. In the meantime, let's use the *DatabaseRead.mq5* script, which has nothing to do with trading, and see how to create a simple database and get information from it. All functions mentioned here will be described in detail later. Now it is important to imagine the general principles.

Creating and closing a database using built-in *DatabaseOpen/DatabaseClose* functions are similar to working with files as we also create a descriptor for the database, check it, and close it at the end.

```
void OnStart()
{
   string filename = "company.sqlite";
   // create or open a database
   int db = DatabaseOpen(filename, DATABASE_OPEN_READWRITE | DATABASE_OPEN_CREATE);
   if(db == INVALID_HANDLE)
   {
      Print("DB: ", filename, " open failed with code ", _LastError);
      return;
   }
   ...// further work with the database
   // close the database
   DatabaseClose(db);
}
```

After opening the database, we will make sure that there is no table in it under the name we need. If the table already exists, then when trying to insert the same data into it as in our example, an error will occur, so we use the *DatabaseTableExists* function.

Deleting and creating a table is done using queries that are sent to the database with two calls to the *DatabaseExecute* function and accompanied by error checking.

```
   ...
   // if the table COMPANY exists, then delete it
   if(DatabaseTableExists(db, "COMPANY"))
   {
      if(!DatabaseExecute(db, "DROP TABLE COMPANY"))
      {
         Print("Failed to drop table COMPANY with code ", _LastError);
         DatabaseClose(db);
         return;
      }
   }
   // creating table COMPANY
   if(!DatabaseExecute(db, "CREATE TABLE COMPANY("
     "ID      INT     PRIMARY KEY NOT NULL,"
     "NAME    TEXT    NOT NULL,"
     "AGE     INT     NOT NULL,"
     "ADDRESS CHAR(50),"
     "SALARY  REAL );"))
   {
      Print("DB: ", filename, " create table failed with code ", _LastError);
      DatabaseClose(db);
      return;
   }
   ...
```

Let's explain the essence of SQL queries. In the COMPANY table, we have only 5 fields: record ID, name, age, address, and salary. Here the ID field is a key, that is, a unique index. Indexes allow each record to be uniquely identified and can be used across tables to link them together. This is similar to how the position ID links all trades and orders that belong to a particular position.

Now you need to fill the table with data, this is done using the "INSERT" query:

```
// insert data into table
if(!DatabaseExecute(db,
   "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (1,'Paul',32,'Californ
   "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (2,'Allen',25,'Texas',
   "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (3,'Teddy',23,'Norway'
   "INSERT INTO COMPANY (ID,NAME,AGE,ADDRESS,SALARY) VALUES (4,'Mark',25,'Rich-Mon
{
   Print("DB: ", filename, " insert failed with code ", _LastError);
   DatabaseClose(db);
   return;
}
...
```

Here, 4 records are added to the table COMPANY, for each record there is a list of fields, and values that will be written to these fields are indicated. Records are inserted by separate "INSERT..." queries, which are combined into one line, through a special delimiter character ';', but we could insert each record into the table with a separate *DatabaseExecute* call.

Since at the end of the script the database will be saved to the "company.sqlite" file, the next time it is run, we would try to write the same data to the COMPANY table with the same ID. This would lead to an error, which is why we previously deleted the table so that we would start from scratch every time the script was run.

Now we get all records from the COMPANY table with the field *SALARY > 15000*. This is done using the *DatabasePrepare* function, which "compiles" the request text and returns its handle for later use in the *DatabaseRead* or *DatabaseReadBind* functions.

```
// prepare a request with a descriptor
int request = DatabasePrepare(db, "SELECT * FROM COMPANY WHERE SALARY>15000");
if(request == INVALID_HANDLE)
{
   Print("DB: ", filename, " request failed with code ", _LastError);
   DatabaseClose(db);
   return;
}
...
```

After the request has been successfully created, we need to get the results of its execution. This can be done using the *DatabaseRead* function, which on the first call will execute the query and jump to the first record in the results. On each subsequent call, it will read the next record until it reaches the end. In this case, it will return *false*, which means "there are no more records".

```
   // printing all records with salary over 15000
   int id, age;
   string name, address;
   double salary;
   Print("Persons with salary > 15000:");
   for(int i = 0; DatabaseRead(request); i++)
   {
      // read the values of each field from the received record by its number
      if(DatabaseColumnInteger(request, 0, id) && DatabaseColumnText(request, 1, name
         DatabaseColumnInteger(request, 2, age) && DatabaseColumnText(request, 3, add
         DatabaseColumnDouble(request, 4, salary))
         Print(i, ":  ", id, " ", name, " ", age, " ", address, " ", salary);
      else
      {
         Print(i, ": DatabaseRead() failed with code ", _LastError);
         DatabaseFinalize(request);
         DatabaseClose(db);
         return;
      }
   }
   // deleting handle after use
   DatabaseFinalize(request);
```

The result of execution will be:

```
Persons with salary > 15000:
0:  1 Paul 32 California 25000.0
1:  3 Teddy 23 Norway 20000.0
2:  4 Mark 25 Rich-Mond  65000.0
```

The *DatabaseRead* function allows you to go through all the records from the query result and then get complete information about each column in the resulting table via *DatabaseColumn* functions. These functions are designed to work universally with the results of any query but the cost is a redundant code.

If the structure of the query results is known in advance, it is better to use the *DatabaseReadBind* function, which allows you to read the entire record at once into a structure. We can remake the previous example in this way and present it under a new name *DatabaseReadBind.mq5*. Let's first declare the *Person* structure:

```
struct Person
{
   int    id;
   string name;
   int    age;
   string address;
   double salary;
};
```

Then we will subtract each record from the query results with *DatabaseReadBind(request, person)* in a loop as long as the function returns *true*:

```
Person person;
Print("Persons with salary > 15000:");
for(int i = 0; DatabaseReadBind(request, person); i++)
   Print(i, ":  ", person.id, " ", person.name, " ", person.age,
      " ", person.address, " ", person.salary);
DatabaseFinalize(request);
```

Thus, we immediately get the values of all fields from the current record and we do not need to read them separately.

This introductory example was taken from the article SQLite: native work with SQL databases in MQL5, where, in addition to it, several options for the application of the database for traders are considered. Specifically, you can find there restoring the history of positions from trades, analyzing a trading report in terms of strategies, working symbols, or the most preferred trading hours, as well as techniques for working with optimization results.

Some basic knowledge of SQL may be required to master this material, so we will cover it briefly in the following sections.

7.6.1 SQL Basics

All tasks performed in SQLite assume the presence of a working database (one or more), so creating and opening a database (similar to a file) are mandatory framework operations that establish the necessary programming environment. There is no facility for programmatic deletion of the database in SQLite as it is assumed that you can simply delete the database file from disk.

The actions available in the context of an open base can be conditionally divided into the following main groups:

- Creating and deleting tables, as well as modifying their schemas, i.e., column descriptions, including the identification of types, names, and restrictions
- Creating (adding), reading, editing, and deleting records in tables; these operations are often denoted by the common abbreviation CRUD (Create, Read, Update, Delete)
- Building queries to select records from one or a combination of several tables according to complex conditions
- Optimizing algorithms by building indexes on selected columns, using views (view), wrapping batch actions in transactions, declaring event processing triggers, and other advanced tools

In SQL databases, all of these actions are performed using reserved SQL commands (or statements). Due to the specifics of integration with MQL5, some of the actions are performed by built-in MQL5 functions. For example, opening, applying, or canceling a transaction is performed by the trinity of *DatabaseTransaction* functions, although the SQL standard (and the public implementation of SQLite) has corresponding SQL commands (BEGIN TRANSACTION, COMMIT, and ROLLBACK).

Most SQL commands are also available in MQL programs: they are passed to the SQLite executing engine as string parameters of the *DatabaseExecute* or *DatabasePrepare* functions. The difference between these two options lies in several nuances.

DatabasePrepare allows you to prepare a query for its subsequent mass cyclic execution with different parameter values at each iteration (the parameters themselves, that is, their names in the query, are the same). In addition, these prepared queries provide a mechanism to read the results using

DatabaseRead and *DatabaseReadBind*. So, you can use them for operations with a set of selected records.

In contrast, the *DatabaseExecute* function executes the passed single query unilaterally: the command goes inside the SQLite engine, performs some actions on the data, but returns nothing. This is commonly used for table creation or batch modification of data.

In the future, we will often have to operate with several basic concepts. Let's introduce them:

Table – a structured set of data, consisting of rows and columns. Each row is a separate data record with fields (properties) described using the name and type of the corresponding columns. All database tables are physically stored in the database file and are available for reading and writing (if rights were not restricted when opening the database).

View – a kind of virtual table calculated by the SQLite engine based on a given SQL query, other tables, or views. Views are read-only. Unlike any tables (including temporary ones that SQL allows you to create in memory for the duration of a program session), views are dynamically recalculated each time they are accessed.

Index – a service data structure (the balanced tree, B-tree) for quick search of records by the values of predefined fields (properties) or their combinations.

Trigger – a subroutine of one or more SQL statements assigned to be automatically run in response to events (before or after) adding, changing, or deleting a record in a particular table.

Here is a short list of the most popular SQL statements and the actions they perform:

- CREATE – creates a database object (table, view, index, trigger);
- ALTER – changes an object (table);
- DROP – deletes an object (table, view, index, trigger);
- SELECT – selects records or calculates values that satisfy the given conditions;
- INSERT – adds new data (one or a set of records);
- UPDATE – changes existing records;
- DELETE – deletes records from the table;

The list only shows the keywords that start the corresponding SQL language construct. A more detailed syntax will be shown below. Their practical application will be shown in the following examples.

Each statement can span multiple lines (linefeed characters and extra spaces are ignored). If necessary, you can send several commands to SQLite at once. In this case, after each command, you should use the command termination character ';' (semicolon).

The text in commands is analyzed by the system regardless of case, but in SQL it is customary to write keywords in capital letters.

When creating a table, we must specify its name, as well as a list of columns in parentheses, separated by commas. Each column is given a name, a type, and optionally a constraint. The simplest form:

```
CREATE TABLE table_name
  ( column_name type [ constraints ] [, column_name type [ constraints ...] ...]);
```

We will see the restrictions in SQL in the next section. In the meantime, let's have a look at a clear example (with different types and options):

```
CREATE TABLE IF NOT EXISTS example_table
   (id INTEGER PRIMARY KEY,
    name TEXT,
    timestamp INTEGER DEFAULT CURRENT_STAMP,
    income REAL,
    data BLOB);
```

The syntax for creating an index is:

```
CREATE [ UNIQUE ] INDEX index_name
  ON table_name( column_name [, column_name ...]);
```

Existing indexes are automatically used in queries with filter conditions on the corresponding columns. Without indexes, the process is slower.

Deleting a table (along with the data, if something has been written to it) is quite simple:

```
DROP TABLE table_name;
```

You can insert data into a table like this:

```
INSERT INTO table_name [ ( column_name [, column_name ...] ) ]
  VALUES( value [, value ...]);
```

The first list in parentheses includes the column names and is optional (see explanation below). It must match the second list with values for them. For example,

```
INSERT INTO example_table (name, income) VALUES ('Morning Flat Breakout', 1000);
```

Note that string literals are enclosed in single quotes in SQL.

If the column names are omitted from the INSERT statement, the VALUES keyword is assumed to be followed by the values for all the columns in the table, and in the exact order in which they are described in the table.

There are also more complex forms of the operator, allowing, in particular, the insertion of records from other tables or query results.

Selecting records by condition, with an optional limitation of the list of returned fields (columns), is performed by the SELECT command.

```
SELECT column_name [, column_name ...] FROM table_name [WHERE condition ];
```

If you want to return every matching record in its entirety (all columns), use the star notation:

```
SELECT *FROM table_name [WHERE condition ];
```

When the condition is not present, the system returns all records in the table.

As a condition, you can substitute a logical expression that includes column names and various comparison operators, as well as built-in SQL functions and the results of a nested SELECT query (such queries are written in parentheses). Comparison operators include:

- Logical AND
- Logical OR
- IN for a value from the list
- NOT IN for a value outside the list

- BETWEEN for a value in the range
- LIKE – similar in spelling to a pattern with special wildcard characters ('%', '_')
- EXISTS – check for non-emptiness of the results of the nested query

For example, a selection of record names with an income of at least 1000 and no older than one year (preliminarily rounded to the nearest month):

```
SELECT name FROM example_table
  WHERE income >= 1000 AND timestamp > datetime('now', 'start of month', '-1 year');
```

Additionally, the selection can be sorted in ascending or descending order (ORDER BY), grouped by characteristics (GROUP BY), and filtered by groups (HAVING). We can also limit the number of records in it (LIMIT, OFFSET). For each group, you can return the value of any aggregate function, in particular, COUNT, SUM, MIN, MAX, and AVG, calculated on all group records.

```
SELECT [ DISTINCT ] column_name [, column_name...](i) FROM table_name
  [ WHERE condition ]
  [ORDER BY column_name [ ASC | DESC ]
     [ LIMIT quantity OFFSET start_offset ] ]
  [ GROUP BY column_name [ HAVING condition ] ];
```

The optional keyword DISTINCT allows you to remove duplicates (if they are found in the results according to the current selection criteria). It only makes sense in the absence of grouping.

LIMIT will only give reproducible results if sorting is present.

If necessary, the SELECT selection can be made not from one table but from several, combining them according to the required combination of fields. The keyword JOIN is used for this.

```
SELECT [...] FROM table name_1
  [ INNER | OUTER | CROSS ] JOIN table_name_2
  ON boolean_condition
```

or

```
SELECT [...] FROM table name_1
  [ INNER | OUTER | CROSS ] JOIN table_name_2
  USING ( common_column_name [, common_column_name ...] )
```

SQLite supports three kinds of JOINs: INNER JOIN, OUTER JOIN, and CROSS JOIN. The book provides a general idea of them from examples, while you can further explore the details on your own.

For example, using JOIN, you can build all combinations of records from one table with records from another table or compare deals from the deals table (let's call it "deals") with deals from the same table according to the principle of matching position identifiers, but in such a way that the direction of deals (entry to the market/exit from the market) was the opposite, resulting in a virtual table of trades.

```
SELECT // list the columns of the results table with aliases (after 'as')
  d1.time as time_in, d1.position_id as position, d1.type as type, // table d1
   d1.volume as volume, d1.symbol as symbol, d1.price as price_in,
  d2.time as time_out, d2.price as price_out,                      // table d2
   d2.swap as swap, d2.profit as profit,
  d1.commission + d2.commission as commission                      // combination
  FROM deals d1 INNER JOIN deals d2      // d1 and d2 - aliases of one table "deals"
  ON d1.position_id = d2.position_id     // merge condition by position
  WHERE d1.entry = 0 AND d2.entry = 1    // selection condition "entry/exit"
```

This is an SQL query from the MQL5 help, where JOIN examples are available in descriptions of the *DatabaseExecute* and *DatabasePrepare* functions.

The fundamental property of SELECT is that it always returns results to the calling program, unlike other queries such as CREATE, INSERT, etc. However, starting from SQLite 3.35, INSERT, UPDATE, and DELETE statements also have the ability to return values, if necessary, using the additional RETURNING keyword. For example,

```
INSERT INTO example_table (name, income) VALUES ('Morning Flat Breakout', 1000)
   RETURNING id;
```

In any case, query results in MQL5 are accessed through *DatabaseColumn* functions, *DatabaseRead*, and *DatabaseReadBind*.

In addition, SELECT allows you to evaluate the results of expressions and return them as they are or combine them with results from tables. Expressions can include most of the operators we are familiar with from MQL5 expressions, as well as built-in SQL functions. See the SQLite documentation for a complete list. For example, here's how you can find the current build version of SQLite in your terminal and editor instance, which can be important for finding out which options are available.

```
SELECT sqlite_version();
```

Here the entire expression consists of a single call of the *sqlite_version* function. Similar to selecting multiple columns from a table, you can evaluate multiple expressions separated by commas.

Several popular statistical and mathematical functions are also available.

Records should be edited with an UPDATE statement.

```
UPDATE table_name SET column_name = value [, column_name = value ...]
  WHERE condition;
```

The syntax for the deletion command is as follows:

```
DELETE FROM table_name WHERE condition;
```

7.6.2 Structure of tables: data types and restrictions

When describing table fields, you need to specify data types for them, but the concept of a data type in SQLite is very different from MQL5.

MQL5 is a strongly typed language: each variable or structure field always retains the data type according to the declaration. SQL, on the other hand, is a loosely typed language: the types that we specify in the table description are nothing more than a recommendation. The program can write a

value of an arbitrary type to any "cell" (a field in the record), and the "cell" will change its type, which, in particular, can be detected by the built-in MQL function *DatabaseColumnType*.

Of course, in practice, most users tend to stick to "respect" column types.

The second significant difference in the SQL type mechanism is the presence of a large number of keywords that describe types, but all these words ultimately come down to five storage classes. Being a simplified version of SQL, SQLite in most cases does not distinguish between keywords of the same group (for example, in the description of a string with a VARCHAR(80) length limit, this limit is not controlled, and the description is equivalent to the TEXT storage class), so it is more logical to describe the type by the group name. Specific types are left only for compatibility with other DBMS (but this is not important for us).

The following table lists the MQL5 types and their corresponding "affinities" (which mean generalizing features of SQL types).

MQL5 types	Generic SQL types
NULL (not a type in MQL5)	NULL (no value)
bool, char, short, int, long, uchar, ushort, uint, ulong, datetime, color, enum	INTEGER
float, double	REAL
(real number of fixed precision, no analog in MQL5)	NUMERIC
string	TEXT
(arbitrary "raw" data, analog of uchar[] array or others)	BLOB (binary large object), NONE

When writing a value to the SQL database, it determines its type according to several rules:

- The absence of quotes, decimal point, or exponent give INTEGER
- The presence of a decimal point and an exponent means REAL
- framing of single or double quotes signals the TEXT type
- a NULL value without quotes corresponds to the NULL class
- literals (constants) with binary data are written as a hexadecimal string prefixed with 'x'

Special SQL function *typeof* allows you to check the type of a value. For example, the following query can be run in the MetaEditor.

```
SELECT typeof(100), typeof(10.0), typeof('100'), typeof(x'1000'), typeof(NULL);
```

It will output to the results table:

```
integer       |      real   |      text   |      blob   |      null
```

You cannot check values for NULL by comparing '=' (because the result will also give NULL), you should use the special NOT NULL operator.

SQLite imposes some limits on stored data: some of them are difficult to achieve (and therefore we will omit them here), but others can be taken into account when designing a program. So, the maximum number of columns in the table is 2000, and the size of one row, BLOB, and in general one record cannot exceed one million bytes. The same value is chosen as the SQL query length limit.

As far as dates and times are concerned, SQL can in theory store them in three formats, but only the first one matches *datetime* in MQL5:

- INTEGER – the number of seconds since 1970.01.01 (also known as the "Unix epoch")
- REAL – the number of days (with fractions) from November 24, 4714 BC
- TEXT – date and time with accuracy to the millisecond in the format "YYYY-MM-DD HH:mm:SS.sss", optionally with the time zone, for which the suffix "[±]HH:mm" is added with an offset from UTC

A real date storage type (also called the Julian day, for which there is a built-in SQL function *Julianday*) is interesting in that it allows you to store time accurate to milliseconds. In theory, this can also be done as a 'YYYY-MM-DDTHH:mm:SS.sssZ' format string, but such storage is very uneconomical. The conversion of the "day" into the number of seconds with a fractional part, starting from the familiar date 1970.01.01 00:00:00, is made according to the formula: *julianday('now') - 2440587.5) * 86400.0*. 'Now' here denotes the current UTC time but can be changed to other values described in the SQLite documentation. The constant 2440587.5 is exactly equal to the number of "calendar" days for the specified "zero" date – the starting point of the "Unix epoch".

In addition to the type, each field can have one or more constraints, which are written with special keywords after the type. A constraint describes what values the field can take and even allows you to automate the completion according to the field's predefined purpose.

Let's consider the main constraints.

```
... DEFAULT expression
```

When adding a new record, if the field value is not specified, the system will automatically enter the value (constant) specified here or calculate the expression (function).

```
... CHECK ( boolean_expression )
```

When adding a new record, the system will check that the expression, which can contain field names as variables, is true. If the expression is false, the record will not be inserted and the system will return an error.

```
... UNIQUE
```

The system checks that all records in the table have different values for this field. Attempting to add an entry with a value that already exists will result in an error and the addition will not occur.

To track uniqueness, the system implicitly creates an index for the specified field.

```
... PRIMARY KEY
```

A field marked with this attribute is used by the system to identify records in a table and links to them from other tables (this is how relational relationships are formed, giving the name to relational databases in question like SQLite). Obviously, this feature also includes a unique index.

If the table does not have an INTEGER type field with the PRIMARY KEY attribute, the system automatically implicitly creates such a column named *rowid*. If your table has an integer field declared as a primary key, then it is also available under the alias *rowid*.

If a record with an omitted or NULL *rowid* is added to the table, SQLite will automatically assign it the next integer (64-bit, corresponding to *long* in MQL5), larger than the maximum *rowid* in the table by 1. The initial value is 1.

Usually the counter just increments by 1 each time, but if the number of records ever inserted into one table (and possibly then deleted) exceeds *long*, the counter will jump to the beginning and the system will try to find free numbers. But this is unlikely. For example, if you write ticks to a table at an average rate of 1 tick per millisecond, then the overflow will occur in 292 million years.

There can be only one primary key, but it can consist of several columns, which is done using a syntax other than constraints directly in the table description.

```
CREATE TABLE table_name (
  column_name type [ restrictions ]
  [, column_name type [ restrictions ] ...]
  , PRIMARY KEY ( column_name [, column_name ...] ) );
```

Let's get back to constraints.

```
... AUTOINCREMENT
```

This constraint can only be specified as a complement to the PRIMARY KEY, ensuring that identifiers are incremented all the time. This means that any previous IDs, even those used on deleted entries, will not be reselected. However, this mechanism is implemented in SQLite less efficiently than a simple PRIMARY KEY in terms of computing resources and therefore is not recommended for use.

```
... NOT NULL
```

This constraint prohibits adding a record to the table in which this field is not filled. By default, when there is no constraint, any non-unique field can be omitted from the added record and will be set to NULL.

```
... CURRENT_TIME
... CURRENT_DATE
... CURRENT_TIMESTAMP
```

These instructions allow you to automatically populate a field with the time (no date), date (no time), or full UTC time at the time the record was inserted (provided that the INSERT SQL statement does not explicitly write anything to this field, even NULL). SQLite does not know how to automatically detect the time of a record change in a similar way – for this purpose you will have to write a trigger (which is beyond the scope of the book).

Unfortunately, the CURRENT_TIMESTAMP group restrictions are implemented in SQLite with an omission: the timestamp is not applied if the field is NULL. This distinguishes SQLite from other SQL engines and from how SQLite itself handles NULLs in primary key fields. It turns out that for automatic labeling, you cannot write the entire object to the database, but you need to explicitly specify all the fields except for the field with the date and time. To solve the problem, we need an alternative option in which the SQL function STRFTIME('%s') is substituted in the compiled query for the corresponding columns.

7.6.3 OOP (MQL5) and SQL integration: ORM concept

The use of a database in an MQL program implies that the algorithm is divided into 2 parts: the control part is written in MQL5, and the execution part is written in SQL. As a result, the source code may

start to look like a patchwork and require attention to maintain consistency. To avoid this, object-oriented languages have developed the concept of Object-Relational Mapping (ORM), i.e., mapping of objects to relational table records and vice versa.

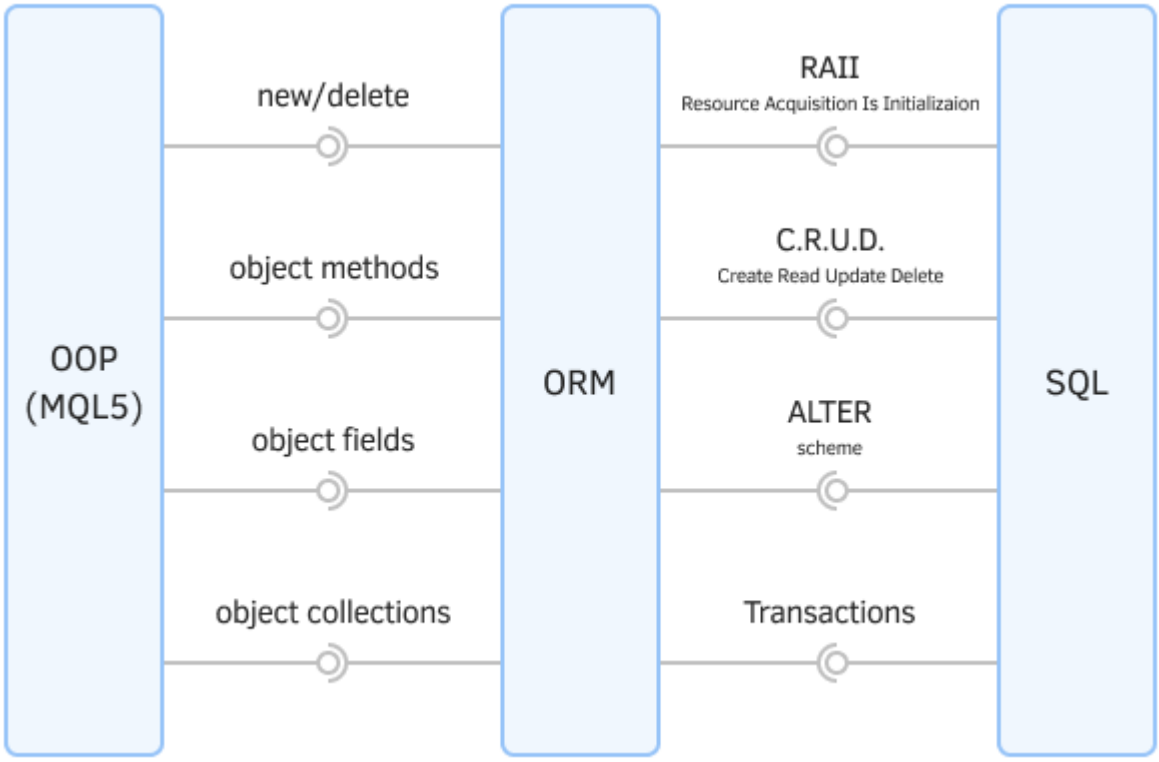
The essence of the approach is to encapsulate all actions in the SQL language in classes/structures of a special layer. As a result, the application part of the program can be written in a pure OOP language (for example, MQL5), without being distracted by the nuances of SQL.

In the presence of a full-fledged ORM implementation (in the form of a "black box" with a set of all commands), an application developer generally has the opportunity not to learn SQL.

In addition, ORM allows you to "imperceptibly" change the "engine" of the DBMS if necessary. This is not particularly relevant for MQL5, because only the SQLite database is built into it, but some developers prefer to use full-fledged DBMS and connect them to MetaTrader 5 using import of DLLs.

The use of objects with constructors and destructors is very useful when we need to automatically acquire and release resources. We have covered this concept (RAII, Resource Acquisition Is Initialization) in the section File descriptor management, however, as we will see later, work with the database is also based on the allocation and release of different types of descriptors.

The following picture schematically depicts the interaction of different software layers when integrating OOP and SQL in the form of an ORM.



ORM, Object-Relational Mapping

As a bonus, an object "wrapper" (not just a database-specific ORM) will automate data preparation and transformation, as well as check for correctness in order to prevent some errors.

In the following sections, as we walk through the built-in functions for working with the base, we will implement the examples, gradually building our own simple ORM layer. Due to some specifics of MQL5,

our classes will not be able to provide universalism that covers 100% of tasks but will be useful for many projects.

7.6.4 Creating, opening, and closing databases

The *DatabaseOpen* and *DatabaseClose* functions enable the creation and opening of databases.

int DatabaseOpen(const string filename, uint flags)

The function opens or creates a database in a file named *filename*. The parameter can contain not only the name but also the path with subfolders relative to *MQL5/Files* (of a specific terminal instance or in a shared folder, see flags below). The extension can be omitted, which adds ".sqlite" to the default name.

If NULL or an empty string "" is specified in the *filename* parameter, then the database is created in a temporary file, which will be automatically deleted after the database is closed.

If the string ":memory:" is specified in the *filename* parameter, the database will be created in memory. Such a temporary base will be automatically deleted after closing.

The *flags* parameter contains a combination of flags that describe additional conditions for creating or opening a database from the ENUM_DATABASE_OPEN_FLAGS enumeration.

Identifier	Description
DATABASE_OPEN_READONLY	Open for reading only
DATABASE_OPEN_READWRITE	Open for reading and writing
DATABASE_OPEN_CREATE	Create a file on disk if it doesn't exist
DATABASE_OPEN_MEMORY	Create an in-memory database
DATABASE_OPEN_COMMON	The file is located in the shared folder of all terminals

If none of the DATABASE_OPEN_READONLY or DATABASE_OPEN_READWRITE flags are specified in the *flags* parameter, the DATABASE_OPEN_READWRITE flag will be used.

On success, the function returns a handle to the database, which is then used as a parameter for other functions to access it. Otherwise, INVALID_HANDLE is returned, and the error code can be found in *_LastError*.

void DatabaseClose(int database)

The *DatabaseClose* function closes the database by its handle, which was previously received from the *DatabaseOpen* function.

After calling *DatabaseClose*, all query handles that we will learn to create for an open base in the following sections are automatically removed and invalidated.

The function does not return anything. However, if an incorrect handle is passed to it, it will set *_LastError* to ERR_DATABASE_INVALID_HANDLE.

Let's start developing an object-oriented wrapper for databases in a file *DBSQLite.mqh*.

The DBSQ*lite* class will ensure the creation, opening, and closing of databases. We will extend it later.

```
class DBSQLite
{
protected:
   const string path;
   const int handle;
   const uint flags;

public:
   DBSQLite(const string file, const uint opts =
      DATABASE_OPEN_CREATE | DATABASE_OPEN_READWRITE):
      path(file), flags(opts), handle(DatabaseOpen(file, opts))
   {
   }

   ~DBSQLite(void)
   {
      if(handle != INVALID_HANDLE)
      {
         DatabaseClose(handle);
      }
   }

   int getHandle() const
   {
      return handle;
   }

   bool isOpen() const
   {
      return handle != INVALID_HANDLE;
   }
};
```

Note that the database is automatically created or opened when the object is created, and closed when the object is destroyed.

Using this class, let's write a simple script *DBinit.mq5*, which will create or open the specified database.

```
input string Database = "MQL5Book/DB/Example1";

void OnStart()
{
   DBSQLite db(Database);                  // create or open the base in the constru
   PRTF(db.getHandle());                   // 65537 / ok
   PRTF(FileIsExist(Database + ".sqlite")); // true / ok
} // the base is closed in the destructor
```

After the first run, with default settings, we should get a new file *MQL5/Files/MQL5Book/DB/Example1.sqlite*. This is confirmed in the code by checking for the existence of the file. On subsequent runs with the same name, the script simply opens the database and logs the current descriptor (an integer number).

7.6.5 Executing queries without MQL5 data binding

Some SQL queries are commands that you just need to send to the engine as is. They require neither variable input nor results. For example, if our MQL program needs to create a table, index, or view with a certain structure and name in the database, we can write it as a constant string with the "CREATE ..." statement. In addition, it is convenient to use such queries for batch processing of records or their combination (merging, calculating aggregated indicators, and same-type modifications). That is, with one query, you can convert the entire table data or fill other tables based on it. These results can be analyzed in the subsequent queries.

In all these cases, it is only important to obtain confirmation of the success of the action. Requests of this type are performed using the *DatabaseExecute* function.

bool DatabaseExecute(int database, const string sql)

The function executes a query in the database specified by the *database* descriptor. The request itself is sent as a ready string *sql*.

The function returns an indicator of success (*true*) or error (*false*).

For example, we can complement our *DBSQLite* class with this method (the descriptor is already inside the object).

```
class DBSQLite
{
   ...
   bool execute(const string sql)
   {
      return DatabaseExecute(handle, sql);
   }
};
```

Then the script that creates a new table (and, if necessary, beforehand, the database itself) may look like this (*DBcreateTable.mq5*).

```
input string Database = "MQL5Book/DB/Example1";
input string Table = "table1";

void OnStart()
{
   DBSQLite db(Database);
   if(db.isOpen())
   {
      PRTF(db.execute(StringFormat("CREATE TABLE %s (msg text)", Table))); // true
   }
}
```

After executing the script, try to open the specified database in MetaEditor and make sure that it contains an empty table with a single "msg" text field. But it can also be done programmatically (see the next section).

If we run the script a second time with the same parameters, we will get an error (albeit a non-critical one, without forcing the program to close).

```
database error, table table1 already exists
db.execute(StringFormat(CREATE TABLE %s (msg text),Table))=false / DATABASE_ERROR(560
```

This is because you can't re-create an existing table. But SQL allows you to suppress this error and create a table only if it hasn't existed yet, otherwise do almost nothing and return a success indicator. To do this, just add "IF NOT EXISTS" in front of the name in the query.

```
db.execute(StringFormat("CREATE TABLE IF NOT EXISTS %s (msg text)", Table));
```

In practice, tables are required to store information about objects in the application area, such as quotes, deals, and trading signals. Therefore, it is desirable to automate the creation of tables based on the description of objects in MQL5. As we will see below, SQLite functions provide the ability to bind query results to MQL5 structures (but not classes). In this regard, within the framework of the ORM wrapper, we will develop a mechanism for generating the SQL query "CREATE TABLE" according to the *struct* description of the specific type in MQL5.

This requires registering the names and types of structure fields in some way in the general list at the time of compilation, and then, already at the program execution stage, SQL queries can be generated from this list.

Several categories of MQL5 entities are parsed at the compilation stage, which can be used to identify types and names:

- macros
- inheritance
- templates

First of all, it should be recalled that the collected field descriptions are related to the context of a particular structure and should not be mixed, because the program may contain many different structures with potentially matching names and types. In other words, it is desirable to accumulate information in separate lists for each type of structure. A template type is ideal for this, the template parameter of which (S) will be the application structure. Let's call the template *DBEntity*.

```
template<typename S>
struct DBEntity
{
   static string prototype[][3]; // 0 - type, 1 - name, 2 - constraints
   ...
};

template<typename T>
static string DBEntity::prototype[][3];
```

Inside the template, there is a multidimensional array *prototype*, in which we will write the description of the fields. To intercept the type and name of the applied field, you will need to declare another template structure, *DBField*, inside *DBEntity*: this time its parameter T is the type of the field itself. In the constructor, we have information about this type (*typename(T)*), and we also get the name of the field (and optionally, the constraint) as parameters.

```
template<typename S>
struct DBEntity
{
   ...
   template<typename T>
   struct DBField
   {
      T f;
      DBField(const string name, const string constraints = "")
      {
         const int n = EXPAND(prototype);
         prototype[n][0] = typename(T);
         prototype[n][1] = name;
         prototype[n][2] = constraints;
      }
   };
```

The *f* field is not used but is needed because structures cannot be empty.

Let's say we have an application structure *Data* (*DBmetaProgramming.mq5*).

```
struct Data
{
   long id;
   string name;
   datetime timestamp;
   double income;
};
```

We can make its analog inherited from *DBEntity<DataDB>*, but with substituted fields based on *DBField*, identical to the original set.

```
struct DataDB: public DBEntity<DataDB>
{
   DB_FIELD(long, id);
   DB_FIELD(string, name);
   DB_FIELD(datetime, timestamp);
   DB_FIELD(double, income);
} proto;
```

By substituting the name of the structure into the parent template parameter, the structure provides the program with information about its own properties.

Pay attention to the one-time definition of the *proto* variable along with the structure declaration. This is necessary because, in templates, each specific parameterized type is compiled only if at least one object of this type is created in the source code. It is important for us that the creation of this proto-object occurs at the very beginning of the program launch, at the moment of initialization of global variables.

A macro is hidden under the DB_FIELD identifier:

```
#define DB_FIELD(T,N) struct T##_##N: DBField<T> { T##_##N() : DBField<T>(#N) { } } \
   _##T##_##N;
```

Here's how it expands for a single field:

```
struct Type_Name: DBField<Type>
{
   Type_Name() : DBField<Type>(Name) { }
} _Type_Name;
```

Here the structure is not only defined but is also instantly created: in fact, it replaces the original field.

Since the *DBField* structure contains a single *f* variable of the desired type, dimensions and internal binary representation of *Data* and *DataDB* are identical. This can be easily verified by running the script *DBmetaProgramming.mq5*.

```
void OnStart()
{
   PRTF(sizeof(Data));
   PRTF(sizeof(DataDB));
   ArrayPrint(DataDB::prototype);
}
```

It outputs to the log:

```
DBEntity<Data>::DBField<long>::DBField<long>(const string,const string)
long id
DBEntity<Data>::DBField<string>::DBField<string>(const string,const string)
string name
DBEntity<Data>::DBField<datetime>::DBField<datetime>(const string,const string)
datetime timestamp
DBEntity<Data>::DBField<double>::DBField<double>(const string,const string)
double income
sizeof(Data)=36 / ok
sizeof(DataDB)=36 / ok
            [,0]        [,1]        [,2]
[0,] "long"      "id"        ""
[1,] "string"    "name"      ""
[2,] "datetime"  "timestamp" ""
[3,] "double"    "income"    ""
```

However, to access the fields, you would need to write something inconvenient: *data._long_id.f*, *data._string_name.f*, *data._datetime_timestamp.f*, *data._double_income.f*.

We will not do this, not only and not so much because of inconvenience, but because this way of constructing meta-structures is not compatible with the principles of data binding to SQL queries. In the following sections, we will explore *database* functions that allow you to get records of tables and results of SQL queries in MQL5 structures. However, it is allowed to use only simple structures without inheritance and static members of object types. Therefore, it is required to slightly change the principle of revealing meta-information.

We will have to leave the original types of structures unchanged and actually repeat the description for the database, making sure that there are no discrepancies (typos). This is not very convenient, but there is no other way at the moment.

We will transfer the declaration of instances *DBEntity* and *DBField* beyond application structures. In this case, the DB_FIELD macro will receive an additional parameter (S), in which it will be necessary to pass the type of the application structure (previously it was implicitly taken by declaring it inside the structure itself).

```
#define DB_FIELD(S,T,N) \
   struct S##_##T##_##N: DBEntity<S>::DBField<T> \
   { \
      S##_##T##_##N() : DBEntity<S>::DBField<T>(#N) {} \
   }; \
   const S##_##T##_##N _##S##_##T##_##N;
```

Since table columns can have constraints, they will also need to be passed to the *DBField* constructor if necessary. For this purpose, let's add a couple of macros with the appropriate parameters (in theory, one column can have several restrictions, but usually no more than two).

```
#define DB_FIELD_C1(S,T,N,C1) \
   struct S##_##T##_##N: DBEntity<S>::DBField<T> \
   { \
      S##_##T##_##N() : DBEntity<S>::DBField<T>(#N, C1) {} \
   }; \
   const S##_##T##_##N _##S##_##T##_##N;

#define DB_FIELD_C2(S,T,N,C1,C2) \
   struct S##_##T##_##N: DBEntity<S>::DBField<T> \
   { \
      S##_##T##_##N() : DBEntity<S>::DBField<T>(#N, C1 + " " + C2) {} \
   }; \
   const S##_##T##_##N _##S##_##T##_##N;
```

All three macros, as well as further developments, are added to the header file *DBSQLite.mqh*.

> It is important to note that this "self-made" binding of objects to a table is required only for entering data into the database because reading data from a table into an object is implemented in MQL5 using the *DatabaseReadBind* function.

Let's also improve the implementation of *DBField*. MQL5 types do not exactly correspond to SQL storage classes, and therefore it is necessary to perform a conversion when filling the *prototype[n][0]* element. This is done by the static method *affinity*.

```
template<typename T>
struct DBField
{
   T f;
   DBField(const string name, const string constraints = "")
   {
      const int n = EXPAND(prototype);
      prototype[n][0] = affinity(typename(T));
      ...
   }

   static string affinity(const string type)
   {
      const static string ints[] =
      {
         "bool", "char", "short", "int", "long",
         "uchar", "ushort", "uint", "ulong", "datetime",
         "color", "enum"
      };
      for(int i = 0; i < ArraySize(ints); ++i)
      {
         if(type == ints[i]) return DB_TYPE::INTEGER;
      }

      if(type == "float" || type == "double") return DB_TYPE::REAL;
      if(type == "string") return DB_TYPE::TEXT;
      return DB_TYPE::BLOB;
   }
};
```

The text constants of SQL generic types used here are placed in a separate namespace: they may be needed in different places in MQL programs at some point, and it is necessary to ensure that there are no name conflicts.

```
namespace DB_TYPE
{
   const string INTEGER = "INTEGER";
   const string REAL = "REAL";
   const string TEXT = "TEXT";
   const string BLOB = "BLOB";
   const string NONE = "NONE";
   const string _NULL = "NULL";
}
```

Presets of possible restrictions are also described in their group for convenience (as a hint).

```
namespace DB_CONSTRAINT
{
   const string PRIMARY_KEY = "PRIMARY KEY";
   const string UNIQUE = "UNIQUE";
   const string NOT_NULL = "NOT NULL";
   const string CHECK = "CHECK (%s)"; // requires an expression
   const string CURRENT_TIME = "CURRENT_TIME";
   const string CURRENT_DATE = "CURRENT_DATE";
   const string CURRENT_TIMESTAMP = "CURRENT_TIMESTAMP";
   const string AUTOINCREMENT = "AUTOINCREMENT";
   const string DEFAULT = "DEFAULT (%s)"; // requires an expression (constants, funct
}
```

Since some of the constraints require parameters (places for them are marked with the usual '%s' format modifier), let's add a check for their presence. Here is the final form of the *DBField* constructor.

```
   template<typename T>
   struct DBField
   {
      T f;
      DBField(const string name, const string constraints = "")
      {
         const int n = EXPAND(prototype);
         prototype[n][0] = affinity(typename(T));
         prototype[n][1] = name;
         if(StringLen(constraints) > 0       // avoiding error STRING_SMALL_LEN(5035)
            && StringFind(constraints, "%") >= 0)
         {
            Print("Constraint requires an expression (skipped): ", constraints);
         }
         else
         {
            prototype[n][2] = constraints;
         }
      }
```

Due to the fact that the combination of macros and auxiliary objects *DBEntity<S>* and *DBField<T>* populates an array of prototypes, inside the *DBSQlite* class, it becomes possible to implement the automatic generation of an SQL query to create a table of structures.

The *createTable* method is templated with an application structure type and contains a query stub ("CREATE TABLE %s %s (%s);"). The first argument for it is the optional instruction "IF NOT EXISTS". The second parameter is the name of the table, which by default is taken as the type of the template parameter *typename(S)*, but it can be replaced with something else if necessary using the input parameter name (if it is not NULL). Finally, the third argument in brackets is the list of table columns: it is formed by the helper method *columns* based on the array *DBEntity <S>::prototype*.

```
class DBSQLite
{
   ...
   template<typename S>
   bool createTable(const string name = NULL,
      const bool not_exist = false, const string table_constraints = "") const
   {
      const static string query = "CREATE TABLE %s %s (%s);";
      const string fields = columns<S>(table_constraints);
      if(fields == NULL)
      {
         Print("Structure '", typename(S), "' with table fields is not initialized");
         SetUserError(4);
         return false;
      }
      // attempt to create an already existing table will give an error,
      // if not using IF NOT EXISTS
      const string sql = StringFormat(query,
         (not_exist ? "IF NOT EXISTS" : ""),
         StringLen(name) ? name : typename(S), fields);
      PRTF(sql);
      return DatabaseExecute(handle, sql);
   }

   template<typename S>
   string columns(const string table_constraints = "") const
   {
      static const string continuation = ",\n";
      string result = "";
      const int n = ArrayRange(DBEntity<S>::prototype, 0);
      if(!n) return NULL;
      for(int i = 0; i < n; ++i)
      {
         result += StringFormat("%s%s %s %s",
            i > 0 ? continuation : "",
            DBEntity<S>::prototype[i][1], DBEntity<S>::prototype[i][0],
            DBEntity<S>::prototype[i][2]);
      }
      if(StringLen(table_constraints))
      {
         result += continuation + table_constraints;
      }
      return result;
   }
};
```

For each column, the description consists of a name, a type, and an optional constraint. Additionally, it is possible to pass a general constraint on the table (*table_constraints*).

Before sending the generated SQL query to the *DatabaseExecute* function, the *createTable* method produces a debug output of the query text to the log (all such output in the ORM classes can be centrally disabled by replacing the PRTF macro).

Now everything is ready to write a test script *DBcreateTableFromStruct.mq5*, which, by structure declaration, would create the corresponding table in SQLite. In the input parameter, we set only the name of the database, and the program will choose the name of the table itself according to the type of structure.

```
#include <MQL5Book/DBSQLite.mqh>

input string Database = "MQL5Book/DB/Example1";

struct Struct
{
   long id;
   string name;
   double income;
   datetime time;
};

DB_FIELD_C1(Struct, long, id, DB_CONSTRAINT::PRIMARY_KEY);
DB_FIELD(Struct, string, name);
DB_FIELD(Struct, double, income);
DB_FIELD(Struct, string, time);
```

In the main *OnStart* function, we create a table by calling *createTable* with default settings. If we do not want to receive an error sign when we try to create it next time, we need to pass *true* as the first parameter (*db.createTable<Struct> (true)*).

```
void OnStart()
{
   DBSQLite db(Database);
   if(db.isOpen())
   {
      PRTF(db.createTable<Struct>());
      PRTF(db.hasTable(typename(Struct)));
   }
}
```

The *hasTable* method checks for the presence of a table in the database by the table name. We will consider the implementation of this method in the next section. Now, let's run the script. After the first run, the table is successfully created and you can see the SQL query in the log (it is displayed with line breaks, as we formed it in the code).

```
sql=CREATE TABLE  Struct (id INTEGER PRIMARY KEY,
name TEXT ,
income REAL ,
time TEXT ); / ok
db.createTable<Struct>()=true / ok
db.hasTable(typename(Struct))=true / ok
```

The second run will return an error from the *DatabaseExecute* call, because this table already exists, which is additionally indicated by the *hasTable* result.

```
sql=CREATE TABLE  Struct (id INTEGER PRIMARY KEY,
name TEXT ,
income REAL ,
time TEXT ); / ok
database error, table Struct already exists
db.createTable<Struct>()=false / DATABASE_ERROR(5601)
db.hasTable(typename(Struct))=true / ok
```

7.6.6 Checking if a table exists in the database

The built-in *DatabaseTableExists* function allows you to check the existence of a table by its name.

bool DatabaseTableExists(int database, const string table)

The database descriptor and the table name are specified in the parameters. The result of the function call is *true* if the table exists.

Let's extend the *DBSQLite* class by adding the *hasTable* method.

```
class DBSQLite
{
   ...
   bool hasTable(const string table) const
   {
      return DatabaseTableExists(handle, table);
   }
```

The script *DBcreateTable.mq5* will check if the table has appeared.

```
void OnStart()
{
   DBSQLite db(Database);
   if(db.isOpen())
   {
      PRTF(db.execute(StringFormat("CREATE TABLE %s (msg text)", Table)));
      PRTF(db.hasTable(Table));
   }
}
```

Again, don't worry about potentially getting an error when trying to recreate. This does not affect the existence of the table in any way.

```
database error, table table1 already exists
db.execute(StringFormat(CREATE TABLE %s (msg text),Table))=false / DATABASE_ERROR(560
db.hasTable(Table)=true / ok
```

Since we are writing a generic helper class *DBSQLite*, we will provide a mechanism for deleting tables in it. SQL has the DROP command for this purpose.

```
class DBSQLite
{
   ...
   bool deleteTable(const string name) const
   {
      const static string query = "DROP TABLE '%s';";
      if(!DatabaseTableExists(handle, name)) return true;
      if(!DatabaseExecute(handle, StringFormat(query, name))) return false;
      return !DatabaseTableExists(handle, name)
         && ResetLastErrorOnCondition(_LastError == DATABASE_NO_MORE_DATA);
   }

   static bool ResetLastErrorOnCondition(const bool cond)
   {
      if(cond)
      {
         ResetLastError();
         return true;
      }
      return false;
   }
```

Before executing the query, we check for the existence of the table and immediately exit if it does not exist.

After executing the query, we additionally check whether the table has been deleted by calling *DatabaseTableExists* again. Since the absence of a table will be flagged with the DATABASE_NO_MORE_DATA error code, which is the expected result for this method, we clear the error code with *ResetLastErrorOnCondition*.

It can be more efficient to use the capabilities of SQL to exclude an attempt to delete a non-existent table: just add the phrase "IF EXISTS" to the query. Therefore, the final version of the method *deleteTable* is simplified:

```
   bool deleteTable(const string name) const
   {
      const static string query = "DROP TABLE IF EXISTS '%s';";
      return DatabaseExecute(handle, StringFormat(query, name));
   }
```

You can try to write a test script for deleting the table, but be careful not to delete a working table by mistake. Tables are deleted immediately with all data, without confirmation and without the possibility of recovery. For important projects, keep database backups.

7.6.7 Preparing bound queries: DatabasePrepare

In many cases, parameters need to be embedded in SQL queries. Since the SQL query is "originally" a string that corresponds to a special syntax, it can be formed by a simple *StringFormat* call or by concatenation, adding parameter values in the right places. We have already used this technique in queries to create a table ("CREATE TABLE %s '%s' (%s);"), but here only part of the parameters contained data (the list of values was substituted for %s inside parentheses), and the rest represented

an option and a table name. In this section, we will focus exclusively on substituting data into a query. Doing this in a native SQL way is important for several reasons.

First of all, the SQL query is only passed to the SQLite engine as a string, and there it is parsed into components, checked for correctness, and "compiled" in a certain way (of course, this is not an MQL5 compiler). The compiled query is then executed by the database. That is why we put the word "originally" in quotation marks.

When the same query needs to be executed with different parameters (for example, inserting many records into a table; we are slowly approaching this task), separately compiling and checking the query for each record is rather inefficient. It is more correct to compile the query once, and then execute it in bulk, simply substituting different values.

This compilation operation is called query preparation and is performed by the *DatabasePrepare* function.

Prepared queries have one more purpose: with their help, the SQLite engine returns the results of query execution to the MQL5 code (you will find more on this in the sections Executing prepared queries and Separate reading of query result record fields).

The last, but not least, moment associated with parameterized queries is that they protect your program from potential hacker attacks called SQL injection. First of all, this is critical for databases of public sites, where information entered by users is recorded in the database by embedding it in SQL queries: if in this case a simple format substitution '%s' is used, the user will be able to enter some long string instead of the expected data with additional SQL commands, and it will become part of the original SQL query, distorting its meaning. But if the SQL query is compiled, it cannot be changed by the input data: it is always treated as data.

Although the MQL program is not a server program, it can still store information received from the user in the database.

int DatabasePrepare(int database, const string sql, ...)

The *DatabasePrepare* function creates a handle in the specified database for the query in the string *sql*. The *database* must be opened beforehand by the *DatabaseOpen* function.

The query parameter locations are specified in the *sql* string using fragments '?1', '?2', '?3', and so on. The numbering means the parameter index used in the future when assigning an input value to it, in *DatabaseBind* functions. Numbers in the *sql* string are not required to go in order and can be repeated if the same parameter needs to be inserted in different places in the query.

> Attention! Indexing in substituted fragments '?n' starts from 1, while in *DatabaseBind* functions it starts from 0. For example, the '?1' parameter in the query body will get the value when calling *DatabaseBind* at index 0, parameter '?2' at index 1, and so on. This constant offset of 1 is maintained even if there are gaps (whether it was accidental or intentional) in the numbering of the '?n' parameters.

If you plan to bind all the parameters strictly in order, you can use an abbreviated notation: in place of each parameter, simply indicate the symbol '?' without a number: in this case, the parameters are automatically numbered. Any parameter '?' without a number gets the number which is by 1 larger than the maximum of the parameters read to the left (with explicit numbers or calculated according to the same principle, and the very first one will get the number 1, that is, '?1').

Thus, the request

```
SELECT * FROM table WHERE risk > ?1 AND signal = ?2
```

is equivalent to:

```
SELECT * FROM table WHERE risk > ? AND signal = ?
```

If some of the parameters are constant or the query is being prepared for one-time execution in order to get a result, the parameter values can be passed to the *DatabasePrepare* function as a comma-separated list instead of an ellipsis (same as in *Print* or *Comment*).

> Query parameters can only be used to set values in table columns (when writing, changing, or filtering conditions). Names of tables, columns, options, and SQL keywords cannot be passed through '?'/'?n' parameters.

The *DatabasePrepare* function itself does not fulfill the query. The handle returned from it must then be passed to *DatabaseRead* or *DatabaseReadBind* function calls. These functions execute the query and make the result available for reading (it can be one record or many). Of course, if there are parameter placeholders ('?' or '?n') in the query, and the values for them were not specified in *DatabasePrepare*, before executing the query, you need to bind the parameters and data using the appropriate *DatabaseBind* functions.

If a value is not assigned to a parameter, NULL is substituted for it during query execution.

In case of an error, the *DatabasePrepare* function will return INVALID_HANDLE.

An example of using *DatabasePrepare* will be introduced in the following sections, after exploring other features related to prepared queries.

7.6.8 Deleting and resetting prepared queries

Since prepared queries can be executed multiple times, in a loop for different parameter values, it is required to reset the query to the initial state at each iteration. This is done by the *DatabaseReset* function. But it does not make sense to call it if the prepared query is executed once.

bool DatabaseReset(int request)

The function resets the internal compiled query structures to the initial state, similarly to calling *DatabasePrepare*. However, *DatabaseReset* does not recompile the query and is therefore very fast.

It is also important that the function does not reset already established data bindings in the query if any have been made. Thus, if necessary, you can change the value of only one or a small number of parameters. Then, after calling *DatabaseReset*, you can simply call *DatabaseBind* functions only for changed parameters.

> At the time of writing the book, the MQL5 API did not provide a function to reset the data binding, an analog of the *sqlite_clear_bindings* function in the standard SQLite distribution.

In the *request* parameter, specify the valid handle of the query obtained earlier from *DatabasePrepare*. If you pass a handle of the query that was previously removed with *DatabaseFinalize* (see below), an error will be returned.

The function returns an indicator of success (*true*) or error (*false*).

The general principle of working with recurring queries is shown in the following pseudo-code. The *DatabaseBind* and *DatabaseRead* functions will be described in the following sections and will be "packed" into ORM classes.

```
struct Data                                          // structure example
{
   long count;
   double value;
   string comment;
};
Data data[];
...                                                  // getting data array
int r =
     DatabasePrepare(db, "INSERT... (?, ?, ?)")); // compile query with parameters
for(int i = 0; i < ArraySize(data); ++i)             // data loop
{
   DatabaseBind(r, 0, data[i].count);                // make data binding to parameters
   DatabaseBind(r, 1, data[i].value);
   DatabaseBind(r, 2, data[i].comment);
   DatabaseRead(r);                                  // execute request
   ...                                               // analyze or save results
   DatabaseReset(r);                                 // initial state at each iteration
}
DatabaseFinalize(r);
```

After the prepared query is no longer needed, you should release the computer resources it occupies using *DatabaseFinalize*.

void DatabaseFinalize(int request)

The function deletes the query with the specified handle, created in *DatabasePrepare*.

If an incorrect descriptor is passed, the function will record ERR_DATABASE_INVALID_HANDLE to *_LastError*.

When closing the database with *DatabaseClose*, all query handles created for it are automatically removed and invalidated.

Let's complement our ORM layer (*DBSQLite.mqh*) with a new class *DBQuery* to work with prepared queries. For now, it will only contain the initialization and deinitialization functionality inherent in the RAII concept, but we will expand it soon.

```
class DBQuery
{
protected:
   const string sql;  // query
   const int db;      // database handle (constructor argument)
   const int handle;  // prepared request handle

public:
   DBQuery(const int owner, const string s): db(owner), sql(s),
      handle(PRTF(DatabasePrepare(db, sql)))
   {
   }

   ~DBQuery()
   {
      DatabaseFinalize(handle);
   }

   bool isValid() const
   {
      return handle != INVALID_HANDLE;
   }

   virtual bool reset()
   {
      return DatabaseReset(handle);
   }
   ...
};
```

In the *DBSQLite* class, we initiate the preparation of the request in the *prepare* method by creating an instance of *DBQuery*. All query objects will be stored in the internal array *queries* in the form of autopointers, which allows the calling code not to follow their explicit deletion.

```
class DBSQLite
{
   ...
protected:
   AutoPtr<DBQuery> queries[];
public:
   DBQuery *prepare(const string sql)
   {
      return PUSH(queries, new DBQuery(handle, sql));
   }
   ...
};
```

7.6.9 Binding data to query parameters: DatabaseBind/Array

After the SQL query has been compiled by the *DatabasePrepare* function, you can use the received query handle to bind data to the query parameters, which is what the *DatabaseBind* and

DatabaseBindArray functions are for. Both functions can be called not only immediately after creating a query in *DatabasePrepare* but also after resetting the request to its initial state with *DatabaseReset* (if the request is executed many times in a loop).

The data binding step is not always required because prepared queries may not have parameters. As a rule, this situation occurs when a query returns data from SQL to MQL5, and therefore a query descriptor is required: how to read query results by their handles is described in the sections on *DatabaseRead/DatabaseReadBind* and *DatabaseColumn*-functions.

bool DatabaseBind(int request, int index, T value)

The *DatabaseBind* function sets the value of the *index* parameter for the query with the *request* handle. By default, numbering starts from 0 if the parameters in the query are marked with substituted symbols '?' (without a number). However, parameters can be specified in the query string and with a number (?1, '?5', ?21): in this case, the actual indexes to be passed to the function must be 1 less than the corresponding number in the string. This is because the numbering in the query string starts from 1.

For example, the following query requires one parameter (index 0):

```
int r = DatabasePrepare(db, "SELECT * FROM table WHERE id=?");
DatabaseBind(r, 0, 1234);
```

If the "... id=?10" substitution were used in the query string, it would be necessary to call *DatabaseBind* with index 9.

The *value* in the *DatabaseBind* prototype can be of any simple type or string. If a parameter needs to map composite type data (structures) or arbitrary binary data that can be represented as an array of bytes, use the *DatabaseBindArray* function.

The function returns *true* if successful. Otherwise, it returns *false*.

bool DatabaseBindArray(int request, int index, T &array[])

The *DatabaseBindArray* function sets the value of the *index* parameter as an array of a simple type or of simple structures (including strings) for the query with the *request* handle. This function allows you to write BLOB and NULL (the absence of a value that is considered a separate type in SQL and is not equal to 0) to the database.

Now let's go back to the *DBQuery* class in the *DBSQLite.mqh* file and add data binding support.

```
class DBQuery
{
   ...
public:
   template<typename T>
   bool bind(const int index, const T value)
   {
      return PRTF(DatabaseBind(handle, index, value));
   }
   template<typename T>
   bool bindBlob(const int index, const T &value[])
   {
      return PRTF(DatabaseBindArray(handle, index, value));
   }

   bool bindNull(const int index)
   {
      static const uchar null[] = {};
      return bindBlob(index, null);
   }
   ...
};
```

BLOB is suitable for transferring any file to the database unchanged, for example, if you first read it into a byte array using the *FileLoad* function.

The need to explicitly bind a null value is not so obvious. When inserting new records into the database, the calling program usually passes only the fields known to it, and all the missing ones (if they are not marked with the NOT NULL constraint or do not have a different DEFAULT value in the table description) will be automatically left equal to NULL by the engine. However, when using the ORM approach, it is convenient to write the entire object to the database, including the field with a unique primary key (PRIMARY KEY). The new object does not yet have this identifier, since the database itself adds it when the object is first written, so it is important to bind this field in the new object to the NULL value.

7.6.10 Executing prepared queries: DatabaseRead/Bind

Prepared queries are executed using the *DatabaseRead* and *DatabaseReadBind* functions. The first function extracts the results from the database in such a way that later individual fields can be read from each record received in turn in response, and the second extracts each matching record in its entirety, in the form of a structure.

bool DatabaseRead(int request)

On the first call, after *Database Prepare* or *DatabaseReset*, the *DatabaseRead* function executes the query and sets the internal query result pointer to the first record retrieved (if the query expects records to be returned). The *DatabaseColumn* functions enable the reading of the values of the record fields, i.e., the columns specified in the query.

On subsequent calls, the *DatabaseRead* function jumps to the next record in the query results until the end is reached.

The function returns *true* upon successful completion. The *false* value is used as an indicator of an error (for example, the database may be blocked or busy), as well as when the end of the results is normally reached, so you should analyze the code in *_LastError*. In particular, the value ERR_DATABASE_NO_MORE_DATA (5126) indicates that the results are finished.

> Attention! If *DatabaseRead* is used to execute queries that don't return data, such as INSERT, UPDATE, etc., the function immediately returns *false* and sets the error code ERR_DATABASE_NO_MORE_DATA if the request was successful.

The usual pattern of using the function is illustrated by the following pseudo-code (*DatabaseColumn* functions for different types are presented in the next section).

```
int r = DatabasePrepare(db, "SELECT... WHERE...?",
   param));                              //compiling the query(optional with parameters
while(DatabaseRead(r))                   // query execution (on the first iteration)
{                                        //    and loop through result records
   int count;
   DatabaseColumnInteger(r, 0, count); // read one field from the current record
   double number;
   DatabaseColumnDouble(r, 1, number); // read another field from the current record
   ...                                   // column types and numbers in record are dete
                                         // process the received values of count, numbe
}                                        // loop is interrupted when the end of the res
DatabaseFinalize(r);
```

Note that since the query (reading conditional data) is actually executed only once (on the very first iteration), there is no need to call *DatabaseReset*, as we did when recording changing data. However, if we want to run the query again and "walk" through the new results, calling *DatabaseReset* would be necessary.

bool DatabaseReadBind(int request, void &object)

The *DatabaseReadBind* function works in a similar way to *DatabaseRead*: the first call executes the SQL query and, in case of success (there is suitable data in the result), fills the *object* structure passed by reference with fields of the first record; subsequent calls continue moving the internal pointer through the records in the query results, filling the structure with the data of the next record.

The structure must have only numeric types and/or strings as members (arrays are not allowed), it cannot cannot inherit from or contain static members of object types.

The number of fields in the *object* structure should not exceed the number of columns in the query results; otherwise, we will get an error. The number of columns can be found dynamically using the *DatabaseColumnsCount* function, however, the caller usually needs to "know" in advance the expected data configuration according to the original request.

If the number of fields in the structure is less than the number of fields in the record, a partial read will be performed. The rest of the data can be obtained using the appropriate *DatabaseColumn* functions.

It is assumed that the field types of the structure match the data types in the result columns. Otherwise, an automatic implicit conversion will be performed, which can lead to unexpected consequences (for example, a string read into a numeric field will give 0).

In the simplest case, when we calculate a certain total value for the database records, for example, by calling an aggregate function like *SUM(column)*, *COUNT(column)*, or *AVERAGE(column)*, the result of the query will be a single record with a single field.

```
SELECT SUM(swap) FROM trades;
```

Because reading the results is related to *DatabaseColumn* functions, we will defer the development of the example until the next section, where they are presented.

7.6.11 Reading fields separately: DatabaseColumn Functions

As a result of query execution by the *DatabaseRead* or *DatabaseReadBind* functions, the program gets the opportunity to scroll through the records selected according to the specified conditions. At each iteration, in the internal structures of the SQLite engine, one specific record is allocated, the fields (columns) of which are available through the group of *DatabaseColumn* functions.

int DatabaseColumnsCount(int request)

Based on the query descriptor, the function returns the number of fields (columns) in the query results. In case of an error, it returns -1.

You can find out the number of fields in the query created in *DatabasePrepare* even before calling the *DatabaseRead* function. For other *DatabaseColumn* functions, you should initially call *DatabaseRead* (at least once).

Using the original number of a field in the query results, the program can find the field name (*DatabaseColumnName*), type (*DatabaseColumnType*), size (*DatabaseColumnSize*), and the value of the corresponding type (each type has its function).

bool DatabaseColumnName(int request, int column, string &name)

The function fills the string parameter passed by reference (*name*) with the name of the column specified by number (*column*) in the query results (*request*).

Field numbering starts from 0 and cannot exceed the value of *DatabaseColumnsCount() - 1*. This applies not only to this function but also to all other functions of the section.

The function returns *true* if successful or *false* in case of an error.

ENUM_DATABASE_FIELD_TYPE DatabaseColumnType(int request, int column)

The *DatabaseColumnType* function returns the type of the value in the specified column in the current record of the query results. The possible types are collected in the ENUM_DATABASE_FIELD_TYPE enumeration.

Identifier	Description
DATABASE_FIELD_TYPE_INVALID	Error getting type, error code in *_LastError*
DATABASE_FIELD_TYPE_INTEGER	Integer number
DATABASE_FIELD_TYPE_FLOAT	Real number
DATABASE_FIELD_TYPE_TEXT	String
DATABASE_FIELD_TYPE_BLOB	Binary data
DATABASE_FIELD_TYPE_NULL	Void (special type NULL)

More details about SQL types and their correspondence to MQL5 types were described in the section Structure (schema) of tables: data types and restrictions.

int DatabaseColumnSize(int request, int column)

The function returns the size of the value in bytes for the field with the *column* index in the current record of results of the *request* query. For example, integer values can be represented by a different number of bytes (we know this from MQL5 types, in particular, *short/int/long*).

The next group of functions allows you to get the value of a particular type from the corresponding field of the record. To read values from the next record, you need to call *DatabaseRead* again.

bool DatabaseColumnText(int request, int column, string &value)
bool DatabaseColumnInteger(int request, int column, int &value)
bool DatabaseColumnLong(int request, int column, long &value)
bool DatabaseColumnDouble(int request, int column, double &value)
bool DatabaseColumnBlob(int request, int column, void &data[])

All functions return *true* on success and put the field value in the receiving variable *value*. The only special case is the function *DatabaseColumnBlob*, which passes an array of an arbitrary simple type or simple structures as an output variable. By specifying the *uchar[]* array as the most versatile option, you can read the byte representation of any value (including binary files marked with the DATABASE_FIELD_TYPE_BLOB type).

> The SQLite engine does not check that for a column a function corresponding to its type is called. If the types are inadvertently or intentionally different, the system will automatically implicitly convert the field value to the type of the receiving variable.

Now, after getting familiar with the majority of *Database* functions, we can complete the development of a set of SQL classes in the *DBSQLite.mqh* file and proceed to practical examples.

7.6.12 Examples of CRUD operations in SQLite via ORM objects

We have studied all the functions required for the implementation of the complete lifecycle of information in the database, that is CRUD (Create, Read, Update, Delete). But before proceeding to practice, we need to complete the ORM layer.

From the previous few sections, it is already clear that the unit of work with the database is a record: it can be a record in a database table or an element in the results of a query. To read a single record at the ORM level, let's introduce the DBRow class. Each record is generated by an SQL query, so its handle is passed to the constructor.

As we know, a record can consist of several columns, the number and types of which allow us to find *DatabaseColumn* functions. To expose this information to an MQL program using *DBRow*, we reserved the relevant variables: *columns* and an array of structures *DBRowColumn* (the last one contains three fields for storing the name, type, and size of the column).

In addition, *DBRow* objects may, if necessary, cache in themselves the values obtained from the database. For this purpose, the *data* array of type *MqlParam* is used. Since we do not know in advance what type of values will be in a particular column, we use *MqlParam* as a kind of universal type *Variant* available in other programming environments.

```
class DBRow
{
protected:
   const int query;
   int columns;
   DBRowColumn info[];
   MqlParam data[];
   const bool cache;
   int cursor;
   ...
public:
   DBRow(const int q, const bool c = false):
      query(q), cache(c), columns(0), cursor(-1)
   {
   }

   int length() const
   {
      return columns;
   }
   ...
};
```

The *cursor* variable tracks the current record number from the query results. Until the request is completed, *cursor* equals -1.

The virtual method *DBread* is responsible for executing the query; it calls *DatabaseRead*.

```
protected:
   virtual bool DBread()
   {
      return PRTF(DatabaseRead(query));
   }
```

We will see later why we needed a virtual method. The public method *next*, which uses *DBread*, provides "scrolling" through the result records and looks like this.

```
public:
   virtual bool next()
   {
      ...
      const bool success = DBread();
      if(success)
      {
         if(cursor == -1)
         {
            columns = DatabaseColumnsCount(query);
            ArrayResize(info, columns);
            if(cache) ArrayResize(data, columns);
            for(int i = 0; i < columns; ++i)
            {
               DatabaseColumnName(query, i, info[i].name);
               info[i].type = DatabaseColumnType(query, i);
               info[i].size = DatabaseColumnSize(query, i);
               if(cache) data[i] = this[i]; // overload operator[](int)
            }
         }
         ++cursor;
      }
      return success;
   }
```

If the query is accessed for the first time, we allocate memory and read the column information. If caching was requested, we additionally populate the *data* array. To do this, the overloaded operator '[]' is called for each column. In it, depending on the type of value, we call the appropriate *DatabaseColumn* function and put the resulting value in one or another field of the *MqlParam* structure.

```
virtual MqlParam operator[](const int i = 0) const
{
   MqlParam param = {};
   if(i < 0 || i >= columns) return param;
   if(ArraySize(data) > 0 && cursor != -1) // if there is a cache, return from it
   {
      return data[i];
   }
   switch(info[i].type)
   {
   case DATABASE_FIELD_TYPE_INTEGER:
      switch(info[i].size)
      {
      case 1:
         param.type = TYPE_CHAR;
         break;
      case 2:
         param.type = TYPE_SHORT;
         break;
      case 4:
         param.type = TYPE_INT;
         break;
      case 8:
      default:
         param.type = TYPE_LONG;
         break;
      }
      DatabaseColumnLong(query, i, param.integer_value);
      break;
   case DATABASE_FIELD_TYPE_FLOAT:
      param.type = info[i].size == 4 ? TYPE_FLOAT : TYPE_DOUBLE;
      DatabaseColumnDouble(query, i, param.double_value);
      break;
   case DATABASE_FIELD_TYPE_TEXT:
      param.type = TYPE_STRING;
      DatabaseColumnText(query, i, param.string_value);
      break;
   case DATABASE_FIELD_TYPE_BLOB: // return base64 only for information we can't
      {                           // return binary data in MqlParam - exact
         uchar blob[];            // representation of binary fields is given by g
         DatabaseColumnBlob(query, i, blob);
         uchar key[], text[];
         if(CryptEncode(CRYPT_BASE64, blob, key, text))
         {
            param.string_value = CharArrayToString(text);
         }
      }
      param.type = TYPE_BLOB;
      break;
   case DATABASE_FIELD_TYPE_NULL:
      param.type = TYPE_NULL;
```

```
            break;
         }
         return param;
      }
```

The *getBlob* method is provided to fully read binary data from BLOB fields (use type *uchar* as S to get a byte array if there is no more specific information about the content format).

```
   template<typename S>
   int getBlob(const int i, S &object[])
   {
      ...
      return DatabaseColumnBlob(query, i, object);
   }
```

For the described methods, the process of executing a query and reading its results can be represented by the following pseudo-code (it leaves behind the scenes the existing *DBSQLite* and *DBQuery* classes, but we will bring them all together soon):

```
int query = ...
DBRow *row = new DBRow(query);
while(row.next())
{
   for(int i = 0; i < row.length(); ++i)
   {
      StructPrint(row[i]); // print the i-th column as an MqlParam structure
   }
}
```

It is not elegant to explicitly write a loop through the columns every time, so the class provides a method for obtaining the values of all fields of the record.

```
   void readAll(MqlParam &params[]) const
   {
      ArrayResize(params, columns);
      for(int i = 0; i < columns; ++i)
      {
         params[i] = this[i];
      }
   }
```

Also, the class received for convenience overloads of the operator '[]' and the *getBlob* method for reading fields by their names instead of indexes. For example,

```
class DBRow
{
   ...
public:
   int name2index(const string name) const
   {
      for(int i = 0; i < columns; ++i)
      {
         if(name == info[i].name) return i;
      }
      Print("Wrong column name: ", name);
      SetUserError(3);
      return -1;
   }

   MqlParam operator[](const string name) const
   {
      const int i = name2index(name);
      if(i != -1) return this[i]; // operator()[int] overload
      static MqlParam param = {};
      return param;
   }
   ...
};
```

This way you can access selected columns.

```
int query = ...
DBRow *row = new DBRow(query);
for(int i = 1; row.next(); )
{
   Print(i++, " ", row["trades"], " ", row["profit"], " ", row["drawdown"]);
}
```

But still getting the elements of the record individually, as a *MqlParam* array, can not be called a truly OOP approach. It would be preferable to read the entire database table record into an object, an application structure. Recall that the MQL5 API provides a suitable function: *DatabaseReadBind*. This is where we get the advantage of the ability to describe a derived class *DBRow* and override its virtual method *DBRead*.

This class of *DBRowStruct* is a template and expects as parameter S one of the simple structures allowed to be bound in *DatabaseReadBind*.

```
template<typename S>
class DBRowStruct: public DBRow
{
protected:
   S object;

   virtual bool DBread() override
   {
      // NB: inherited structures and nested structures are not allowed;
      // count of structure fields should not exceed count of columns in table/query
      return PRTF(DatabaseReadBind(query, object));
   }

public:
   DBRowStruct(const int q, const bool c = false): DBRow(q, c)
   {
   }

   S get() const
   {
      return object;
   }
};
```

With a derived class, we can get objects from the base almost seamlessly.

```
int query = ...
DBRowStruct<MyStruct> *row = new DBRowStruct<MyStruct>(query);
MyStruct structs[];
while(row.next())
{
   PUSH(structs, row.get());
}
```

Now it's time to turn the pseudo-code into working code by linking *DBRow/DBRowStruct* with *DBQuery*. In *DBQuery*, we add an autopointer to the *DBRow* object, which will contain data about the current record from the results of the query (if it was executed). Using an autopointer frees the calling code from worrying about freeing *DBRow* objects: they are deleted either with *DBQuery* or when re-created due to query restart (if required). The initialization of the *DBRow* or *DBRowStruct* object is completed by a template method *start*.

```
class DBQuery
{
protected:
   ...
   AutoPtr<DBRow> row;    // current entry
public:
   DBQuery(const int owner, const string s): db(owner), sql(s),
      handle(PRTF(DatabasePrepare(db, sql)))
   {
      row = NULL;
   }

   template<typename S>
   DBRow *start()
   {
      DatabaseReset(handle);
      row = typename(S) == "DBValue" ? new DBRow(handle) : new DBRowStruct<S>(handle)
      return row[];
   }
```

The *DBValue* type is a dummy structure that is needed only to instruct the program to create the underlying *DBRow* object, without violating the compilability of the line with the *DatabaseReadBind* call.

With the *start* method, all of the above pseudo-code fragments become working due to the following preparation of the request:

```
DBSQLite db("MQL5Book/DB/Example1");                              // open base
DBQuery *query = db.prepare("PRAGMA table_xinfo('Struct')");      // prepare the reques
DBRowStruct<DBTableColumn> *row = query.start<DBTableColumn>(); // get object cursor
DBTableColumn columns[];                                          // receiving array of
while(row.next())             // loop while there are records in the query result
{
   PUSH(columns, row.get());  // getting an object from the current record
}
ArrayPrint(columns);
```

This example reads meta-information about the configuration of a particular table from the database (we created it in the example *DBcreateTableFromStruct.mq5* in the section Executing queries without MQL5 data binding): each column is described by a separate record with several fields (SQLite standard), which is formalized in the structure *DBTableColumn*.

```
struct DBTableColumn
{
   int cid;              // identifier (serial number)
   string name;          // name
   string type;          // type
   bool not_null;        // attribute NOT NULL (yes/no)
   string default_value; // default value
   bool primary_key;     // PRIMARY KEY sign (yes/no)
};
```

To save the user from having to write a loop every time with the translation of results records into structure objects, the *DBQuery* class provides a template method *readAll* that populates a referenced

array of structures with information from the query results. A similar *readAll* method fills an array of pointers to *DBRow* objects (this is more suitable for receiving the results of synthetic queries with columns from different tables).

In a quartet of operations, the CRUD method *DBRowStruct::get* is responsible for the letter R (Read). To make the reading of an object more functionally complete, we will support point recovery of an object from the database by its identifier.

The vast majority of tables in SQLite databases have a primary key *rowid* (unless the developer for one reason or another used the "WITHOUT ROWID" option in the description), so the new *read* method will take a key value as a parameter. By default, the name of the table is assumed to be equal to the type of the receiving structure but can be changed to an alternative one through the *table* parameter. Considering that such a request is a one-time request and should return one record, it makes sense to place the *read* method directly to the class *DBSQLite* and manage short-lived objects *DBQuery* and *DBRowStruct<S>* inside.

```
class DBSQLite
{
   ...
public:
   template<typename S>
   bool read(const long rowid, S &s, const string table = NULL,
      const string column = "rowid")
   {
      const static string query = "SELECT * FROM '%s' WHERE %s=%ld;";
      const string sql = StringFormat(query,
         StringLen(table) ? table : typename(S), column, rowid);
      PRTF(sql);
      DBQuery q(handle, sql);
      if(!q.isValid()) return false;
      DBRowStruct<S> *r = q.start<S>();
      if(r.next())
      {
         s = r.get();
         return true;
      }
      return false;
   }
};
```

The main work is done by the SQL query "SELECT * FROM '%s' WHERE %s=%ld;", which returns a record with all fields from the specified table by matching the *rowid* key.

Now you can create a specific object from the database like this (it is assumed that the identifier of interest to us must be stored somewhere).

```
DBSQLite db("MQL5Book/DB/Example1");
long rowid = ... // ill in the identifier
Struct s;
if(db.read(rowid, s))
   StructPrint(s);
```

Finally, in some complex cases where maximum flexibility in querying is required (for example, a combination of several tables, usually a SELECT with a JOIN, or nested queries), we still have to allow an explicit SQL command to get a selection, although this violates the ORM principle. This possibility is opened by the method *DBSQLite::prepare*, which we have already presented in the context of the management of prepared queries.

We have considered all the main ways of reading.

However, we don't have anything to read from the database yet, because we skipped the step of adding records.

Let's try to implement object creation (C). Recall that in our object concept, structure types semi-automatically define database tables (using DB_FIELD macros). For example, the *Struct* structure allowed the creation of a "Struct" table in the database with a set of columns corresponding to the fields of the structure. We provided this with a template method *createTable* in the *DBSQLite* class. Now, by analogy, you need to write a template method *insert*, which would add a record to this table.

An object of a structure is passed to the method, for the type of which the filled *DBEntity<S>::prototype* <S> array must exist (it is filled with macros). Thanks to this array, we can form a list of parameters (more precisely, their substitutes '?n'): this is done by the static method *qlist*. However, the preparation of the query is still half a battle. In the code below, we will need to bind the input data based on the properties of the object.

A "RETURNING rowid" statement has been added to the "INSERT" command, so when the query succeeds, we expect a single result row with one value: new *rowid*.

```
class DBSQLite
{
   ...
public:
   template<typename S>
   long insert(S &object, const string table = NULL)
   {
      const static string query = "INSERT INTO '%s' VALUES(%s) RETURNING rowid;";
      const int n = ArrayRange(DBEntity<S>::prototype, 0);
      const string sql = StringFormat(query,
         StringLen(table) ? table : typename(S), qlist(n));
      PRTF(sql);
      DBQuery q(handle, sql);
      if(!q.isValid()) return 0;
      DBRow *r = q.start<DBValue>();
      if(object.bindAll(q))
      {
         if(r.next()) // the result should be one record with one new rowid value
         {
            return object.rowid(r[0].integer_value);
         }
      }
      return 0;
   }

   static string qlist(const int n)
   {
      string result = "?1";
      for(int i = 1; i < n; ++i)
      {
         result += StringFormat(",?%d", (i + 1));
      }
      return result;
   }
};
```

The source code of the *insert* method has one point to which special attention should be paid. To bind values to query parameters, we call the *object.bindAll(q)* method. This means that in the application structure that you want to integrate with the base, you need to implement such a method that provides all member variables for the engine.

In addition, to identify objects, it is assumed that there is a field with a primary key, and only the object "knows" what this field is. So, the structure has the *rowid* method, which serves a dual action: first, it transfers the record identifier assigned in the database to the object, and second, it allows finding out this identifier from the object, if it has already been assigned earlier.

The *DBSQLite::update* (U) method for changing a record is similar in many ways to *insert*, and therefore it is proposed to familiarize yourself with it. Its basis is the SQL query "UPDATE '%s' SET (%s)=(%s) WHERE rowid=%ld;", which is supposed to pass all the fields of the structure (*bindAll()* object) and key (*rowid()* object).

Finally, we mention that the point deletion (D) of a record by an object is implemented in the method *DBSQLite::remove* (word *delete* is an MQL5 operator).

Let's show all methods in an example script *DBfillTableFromStructArray.mq5*, where the *Struct* new structure is defined.

We will make several values of commonly used types as fields of the structure.

```
struct Struct
{
   long id;
   string name;
   double number;
   datetime timestamp;
   string image;
   ...
};
```

In the string field *image*, the calling code will specify the name of the graphic resource or the name of the file, and at the time of binding to the database, the corresponding binary data will be copied as a BLOB. Subsequently, when we read data from the database into *Struct* objects, the binary data will end up in the *image* string but, of course, with distortions (because the line will break on the first null byte). To accurately extract BLOBs from the database, you will need to call the method *DBRow::getBlob* (based on *DatabaseColumnBlob*).

Creating meta-information about fields of the *Struct* structure provides the following macros. Based on them, an MQL program can automatically create a table in the database for *Struct* objects, as well as initiate the binding of the data passed to the queries based on the properties of the objects (this binding should not be confused with the reverse binding for obtaining query results, i.e. *DatabaseReadBind*).

```
DB_FIELD_C1(Struct, long, id, DB_CONSTRAINT::PRIMARY_KEY);
DB_FIELD(Struct, string, name);
DB_FIELD(Struct, double, number);
DB_FIELD_C1(Struct, datetime, timestamp, DB_CONSTRAINT::CURRENT_TIMESTAMP);
DB_FIELD(Struct, blob, image);
```

To fill a small test array of structures, the script has input variables: they specify a trio of currencies whose quotes will fall into the *number* field. We have also embedded two standard images into the script in order to test the work with BLOBs: they will "go" to the *image* field. The *timestamp* field will be automatically populated by our ORM classes with the current insertion or modification timestamp of the record. The primary key in the *id* field will have to be populated by SQLite itself.

```
#resource "\\Images\\euro.bmp"
#resource "\\Images\\dollar.bmp"

input string Database = "MQL5Book/DB/Example2";
input string EURUSD = "EURUSD";
input string USDCNH = "USDCNH";
input string USDJPY = "USDJPY";
```

Since the values for the input query variables (those same '?n') are bound, ultimately, using the functions *DatabaseBind* or *DatabaseBindArray* under the numbers, our *bindAll* structure in the method should establish a correspondence between the numbers and their fields: a simple numbering is assumed in the order of declaration.

```
struct Struct
{
   ...
   bool bindAll(DBQuery &q) const
   {
      uint pixels[] = {};
      uint w, h;
      if(StringLen(image))                // load binary data
      {
         if(StringFind(image, "::") == 0) // this is a resource
         {
            ResourceReadImage(image, pixels, w, h);
            // debug/test example (not BMP, no header)
            FileSave(StringSubstr(image, 2) + ".raw", pixels);
         }
         else                             // it's a file
         {
            const string res = "::" + image;
            ResourceCreate(res, image);
            ResourceReadImage(res, pixels, w, h);
            ResourceFree(res);
         }
      }
      // when id = NULL, the base will assign a new rowid
      return (id == 0 ? q.bindNull(0) : q.bind(0, id))
         && q.bind(1, name)
         && q.bind(2, number)
         // && q.bind(3, timestamp) // this field will be autofilled CURRENT_TIMESTAM
         && q.bindBlob(4, pixels);
   }
   ...
};
```

Method *rowid* is very simple.

```
struct Struct
{
   ...
   long rowid(const long setter = 0)
   {
      if(setter) id = setter;
      return id;
   }
};
```

Having defined the structure, we describe a test array of 4 elements. Only 2 of them have attached images. All objects have zero identifiers because they are not yet in the database.

```
Struct demo[] =
{
   {0, "dollar", 1.0, 0, "::Images\\dollar.bmp"},
   {0, "euro", SymbolInfoDouble(EURUSD, SYMBOL_ASK), 0, "::Images\\euro.bmp"},
   {0, "yuan", 1.0 / SymbolInfoDouble(USDCNH, SYMBOL_BID), 0, NULL},
   {0, "yen", 1.0 / SymbolInfoDouble(USDJPY, SYMBOL_BID), 0, NULL},
};
```

In the main *OnStart* function, we create or open a database (by default *MQL5Book/DB/Example2.sqlite*). Just in case, we try to delete the "Struct" table in order to ensure reproducibility of the results and debugging when the script is repeated, then we will create a table for the *Struct* structure.

```
void OnStart()
{
   DBSQLite db(Database);
   if(!PRTF(db.isOpen())) return;
   PRTF(db.deleteTable(typename(Struct)));
   if(!PRTF(db.createTable<Struct>(true))) return;
   ...
```

Instead of adding objects one at a time, we use a loop:

```
  // -> this option (set aside)
   for(int i = 0; i < ArraySize(demo); ++i)
   {
      PRTF(db.insert(demo[i])); // get a new rowid on each call
   }
```

In this loop, we will use an alternative implementation of the *insert* method, which takes an array of objects as input at once and processes them in a single request, which is more efficient (but the general ditch of the method is the previously considered *insert* method for one object).

```
   db.insert(demo);  // new rowids are placed in objects
   ArrayPrint(demo);
   ...
```

Now let's try to select records from the database according to some conditions, for example, those that do not have an image assigned. To do this, let's prepare an SQL query wrapped in the *DBQuery* object, and then we get its results in two ways: through binding to *Struct* structures or via the instances of the generic class *DBRow*.

```
DBQuery *query = db.prepare(StringFormat("SELECT * FROM %s WHERE image IS NULL",
   typename(Struct)));

// approach 1: application type of the Struct structure
Struct result[];
PRTF(query.readAll(result));
ArrayPrint(result);

query.reset(); // reset the query to try again

// approach 2: generic DBRow record container with MqlParam values
DBRow *rows[];
query.readAll(rows); // get DBRow objects with cached values
for(int i = 0; i < ArraySize(rows); ++i)
{
   Print(i);
   MqlParam fields[];
   rows[i].readAll(fields);
   ArrayPrint(fields);
}
...
```

Both options should give the same result, albeit presented differently (see the log below).

Next, our script pauses for 1 second so that we can notice the changes in the timestamps of the next entries that we will change.

```
Print("Pause...");
Sleep(1000);
...
```

To objects in the *result[]* array, we assign the "yuan.bmp" image located in the folder next to the script. Then we update the objects in the database.

```
for(int i = 0; i < ArraySize(result); ++i)
{
   result[i].image = "yuan.bmp";
   db.update(result[i]);
}
...
```

After running the script, you can make sure that all four records have BLOBs in the database navigator built into MetaEditor, as well as the difference in timestamps for the first two and the last two records.

Let's demonstrate the extraction of binary data. We will first see how a BLOB is mapped to the *image* string field (binary data is not for the log, we only do this for demonstration purposes).

```
const long id1 = 1;
Struct s;
if(db.read(id1, s))
{
   Print("Length of string with Blob: ", StringLen(s.image));
   Print(s.image);
}
...
```

Then we read the entire data with *getBlob* (total length is greater than the line above).

```
DBRow *r;
if(db.read(id1, r, "Struct"))
{
   uchar bytes[];
   Print("Actual size of Blob: ", r.getBlob("image", bytes));
   FileSave("temp.bmp.raw", bytes); // not BMP, no header
}
```

We need to get the *temp.bmp.raw* file, identical to *MQL5/Files/Images/dollar.bmp.raw*, which is created in the method *Struct::bindAll* for debugging purposes. Thus, it is easy to verify the exact correspondence of written and read binary data.

> Note that since we are storing the resource's binary content in the database, it is not a BMP source file: resources produce color normalization and store a headerless array of pixels with meta-information about the image.

While running, the script generates a detailed log. In particular, the creation of a database and a table is marked with the following lines.

```
db.isOpen()=true / ok
db.deleteTable(typename(Struct))=true / ok
sql=CREATE TABLE IF NOT EXISTS Struct (id INTEGER PRIMARY KEY,
name TEXT ,
number REAL ,
timestamp INTEGER CURRENT_TIMESTAMP,
image BLOB ); / ok
db.createTable<Struct>(true)=true / ok
```

The SQL query for inserting an array of objects is prepared once and then executed many times with pre-binding different data (only one iteration is shown here). The number of *DatabaseBind* function calls matches the '?n' variables in the query ('?4' is automatically replaced by our classes with the SQL STRFTIME('%s') function call to get the current UTC timestamp).

```
sql=INSERT INTO 'Struct' VALUES(?1,?2,?3,STRFTIME('%s'),?5) RETURNING rowid; / ok
DatabasePrepare(db,sql)=131073 / ok
DatabaseBindArray(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBindArray(handle,index,value)=true / ok
DatabaseRead(query)=true / ok
...
```

Next, an array of structures with already assigned primary keys *rowid* is output to the log in the first column.

```
    [id]   [name] [number]         [timestamp]               [image]
[0]    1 "dollar"  1.00000 1970.01.01 00:00:00 "::Images\dollar.bmp"
[1]    2 "euro"    1.00402 1970.01.01 00:00:00 "::Images\euro.bmp"
[2]    3 "yuan"    0.14635 1970.01.01 00:00:00 null
[3]    4 "yen"     0.00731 1970.01.01 00:00:00 null
```

Selecting records without images gives the following result (we execute this query twice with different methods: the first time we fill the array of *Struct* structures, and the second is the *DBRow* array, from which for each field we get the "value" in the form of *MqlParam*).

```
DatabasePrepare(db,sql)=196609 / ok
DatabaseReadBind(query,object)=true / ok
DatabaseReadBind(query,object)=true / ok
DatabaseReadBind(query,object)=false / DATABASE_NO_MORE_DATA(5126)
query.readAll(result)=true / ok
    [id] [name] [number]         [timestamp] [image]
[0]    3 "yuan"  0.14635 2022.08.20 13:14:38 null
[1]    4 "yen"   0.00731 2022.08.20 13:14:38 null
DatabaseRead(query)=true / ok
DatabaseRead(query)=true / ok
DatabaseRead(query)=false / DATABASE_NO_MORE_DATA(5126)
0
    [type] [integer_value] [double_value] [string_value]
[0]      4               3        0.00000 null
[1]     14               0        0.00000 "yuan"
[2]     13               0        0.14635 null
[3]     10      1661001278        0.00000 null
[4]      0               0        0.00000 null
1
    [type] [integer_value] [double_value] [string_value]
[0]      4               4        0.00000 null
[1]     14               0        0.00000 "yen"
[2]     13               0        0.00731 null
[3]     10      1661001278        0.00000 null
[4]      0               0        0.00000 null
...
```

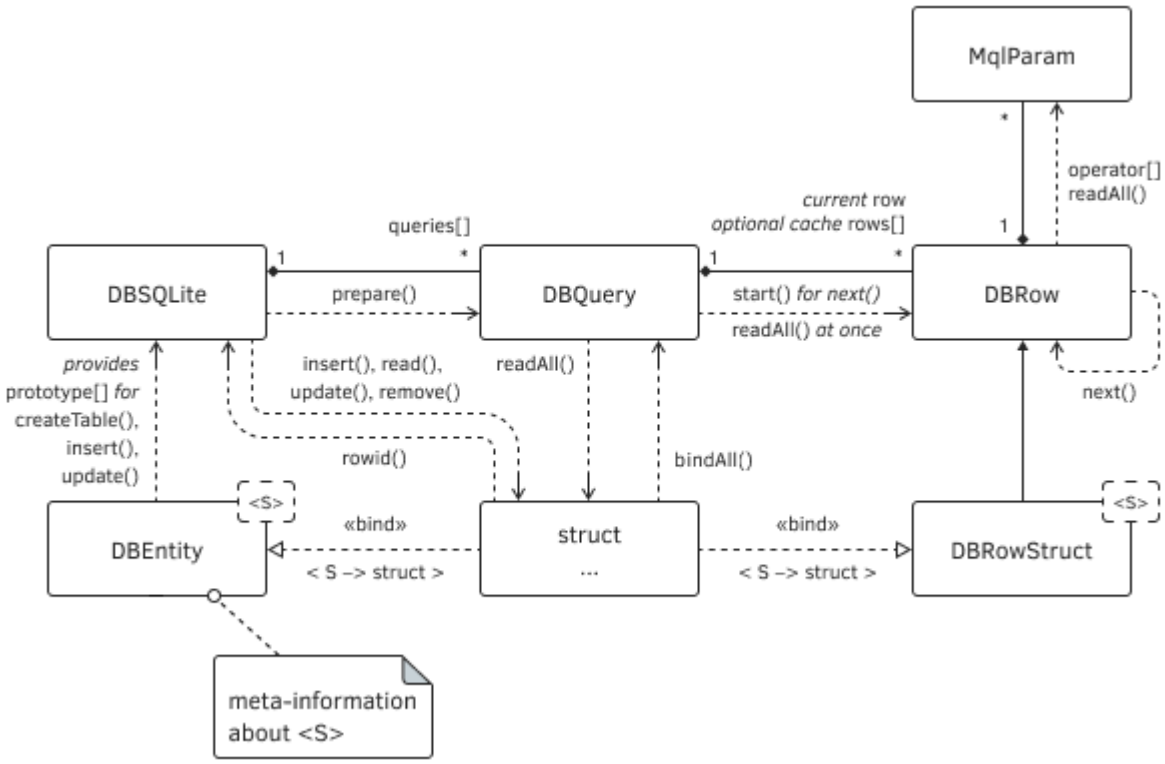
The second part of the script updates a couple of found records without images and adds BLOBs to them.

```
Pause...
sql=UPDATE 'Struct' SET (id,name,number,timestamp,image)=
   (?1,?2,?3,STRFTIME('%s'),?5) WHERE rowid=3; / ok
DatabasePrepare(db,sql)=262145 / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBindArray(handle,index,value)=true / ok
DatabaseRead(handle)=false / DATABASE_NO_MORE_DATA(5126)
sql=UPDATE 'Struct' SET (id,name,number,timestamp,image)=
   (?1,?2,?3,STRFTIME('%s'),?5) WHERE rowid=4; / ok
DatabasePrepare(db,sql)=327681 / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBind(handle,index,value)=true / ok
DatabaseBindArray(handle,index,value)=true / ok
DatabaseRead(handle)=false / DATABASE_NO_MORE_DATA(5126)
...
```

Finally, when getting binary data in two ways – incompatible, via the *image* string field as a result of reading the entire *DatabaseReadBind* object (this is only done to visualize the sequence of bytes in the log) and compatible, via *DatabaseRead* and *DatabaseColumnBlob* – we get different results: of course, the second method is correct: the length and contents of the BLOB in 4096 bytes are restored.

```
sql=SELECT * FROM 'Struct' WHERE rowid=1; / ok
DatabasePrepare(db,sql)=393217 / ok
DatabaseReadBind(query,object)=true / ok
Length of string with Blob: 922
□7?□7?□7?□7?□7?□7?ł7?ő6?ũ6?Ĩ5???5?¦5?Ĩ5?ǫ6?ő6?Ő7?ł7?ł7?□7?□7?□7?□7?□7?□7?□7?□7?□7?
sql=SELECT * FROM 'Struct' WHERE rowid=1; / ok
DatabasePrepare(db,sql)=458753 / ok
DatabaseRead(query)=true / ok
Actual size of Blob: 4096
```

Summarizing the intermediate result of developing our own ORM wrapper, we present a generalized scheme of its classes.



ORM Class Diagram (MQL5<->SQL)

7.6.13 Transactions

SQLite supports *transactions* – logically related sets of actions that can be performed either entirely or not performed at all, which ensures the consistency of data in the database.

> The concept of a *transaction* has a new meaning in the context of databases, different from what we used to describe in trade transactions. A trade transaction means a separate operation on the entities of a trading account, including orders, deals, and positions.

Transactions provide 4 main characteristics of database changes:

- Atomic (indivisible) – upon successful completion of the transaction, all the changes included in it will get into the database, and in case of an error, nothing will get into it.
- Consistent – the current correct state of the base can only change to another correct state (intermediate, according to application logic, states are excluded).
- Isolated – changes in the transaction of the current connection are not visible until the end of this transaction in other connections to the same database and vice versa, changes from other connections are not visible in the current connection while there is an incomplete transaction.
- Durable – changes from a successful transaction are guaranteed to be stored in the database.

The terms for these characteristics – Atomic, Consistent, Isolated, and Durable – form the acronym ACID, well-known in database theory.

Even if the normal course of the program is interrupted due to a system failure, the database will retain its working state.

Most often, the use of transactions is illustrated by the example of a banking system, in which funds are transferred from the account of one client to the account of another. It should affect two records with

customer balances: in one, the balance is reduced by the amount of the transfer, and in the other, it is increased. A situation where only one of these changes applies would upset the balance of bank accounts: depending on which operation failed, the transferred amount could disappear or, conversely, come from nowhere.

It is possible to give an example that is closer to trading practice but on the basis of the "opposite" principle. The fact is that the system for accounting for orders, deals, and positions in MetaTrader 5 is not transactional.

In particular, as we know from the chapter on Creating Expert Advisors, a triggered order (market or pending), missing from the list of active ones, may not immediately be displayed in the list of positions. Therefore, in order to analyze the actual result, it is necessary to implement in the MQL program the expectation of updating (actualization) the trading environment. If the accounting system was based on transactions, then the execution of an order, the registration of a transaction in history, and the appearance of a position would be enclosed in a transaction and coordinated with each other. The terminal developers have chosen a different approach: to return any modifications of the trading environment as quickly and asynchronously as possible, and their integrity must be monitored by an MQL program.

Any SQL command that changes the base (that is, in fact, everything except SELECT) will automatically be wrapped in a transaction if this was not done explicitly beforehand.

The MQL5 API provides 3 functions for managing transactions: *DatabaseTransactionBegin*, *DatabaseTransactionCommit*, and *DatabaseTransactionRollback*. All functions return *true* if successful or *false* in case of an error.

bool DatabaseTransactionBegin(int database)

The *DatabaseTransactionBegin* function starts executing a transaction in the database with the specified descriptor obtained from *DatabaseOpen*.

All subsequent changes made to the database are accumulated in the internal transaction cache and do not get into the database until the *DatabaseTransactionCommit* function is called.

Transactions in MQL5 cannot be nested: if a transaction has already been started, then re-calling *DatabaseTransactionBegin* will return an error flag and output a message to the log.

```
database error, cannot start a transaction within a transaction
DatabaseTransactionBegin(db)=false / DATABASE_ERROR(5601)
```

Respectively, you cannot try and complete the transaction multiple times.

bool DatabaseTransactionCommit(int database)

The function *DatabaseTransactionCommit* ends a transaction previously started in the database with the specified handle and applies all accumulated changes (saves them). If an MQL program starts a transaction but does not apply it before closing the database, all changes will be lost.

If necessary, the program can undo the transaction, and thus all changes since the beginning of the transaction.

bool DatabaseTransactionRollback(int database)

The *DatabaseTransactionRollback* function performs a "rollback" of all actions included in the previously started transaction for the database with the *database* handle.

Let's complete the *DBSQLite* class methods for working with transactions, taking into account the restriction on their nesting, which we will calculate in the *transaction* variable. If it is 0, the *begin* method starts a transaction by calling *DatabaseTransactionBegin*. All subsequent attempts to start a transaction simply increase the counter. In the *commit* method, we decrement the counter, and when it reaches 0 we call *DatabaseTransactionCommit*.

```
class DBSQLite
{
protected:
   int transaction;
   ...
public:
   bool begin()
   {
      if(transaction > 0)    // already in transaction
      {
         transaction++;      // keep track of the nesting level
         return true;
      }
      return (bool)(transaction = PRTF(DatabaseTransactionBegin(handle)));
   }

   bool commit()
   {
      if(transaction > 0)
      {
         if(--transaction == 0) // outermost transaction
            return PRTF(DatabaseTransactionCommit(handle));
      }
      return false;
   }
   bool rollback()
   {
      if(transaction > 0)
      {
         if(--transaction == 0)
            return PRTF(DatabaseTransactionRollback(handle));
      }
      return false;
   }
};
```

Also, let's create the *DBTransaction* class, which will allow describing objects inside blocks (for example, functions) that ensure the automatic start of a transaction with its subsequent application (or cancellation) when the program exits the block.

```
class DBTransaction
{
   DBSQLite *db;
   const bool autocommit;
public:
   DBTransaction(DBSQLite &owner, const bool c = false): db(&owner), autocommit(c)
   {
      if(CheckPointer(db) != POINTER_INVALID)
      {
         db.begin();
      }
   }

   ~DBTransaction()
   {
      if(CheckPointer(db) != POINTER_INVALID)
      {
         autocommit ? db.commit() : db.rollback();
      }
   }

   bool commit()
   {
      if(CheckPointer(db) != POINTER_INVALID)
      {
         const bool done = db.commit();
         db = NULL;
         return done;
      }
      return false;
   }
};
```

The policy of using such objects eliminates the need to process various options for exiting a block (function).

```
void DataFunction(DBSQLite &db)
{
   DBTransaction tr(db);
   DBQuery *query = db.prepare("UPDATE..."); // batch changes
   ... // base modification
   if(... /* error1 */) return;             // automatic rollback
   ... // base modification
   if(... /* error2 */) return;             // automatic rollback
   tr.commit();
}
```

For an object to automatically apply changes at any stage, pass *true* in the second parameter of its constructor.

```
void DataFunction(DBSQLite &db)
{
   DBTransaction tr(db, true);
   DBQuery *query = db.prepare("UPDATE...");  // batch changes
   ... // base modification
   if(... /* condition1 */) return;           // automatic commit
   ... // base modification
   if(... /* condition2 */) return;           // automatic commit
   ...
}                                             // automatic commit
```

You can describe the *DBTransaction* object inside the loop and then, at each iteration, a separate transaction will start and close.

A demonstration of transactions will be given in the section An example of searching for a trading strategy using SQLite.

7.6.14 Import and export of database tables

MQL5 allows the export and import of individual database tables to/from CSV files. Export/import of the entire database, as a file with SQL commands, is not provided.

long DatabaseImport(int database, const string table, const string filename, uint flags,
  const string separator, ulong skip_rows, const string comment_chars)

The *DatabaseImport* function imports data from the specified file into the table. The open database descriptor and the table name are given by the first two parameters.

If tables named *table* does not exist, it will be created automatically. The names and types of fields in the table will be recognized automatically based on the data contained in the file.

The imported file can be not only a ready-made CSV file but also a ZIP archive with a CSV file. The filename may contain a path. The file is searched relative to the *MQL5/Files* directory.

Valid flags that can be bitwise combined are described in the ENUM_DATABASE_IMPORT_FLAGS enumeration:

- DATABASE_IMPORT_HEADER – the first line contains the names of the table fields
- DATABASE_IMPORT_CRLF – for line breaks, the CRLF character sequence is used
- DATABASE_IMPORT_APPEND – add data to an existing table
- DATABASE_IMPORT_QUOTED_STRINGS – string values in double quotes
- DATABASE_IMPORT_COMMON_FOLDER – common folder of terminals

Parameter *separator* sets the delimiter character in the CSV file.

Parameter *skip_rows* skips the specified number of leading lines in the file.

Parameter *comment_chars* contains the characters used in the file as a comment flag. Lines starting with any of these characters will be considered comments and will not be imported.

The function returns the number of imported rows or -1 on error.

long DatabaseExport(int database, const string table_or_sql, const string filename, uint flags, const string separator)

The *DatabaseExport* function exports a table or the result of an SQL query to a CSV file. The database handle, as well as the table name or query text, are specified in the first two parameters.

If query results are exported, then the SQL query must begin with "SELECT" or "select". In other words, a SQL query cannot change the database state; otherwise, *DatabaseExport* will end with an error.

File *filename* name may contain a path inside the *MQL5/Files* directory of the current instance of the terminal or the shared folder of terminals, depending on the flags.

The *flags* parameter allows you to specify a combination of flags that controls the format and location of the file.

- DATABASE_EXPORT_HEADER – output a string with field names
- DATABASE_EXPORT_INDEX – display line numbers
- DATABASE_EXPORT_NO_BOM – do not insert a label BOM at the beginning of the file (BOM is inserted by default)
- DATABASE_EXPORT_CRLF – use CRLF to break a line (LF by default)
- DATABASE_EXPORT_APPEND – append data to the end of an existing file (by default, the file is overwritten), if the file does not exist, it will be created
- DATABASE_EXPORT_QUOTED_STRINGS – output string values in double quotes
- DATABASE_EXPORT_COMMON_FOLDER – CSV file will be created in the common folder of all terminals *MetaQuotes/Terminal/Common/File*

Parameter *separator* specifies the column separator character. If it is NULL, then the tab character '\t' will be used as a separator. The empty string "" is considered a valid delimiter, but the resulting CSV file cannot be read as a table and it will be a set of rows.

Text fields in the database can contain newlines ('\r' or '\r\n') as well as the delimiter character specified in the separator parameter. In this case, it is necessary to use the DATABASE_EXPORT_QUOTED_STRINGS flag in the *flags* parameter. If this flag is present, all output strings will be enclosed in double quotes, and if the string contains a double quote, it will be replaced by two double quotes.

The function returns the number of exported records or a negative value in case of an error.

7.6.15 Printing tables and SQL queries to logs

If necessary, an MQL program can output the contents of a table or the results of an SQL query to a log using the *DatabasePrint* function.

long DatabasePrint(int database, const string table_or_sql, uint flags)

The database handle is passed in the first parameter, followed by the table name or query text (*table_or_sql*). The SQL query must start with "SELECT" or "select", i.e. it must not change the state of the database. Otherwise, the *DatabasePrint* function will end with an error.

The *flags* parameter specifies a combination of flags that determine the formatting of the output.

- DATABASE_PRINT_NO_HEADER – do not display table column names (field names)

- DATABASE_PRINT_NO_INDEX – do not display line numbers
- DATABASE_PRINT_NO_FRAME – do not display a frame that separates the header and data
- DATABASE_PRINT_STRINGS_RIGHT – align strings to the right

If *flags* = *0*, then columns and rows are displayed, the header and data are separated by a frame, and the rows are aligned to the left.

The function returns the number of displayed records or -1 in case of an error.

We will use the function in the next section.

Unfortunately, the function does not allow an output of prepared queries with parameters. If there are parameters, they will need to be embedded in the query text at the MQL5 level.

7.6.16 Example of searching for a trading strategy using SQLite

Let's try to use SQLite to solve practical problems. We will import structures into the *MqlRates* database with the history of quotes and analyze them in order to identify patterns and search for potential trading strategies. Of course, any chosen logic can also be implemented in MQL5, but SQL allows you to do it in a different way, in many cases more efficiently and using many interesting built-in SQL functions. The subject of the book, aimed at learning MQL5, does not allow going deep into this technology, but we mention it as worthy of the attention of an algorithmic trader.

The script for converting quotes history into a database format is called *DBquotesImport.mq5*. In the input parameters, you can set the prefix of the database name and the size of the transaction (the number of records in one transaction).

```
input string Database = "MQL5Book/DB/Quotes";
input int TransactionSize = 1000;
```

To add *MqlRates* structures to the database using our ORM layer, the script defines an auxiliary *MqlRatesDB* structure which provides the rules for binding structure fields to base columns. Since our script only writes data to the database and does not read it from there, it does not need to be bound using the *DatabaseReadBind* function, which would impose a restriction on the "simplicity" of the structure. The absence of a constraint makes it possible to derive the *MqlRatesDB* structure from *MqlRates* (and do not repeat the description of the fields).

```
struct MqlRatesDB: public MqlRates
{
   /* for reference:

      datetime time;
      double   open;
      double   high;
      double   low;
      double   close;
      long     tick_volume;
      int      spread;
      long     real_volume;
   */

   bool bindAll(DBQuery &q) const
   {
      return q.bind(0, time)
         && q.bind(1, open)
         && q.bind(2, high)
         && q.bind(3, low)
         && q.bind(4, close)
         && q.bind(5, tick_volume)
         && q.bind(6, spread)
         && q.bind(7, real_volume);
   }

   long rowid(const long setter = 0)
   {
 // rowid is set by us according to the bar time
      return time;
   }
};

DB_FIELD_C1(MqlRatesDB, datetime, time, DB_CONSTRAINT::PRIMARY_KEY);
DB_FIELD(MqlRatesDB, double, open);
DB_FIELD(MqlRatesDB, double, high);
DB_FIELD(MqlRatesDB, double, low);
DB_FIELD(MqlRatesDB, double, close);
DB_FIELD(MqlRatesDB, long, tick_volume);
DB_FIELD(MqlRatesDB, int, spread);
DB_FIELD(MqlRatesDB, long, real_volume);
```

The database name is formed from the prefix *Database*, name, and timeframe of the current chart on which the script is running. A single table "MqlRatesDB" is created in the database with the field configuration specified by the DB_FIELD macros. Please note that the primary key will not be generated by the database, but is taken directly from the bars, from the *time* field (bar opening time).

```
void OnStart()
{
   Print("");
   DBSQLite db(Database + _Symbol + PeriodToString());
   if(!PRTF(db.isOpen())) return;

   PRTF(db.deleteTable(typename(MqlRatesDB)));

   if(!PRTF(db.createTable<MqlRatesDB>(true))) return;
   ...
```

Next, using packages of *TransactionSize* bars, we request bars from the history and add them to the table. This is a job of the helper function *ReadChunk*, called in a loop as long as there is data (the function returns *true*) or the user won't stop the script manually. The function code is shown below.

```
   int offset = 0;
   while(ReadChunk(db, offset, TransactionSize) && !IsStopped())
   {
      offset += TransactionSize;
   }
```

Upon completion of the process, we ask the database for the number of generated records in the table and output it to the log.

```
   DBRow *rows[];
   if(db.prepare(StringFormat("SELECT COUNT(*) FROM %s",
      typename(MqlRatesDB))).readAll(rows))
   {
      Print("Records added: ", rows[0][0].integer_value);
   }
}
```

The *ReadChunk* function looks as follows.

```
bool ReadChunk(DBSQLite &db, const int offset, const int size)
{
   MqlRates rates[];
   MqlRatesDB ratesDB[];
   const int n = CopyRates(_Symbol, PERIOD_CURRENT, offset, size, rates);
   if(n > 0)
   {
      DBTransaction tr(db, true);
      Print(rates[0].time);
      ArrayResize(ratesDB, n);
      for(int i = 0; i < n; ++i)
      {
         ratesDB[i] = rates[i];
      }

      return db.insert(ratesDB);
   }
   else
   {
      Print("CopyRates failed: ", _LastError, " ", E2S(_LastError));
   }
   return false;
}
```

It calls the built-in *CopyRates* function through which the *rates* bars array is filled. Then the bars are transferred to the *ratesDB* array so that using just one statement *db.insert(ratesDB)* we could write information to the database (we have formalized in *MqlRatesDB* how to do it correctly).

The presence of the *DBTransaction* object (with the automatic "commit" option enabled) inside the block means that all operations with the array are "overlaid" with a transaction. To indicate progress, during the processing of each block of bars, the label of the first bar is displayed in the log.

While the function *CopyRates* returns the data and their insertion into the database is successful, the loop in *OnStart* continues with the shift of the numbers of the copied bars deep into the history. When the end of the available history or the bar limit set in the terminal settings is reached, *CopyRates* will return error 4401 (HISTORY_NOT_FOUND) and the script will exit.

Let's run the script on the EURUSD, H1 chart. The log should show something like this.

```
db.isOpen()=true / ok
db.deleteTable(typename(MqlRatesDB))=true / ok
db.createTable<MqlRatesDB>(true)=true / ok
2022.06.29 20:00:00
2022.05.03 04:00:00
2022.03.04 10:00:00
...
CopyRates failed: 4401 HISTORY_NOT_FOUND
Records added: 100000
```

We now have the base *QuotesEURUSDH1.sqlite*, on which you can experiment to test various trading hypotheses. You can open it in the MetaEditor to make sure that the data is transferred correctly.

Let's check one of the simplest strategies based on regularities in history. We will find the statistics of two consecutive bars in the same direction, broken down by intraday time and day of the week. If there is a tangible advantage for some combination of time and day of the week, it can be considered in the future as a signal to enter the market in the direction of the first bar.

First, let's design an SQL query that requests quotes for a certain period and calculates the price movement on each bar, that is, the difference between adjacent opening prices.

Since the time for bars is stored as a number of seconds (by the standards of *datetime* in MQL5 and, concurrently, the "Unix epoch" of SQL), it is desirable to convert their display to a string for easy reading, so let's start the SELECT query from the *datetime* field based on DATETIME function:

```
SELECT
   DATETIME(time, 'unixepoch') as datetime, open, ...
```

This field will not participate in the analysis and is given here only for the user. After that, the price is displayed for reference, so that we can check the calculation of price increments by debug printing.

Since we are going to, if necessary, select a certain period from the entire file, the condition will require the *time* field in "a pure form", and it should also be added to the request. In addition, according to the planned analysis of quotes, we will need to isolate from the bar label its intraday time, as well as the day of the week (their numbering corresponds to that adopted in MQL5, 0 is Sunday). Let's call the last two columns of the query *intraday* and *day*, respectively, and the TIME and STRFTIME functions are used to get them.

```
SELECT
   DATETIME(time, 'unixepoch') as datetime, open,
   time,
   TIME(time, 'unixepoch') AS intraday,
   STRFTIME('%w', time, 'unixepoch') AS day, ...
```

To calculate the price increment in SQL, you can use the LAG function. It returns the value of the specified column with an offset of the specified number of rows. For example, *LAG(X, 1)* means getting the *X* value in the previous entry, with the second parameter 1 that means the offset defaulting to 1, i.e. it can be omitted to get the equivalent entry *LAG(X)*. To get the value of the next entry, call *LAG(X,-1)*. In any case, when using LAG, an additional syntactic construction is required that specifies the sorting order of records, in the simplest case, in the form of *OVER(ORDER BY column)*.

Thus, to get the price increment between the opening prices of two neighboring bars, we write:

```
...
(LAG(open,-1) OVER (ORDER BY time) - open) AS delta, ...
```

This column is predictive because it looks into the future.

We can reveal that two bars formed in the same direction by multiplying increments by them: positive values indicate a consistent rise or fall:

```
...
(LAG(open,-1) OVER (ORDER BY time) - open) * (open - LAG(open) OVER (ORDER BY time
   AS product, ...
```

This indicator is chosen as the simplest to use in calculation: for real trading systems, you can choose a more complex criterion.

To evaluate the profit generated by the system on the backtest, you need to multiply the direction of the previous bar (which acts as an indicator of future movement) by the price increment on the next bar. The direction is calculated in the column *direction* (using the SIGN function), for reference only. The profit estimate in the *estimate* column is the product of the previous movement *direction* and the increment of the next bar (*delta*): if the direction is preserved, we get a positive result (in points).

```
...
SIGN(open - LAG(open) OVER (ORDER BY time)) AS direction,
(LAG(open,-1) OVER (ORDER BY time) - open) * SIGN(open - LAG(open) OVER (ORDER BY
   AS estimate ...
```

> In expressions in an SQL command, you cannot use AS aliases defined in the same command. That is why we cannot determine *estimate* as *delta * direction*, and we have to repeat the calculation of the product explicitly. However, we recall that columns *delta* and *direction* are not needed for programmatic analysis and are added here only to visualize the table in front of the user.

At the end of the SQL command, we specify the table from which the selection is made, and the filtering conditions for the backtest date range: two parameters "from" and "to".

```
...
FROM MqlRatesDB
WHERE (time >= ?1 AND time < ?2)
```

Optionally, we can add a constraint *LIMIT?3* (and enter some small value, for example, 10) so that visual verification of the query results at first does not force you to look through tens of thousands of records.

You can check the operation of the SQL command using the *DatabasePrint* function, however, the function, unfortunately, does not allow you to work with prepared queries with parameters. Therefore, we will have to replace SQL parameter preparation '?n' with query string formatting using *StringFormat* and substitute parameter values there. Alternatively, it would be possible to completely avoid *DatabasePrint* and output the results to the log independently, line by line (through an array *DBRow*).

Thus, the final fragment of the request will turn into:

```
...
WHERE (time >= %ld AND time < %ld)
ORDER BY time LIMIT %d;
```

It should be noted that the *datetime* values in this query will be coming from MQL5 in the "machine" format, i.e., the number of seconds since the beginning of 1970. If we want to debug the same SQL query in the MetaEditor, then it is more convenient to write the date range condition using date literals (strings), as follows:

```
WHERE (time >= STRFTIME('%s', '2015-01-01') AND time < STRFTIME('%s', '2021-01-01'
```

Again, we need to use the STRFTIME function here (the '%s' modifier in SQL sets the transfer of the specified date string to the "Unix epoch" label; the fact that '%s' resembles an MQL5 format string is just a coincidence).

Save the designed SQL query in a separate text file *DBQuotesIntradayLag.sql* and connect it as a resource to the test script of the same name, *DBQuotesIntradayLag.mq5*.

```
#resource "DBQuotesIntradayLag.sql" as string sql1
```

The first parameter of the script allows you to set a prefix in the name of the database, which should already exist after launching *DBquotesImport.mq5* on the chart with the same symbol and timeframe. The subsequent inputs are for the date range and length limit of the debug printout to the log.

```
input string Database = "MQL5Book/DB/Quotes";
input datetime SubsetStart = D'2022.01.01';
input datetime SubsetStop = D'2023.01.01';
input int Limit = 10;
```

The table with quotes is known in advance, from the previous script.

```
const string Table = "MqlRatesDB";
```

In the *OnStart* function, we open the database and make sure that the quotes table is available.

```
void OnStart()
{
   Print("");
   DBSQLite db(Database + _Symbol + PeriodToString());
   if(!PRTF(db.isOpen())) return;
   if(!PRTF(db.hasTable(Table))) return;
   ...
```

Next, we substitute the parameters in the SQL query string. We pay attention not only to the substitution of SQL parameters '?n' for format sequences but also double the percent symbols '%' first because otherwise the function *StringFormat* will perceive them as its own commands, and will not miss them in SQL.

```
   string sqlrep = sql1;
   StringReplace(sqlrep, "%", "%%");
   StringReplace(sqlrep, "?1", "%ld");
   StringReplace(sqlrep, "?2", "%ld");
   StringReplace(sqlrep, "?3", "%d");

   const string sqlfmt = StringFormat(sqlrep, SubsetStart, SubsetStop, Limit);
   Print(sqlfmt);
```

All these manipulations were required only to execute the request in the context of the *DatabasePrint* function. In the working version of the analytical script, we would read the results of the query and analyze them programmatically, bypassing formatting and calling *DatabasePrint*.

Finally, let's execute the SQL query and output the table with the results to the log.

```
   DatabasePrint(db.getHandle(), sqlfmt, 0);
}
```

Here is what we will see for 10 bars EURUSD,H1 at the beginning of 2022.

```
db.isOpen()=true / ok
db.hasTable(Table)=true / ok
      SELECT
         DATETIME(time, 'unixepoch') as datetime,
         open,
         time,
         TIME(time, 'unixepoch') AS intraday,
         STRFTIME('%w', time, 'unixepoch') AS day,
         (LAG(open,-1) OVER (ORDER BY time) - open) AS delta,
         SIGN(open - LAG(open) OVER (ORDER BY time)) AS direction,
         (LAG(open,-1) OVER (ORDER BY time) - open) * (open - LAG(open) OVER (ORDER B
            AS product,
         (LAG(open,-1) OVER (ORDER BY time) - open) * SIGN(open - LAG(open) OVER (ORD
            AS estimate
      FROM MqlRatesDB
      WHERE (time >= 1640995200 AND time < 1672531200)
      ORDER BY time LIMIT 10;
 #| datetime               open       time intraday day       delta dir       product

```

It is easy to make sure that the intraday time of the bar is correctly allocated, as well as the day of the week - 1, which corresponds to Monday. You can also check the delta increment. The *product* and *estimate* values are empty on the first row because they require the missing previous row to be calculated.

Let's complicate our SQL query by grouping records with the same time of day combinations (*intraday*) and day of the week (*day*), and calculating a certain target indicator that characterizes the success of trading for each of these combinations. Let's take as such an indicator the average cell size *product* divided by the standard deviation of the same products. The larger the average product of price increments of neighboring bars, the greater the expected profit, and the smaller the spread of these products, the more stable the forecast. The name of the indicator in the SQL query is *objective*.

In addition to the target indicator, we will also calculate the profit estimate (*backtest_profit*) and profit factor (*backtest_PF*). We will estimate profit as the sum of price increments (*estimate*) for all bars in the context of intraday time and day of the week (the size of the opening bar as a price increment is an analog of the future profit in points per one bar). The profit factor is traditionally the quotient of positive and negative increments.

```
SELECT
   AVG(product) / STDDEV(product) AS objective,
   SUM(estimate) AS backtest_profit,
   SUM(CASE WHEN estimate >= 0 THEN estimate ELSE 0 END) /
      SUM(CASE WHEN estimate < 0 THEN -estimate ELSE 0 END) AS backtest_PF,
   intraday, day
FROM
(
   SELECT
      time,
      TIME(time, 'unixepoch') AS intraday,
      STRFTIME('%w', time, 'unixepoch') AS day,
      (LAG(open,-1) OVER (ORDER BY time) - open) AS delta,
      SIGN(open - LAG(open) OVER (ORDER BY time)) AS direction,
      (LAG(open,-1) OVER (ORDER BY time) - open) * (open - LAG(open) OVER (ORDER B
         AS product,
      (LAG(open,-1) OVER (ORDER BY time) - open) * SIGN(open - LAG(open) OVER (ORD
         AS estimate
   FROM MqlRatesDB
   WHERE (time >= STRFTIME('%s', '2015-01-01') AND time < STRFTIME('%s', '2021-01-
)
GROUP BY intraday, day
ORDER BY objective DESC
```

The first SQL query has become nested, from which we now accumulate data with an external SQL query. Grouping by all combinations of time and day of the week provides an "extra" from *GROUP BY intraday, day*. In addition, we have added sorting by target indicator (*ORDER BY objective DESC*) so that the best options are at the top of the table.

In the nested query, we removed the LIMIT parameter, because the number of groups became acceptable, much less than the number of analyzed bars. So, for H1 we get 120 options (24 * 5).

The extended query is placed in the text file *DBQuotesIntradayLagGroup.sql*, which in turn is connected as a resource to the test script of the same name, *DBQuotesIntradayLagGroup.mq5*. Its source code differs little from the previous one, so we will immediately show the result of its launch for the default date range: from the beginning of 2015 to the beginning of 2021 (excluding 2021 and 2022).

```
db.isOpen()=true / ok
db.hasTable(Table)=true / ok
   SELECT
      AVG(product) / STDDEV(product) AS objective,
      SUM(estimate) AS backtest_profit,
      SUM(CASE WHEN estimate >= 0 THEN estimate ELSE 0 END) /
         SUM(CASE WHEN estimate < 0 THEN -estimate ELSE 0 END) AS backtest_PF,
      intraday, day
   FROM
   (
      SELECT
         ...
      FROM MqlRatesDB

```

Thus, the analysis tells us that the 16-hour H1 bar on Friday is the best candidate to continue the trend based on the previous bar. Next in preference is the Wednesday 20 o'clock bar. And so on.

However, it is desirable to check the found settings on the forward period.

To do this, we can execute the current SQL query not only on the "past" date range (in our test until 2021) but once more in the "future" (from the beginning of 2021). The results of both queries should be joined (JOIN) by our groups (*intraday*, *day*). Then, while maintaining the sorting by the target indicator, we will see in the adjacent columns the profit and profit factor for the same combinations of time and day of the week, and how much they sank.

Here's the final SQL query (abbreviated):

```
SELECT * FROM
(
   SELECT
      AVG(product) / STDDEV(product) AS objective,
      SUM(estimate) AS backtest_profit,
      SUM(CASE WHEN estimate >= 0 THEN estimate ELSE 0 END) /
         SUM(CASE WHEN estimate < 0 THEN -estimate ELSE 0 END) AS backtest_PF,
      intraday, day
   FROM
   (
      SELECT ...
      FROM MqlRatesDB
      WHERE (time >= STRFTIME('%s', '2015-01-01') AND time < STRFTIME('%s', '2021-01-
   )
   GROUP BY intraday, day
) backtest
JOIN
(
   SELECT
      SUM(estimate) AS forward_profit,
      SUM(CASE WHEN estimate >= 0 THEN estimate ELSE 0 END) /
         SUM(CASE WHEN estimate < 0 THEN -estimate ELSE 0 END) AS forward_PF,
      intraday, day
   FROM
   (
      SELECT ...
      FROM MqlRatesDB
      WHERE (time >= STRFTIME('%s', '2021-01-01'))
   )
   GROUP BY intraday, day
) forward
USING(intraday, day)
ORDER BY objective DESC
```

The full text of the request is provided in the file *DBQuotesIntradayBackAndForward.sql*. It is connected as a resource in the script *DBQuotesIntradayBackAndForward.mq5*.

By running the script with default settings, we get the following indicators (with abbreviations):

```
 #|          objective    backtest_profit    backtest_PF intraday day forward_profit

```

So, the trading system with the best trading schedules found continues to show profit in the "future" period, although not as large as on the backtest.

Of course, the considered example is only a particular case of a trading system. We could, for example, find combinations of the time and day of the week when a reversal strategy works on neighboring bars, or based on other principles altogether (analysis of ticks, calendar, portfolio of trading signals, etc.).

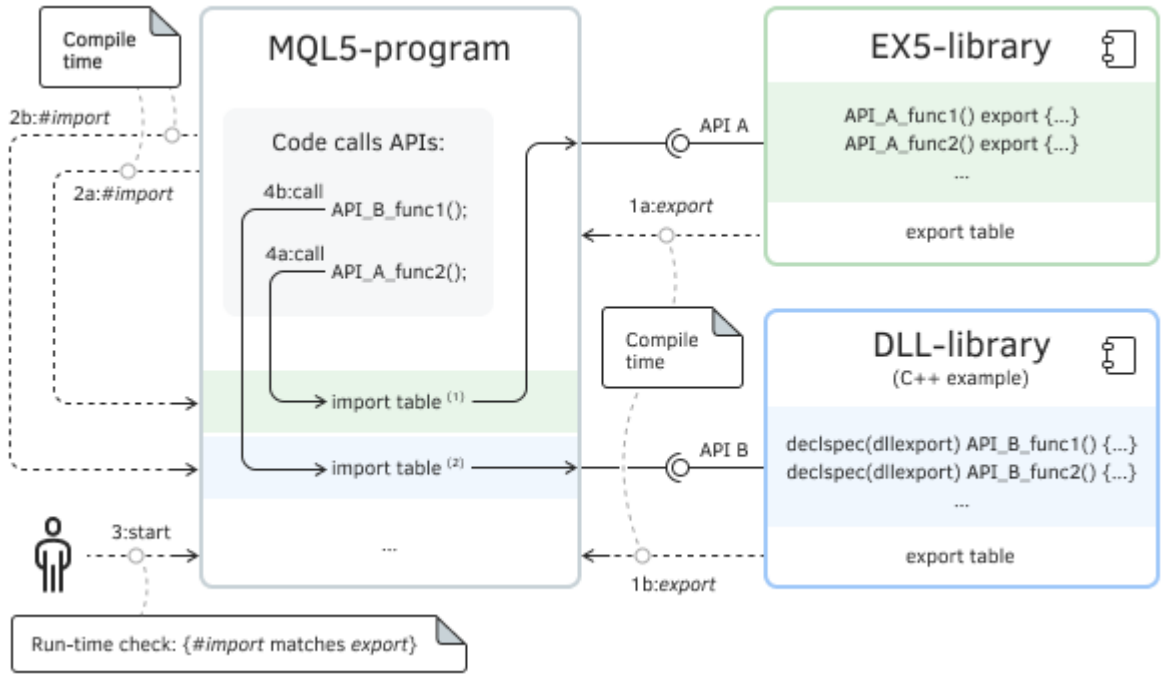
The bottom line is that the SQLite engine provides many convenient tools that would need to be implemented in MQL5 on your own. To tell the truth, learning SQL takes time. The platform allows you to choose the optimal combination of two technologies for efficient programming.

7.7 Development and connection of binary format libraries

In addition to the specialized types of MQL programs – *Expert Advisors*, *indicators*, scripts, and services – the MetaTrader 5 platform allows you to create and connect independent binary modules with arbitrary functionality, compiled as ex5 files or commonly used DLLs (Dynamic Link Library), standard for Windows. These can be analytical algorithms, graphical visualization, network interaction with web services, control of external programs, or the operating system itself. In any case, such libraries work in the terminal not as independent MQL programs but in conjunction with a program of any of the above 4 types.

The idea of integrating the library and the main (parent) program is that the library exports certain functions, i.e., declares them available for use from the outside, and the program imports their prototypes. It is the description of prototypes – sets of names, lists of parameters, and return values – that allows you to call these functions in the code without having their implementation.

Then, during the launch of the MQL program, the early dynamic linking is performed. This implies loading the library after the main program and establishing correspondence between the imported prototypes and the exported functions available in the library. Establishing one-to-one correspondences by names, parameter lists, and return types is a prerequisite for successful loading. If no corresponding exported implementation can be found for the import description of at least one function, the execution of the MQL program will be canceled (it will end with an error at the startup stage).



Communication-component diagram of an MQL program with libraries

You cannot select an included library when starting an MQL program. This linking is set by the developer when compiling the main program along with library imports. However, the user can manually replace one ex5/dll file with another between program starts (provided that the prototypes of the implemented exported functions match in the libraries). This can be used, for example, to switch the user interface language if the libraries contain labeled string resources. However, libraries are most often used as a commercial product with some know-how, which the author is not ready to distribute in the form of open header files.

For programmers who have come to MQL5 from other environments and are already familiar with the DLL technology, we would like to add a note about late dynamic linking, which is one of the advantages of DLLs. Full dynamic connection of one MQL program (or DLL module) to another MQL program during execution is impossible. The only similar action that MQL5 allows you to do "on the go" is linking an Expert Advisor and an indicator via *iCustom* or *IndicatorCreate*, where the indicator acts as a dynamically linked library (however, programmatic interaction with has to be done through the indicators API, which means increased overhead for *CopyBuffer*, compared to direct function calls via *export/#import*).

Note that in normal cases, when an MQL program is compiled from sources without importing external functions, static linking is used, that is, the generated binary code directly refers to the called functions since they are known at the time of compilation.

Strictly speaking, a library can also rely on other libraries, i.e., it can import some of the functions. In theory, the chain of such dependencies can be even longer: for example, an MQL program includes library A, library A uses library B, and library B, in turn, uses library C. However, such chains are undesirable because they complicate the distribution and installation of the product, as well as make identifying the causes of potential startup problems more difficult. Therefore, libraries are usually connected directly to the parent MQL program.

In this chapter, we will describe the process of creating libraries in MQL5, exporting and importing functions (including restrictions on the data types used in them), as well as connecting external (ready-made) DLLs. DLL development is beyond the scope of this book.

7.7.1 Creation of ex5 libraries; *export* of functions

To describe a library, add the *#property library* directive to the source code of the main (compiled) module (usually, at the beginning of the file).

```
#property library
```

Specifying this directive in any other files included in the compilation process via *#include* has no effect.

The *library* property informs the compiler that the given ex5 file is a library: a mark about this is stored in the header of the ex5 file.

A separate folder *MQL5/Libraries* is reserved for libraries in MetaTrader 5. You can organize a hierarchy of nested folders in it, just like for other types of programs in MQL5.

Libraries do not directly participate in event handling, and therefore the compiler does not require the presence of any standard handlers in the code. However, you can call the exported functions of the library from the event handlers of the MQL program to which the library is connected.

To export a function from a library, just mark it with a special keyword *export*. This modifier must be placed at the very end of the function header.

```
result_type function_id ( [ parameter_type parameter_id
                          [ = default_value] ...] ) export
{
   ...
}
```

Parameters must be simple types or strings, structures with fields of such types, or their arrays. Pointers and references are allowed for MQL5 object types (for restrictions on importing DLLs, see the relevant section).

Let's see some examples. The parameter is a prime number:

```
double Algebraic2(const double x) export
{
   return x / sqrt(1 + x * x);
}
```

The parameters are a pointer to an object and a reference to a pointer (allowing you to assign a pointer inside the function).

```
class X
{
public:
   X() { Print(__FUNCSIG__); }
};
void setObject(const X *obj) export { ... }
void getObject(X *&obj) export { obj = new X(); }
```

The parameter is a structure:

```
struct Data
{
   int value;
   double data[];
   Data(): value(0) { }
   Data(const int i): value(i) { ArrayResize(data, i); }
};

void getRefStruct(const int i, Data &data) export { ... }
```

You can only export functions but not entire classes or structures. Some of these limitations can be avoided with the help of pointers and references, which we will discuss in more detail later.

Function templates cannot be declared with the *export* keyword and in the *#import* directive.

The *export* modifier instructs the compiler to include the function in the table of exported functions within the given ex5 executable. Thanks to this, such functions become available ("visible") from other MQL programs, where they can be used after importing with a special directive *#import*.

All functions that are going to be exported must be marked with the *export* modifier. Although the main program is not required to import all of them as it can only import the necessary ones.

If you forget to export a function but include it in the import directive in the main MQL program, then when the latter is launched, an error will occur:

```
cannot find 'function' in 'library.ex5'
unresolved import function call
```

A similar problem will arise if there are discrepancies in the description of the exported function and its imported prototype. This can happen, for example, if you forget to recompile a library or main program after making changes to the programming interface, which is usually described in a separate header file.

> Debugging libraries is not possible, so if necessary, you should have a helper script or another MQL program that is built from the source codes of the library in debugger mode and can be executed with breakpoints or step-by-step. Of course, this will require emulating calls to exported functions using some real or artificial data.
>
> For DLLs, the description of exported functions is done differently, depending on the programming language in which they are created. Look for details in the documentation of your chosen development environments.

Consider an example of a simple library *MQL5/Libraries/MQL5Book/LibRand.mq5*, from which several functions are exported with different types of parameters and results. The library is designed to generate random data:

- of numerical data with a pseudo-normal distribution
- of strings with random characters from the given sets (may be useful for passwords)

In particular, you can get one random number using the *PseudoNormalValue* function, in which the expected value and variance are set as parameters.

```
double PseudoNormalValue(const double mean = 0.0, const double sigma = 1.0,
   const bool rooted = false) export
{
   // use ready-made sqrt for mass generation in a cycle in PseudoNormalArray
   const double s = !rooted ? sqrt(sigma) : sigma;
   const double r = (rand() - 16383.5) / 16384.0; // [-1,+1] excluding borders
   const double x = -(log(1 / ((r + 1) / 2) - 1) * s) / M_PI * M_E + mean;
   return x;
}
```

The *PseudoNormalArray* function fills the array with random values in a given amount (*n*) and with the required distribution.

```
bool PseudoNormalArray(double &array[], const int n,
   const double mean = 0.0, const double sigma = 1.0) export
{
   bool success = true;
   const double s = sqrt(fabs(sigma)); // passing ready sqrt when calling PseudoNorma
   ArrayResize(array, n);
   for(int i = 0; i < n; ++i)
   {
      array[i] = PseudoNormalValue(mean, s, true);
      success = success && MathIsValidNumber(array[i]);
   }
   return success;
}
```

To generate one random string, we write the *RandomString* function, which "selects" from the supplied set of characters (*pattern*) a given quantity (*length*) of arbitrary characters. When the *pattern* parameter is blank (default), a full set of letters and numbers is assumed. Helper functions *StringPatternAlpha* and *StringPatternDigit* are used to get it; these functions are also exportable (not listed in the book, see the source code).

```
string RandomString(const int length, string pattern = NULL) export
{
   if(StringLen(pattern) == 0)
   {
      pattern = StringPatternAlpha() + StringPatternDigit();
   }
   const int size = StringLen(pattern);
   string result = "";
   for(int i = 0; i < length; ++i)
   {
      result += ShortToString(pattern[rand() % size]);
   }
   return result;
}
```

In general, to work with a library, it is necessary to publish a header file describing everything that should be available in it from outside (and the details of the internal implementation can and should be hidden). In our case, such a file is called *MQL5Book/LibRand.mqh*. In particular, it describes user-defined types (in our case, the STRING_PATTERN enumeration) and function prototypes.

Although the exact syntax of the *#import* block is not known to us yet, this should not affect the clarity of the declarations inside it: the headers of the exported functions are repeated here but without the keyword *export*.

```
enum STRING_PATTERN
{
   STRING_PATTERN_LOWERCASE = 1, // lowercase letters only
   STRING_PATTERN_UPPERCASE = 2, // capital letters only
   STRING_PATTERN_MIXEDCASE = 3  // both registers
};

#import "MQL5Book/LibRand.ex5"
string StringPatternAlpha(const STRING_PATTERN _case = STRING_PATTERN_MIXEDCASE);
string StringPatternDigit();
string RandomString(const int length, string pattern = NULL);
void RandomStrings(string &array[], const int n, const int minlength,
   const int maxlength, string pattern = NULL);
void PseudoNormalDefaultMean(const double mean = 0.0);
void PseudoNormalDefaultSigma(const double sigma = 1.0);
double PseudoNormalDefaultValue();
double PseudoNormalValue(const double mean = 0.0, const double sigma = 1.0,
   const bool rooted = false);
bool PseudoNormalArray(double &array[], const int n,
   const double mean = 0.0, const double sigma = 1.0);
#import
```

We will write a test script that uses this library in the next section, after studying the directive *#import*.

7.7.2 Including libraries; *#import* of functions

Functions are imported from compiled MQL5 modules (*.ex5 files) and from Windows dynamic library modules (*.dll files). The module name is specified in the *#import* directive, followed by descriptions of the imported function prototypes. Such a block must end with another *#import* directive, moreover, it can be without a name and simply close the block itself, or the name of another library can be specified in the directive, and thus the next import block begins at the same time. A series of import blocks should always end with a directive without a library name.

In its simplest form, the directive looks like this:

```
#import "[path] module_name [.extension]"
  function_type function_name([parameter_list]);
  [function_type function_name([parameter_list]);]
   ...
#import
```

The name of the library file can be specified without the extension: then the DLL is assumed by default. Extension *ex5* is required.

The name may be preceded by the library location path. By default, if there is no path, the libraries are searched in the folder *MQL5/Libraries* or in the folder next to the MQL program where the library is connected. Otherwise, different rules are applied to search for libraries depending on whether the type is DLL or EX5. These rules are covered in a separate section.

Here is an example of sequential import blocks from two libraries:

```
#import "user32.dll"
   int     MessageBoxW(int hWnd, string szText, string szCaption, int nType);
   int     SendMessageW(int hWnd, int Msg, int wParam, int lParam);
#import "lib.ex5"
   double  round(double value);
#import
```

With such directives, imported functions can be called from the source code in the same way as functions defined directly in the MQL program itself. All technical issues with loading libraries and redirecting calls to third-party modules are handled by the MQL program execution environment.

In order for the compiler to correctly issue the call to the imported function and organize the passing of parameters, a complete description is required: with the result type, with all parameters, modifiers, and default values, if they are present in the source.

Since the imported functions are outside of the compiled module, the compiler cannot check the correctness of the passed parameters and return values. Any discrepancy between the format of the expected and received data will result in an error during the execution of the program, and this may manifest itself as a critical program stop, or unexpected behavior.

If the library could not be loaded or the called imported function was not found, the MQL program terminates with a corresponding message in the log. The program will not be able to run until the problem is resolved, for example, by modifying and recompiling, placing the required library in one of the places along the search path, or allowing the use of the DLL (for DLLs only).

When sharing multiple libraries (doesn't matter if it's DLL or EX5), remember that they must have different names, regardless of their location directories. All imported functions get a scope that matches the name of the library file, that is, it is a kind of namespace, implicitly allocated for each included library.

Imported functions can have any names, including those that match the names of built-in functions (although this is not recommended). Moreover, it is possible to simultaneously import functions with the same names from different modules. In such cases, the operation context permissions should be applied to determine which function should be called.

For example:

```
#import "kernel32.dll"
   int GetLastError();
#import "lib.ex5"
   int GetLastError();
#import

class Foo
{
public:
   int GetLastError() { return(12345); }
   void func()
   {
      Print(GetLastError());           // call a class method
      Print(::GetLastError());         // calling the built-in (global) MQL5 function
      Print(kernel32::GetLastError()); // function call from kernel32.d
      Print(lib::GetLastError());      // function call from lib.ex5
   }
};

void OnStart()
{
   Foo foo;
   foo.func();
}
```

Let's see a simple example of the script *LibRandTest.mq5*, which uses functions from the EX5 library created in the previous section.

```
#include <MQL5Book/LibRand.mqh>
```

In the input parameters, you can select the number of elements in the array of numbers, the distribution parameters, as well as the step of the histogram, which we will calculate to make sure that the distribution approximately corresponds to the normal law.

```
input int N = 10000;
input double Mean = 0.0;
input double Sigma = 1.0;
input double HistogramStep = 0.5;
input int RandomSeed = 0;
```

Initialization of the random number generator built into MQL5 (uniform distribution) is performed by the value of the *RandomSeed* or, if 0 is left here, *GetTickCount* is picked (new at each start).

To build a histogram, we use *MapArray* and *QuickSortStructT* (we have already worked with them in the sections on multicurrency indicators and about array sorting, respectively). The map will accumulate counters of hitting random numbers in the cells of the histogram with a *HistogramStep* step.

```
#include <MQL5Book/MapArray.mqh>
#include <MQL5Book/QuickSortStructT.mqh>
```

To display a histogram based on the map, you need to be able to sort the map in key-value order. To do this, we had to define a derived class.

```
#define COMMA ,

template<typename K,typename V>
class MyMapArray: public MapArray<K,V>
{
public:
   void sort()
   {
      SORT_STRUCT(Pair<K COMMA V>, array, key);
   }
};
```

Note that the COMMA macro becomes an alternate representation of the comma character ',' and is used when another SORT_STRUCT macro is called. If not for this substitution, the comma inside the Pair<K,V> would be interpreted by the preprocessor as a normal macro parameter separator, as a result of which 4 parameters would be received at the input of SORT_STRUCT instead of the expected 3 – this would cause a compilation error. The preprocessor knows nothing about the MQL5 syntax.

At the beginning of *OnStart*, after initialization of the generator, we check the receipt of a single random string and an array of strings of different lengths.

```
void OnStart()
{
   const uint seed = RandomSeed ? RandomSeed : GetTickCount();
   Print("Random seed: ", seed);
   MathSrand(seed);

   // call two library functions: StringPatternDigit and RandomString
   Print("Random HEX-string: ", RandomString(30, StringPatternDigit() + "ABCDEF"));
   Print("Random strings:");
   string text[];
   RandomStrings(text, 5, 10, 20);         // 5 lines from 10 to 20 characters long
   ArrayPrint(text);
   ...
```

Next, we test normally distributed random numbers.

```
   // call another library function: PseudoNormalArray
   double x[];
   PseudoNormalArray(x, N, Mean, Sigma);   // filled array x

   Print("Random pseudo-gaussian histogram: ");

   // take 'long' as key type, because 'int' has already been used for index access
   MyMapArray<long,int> map;

   for(int i = 0; i < N; ++i)
   {
// value x[i] determines the cell of the histogram, where we increase the statistics
      map.inc((long)MathRound(x[i] / HistogramStep));
   }
   map.sort();                             // sort by key (i.e. by value)

   int max = 0;                            // searching for maximum for normalization
   for(int i = 0; i < map.getSize(); ++i)
   {
      max = fmax(max, map.getValue(i));
   }

   const double scale = fmax(max / 80, 1); // the histogram has a maximum of 80 symbo

   for(int i = 0; i < map.getSize(); ++i)  // print the histogram
   {
      const int p = (int)MathRound(map.getValue(i) / scale);
      string filler;
      StringInit(filler, p, '*');
      Print(StringFormat("%+.2f (%4d)",
         map.getKey(i) * HistogramStep, map.getValue(i)), " ", filler);
   }
```

Here is the result when run with default settings (timer randomization - each run will choose a new *seed*).

```
Random seed: 8859858
Random HEX-string: E58B125BCCDA67ABAB2F1C6D6EC677
Random strings:
"K4ZOpdIy5yxq4ble2" "NxTrVRl6q5j3Hr2FY" "6qxRdDzjp3WNA8xV"  "UlOPYinnGd36"      "6OCm

+7.50 (   1)
```

In this library, we have only exported and imported functions with built-in types. However, object interfaces with structures, classes, and templates are much more interesting and more in demand from a practical point of view. We will talk about the nuances of their use in libraries in a separate section.

When testing Expert Advisors and indicators in the tester, one should keep in mind an important point related to libraries. Libraries required for the main tested MQL program are determined automatically from the #import directives. However, if a custom indicator is called from the main program, to which some library is connected, then it is necessary to explicitly indicate in the program properties that it indirectly depends on a particular library. This is done with the directive:

```
#property tester_library "path_library_name.extension"
```

7.7.3 Library file search order

If the library name is specified without a path or with a relative path, the search is performed according to different rules depending on the type of library.

System libraries (DLL) are loaded according to the rules of the operating system. If the library is already loaded (for example, by another Expert Advisor, or even from another client terminal launched in parallel), then the call goes to the already loaded library. Otherwise, the search goes in the following sequence:

1. The folder from which the compiled EX5 program that imported the DLL was launched.
2. The *MQL5/Libraries* folder.
3. The folder where the running MetaTrader 5 terminal is located.
4. System folder (usually inside Windows).
5. Windows directory.
6. The current working folder of the terminal process (may be different from the terminal's location folder).
7. Folders listed in the PATH system variable.

In the *#import* directives, it is not recommended to use a fully qualified loadable module name of the form *Drive:/Directory/FileName.dll*.

If the DLL uses another DLL in its work, then in the absence of the second DLL, the first one will not be able to load.

The search for an imported EX5 library is performed in the following sequence:

1. Folder for launching the importing EX5 program.
2. Folder *MQL5/Libraries* of specific terminal instance.
3. Folder *MQL5/Libraries* in the common folder of all MetaTrader 5 terminals (*Common/MQL5/Libraries*).

Before loading an MQL program, a general list of all EX5 library modules is formed, where the supported modules are to be used both from the program itself and from libraries from this list. It's called a dependency list and can become a very branched "tree".

For EX5 libraries, the terminal also provides a one-time download of reusable modules.

Regardless of the type of the library, each instance of it works with its own data related to the context of the calling Expert Advisor, script, service, or indicator. Libraries are not a tool for shared access to MQL5 variables or arrays.

EX5 libraries and DLLs run on the thread of the calling module.

There are no regular means to find in the library code where it was loaded from.

7.7.4 DLL connection specifics

The following entities cannot be passed as parameters into functions imported from a DLL:

- Classes (objects and pointers to them)
- Structures containing dynamic arrays, strings, classes, and other complex structures

- Arrays of strings or the above complex objects

All simple type parameters are passed by value unless explicitly stated that they are passed by reference. When passing a string, the buffer address of the copied string is passed; if the string is passed by reference, then the buffer address of this particular string is passed to the function imported from the DLL without copying.

When passing an array to DLL, the address of the data buffer beginning is always passed (regardless of the AS_SERIES flag). The function inside the DLL knows nothing about the AS_SERIES flag, the passed array is an array of unknown length, and an additional parameter is needed to specify its size.

When describing the prototype of an imported function, you can use parameters with default values.

When importing DLLs, you should give permission to use them in the properties of a specific MQL program or in the general settings of the terminal. In this regard, in the Permissions section, we presented the script *EnvPermissions.mq5*, which, in particular, has a function for reading the contents of the Windows system clipboard using system DLLs. This function was provided optionally: its call was commented out because we did not know how to work with libraries. Now, we will transfer it to a separate script *LibClipboard.mq5*.

Running the script may prompt the user for confirmation (since DLLs are disabled by default for security reasons). If necessary, enable the option in the dialog, on the tab with dependencies.

Header files are provided in the directory *MQL5/Include/WinApi*, which also includes *#import* directives for much-needed system functions such as clipboard management (*openclipboard*, *GetClipboardData*, and *CloseClipboard*), memory management (*GlobalLock* and *GlobalUnlock*), Windows windows, and many others. We will include only two files: *winuser.mqh* and *winbase.mqh*. They contain the required import directives and, indirectly, through the connection to *windef.mqh*, Windows term macros (HANDLE and PVOID):

```
#define HANDLE  long
#define PVOID   long

#import "user32.dll"
...
int             OpenClipboard(HANDLE wnd_new_owner);
HANDLE          GetClipboardData(uint format);
int             CloseClipboard(void);
...
#import

#import "kernel32.dll"
...
PVOID           GlobalLock(HANDLE mem);
int             GlobalUnlock(HANDLE mem);
...
#import
```

In addition, we import the *lstrcatW* function from the *kernel32.dll* library because we are not satisfied with its description in *winbase.mqh* provided by default: this gives the function a second prototype, suitable for passing the PVOID value in the first parameter.

```
#include <WinApi/winuser.mqh>
#include <WinApi/winbase.mqh>

#define CF_UNICODETEXT 13 // one of the standard exchange formats - Unicode text
#import "kernel32.dll"
string lstrcatW(PVOID string1, const string string2);
#import
```

The essence of working with the clipboard is to "capture" access to it using *OpenClipboard*, after which you should get a data handle (*GetClipboardData*), convert it to a memory address (*GlobalLock*), and finally copy the data from system memory to your variable (*lstrcatW*). Next, the occupied resources are released in reverse order (*GlobalUnlock* and *CloseClipboard*).

```
void ReadClipboard()
{
   if(OpenClipboard(NULL))
   {
      HANDLE h = GetClipboardData(CF_UNICODETEXT);
      PVOID p = GlobalLock(h);
      if(p != 0)
      {
         const string text = lstrcatW(p, "");
         Print("Clipboard: ", text);
         GlobalUnlock(h);
      }
      CloseClipboard();
   }
}
```

Try copying the text to the clipboard and then running the script: the contents of the clipboard should be logged. If the buffer contains an image or other data that does not have a textual representation, the result will be empty.

Functions imported from a DLL follow the binary executable linking convention of Windows API functions. To ensure this convention, compiler-specific keywords are used in the source text of programs, such as, for example, __*stdcall* in C or C++. These linking rules imply the following:

- The calling function (in our case, the MQL program) must see the prototype of the called (imported from the DLL) function in order to correctly stack the parameters on the stack.
- The calling function (in our case, the MQL program) stacks parameters in reverse order, from right to left – this is the order in which the imported function reads the parameters passed to it.
- Parameters are passed by value, except for those that are explicitly passed by reference (in our case, strings).
- The imported function reads the parameters passed to it and clears the stack.

Here is another example of a script that uses a DLL – *LibWindowTree.mq5*. Its task is to go through the tree of all terminal windows and get their class names (according to registration in the system using WinApi) and titles. By windows here we mean the standard elements of the Windows interface, which also include controls. This procedure can be useful for automating work with the terminal: emulating button presses in windows, switching modes that are not available via MQL5, and so on.

To import the required system functions, let's include the header file *WinUser.mqh* that uses *user32.dll*.

```
#include <WinAPI/WinUser.mqh>
```

You can get the name of the window class and its title using the functions *GetClassNameW* and *GetWindowTextW*: they are called in the function *GetWindowData*.

```
void GetWindowData(HANDLE w, string &clazz, string &title)
{
   static ushort receiver[MAX_PATH];
   if(GetWindowTextW(w, receiver, MAX_PATH))
   {
      title = ShortArrayToString(receiver);
   }
   if(GetClassNameW(w, receiver, MAX_PATH))
   {
      clazz = ShortArrayToString(receiver);
   }
}
```

The 'W' suffix in function names means that they are intended for Unicode format strings (2 bytes per character), which are the most commonly used today (the 'A' suffix for ANSI strings makes sense to use only for backward compatibility with old libraries).

Given some initial handle to a Windows window, traversing up the hierarchy of its parent windows is provided by the function *TraverseUp*: its operation is based on the system function *GetParent*. For each found window, *TraverseUp* calls *GetWindowData* and outputs the resulting class name and title to the log.

```
HANDLE TraverseUp(HANDLE w)
{
   HANDLE p = 0;
   while(w != 0)
   {
      p = w;
      string clazz, title;
      GetWindowData(w, clazz, title);
      Print("'", clazz, "' '", title, "'");
      w = GetParent(w);
   }
   return p;
}
```

Traversing deep into the hierarchy is performed by the function *TraverseDown*: the system function *FindWindowExW* is used to enumerate child windows.

```
HANDLE TraverseDown(const HANDLE w, const int level = 0)
{
   // request first child window (if any)
   HANDLE child = FindWindowExW(w, NULL, NULL, NULL);
   while(child)          // oop while there are child windows
   {
      string clazz, title;
      GetWindowData(child, clazz, title);
      Print(StringFormat("%*s", level * 2, ""), "'", clazz, "' '", title, "'");
      TraverseDown(child, level + 1);
      // requesting next child window
      child = FindWindowExW(w, child, NULL, NULL);
   }
   return child;
}
```

In the *OnStart* function, we find the main terminal window by traversing the windows up from the handle of the current chart on which the script is running. Then we build the entire tree of terminal windows.

```
void OnStart()
{
   HANDLE h = TraverseUp(ChartGetInteger(0, CHART_WINDOW_HANDLE));
   Print("Main window handle: ", h);
   TraverseDown(h, 1);
}
```

We can also search for the required windows by class name and/or title, and therefore the main window could be immediately obtained by calling *FindWindowW*, since its attributes are known.

```
   h = FindWindowW("MetaQuotes::MetaTrader::5.00", NULL);
```

Here is an example log (snippet):

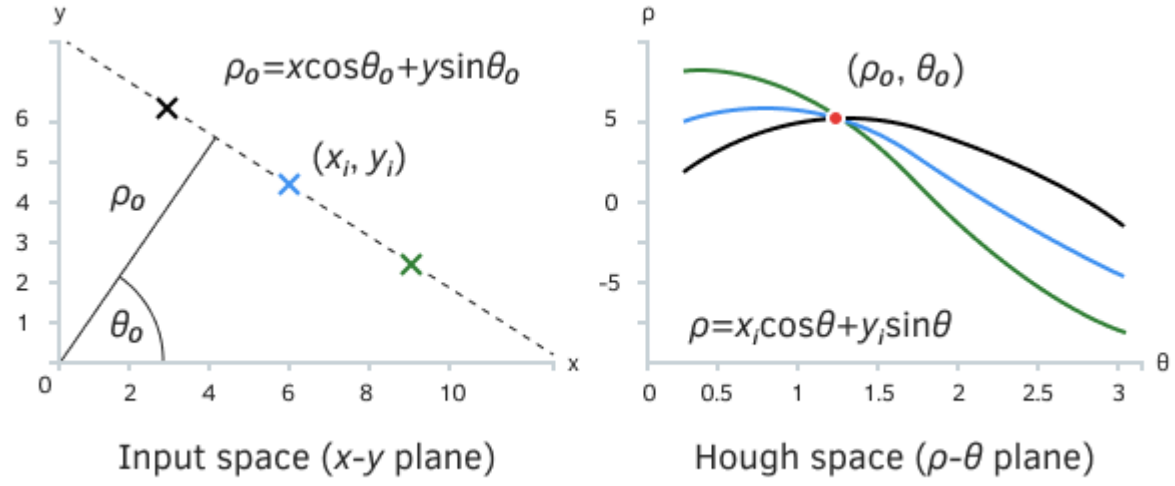
7.7.5 Classes and templates in MQL5 libraries

Although the export and import of classes and templates are generally prohibited, the developer can get around these restrictions by moving the description of the abstract base interfaces into the library header file and passing pointers. Let's illustrate this concept with an example of a library that performs a Hough transform of an image.

The Hough transform is an algorithm for extracting features of an image by comparing it with some formal model (formula) described by a set of parameters.

The simplest Hough transform is the selection of straight lines on the image by converting them to polar coordinates. With this processing, sequences of "filled" pixels, arranged more or less in a row, form peaks in the space of polar coordinates at the intersection of a specific angle ("theta") of the inclination of the straight line and its shift ("ro") relative to the center of coordinates.



Hough transform for straight lines

Each of the three colored dots on the left (original) image leaves a trail in polar coordinate space (right) because an infinite number of straight lines can be drawn through a point at different angles and perpendiculars to the center. Each trace fragment is "marked" only once, with the exception of the red mark: at this point, all three traces intersect and give the maximum response (3). Indeed, as we can see in the original image, there is a straight line that goes through all three points. Thus, the two parameters of the line are revealed by the maximum in polar coordinates.

We can use this Hough transform on price charts to highlight alternative support and resistance lines. If such lines are usually drawn at individual extremes and, in fact, perform an analysis of outliers, then the Hough transform lines can take into account all *High* or all *Low* prices, or even the distribution of tick volumes within bars. All this allows you to get a more reasonable estimate of the levels.

Let's start with the header file *LibHoughTransform.mqh*. Since some abstract image supplies the initial data for analysis, let's define the *HoughImage* interface template.

```
template<typename T>
interface HoughImage
{
   virtual int getWidth() const;
   virtual int getHeight() const;
   virtual T get(int x, int y) const;
};
```

All you need to know about the image when processing it is its dimensions and the content of each pixel, which, for reasons of generality, is represented by the parametric type T. It is clear that in the simplest case, it can be *int* or *double*.

Calling analytical image processing is a little more complicated. In the library, we need to describe the class, the objects of which will be returned from a special factory function (in the form of pointers). It is this function that should be exported from the library. Suppose, it is like this:

```
template<typename T>
class HoughTransformDraft
{
public:
   virtual int transform(const HoughImage<T> &image, double &result[],
      const int elements = 8) = 0;
};

HoughTransformDraft<?> *createHoughTransform() export { ... } // Problem - template!
```

However, template types and template functions cannot be exported. Therefore, we will make an intermediate non-template class *HoughTransform*, in which we will add a template method for the image parameter. Unfortunately, template methods cannot be virtual, and therefore we will manually dispatch calls inside the method (using *dynamic_cast*), redirecting processing to a derived class with a virtual method.

```
class HoughTransform
{
public:
   template<typename T>
   int transform(const HoughImage<T> &image, double &result[],
      const int elements = 8)
   {
      HoughTransformConcrete<T> *ptr = dynamic_cast<HoughTransformConcrete<T> *>(&thi
      if(ptr) return ptr.extract(image, result, elements);
      return 0;
   }
};

template<typename T>
class HoughTransformConcrete: public HoughTransform
{
public:
   virtual int extract(const HoughImage<T> &image, double &result[],
      const int elements = 8) = 0;
};
```

The internal implementation of the class *HoughTransformConcrete* will be written into the library file *MQL5/Libraries/MQL5Book/LibHoughTransform.mq5*.

```
#property library

#include <MQL5Book/LibHoughTransform.mqh>

template<typename T>
class LinearHoughTransform: public HoughTransformConcrete<T>
{
protected:
   int size;

public:
   LinearHoughTransform(const int quants): size(quants) { }
   ...
```

Since we are going to recalculate image points into space in new, polar, coordinates, a certain size should be allocated for the task. Here we are talking about a discrete Hough transform since we consider the original image as a discrete set of points (pixels), and we will accumulate the values of angles with perpendiculars in cells (quanta). For simplicity, we will focus on the variant with a square space, where the number of readings both in the angle and in the distance to the center is equal. This parameter is passed to the class constructor.

```
template<typename T>
class LinearHoughTransform: public HoughTransformConcrete<T>
{
protected:
   int size;
   Plain2DArray<T> data;
   Plain2DArray<double> trigonometric;

   void init()
   {
      data.allocate(size, size);
      trigonometric.allocate(2, size);
      double t, d = M_PI / size;
      int i;
      for(i = 0, t = 0; i < size; i++, t += d)
      {
         trigonometric.set(0, i, MathCos(t));
         trigonometric.set(1, i, MathSin(t));
      }
   }

public:
   LinearHoughTransform(const int quants): size(quants)
   {
      init();
   }
   ...
```

To calculate the "footprint" statistics left by "filled" pixels in the transformed size space with dimensions *size* by *size*, we describe the *data* array. The helper template class *Plain2DArray* (with type parameter T) allows the emulation of a two-dimensional array of arbitrary sizes. The same class but

with a parameter of type *double* is applied to the *trigonometric* table of pre-calculated values of sines and cosines of angles. We will need the table to quickly map pixels to a new space.

The method for detecting the parameters of the most prominent straight lines is called *extract*. It takes an image as input and must fill the output *result* array with found pairs of parameters of straight lines. In the following equation:

```
y = a * x + b
```

the parameter *a* (slope, "theta") will be written to even numbers of the *result* array, and the **b** parameter (indent, "ro") will be written to odd numbers of the array. For example, the first, most noticeable straight line after the completion of the method is described by the expression:

```
y = result[0] * x + result[1];
```

For the second line, the indexes will increase to 2 and 3, respectively, and so on, up to the maximum number of lines requested (*lines*). The *result* array size is equal to twice the number of lines.

```
template<typename T>
class LinearHoughTransform: public HoughTransformConcrete<T>
{
   ...
   virtual int extract(const HoughImage<T> &image, double &result[],
      const int lines = 8) override
   {
      ArrayResize(result, lines * 2);
      ArrayInitialize(result, 0);
      data.zero();

      const int w = image.getWidth();
      const int h = image.getHeight();
      const double d = M_PI / size;     // 180 / 36 = 5 degrees, for example
      const double rstep = MathSqrt(w * w + h * h) / size;
      ...
```

Nested loops over image pixels are organized in the straight line search block. For each "filled" (non-zero) point, a loop through tilts is performed, and the corresponding pairs of polar coordinates are marked in the transformed space. In this case, we simply call the method to increase the contents of the cell by the value returned by the pixel: *data.inc((int)r, i, v)*, but depending on the application and type T, it may require more complex processing.

```
double r, t;
int i;
for(int x = 0; x < w; x++)
{
   for(int y = 0; y < h; y++)
   {
      T v = image.get(x, y);
      if(v == (T)0) continue;

      for(i = 0, t = 0; i < size; i++, t += d) // t < Math.PI
      {
         r = (x * trigonometric.get(0, i) + y * trigonometric.get(1, i));
         r = MathRound(r / rstep); // range [-range, +range]
         r += size; // [0, +2size]
         r /= 2;

         if((int)r < 0) r = 0;
         if((int)r >= size) r = size - 1;
         if(i < 0) i = 0;
         if(i >= size) i = size - 1;

         data.inc((int)r, i, v);
      }
   }
}
...
```

In the second part of the method, the search for maximums in the new space is performed and the output array *result* is filled.

```
      for(i = 0; i < lines; i++)
      {
         int x, y;
         if(!findMax(x, y))
         {
            return i;
         }

         double a = 0, b = 0;
         if(MathSin(y * d) != 0)
         {
            a = -1.0 * MathCos(y * d) / MathSin(y * d);
            b = (x * 2 - size) * rstep / MathSin(y * d);
         }
         if(fabs(a) < DBL_EPSILON && fabs(b) < DBL_EPSILON)
         {
            i--;
            continue;
         }
         result[i * 2 + 0] = a;
         result[i * 2 + 1] = b;
      }

      return i;
   }
```

The *findMax* helper method (see the source code) writes the coordinates of the maximum value in the new space to *x* and *y* variables, additionally overwriting the neighborhood of this place so as not to find it again and again.

The *LinearHoughTransform* class is ready, and we can write an exportable factory function to spawn objects.

```
HoughTransform *createHoughTransform(const int quants,
   const ENUM_DATATYPE type = TYPE_INT) export
{
   switch(type)
   {
   case TYPE_INT:
      return new LinearHoughTransform<int>(quants);
   case TYPE_DOUBLE:
      return new LinearHoughTransform<double>(quants);
   ...
   }
   return NULL;
}
```

Because templates are not allowed for export, we use the ENUM_DATATYPE enumeration in the second parameter to vary the data type during conversion and in the original image representation.

To test the export/import of structures, we also described a structure with meta-information about the transformation in a given version of the library and exported a function that returns such a structure.

```
struct HoughInfo
{
   const int dimension; // number of parameters in the model formula
   const string about;  // verbal description
   HoughInfo(const int n, const string s): dimension(n), about(s) { }
   HoughInfo(const HoughInfo &other): dimension(other.dimension), about(other.about)
};

HoughInfo getHoughInfo() export
{
   return HoughInfo(2, "Line: y = a * x + b; a = p[0]; b = p[1];");
}
```

Various modifications of the Hough transforms can reveal not only straight lines but also other constructions that correspond to a given analytical formula (for example, circles). Such modifications will reveal a different number of parameters and carry a different meaning. Having a self-documenting function can make it easier to integrate libraries (especially when there are a lot of them; note that our header file contains only general information related to any library that implements this Hough transform interface, and not just for straight lines).

Of course, this example of exporting a class with a single public method is somewhat arbitrary because it would be possible to export the transformation function directly. However, in practice, classes tend to contain more functionality. In particular, it is easy to add to our class the adjustment of the sensitivity of the algorithm, the storage of exemplary patterns from lines for detecting signals checked on history, and so on.

Let's use the library in an indicator that calculates support and resistance lines by *High* and *Low* prices on a given number of bars. Thanks to the Hough transform and the programming interface, the library allows you to display several of the most important such lines.

The source code of the indicator is in the file *MQL5/Indicators/MQL5Book/p7/LibHoughChannel.mq5*. It also includes the header file *LibHoughTransform.mqh*, where we added the import directive.

```
#import "MQL5Book/LibHoughTransform.ex5"
HoughTransform *createHoughTransform(const int quants,
   const ENUM_DATATYPE type = TYPE_INT);
HoughInfo getHoughInfo();
#import
```

In the analyzed image, we denote by pixels the position of specific price types (OHLC) in quotes. To implement the image, we need to describe the *HoughQuotes* class derived from *Hough Image<int>*.

We will provide for "painting" pixels in several ways: inside the body of the candles, inside the full range of the candles, as well as directly in the highs and lows. All this is formalized in the PRICE_LINE enumeration. For now, the indicator will use only *HighHigh* and *LowLow*, but this can be taken out in the settings.

```
class HoughQuotes: public HoughImage<int>
{
public:
   enum PRICE_LINE
   {
      HighLow = 0,    // Bar Range |High..Low|
      OpenClose = 1, // Bar Body |Open..Close|
      LowLow = 2,     // Bar Lows
      HighHigh = 3,  // Bar Highs
   };
   ...
```

In the constructor parameters and internal variables, we specify the range of bars for analysis. The number of bars *size* determines the horizontal size of the image. For simplicity, we will use the same number of readings vertically. Therefore, the price discretization step (*step*) is equal to the actual range of prices (*pp*) for *size* bars divided by *size*. For the variable *base*, we calculate the lower limit of prices that are subject to consideration in the indicated bars. This variable will be needed to bind the construction of lines based on the found parameters of the Hough transform.

```
protected:
   int size;
   int offset;
   int step;
   double base;
   PRICE_LINE type;

public:
   HoughQuotes(int startbar, int barcount, PRICE_LINE price)
   {
      offset = startbar;
      size = barcount;
      type = price;
      int hh = iHighest(NULL, 0, MODE_HIGH, size, startbar);
      int ll = iLowest(NULL, 0, MODE_LOW, size, startbar);
      int pp = (int)((iHigh(NULL, 0, hh) - iLow(NULL, 0, ll)) / _Point);
      step = pp / size;
      base = iLow(NULL, 0, ll);
   }
   ...
```

Recall that the *HoughImage* interface requires the implementation of 3 methods: *getWidth*, *getHeight*, and *get*. The first two are easy.

```
virtual int getWidth() const override
{
   return size;
}

virtual int getHeight() const override
{
   return size;
}
```

The *get* method for getting "pixels" based on quotes returns 1 if the specified point falls within the bar or cell range, according to the selected calculation method from PRICE_LINE. Otherwise, 0 is returned. This method can be significantly improved by evaluating fractals, consistently increasing extremes, or "round" prices with a higher weight (pixel fat).

```
   virtual int get(int x, int y) const override
   {
      if(offset + x >= iBars(NULL, 0)) return 0;

      const double price = convert(y);
      if(type == HighLow)
      {
         if(price >= iLow(NULL, 0, offset + x) && price <= iHigh(NULL, 0, offset + x)
         {
            return 1;
         }
      }
      else if(type == OpenClose)
      {
         if(price >= fmin(iOpen(NULL, 0, offset + x), iClose(NULL, 0, offset + x))
         && price <= fmax(iOpen(NULL, 0, offset + x), iClose(NULL, 0, offset + x)))
         {
            return 1;
         }
      }
      else if(type == LowLow)
      {
         if(iLow(NULL, 0, offset + x) >= price - step * _Point / 2
         && iLow(NULL, 0, offset + x) <= price + step * _Point / 2)
         {
            return 1;
         }
      }
      else if(type == HighHigh)
      {
         if(iHigh(NULL, 0, offset + x) >= price - step * _Point / 2
         && iHigh(NULL, 0, offset + x) <= price + step * _Point / 2)
         {
            return 1;
         }
      }
      return 0;
   }
```

The helper method *convert* provides recalculation from pixel y coordinates to price values.

```
   double convert(const double y) const
   {
      return base + y * step * _Point;
   }
};
```

Now everything is ready for writing the technical part of the indicator. First of all, let's declare three input variables to select the fragment to be analyzed, and the number of lines. All lines will be identified by a common prefix.

```
input int BarOffset = 0;
input int BarCount = 21;
input int MaxLines = 3;

const string Prefix = "HoughChannel-";
```

The object that provides the transformation service will be described as global: this is where the factory function *createHoughTransform* is called from the library.

```
HoughTransform *ht = createHoughTransform(BarCount);
```

In the *OnInit* function, we just log the description of the library using the second imported function *getHoughInfo*.

```
int OnInit()
{
   HoughInfo info = getHoughInfo();
   Print(info.dimension, " per ", info.about);
   return INIT_SUCCEEDED;
}
```

We will perform the calculation in *OnCalculate* once, at the opening of the bar.

```
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])
{
   static datetime now = 0;
   if(now != iTime(NULL, 0, 0))
   {
      ... // see the next block
      now = iTime(NULL, 0, 0);
   }
   return rates_total;
}
```

The transformation calculation itself is run twice on a pair of images (*highs* and *lows*) formed by different types of prices. In this case, the work is sequentially performed by the same object *ht*. If the detection of straight lines was successful, we display them on the chart using the function *DrawLine*. Because the lines are listed in the results array in descending order of importance, the lines are assigned a decreasing weight.

```
   HoughQuotes highs(BarOffset, BarCount, HoughQuotes::HighHigh);
   HoughQuotes lows(BarOffset, BarCount, HoughQuotes::LowLow);
   static double result[];
   int n;
   n = ht.transform(highs, result, fmin(MaxLines, 5));
   if(n)
   {
      for(int i = 0; i < n; ++i)
      {
         DrawLine(highs, Prefix + "Highs-" + (string)i,
            result[i * 2 + 0], result[i * 2 + 1], clrBlue, 5 - i);
      }
   }
   n = ht.transform(lows, result, fmin(MaxLines, 5));
   if(n)
   {
      for(int i = 0; i < n; ++i)
      {
         DrawLine(lows, Prefix + "Lows-" + (string)i,
            result[i * 2 + 0], result[i * 2 + 1], clrRed, 5 - i);
      }
   }
```

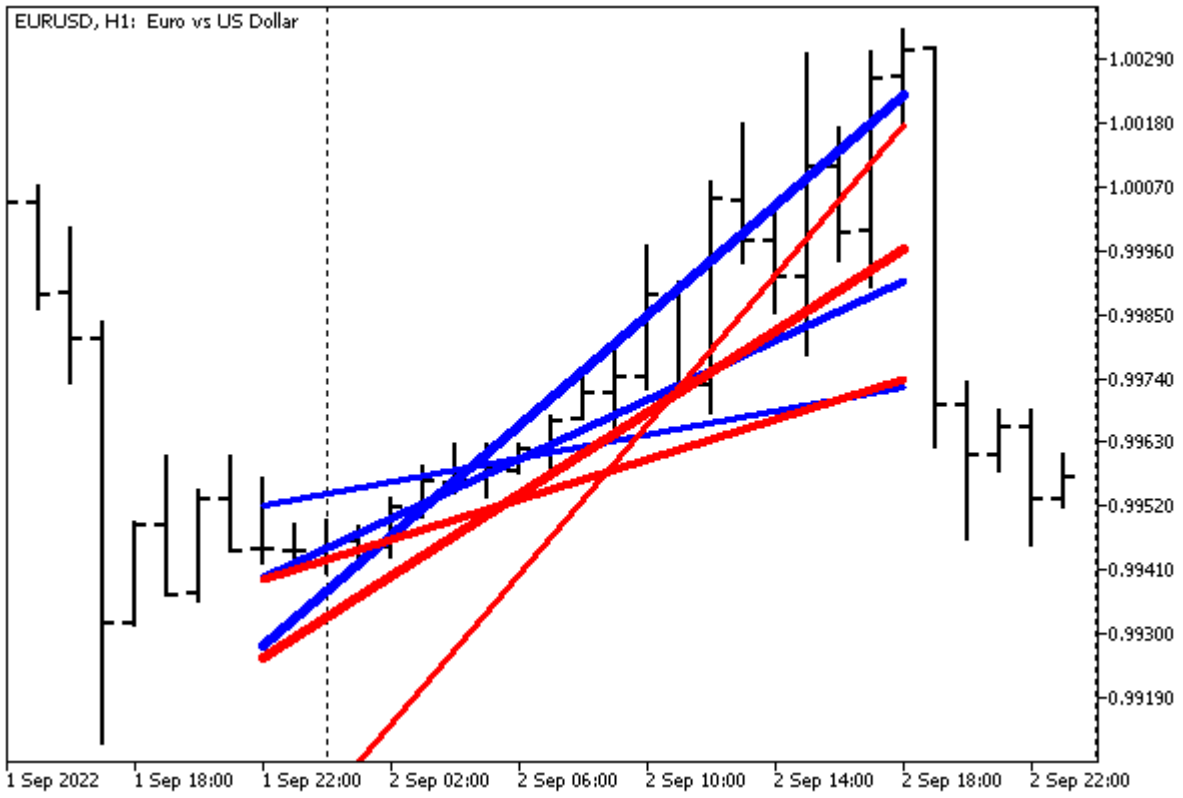
The *DrawLine* function is based on trend graphic objects (OBJ_TREND, see the source code).

When deinitializing the indicator, we delete the lines and the analytical object.

```
void OnDeinit(const int)
{
   AutoPtr<HoughTransform> destructor(ht);
   ObjectsDeleteAll(0, Prefix);
}
```

Before testing a new development, do not forget to compile both the library and the indicator.

Running the indicator with default settings gives something like this.



Indicator with main lines for High/Low prices based on the Hough transform library

In our case, the test was successful. But what if you need to debug the library? There are no built-in tools for this, so the following trick can be used. The library source test is conditionally compiled into a debug version of the product, and the product is tested against the built library. Let's consider the example of our indicator.

Let's provide the LIB_HOUGH_IMPL_DEBUG macro to enable the integration of the library source directly into the indicator. The macro should be placed before including the header file.

```
#define LIB_HOUGH_IMPL_DEBUG
#include <MQL5Book/LibHoughTransform.mqh>
```

In the header file itself, we will overlay the import block from the binary standalone copy of the library with preprocessor conditional compilation instructions. When the macro is enabled, another branch will run, with the *#include* statement.

```
#ifdef LIB_HOUGH_IMPL_DEBUG
#include "../../Libraries/MQL5Book/LibHoughTransform.mq5"
#else
#import "MQL5Book/LibHoughTransform.ex5"
HoughTransform *createHoughTransform(const int quants,
   const ENUM_DATATYPE type = TYPE_INT);
HoughInfo getHoughInfo();
#import
#endif
```

In the library source file *LibHoughTransform.mq5*, inside the *getHoughInfo* function, we add output to the log of information about the compilation method, depending on whether the macro is enabled or disabled.

```
HoughInfo getHoughInfo() export
{
#ifdef LIB_HOUGH_IMPL_DEBUG
   Print("inline library (debug)");
#else
   Print("standalone library (production)");
#endif
   return HoughInfo(2, "Line: y = a * x + b; a = p[0]; b = p[1];");
}
```

If in the indicator code, in the file *LibHoughChannel.mq5* you uncomment the instruction *#define LIB_HOUGH_IMPL_DEBUG*, you can test the step-by-step image analysis.

7.7.6 Importing functions from .NET libraries

MQL5 provides a special service for working with .NET library functions: you can simply import the DLL itself without specifying certain functions. MetaEditor automatically imports all the functions that you can work with:

- Plain Old Data (POD) – structures that contain only simple data types;
- Public static functions whose parameters use only simple POD types and structures or their arrays.

Unfortunately, at the moment, it is not possible to see function prototypes as they are recognized by MetaEditor.

For example, we have the following C# code of the *Inc* function of the *TestClass* class in the *TestLib.dll* library:

```
public class TestClass
{
   public static void Inc(ref int x)
   {
      x++;
   }
}
```

Then, to import and call it, it is enough to write:

```
#import "TestLib.dll"

void OnStart()
{
   int x = 1;
   TestClass::Inc(x);
   Print(x);
}
```

After execution, the script will return the value of 2.

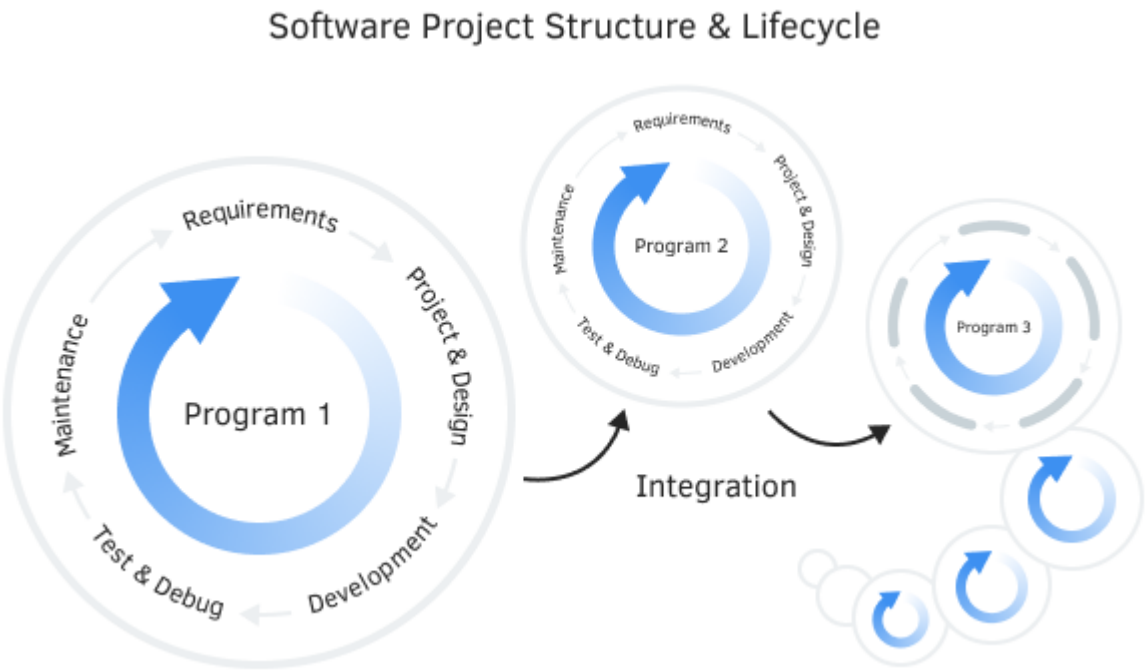
7.8 Projects

Software products, as a rule, are developed within the standard life cycle:

- Collection and addition of requirements

- Design
- Development
- Testing
- Exploitation

As a result of constant improvement and expansion of functionality, it usually becomes necessary to systematize source files, resources, and third-party libraries (here we mean not only binary format libraries but, in a more general sense, any set of files, for example, headers). Even more, individual programs are integrated into a common product that embodies an applied idea.



Structure and life cycle of the project

For example, when developing a trading robot, it is often necessary to connect ready-made or custom indicators, the use of external machine learning algorithms implies writing a script for exporting quote data and a script for re-importing trained models, and programs related to data exchange via the Internet (for example, trading signals) may require web server and its settings in other programming languages, at least for debugging and testing, if not for deploying a public service.

The whole complex of several interrelated products, together with their "dependencies" (which means the used resources and libraries, written independently or taken from third-party sources), form a software project.

When a program exceeds a certain size, its convenient and effective development is difficult without special project management tools. This fully applies to programs based on MQL5, since many traders use complex trading systems.

MetaEditor supports the concept of projects similar to other software packages. Currently, this functionality is at the beginning of its development, and by the time the book is released, it will probably change.

When working with projects in MQL5, keep in mind that the term "project" in the platform is used for two different entities:

- Local project in the form of an mqproj file
- Folders in MQL5 cloud storage

A local project allows you to systematize and gather together all the information about source codes, resources, and settings needed to build a particular MQL program. Such a project is only on your computer and can refer to files from different folders.

The file with the extension *mqproj* has a widely used, universal, JSON (JavaScript Object Notation) text format. It is convenient, simple, and well-suited for describing data of any subject area: all information is grouped into objects or arrays with named properties, with support for values of different types. All this makes JSON conceptually very close to OOP languages; also it comes from object-oriented JavaScript, as you can easily guess from the name.

Cloud storage operates on the basis of a version control system and collective work on software called SVN (Subversion). Here, a project is a top-level folder inside the local directory *MQL5/Shared Projects*, to which another folder is assigned, having the same name but located on the MQL5 Storage server. Within a project folder, you can organize a hierarchy of subfolders. As the name suggests, network projects can be shared with other developers and generally made public (the content can be downloaded by anyone registered on mql5.com).

The system provides on-demand synchronization (using special user commands) between the folder image in the cloud and on the local drive, and vice versa. You can both "pull" other people's project changes to your computer, and "push" your edits to the cloud. Both the full folder image and selective files can be synchronized, including, of course, mq5 files, mqh header files, multimedia, settings (set files), as well as mqproj files. For more information about cloud storage, read the documentation of MetaEditor and SVN systems.

> It is important to note that the existence of an mqproj file does not imply the creation of any cloud project on its basis, just as the creation of a shared folder does not oblige you to use an mqproj project.

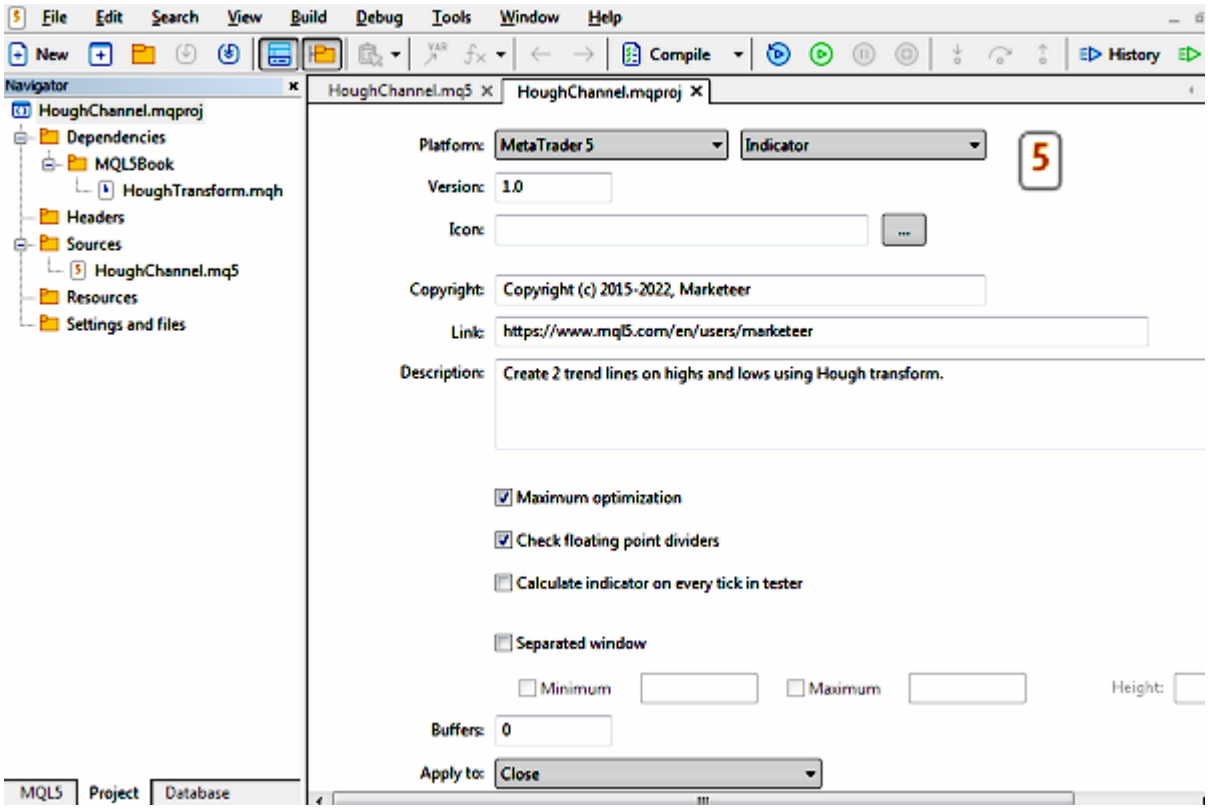
At the time of this writing, an mqproj file can only describe the structure of one program, not several. However, since such a requirement is common when developing complex projects, this functionality will probably be added to MetaEditor in the future.

In this chapter, we will describe the main functions for creating and organizing mqproj projects and give a series of examples.

7.8.1 General rules for working with local projects

A local project (mqproj file) can be created from the MetaEditor main menu or from the *Navigator* context menu using commands *New project* or *New project from source file*. In the latter case, the file must first be selected in *Navigator* or chosen in the *Open* dialog. As a result, the specified mq5 file will be included in the project immediately. The first of the mentioned commands launches the MQL Wizard, in which you should select the program type or an empty project option (source files can be added to it later). The type of an MQL program for a project is chosen following the usual steps of the Wizard.

The project contains several logical sections which resemble a tree (hierarchy) with all the components. They are displayed in the left panel of *Navigator*, in a separate tab *Project*.



Navigator and indicator project properties

Immediately after creating the project or later by double-clicking on the root of the tree, a panel for setting the MQL program properties opens in the right part of the window. The set of properties varies depending on the type of program.

Most of the properties correspond to *#property* directives in the source code. These properties take precedence: if you specify them in both the project and the source code, the values from the project will be used.

Some developers may like to set properties interactively in a dialog rather than hardcoded in source code. Also, you can use the same mq5 file in different projects and build versions of an MQL program with different settings (without changing the source code).

Some properties are only available in a project. These include, for example, enabling/disabling compilation optimizations and built-in divide-by-zero checks.

During project compilation, the system automatically analyzes dependencies, that is, the included header files, resources, and so on. Dependencies appear in different branches of the project hierarchy. In particular, header files from the standard MQL5/Include folders included in the *#include* directives using angle brackets (*<filename>*), fall into *Dependencies*, and custom header files included with double quotes (*#include "filename"*) fall into the *Headers* section.

Additionally, the user can add files to the project that are related to the finished software product and may be required for its normal operation or demonstration (for example, files with trained neural network models) but are not directly embedded in the source code. For these purposes, you can use the *Settings and Files* branch. Its context menu contains commands for adding a single file or an entire directory to the project.

In particular, we will further consider examples of projects that will include not only client MQL programs but also the server part.

Commands *New file* and *New folder* add a new element to the folder with the project file: such elements are always searched relative to the project itself (in the mqproj file they are marked with the *relative_to_project* property equal to *true*, see further).

Commands *Add an existing file* and *Add an existing folder* select one or more elements from the existing directory structure inside the MQL5 folder, and these elements inside the mqproj file are referenced relative to the root MQL5 (the *relative_to_project* property equals *false*).

The *relative_to_project* property is just one of the few defined by the MetaTrader 5 developers to represent a project in JSON format. Recall that as a result of editing the project (hierarchy and properties), an mqproj-file of the JSON format is formed.

Here is what that file looks like for the project in the image above.

```
{
  "platform"    :"mt5",
  "program_type":"indicator",
  "copyright"   :"Copyright (c) 2015-2022, Marketeer",
  "link"        :"https:\/\/www.mql5.com\/en\/users\/marketeer",
  "version"     :"1.0",
  "description" :"Create 2 trend lines on highs and lows using Hough transform.",
  "optimize"    :"1",
  "fpzerocheck" :"1",
  "tester_no_cache":"0",
  "tester_everytick_calculate":"0",
  "unicode_character_set":"0",
  "static_libraries":"0",

  "indicator":
  {
    "window":"0"
  },

  "files":
  [
    {
      "path":"HoughChannel.mq5",
      "compile":true,
      "relative_to_project":true
    },
    {
      "path":"MQL5\\Include\\MQL5Book\\HoughTransform.mqh",
      "compile":false,
      "relative_to_project":false
    }
  ]
}
```

We will talk about the technical features of the JSON format in more detail in the following sections as we will apply it in our demo projects.

It is important to note that all files referenced by the project are not stored inside the mqproj file, and therefore copying to a new location or moving only the project file to another computer will not

restore it. To be able to migrate a project, set up a shared project for it and upload all the contents of the project to the cloud. However, this may require a reorganization of the local file system structure, as all components must be inside the shared project folder, while the mqproj format does not require this.

7.8.2 Project plan of a web service for copying trades and signals

As an end-to-end demonstration project, which we will develop throughout this chapter, we will take a simple, but at the same time quite technologically advanced product: a client-server copy trade system. The client part will be MQL programs that communicate with the central part using the sockets technology. Considering that MQL5 allows you to work only with client sockets, you will need to choose an alternative platform for the socket server (more on that below). Thus, the project will require the symbiosis of several different technologies and the use of many sections of the MQL5 API that we have already studied, including application codes developed on their basis.

Thanks to the socket-based client-server architecture, the system can be used in different scenarios:

- for easy copying of trades between terminals on one computer;
- to establish a private (personal) communication channel between terminals on different computers, including not only in the local network but also via the Internet;
- to organize a publicly open or closed signal service requiring registration;
- to monitor trading;
- to manage your own account remotely.

In all cases, client programs will act in 2 roles: a publisher (publisher, sender) and a subscriber (recipient) of data.

We will not invent our own network protocol but will use the existing and popular WebSocket standard. Their client implementation is built into all browsers, and we will need to repeat it (with a greater or lesser degree of completeness) in MQL5. Of course, WebSocket support is also available for most popular web servers. Therefore, in any case, our developments can not only be adapted to other servers (if someone else suits) but also integrated with well-known sites that provide similar web services. Here the whole point is to strictly follow the specification of their API, built on top of WebSockets.

When developing software systems that are more complex than one standalone program, it is important to draw up an action plan and, possibly, even design a technical project, including the structure of modules, their interaction, and the sequence of coding.

So our plan includes:

1. Theoretical analysis of the WebSocket protocol;
2. Selecting and installing a web server with the implementation of a WebSocket server;
3. Creating a simple echo server (sending a copy of incoming messages back to the client) to get familiar with the technology;
4. Creating a simple client-side web page to test the functionality of the echo server from a browser;
5. Creating a simple chat server that sends messages to all connected clients, and a test web page for it;
6. Creating a messaging server between identifiable providers and subscribers, and a test web client for it;

7. Designing and implementing WebSockets in MQL5;
8. Creating a simple script as a client for an echo server;
9. Creating a simple Expert Advisor as a chat server client;
10. Finally, creating a trade copier in MQL5 which it will act as both an information provider (monitor of account changes and status) and an information consumer (reproducing trades), depending on the settings.

But before we start implementing the plan, we need to install a web server.

7.8.3 Nodejs based web server

To organize the server part of our projects, we need a web server. We will use the lightest and most technologically advanced nodejs. Server-side scripts for it can be written in JavaScript, which is the same language used in browsers for interactive web pages. This is convenient from the point of view of unified writing of the client and server parts of the system; the client part of any web service, as a rule, is required sooner or later, for example, for administration, registration, and displaying beautiful statistics on the use of the service.

Anyone who knows MQL5 virtually knows JavaScript, so believe in yourselves. The main differences are discussed in the sidebar.

MQL5 vs JavaScript

JavaScript is an interpreted language, unlike the compiled MQL5. For us as developers, this makes life easier because we don't need a separate compilation phase to get a working program. Don't worry about the efficiency of JavaScript: all JavaScript runtimes use JIT (just-in-time) compilation of JavaScript on demand, i.e., the first time a module is accessed. This process occurs automatically, implicitly, once per session, after which the script is executed in compiled form.

MQL5 refers to languages with static typing, that is, when describing variables, we must explicitly specify their type, and the compiler monitors type compatibility. In contrast, JavaScript is a dynamically typed language: the type of a variable is determined by what value we put in it and can change during the life of the variable. This provides flexibility but requires caution in order to avoid unforeseen errors.

JavaScript is, in a sense, a more object-oriented language than MQL5, because almost all entities in it are objects. For example, a function is also an object, and a class, as a descriptor of the properties of objects, is also an object (of a prototype).

JavaScript itself "collects garbage", i.e., frees the memory allocated by the application program for objects. In MQL5 we have to provide the timely call of *delete* for dynamic objects.

The JavaScript syntax contains many convenient "abbreviations" for writing constructions that in MQL5 have to be implemented in a longer way. For example, in order to pass a parameter pointing to another function to a certain function in MQL5, we need to describe the type of such a pointer using typedef, separately define a function that matches this prototype, and only then pass its identifier as a parameter. In JavaScript, you can define the function you're pointing to (in its entirety!) directly in the argument list instead of a pointer parameter.

If you are a web developer or already familiar with nodejs, you can skip the installation and configuration steps.

You can download nodejs from the official site nodejs.org. Installation is available in different versions, for example, using an installer or unpacking an archive. As a result of the installation, you will receive an executable file in the specified directory *node.exe* and several supporting files and folders.

If nodejs was not added to the system path by the installer, this can be done for the current Windows user by running the following command in the folder where nodejs is installed (where the file *node.exe* is located):

```
setx PATH "%CD%"
```

Alternatively, you can edit the Windows environment variables from the system properties dialog (*Computer -> Properties -> Extra options -> Environment Variables*; the specific dialog type depends on the version of the operating system). In any case, in this way, we will ensure the ability to run nodejs from any folder on the computer, which will be useful to us in the future.

You can check the health of nodejs by running the following commands (in the Windows command line):

```
node -v
npm version
```

The first command outputs the version of nodejs, and the second one outputs the version of an important built-in nodejs service, the *npm* package manager.

A package is a ready-to-use module that adds specific functionality to nodejs. By itself, nodejs is very small, and without packages, it would require a lot of routine coding.

The most requested packages are stored in a centralized repository on the web and can be downloaded and installed on a specific copy of nodejs or globally (for all copies of nodejs if there are several on the machine). Installing a package to a specific copy is done with the following command:

```
npm install <package name>
```

Run it in the folder where nodejs was installed. This command will place the package locally and will not affect other copies of nodejs that already exist or may appear on the computer later on, with unexpected edits.

We, in particular, need the ws package, which implements the WebSocket protocol. That is, you need to run the command:

```
npm install ws
```

and wait for the process to complete. As a result, the folder *<nodejs_install_path>/node_modules/* should contain a new subfolder *ws* with the necessary content (you can look in the README.md file with the description of the package to make sure it's a WebSocket protocol library).

The package contains implementations of both the server and the client. But instead of the latter, we will write our own in MQL5.

All the functionality of the nodejs server is concentrated in the folder */node_modules*. It can be compared in purpose with a standard folder *MQL5/Include* in MetaTrader 5. When writing application programs in JavaScript, we will include or "import" the necessary modules in a special way, by analogy with including mqh header files using the directive *#include* in MQL5.

7.8.4 Theoretical foundations of the WebSockets protocol

The WebSocket protocol is built on top of TCP/IP network connections, which are characterized by an IP address (or a domain name that replaces it) and a port number. The HTTP/HTTPS protocol, with which we have already practiced in the chapter on network functions, works based on the same principle. There, the standard port numbers were 80 (for insecure connections) and 443 (for secure connections). There is no dedicated port number for WebSocket, so web service providers can choose any available number. All of our examples will use port 9000.

When specifying URLs as WebSocket protocol prefixes, we use *ws* (for non-secure connections) and *wss* (for secure connections).

The WebSocket format is more efficient in terms of data transfer than HTTP as it uses much less control data.

The initial connection establishment for a WebSocket service completely repeats an HTTP/HTTPS web page request: you need to send a GET request with specially prepared headers. A feature of these headers is the presence of lines:

```
Connection: Upgrade
Upgrade: websocket
```

as well as some additional lines that report the version of the WebSocket protocol and special randomly generated strings. The keys involved in the "handshaking" procedure between the client and the server.

```
Sec-WebSocket-Key: ...
Sec-WebSocket-Version: 13
```

In practice, the "handshake" implies that the server checks the availability of those options that the client requested, and in response with standard HTTP headers confirms the switch to WebSocket mode or rejects it. The simplest reason for rejection can be if you are trying to connect via WebSockets to a simple web server where the WebSocket server is not provided or the required version is not supported.

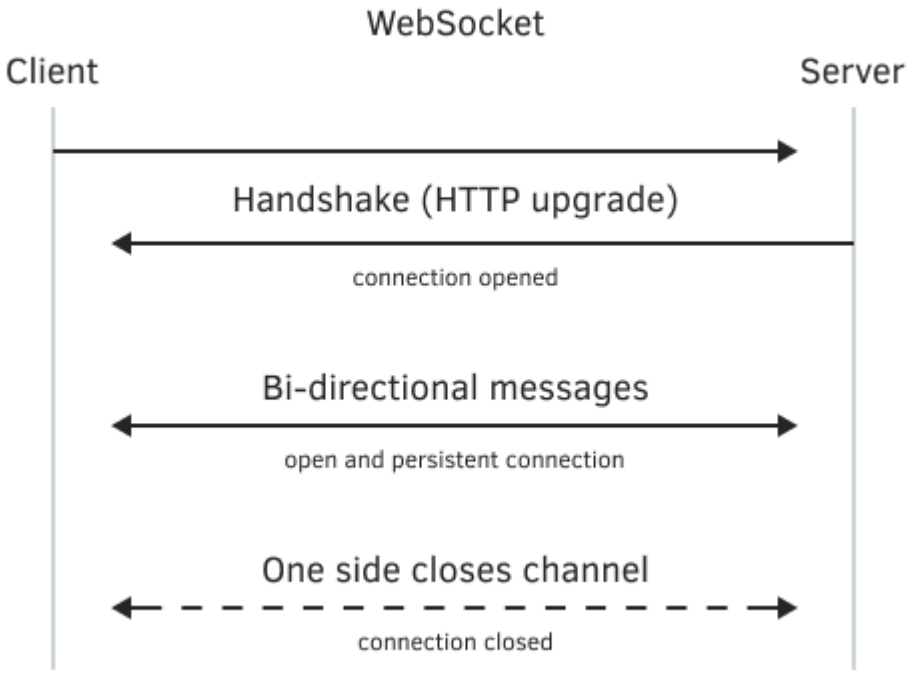
The current version of the WebSockets protocol is known under the symbolic name Hybi and number 13. An earlier and simpler version called Hixie may be useful for backward compatibility. In what follows, we will only use Hybi, although a Hixie implementation is also included.

A successful connection is indicated by the following HTTP headers in the server response:

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: ...
```

The Sec-WebSocket-Accept field here is calculated and populated by the server based on the Sec-WebSocket-Key to confirm compliance with the protocol. All this is regulated by the specification RFC6455 and will be supported in our MQL programs as well.

For clarity, the procedure is shown in the following image:



Interaction between client and server via WebSocket protocol

After establishing a WebSocket connection, the client and server can exchange information packed into special blocks: frames and messages. A message may consist of one or more frames. The frame size, according to the specification, is limited to an astronomical number of 2^{63} bytes (9223372036854775807 ~ 9.22 exabytes!), but specific implementations may of course have more mundane limits since this theoretical limit does not seem practical for sending in one packet.

At any time, the client or server can terminate the connection, having previously "politely said goodbye" (see below) or by simply closing the network socket.

Frames can be of different types as specified in their header (4 to 16 bytes long) that comes at the beginning of each frame. For reference, let's list the operational codes (they are present in the first byte of the header) and the purpose of frames of different types.

- 0 – continuation frame (inherits the properties of the previous frame);
- 1 – frame with text information;
- 2 – frame with binary information;
- 8 – frame request to close and confirmation of closing the connection (sent for "polite farewell");
- 9 – ping frame, can be periodically sent by either side to make sure the connection is physically saved;
- 10 – pong frame, sent in response to a ping frame.

The last frame in a message is marked with a special bit in the header. Of course, when a message consists of one frame, it is also the last one. The length of the payload is also passed in the header.

7.8.5 Server component of web services based on the WebSocket protocol

To organize a common server component of all projects, we will create a separate folder *Web* inside *MQL5/Experts/MQL5Book/p7/*. Ideally, it would be convenient to place *Web* as a subfolder into *Shared Projects*. The fact is that *MQL5/Shared Projects* is available in the standard distribution of MetaTrader 5

and reserved for cloud storage projects. Therefore, later, by using the functionality of shared projects, it would be possible to upload all the files of our projects to the server (not only web files but also MQL programs).

Later, when we create an mqproj file with MQL5 client programs, we will add all the files in this folder to the project section *Settings and Files*, since all these files form an integral part of the project – the server part.

Since a separate directory has been allocated for the project server, it is necessary to ensure the possibility of importing modules from nodejs in this directory. By default, nodejs looks for modules in the */node_modules* subfolder of the current directory, and we will run the server from the project. Therefore, being in the folder where we will place the web files of the project, run the command:

```
mklink /j node_modules {drive:/path/to/folder/nodejs}/node_modules
```

As a result, a "symbolic" directory link called *node_modules* will appear, pointing to the original folder of the same name in the installed nodejs.

The easiest way to check the functionality of WebSockets is the echo service. Its model of operation is to return any received message back to the sender. Let's consider how it would be possible to organize such a service in a minimal configuration. An example is included in the file *wsintro.js*.

First of all, we connect the package (module) *ws*, which provides WebSocket functionality for nodejs and which we installed along with the web server.

```
// JavaScript
const WebSocket = require('ws');
```

The *require* function works similarly to the *#include* directive in MQL5, but additionally returns a module object with the API of all files in the *ws* package. Thanks to this, we can call the methods and properties of the *WebSocket* object. In this case, we need to create a WebSocket server on port 9000.

```
// JavaScript
const port = 9000;
const wss = new WebSocket.Server({ port: port });
```

Here we see the usual MQL5 constructor call by the *new* operator, but an unnamed object (structure) is passed as a parameter, in which, as in a map, a set of named properties and their values can be stored. In this case, only one property *port* is used, and its value is set equal to the (more precisely, a constant) *port* variable described above. Basically, we can pass the port number (and other settings) on the command line when running the script.

The server object gets into the *wss* variable. On success, we signal to the command line window that the server is running (waiting for connections).

```
// JavaScript
console.log('listening on port: ' + port);
```

The *console.log* call is similar to the usual *Print* in MQL5. Also note that strings in JavaScript can be enclosed not only in double quotes but also in single quotes, and even in backticks *`this is a ${template}text`*, which adds some useful features.

Next, for the *wss* object, we assign a "connection" event handler, which refers to the connection of a new client. Obviously, the list of supported object events is defined by the developers of the package, in this case, the package *ws* that we use. All this is reflected in the documentation.

The handler is bound by the *on* method, which specifies the name of the event and the handler itself.

```
// JavaScript
wss.on('connection', function(channel)
{
   ...
});
```

The handler is an unnamed (anonymous) function defined directly in the place where a reference parameter is expected for the callback code to be executed on a new connection. The function is made anonymous because it is used only here, and JavaScript allows such simplifications in the syntax. The function has only one parameter which is the object of the new connection. We are free to choose the name for the parameter ourselves, and in this case, it is *channel*.

Inside the handler, another handler should be set for the "message" event related to the arrival of a new message in a specific channel.

```
// JavaScript
   channel.on('message', function(message)
   {
      console.log('message: ' + message);
      channel.send('echo: ' + message);
   });
   ...
```

It also uses an anonymous function with a single parameter, the received message object. We print it to the console log for debugging. But the most important thing happens in the second line: by calling *channel.send*, we send a response message to the client.

To complete the picture, let's add our own welcome message to the "connection" handler. When complete, it looks like this:

```
// JavaScript
wss.on('connection', function(channel)
{
   channel.on('message', function(message)
   {
      console.log('message: ' + message);
      channel.send('echo: ' + message);
   });
   console.log('new client connected!');
   channel.send('connected!');
});
```

It's important to understand that while binding the "message" handler is higher in the code than sending the "hello", the message handler will be called later, and only if the client sends a message.

We have reviewed a script outline for organizing an echo service. However, it would be good to test it. This can be done in the most efficient way by using a regular browser, but this will require complicating the script slightly: turning it into the smallest possible web server that returns a web page with the smallest possible WebSocket client.

Echo service and test web page

The echo server script that we will now look at is in the file *wsecho.js*. One of the main points is that it is desirable to support not only open protocols on the server *http/ws* but also protected protocols *https/wss*. This possibility will be provided in all our examples (including clients based on MQL5), but for this, you need to perform some actions on the server.

You should start with a couple of files containing encryption keys and certificates. The files are usually obtained from authorized sources, i.e. certifying centers, but for informational purposes, you can generate the files yourself. Of course, they cannot be used on public servers, and pages with such certificates will cause warnings in any browser (the page icon to the left of the address bar is highlighted in red).

The description of the device of certificates and the process of generating them on their own is beyond the scope of the book, but two ready-made files are included in the book: *MQL5Book.crt* and *MQL5Book.key* (there are other extensions) with a limited duration. These files must be passed to the constructor of the web server object in order for the server to work over the HTTPS protocol.

We will pass the name of the certificate files in the script launch command line. For example, like this:

```
node wsecho.js MQL5Book
```

If you run the script without an additional parameter, the server will work using the HTTP protocol.

```
node wsecho.js
```

Inside the script, command line arguments are available through the built-in object *process.argv*, and the first two arguments always contain, respectively, the name of the server *node.exe* and the name of the script to run (in this case, *wsecho.js*), so we discard them by the *splice* method.

```
// JavaScript
const args = process.argv.slice(2);
const secure = args.length > 0 ? 'https' : 'http';
```

Depending on the presence of the certificate name, the *secure* variable gets the name of the package that should be loaded next to create the server: *https* or *http*. In total, we have 3 dependencies in the code:

```
// JavaScript
const fs = require('fs');
const http1 = require(secure);
const WebSocket = require('ws');
```

We already know all about the *ws* package; the *https* and *http* packages provide a web server implementation, and the built-in *fs* package provides work with the file system.

Web server settings are formatted as the *options* object. Here we see how the name of the certificate from the command line is substituted in strings with slash quotes using the expression *${args[0]}*. Then the corresponding pair of files is read by the method *fs.readFileSync*.

```
// JavaScript
const options = args.length > 0 ?
{
   key : fs.readFileSync(`${args[0]}.key`),
   cert : fs.readFileSync(`${args[0]}.crt`)
} : null;
```

The web server is created by calling the *createServer* method, to which we pass the options object and an anonymous function – an HTTP request handler. The handler has two parameters: the *req* object with an HTTP request and the *res* object with which we should send the response (HTTP headers and web page).

```
// JavaScript
http1.createServer(options, function (req, res)
{
   console.log(req.method, req.url);
   console.log(req.headers);

   if(req.url == '/') req.url = "index.htm";

   fs.readFile('./' + req.url, (err, data) =>
   {
      if(!err)
      {
         var dotoffset = req.url.lastIndexOf('.');
         var mimetype = dotoffset == -1 ? 'text/plain' :
         {
            '.htm' : 'text/html',
            '.html' : 'text/html',
            '.css' : 'text/css',
            '.js' : 'text/javascript'
         }[ req.url.substr(dotoffset) ];
         res.setHeader('Content-Type',
            mimetype == undefined ? 'text/plain' : mimetype);
         res.end(data);
      }
      else
      {
         console.log('File not fount: ' + req.url);
         res.writeHead(404, "Not Found");
         res.end();
      }
  });
}).listen(secure == 'https' ? 443 : 80);
```

The main index page (and the only one) is *index.htm* (to be written now). In addition, the handler can send js and css files, which will be useful to us in the future. Depending on whether protected mode is enabled, the server is started by calling the method *listen* on standard ports 443 or 80 (change to others if these are already taken on your computer).

To accept connections on port 9000 for web sockets, we need to deploy another web server instance with the same options. But in this case, the server is there for the sole purpose of handling an HTTP request to "upgrade" the connection up to the Web Sockets protocol.

```
// JavaScript
const server = new http1.createServer(options).listen(9000);
server.on('upgrade', function(req, socket, head)
{
   console.log(req.headers); // TODO: we can add authorization!
});
```

Here, in the "upgrade" event handler, we accept any connections that have already passed the handshake and print the headers to the log, but potentially we could request user authorization if we were doing a closed (paid) service.

Finally, we create a WebSocket server object, as in the previous introductory example, with the only difference being that a ready-made web server is passed to the constructor. All connecting clients are counted and welcomed by sequence number.

```
// JavaScript
var count = 0;

const wsServer = new WebSocket.Server({ server });
wsServer.on('connection', function onConnect(client)
{
   console.log('New user:', ++count);
   client.id = count;
   client.send('server#Hello, user' + count);

   client.on('message', function(message)
   {
      console.log('%d : %s', client.id, message);
      client.send('user' + client.id + '#' + message);
   });

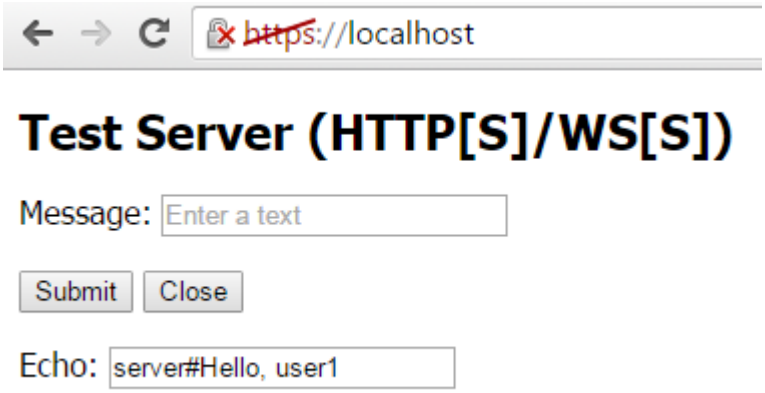
   client.on('close', function()
   {
      console.log('User disconnected:', client.id);
   });
});
```

For all events, including connection, disconnection, and message, debug information is displayed in the console.

Well, the web server with web socket server support is ready. Now we need to create a client web page *index.htm* for it.

```
<!DOCTYPE html>
<html>
  <head>
  <title>Test Server (HTTP[S]/WS[S])</title>
  </head>
  <body>
    <div>
      <h1>Test Server (HTTP[S]/WS[S])</h1>
      <p><label>
         Message: <input id="message" name="message" placeholder="Enter a text">
      </label></p>
      <p><button>Submit</button> <button>Close</button></p>
      <p><label>
         Echo: <input id="echo" name="echo" placeholder="Text from server">
      </label></p>
    </div>
  </body>
  <script src="wsecho_client.js"></script>
</html>
```

The page is a form with a single input field and a button for sending a message.



Echo service web page on WebSocket

The page uses the *wsecho_client.js* script, which provides websocket client response. In browsers, web sockets are built in as "native" JavaScript objects, so you don't need to connect anything external: just call the constructor *web socket* with the desired protocol and port number.

```
// JavaScript
const proto = window.location.protocol.startsWith('http') ?
              window.location.protocol.replace('http', 'ws') : 'ws:';
const ws = new WebSocket(proto + '//' + window.location.hostname + ':9000');
```

The URL is formed from the address of the current web page (*window.location.hostname*), so the web socket connection is made to the same server.

Next, the *ws* object allows you to react to events and send messages. In the browser, the open connection event is called "open"; it is connected via the *onopen* property. The same syntx, slightly different from the server implementation, is also used for the new message arrival event – the handler for it is assigned to the *onmessage* property.

```
// JavaScript
ws.onopen = function()
{
   console.log('Connected');
};

ws.onmessage = function(message)
{
   console.log('Message: %s', message.data);
   document.getElementById('echo').value = message.data;
};
```

The text of the incoming message is displayed in the form element with the id "echo". Note that the message event object (handler parameter) is not the message which is available in the *data* property. This is an implementation feature in JavaScript.

The reaction to the form buttons is assigned using the *addEventListener* method for each of the two *button* tag objects. Here we see another way of describing an anonymous function in JavaScript: parentheses with an argument list that can be empty, and the body of the function after the arrow can be *(arguments) => { ... }*.

```
// JavaScript
const button = document.querySelectorAll('button'); // request all buttons
// button "Submit"
button[0].addEventListener('click', (event) =>
{
   const x = document.getElementById('message').value;
   if(x) ws.send(x);
});
// button "close"
button[1].addEventListener('click', (event) =>
{
   ws.close();
   document.getElementById('echo').value = 'disconnected';
   Array.from(document.getElementsByTagName('button')).forEach((e) =>
   {
      e.disabled = true;
   });
});
```

To send messages, we call the *ws.send* method, and to close the connection we call the *ws.close* method.

This completes the development of the first example of client-server scripts for demonstrating the echo service. You can run *wsecho.js* using one of the commands shown earlier, and then open in your browser the page at *http://localhost* or *https://localhost* (depending on server settings). After the form appears on the screen, try chatting with the server and make sure the service is running.

Gradually complicating this example, we will pave the way for the web service for copying trading signals. But the next step will be a chat service, the principle of which is similar to the service of trading signals: messages from one user are transmitted to other users.

Chat service and test web page

The new server script is called *wschat.js*, and it repeats a lot from *wsecho.js*. Let's list the main differences. In the web server HTTP request handler, change the initial page from *index.htm* to *wschat.htm*.

```
// JavaScript
http1.createServer(options, function (req, res)
{
   if(req.url == '/') req.url = "wschat.htm";
   ...
});
```

To store information about users connected to the chat, we will describe the *clients* map array. *Map* is a standard JavaScript associative container, into which arbitrary values can be written using keys of an arbitrary type, including objects.

```
// JavaScript
const clients = new Map();                    // added this line
var count = 0;
```

In the new user connection event handler, we will add the *client* object, received as a function parameter, into the map under the current client sequence number.

```
// JavaScript
wsServer.on('connection', function onConnect(client)
{
   console.log('New user:', ++count);
   client.id = count;
   client.send('server#Hello, user' + count);
   clients.set(count, client);                // added this line
   ...
```

Inside the *onConnect* function, we set a handler for the event about the arrival of a new message for a specific client, and it is inside the nested handler that we send messages. However, this time we loop through all the elements of the map (that is, through all the clients) and send the text to each of them. The loop is organized with the *forEach* method calls for an array from the map, and the next anonymous function that will be performed for each element (*elem*) is passed to the method in place. The example of this loop clearly demonstrates the *functional-declarative* programming paradigm that prevails in JavaScript (in contrast to the *imperative* approach in MQL5).

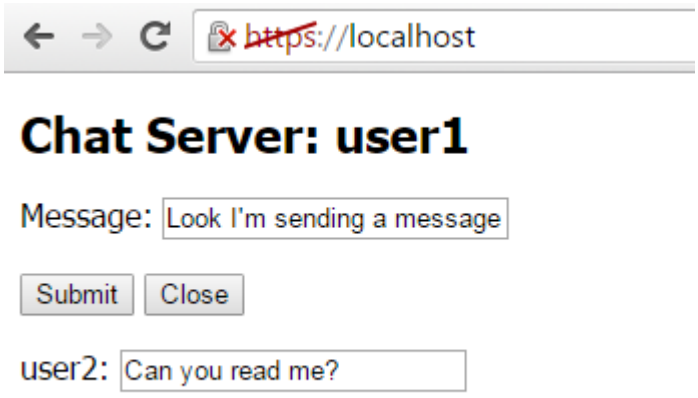
```
// JavaScript
   client.on('message', function(message)
   {
      console.log('%d : %s', client.id, message);
      Array.from(clients.values()).forEach(function(elem) // added a loop
      {
         elem.send('user' + client.id + '#' + message);
      });
   });
```

It is important to note that we send a copy of the message to all clients, including the original author. It could be filtered out, but for debugging purposes, it's better to have confirmation that the message was sent.

The last difference from the previous echo service is that when a client disconnects, it needs to be removed from the map.

```
// JavaScript
   client.on('close', function()
   {
      console.log('User disconnected:', client.id);
      clients.delete(client.id);                  // added this line
   });
```

Regarding the replacement of the page *index.htm* by *wschat.htm*, here we added a "field" to display the author of the message (*origin*) and connected a new browser script *wschat_client.js*. It parses the messages (we use the '#' symbol to separate the author from the text) and fills in the form fields with the information received. Since nothing has changed from the point of view of the WebSocket protocol, we will not provide the source code.



Chat service webpage on WebSocket

You can start nodejs with the *wschat.js* chat server and then connect to it from several browser tabs. Each connection gets a unique number displayed in the header. Text from the *Message* field is sent to all clients upon the click on *Submit*. Then, the client forms show both the author of the message (label at the bottom left) and the text itself (field at the bottom center).

So, we have made sure that the web server with web socket support is ready. Let's turn to writing the client part of the protocol in MQL5.

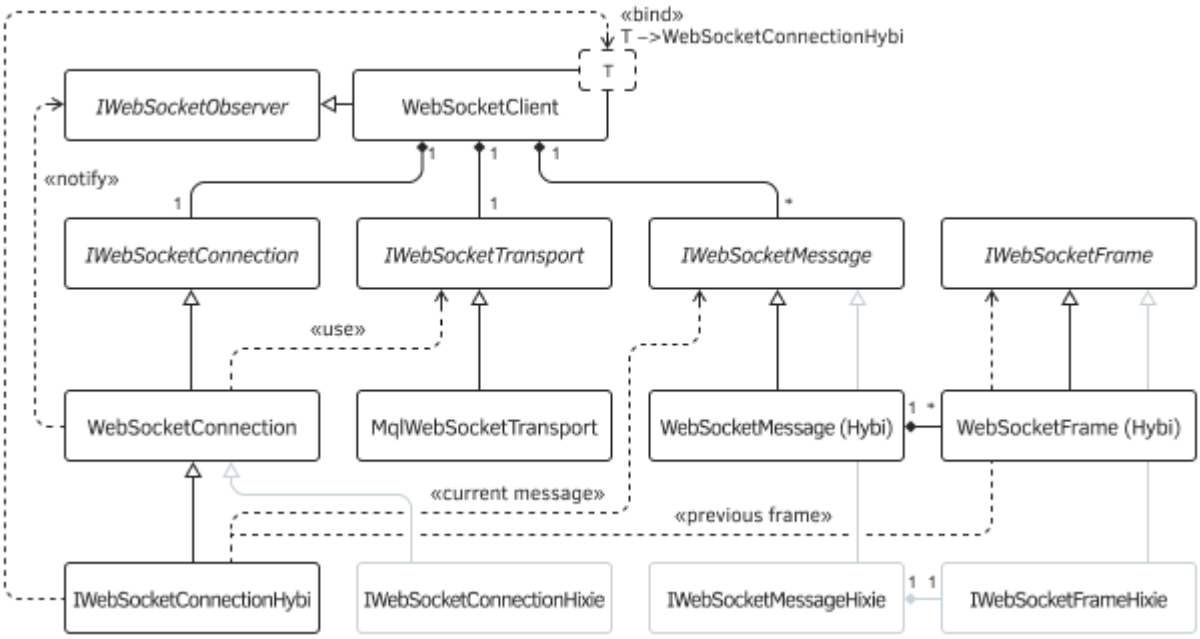
7.8.6 WebSocket protocol in MQL5

We have previously looked at Theoretical foundations of the WebSockets protocol. The complete specification is quite extensive, and a detailed description of its implementation would require a lot of space and time. Therefore, we present the general structure of ready-made classes and their programming interfaces. All files are located in the directory *MQL5/Include/MQL5Book/ws/*.

- wsinterfaces.mqh – general abstract description of all interfaces, constants, and types;
- wstransport.mqh – MqlWebSocketTransport class that implements the IWebSocketTransport low-level network data transfer interface based on MQL5 socket functions;
- wsframe.mqh – WebSocketFrame and WebSocketFrameHixie classes that implement the IWebSocketFrame interface, which hides the algorithms for generating (encoding and decoding) frames for the Hybi and Hixie protocols, respectively;

- wsmessage.mqh – WebSocketMessage and WebSocketMessageHixie classes that implement the IWebSocketMessage interface, which formalizes the formation of messages from frames for the Hybi and Hixie protocols, respectively;
- wsprotocol.mqh – WebSocketConnection, WebSocketConnectionHybi, WebSocketConnectionHixie classes inherited from IWebSocketConnection; it is here that the coordinated management of the formation of frames, messages, greetings, and disconnection according to the specification takes place, for which the above interfaces are used;
- wsclient.mqh – ready-made implementation of a WebSocket client; a WebSocketClient template class that supports the IWebSocketObserver interface (for event processing) and expects WebSocketConnectionHybi or WebSocketConnectionHixie as a parameterized type;
- wstools.mqh – useful utilities in the WsTools namespace.

These header files will be automatically included in our future mqporj projects as dependencies from *#include* directives.



WebSocket class diagram in MQL5

The low-level network interface *IWebSocketTransport* has the following methods.

```
interface IWebSocketTransport
{
   int write(const uchar &data[]); // write the array of bytes to the network
   int read(uchar &buffer[]);      // read data from network into byte array
   bool isConnected(void) const;   // check for connection
   bool isReadable(void) const;    // check for the ability to read from the network
   bool isWritable(void) const;    // check for the possibility of writing to the net
   int getHandle(void) const;      // system socket descriptor
   void close(void);               // close connection
};
```

It is not difficult to guess from the names of the methods which MQL5 API Socket functions will be used to build them. But if necessary, those who wish can implement this interface by their own means, for example, through a DLL.

The *MqlWebSocketTransport* class that implements this interface requires the protocol, hostname, and port number to which the network connection is made when creating an instance. Additionally, you can specify a timeout value.

Frame types are collected in the WS_FRAME_OPCODE enum.

```
enum WS_FRAME_OPCODE
{
   WS_DEFAULT = 0,
   WS_CONTINUATION_FRAME = 0x00,
   WS_TEXT_FRAME = 0x01,
   WS_BINARY_FRAME = 0x02,
   WS_CLOSE_FRAME = 0x08,
   WS_PING_FRAME = 0x09,
   WS_PONG_FRAME = 0x0A
};
```

The interface for working with frames contains both static and regular methods related to frame instances. Static methods act as factories for creating frames of the required type by the transmitting side (*create*) and incoming frames (*decode*).

```
class IWebSocketFrame
{
public:
   class StaticCreator
   {
   public:
      virtual IWebSocketFrame *decode(uchar &data[], IWebSocketFrame *head = NULL) =
      virtual IWebSocketFrame *create(WS_FRAME_OPCODE type, const string data = NULL,
         const bool deflate = false) = 0;
      virtual IWebSocketFrame *create(WS_FRAME_OPCODE type, const uchar &data[],
         const bool deflate = false) = 0;
   };
   ...
```

The presence of factory methods in descendant classes is made mandatory due to the presence of a template *Creator* and an instance of the *getCreator* method returning it (assuming return "singleton").

```
protected:
   template<typename P>
   class Creator: public StaticCreator
   {
   public:
     // decode received binary data in IWebSocketFrame
     // (in case of continuation, previous frame in 'head')
      virtual IWebSocketFrame *decode(uchar &data[],
         IWebSocketFrame *head = NULL) override
      {
         return P::decode(data, head);
      }
      // create a frame of the desired type (text/closing/other) with optional text
      virtual IWebSocketFrame *create(WS_FRAME_OPCODE type, const string data = NULL,
         const bool deflate = false) override
      {
         return P::create(type, data, deflate);
      };
      // create a frame of the desired type (binary/text/closure/other) with data
      virtual IWebSocketFrame *create(WS_FRAME_OPCODE type, const uchar &data[],
         const bool deflate = false) override
      {
         return P::create(type, data, deflate);
      };
   };
public:
   // require a Creator instance
   virtual IWebSocketFrame::StaticCreator *getCreator() = 0;
   ...
```

The remaining methods of the interface provide all the necessary manipulations with data in frames (encoding/decoding, receiving data and various flags).

```
    // encode the "clean" contents of the frame into data for transmission over the ne
    virtual int encode(uchar &encoded[]) = 0;

    // get data as text
    virtual string getData() = 0;

    // get data as bytes, return size
    virtual int getData(uchar &buf[]) = 0;

    // return frame type (opcode)
    virtual WS_FRAME_OPCODE getType() = 0;

    // check if the frame is a control frame or with data:
    // control frames are processed inside classes
    virtual bool isControlFrame()
    {
       return (getType() >= WS_CLOSE_FRAME);
    }

    virtual bool isReady() { return true; }
    virtual bool isFinal() { return true; }
    virtual bool isMasked() { return false; }
    virtual bool isCompressed() { return false; }
};
```

The *IWebSocketMessage* interface contains methods for performing similar actions but at the message level.

```
class IWebSocketMessage
{
public:
   // get an array of frames that make up this message
   virtual void getFrames(IWebSocketFrame *&frames[]) = 0;

   // set text as message content
   virtual bool setString(const string &data) = 0;

   // return message content as text
   virtual string getString() = 0;

   // set binary data as message content
   virtual bool setData(const uchar &data[]) = 0;

   // return the contents of the message in "raw" binary form
   virtual bool getData(uchar &data[]) = 0;

   // sign of completeness of the message (all frames received)
   virtual bool isFinalised() = 0;

   // add a frame to the message
   virtual bool takeFrame(IWebSocketFrame *frame) = 0;
};
```

Taking into account the interfaces of frames and messages, a common interface for WebSocket connections *IWebSocketConnection* is defined.

```
interface IWebSocketConnection
{
   // open a connection with the specified URL and its parts,
   // and optional custom headers
   bool handshake(const string url, const string host, const string origin,
      const string custom = NULL);

   // low-level read frames from the server
   int readFrame(IWebSocketFrame *&frames[]);

   // low-level send frame (e.g. close or ping)
   bool sendFrame(IWebSocketFrame *frame);

   // low-level message sending
   bool sendMessage(IWebSocketMessage *msg);

   // custom check for new messages (event generation)
   int checkMessages();

   // custom text submission
   bool sendString(const string msg);

   // custom posting of binary data
   bool sendData(const uchar &data[]);

   // close the connection
   bool disconnect(void);
};
```

Notifications about disconnection and new messages are received via the *IWebSocketObserver* interface methods.

```
interface IWebSocketObserver
{
  void onConnected();
  void onDisconnect();
  void onMessage(IWebSocketMessage *msg);
};
```

In particular, the *WebSocketClient* class was made a successor of this interface and by default simply outputs information to the log. The class constructor expects an address to connect to the protocol *ws* or *wss*.

```
template<typename T>
class WebSocketClient: public IWebSocketObserver
{
protected:
   IWebSocketMessage *messages[];

   string scheme;
   string host;
   string port;
   string origin;
   string url;
   int timeOut;
   ...
public:
   WebSocketClient(const string address)
   {
      string parts[];
      URL::parse(address, parts);

      url = address;
      timeOut = 5000;

      scheme = parts[URL_SCHEME];
      if(scheme != "ws" && scheme != "wss")
      {
        Print("WebSocket invalid url scheme: ", scheme);
        scheme = "ws";
      }

      host = parts[URL_HOST];
      port = parts[URL_PORT];

      origin = (scheme == "wss" ? "https://" : "http://") + host;
   }
   ...

   void onDisconnect() override
   {
      Print(" > Disconnected ", url);
   }

   void onConnected() override
   {
      Print(" > Connected ", url);
   }

   void onMessage(IWebSocketMessage *msg) override
   {
      // NB: message can be binary, print it just for notification
      Print(" > Message ", url, " " , msg.getString());
      WsTools::push(messages, msg);
```

```
      }
      ...
  };
```

The *WebSocketClient* class collects all message objects into an array and takes care of deleting them if the MQL program doesn't do it.

The connection is established in the *open* method.

```
  template<typename T>
  class WebSocketClient: public IWebSocketObserver
  {
  protected:
     IWebSocketTransport *socket;
     IWebSocketConnection *connection;
     ...
  public:
     ...
     bool open(const string custom_headers = NULL)
     {
        uint _port = (uint)StringToInteger(port);
        if(_port == 0)
        {
           if(scheme == "ws") _port = 80;
           else _port = 443;
        }

        socket = MqlWebSocketTransport::create(scheme, host, _port, timeOut);
        if(!socket || !socket.isConnected())
        {
           return false;
        }

        connection = new T(&this, socket);
        return connection.handshake(url, host, origin, custom_headers);
     }
     ...
```

The most convenient ways to send data are provided by the overloaded *send* methods for text and binary data.

```
     bool send(const string str)
     {
        return connection ? connection.sendString(str) : false;
     }

     bool send(const uchar &data[])
     {
        return connection ? connection.sendData(data) : false;
     }
```

To check for new incoming messages, you can call the *checkMessages* method. Depending on its *blocking* parameter, the method will either wait for a message in a loop until the timeout or return

immediately if there are no messages. Messages will go to the *IWebSocketObserver::onMessage* handler.

```
void checkMessages(const bool blocking = true)
{
   if(connection == NULL) return;

   uint stop = GetTickCount() + (blocking ? timeOut : 1);
   while(ArraySize(messages) == 0 && GetTickCount() < stop && isConnected())
   {
      // all frames are collected into the appropriate messages, and they become
      // available through event notifications IWebSocketObserver::onMessage,
      // however, control frames have already been internally processed and remove
      if(!connection.checkMessages()) // while no messages, let's make micro-pause
      {
         Sleep(100);
      }
   }
}
```

An alternative way to receive messages is implemented in the *readMessage* method: it returns a pointer to the message to the calling code (in other words, the application handler *onMessage* is not required). After that, the MQL program is responsible for releasing the object.

```
IWebSocketMessage *readMessage(const bool blocking = true)
{
   if(ArraySize(messages) == 0) checkMessages(blocking);

   if(ArraySize(messages) > 0)
   {
      IWebSocketMessage *top = messages[0];
      ArrayRemove(messages, 0, 1);
      return top;
   }
   return NULL;
}
```

The class also allows you to change the timeout, check the connection, and close it.

```
      void setTimeOut(const int ms)
      {
         timeOut = fabs(ms);
      }

      bool isConnected() const
      {
         return socket && socket.isConnected();
      }

      void close()
      {
         if(isConnected())
         {
            if(connection)
            {
               connection.disconnect(); // this will close socket after server acknowled
               delete connection;
               connection = NULL;
            }
            if(socket)
            {
               delete socket;
               socket = NULL;
            }
         }
      }
   };
```

The library of the considered classes allows you to create client applications for echo and chat services.

7.8.7 Client programs for echo and chat services in MQL5

Let's write a simple script to connect to the echo service *MQL5/Experts/MQL5Book/p7/wsEcho/wsecho.mq5* (note that this is a script, but we placed it inside the folder *MQL5/Experts/MQL5Book/p7/*, making it a single container for web-related MQL programs, since all subsequent examples will be Experts Advisors). Since in this chapter, we are considering the creation of software complexes within projects, we will design the script as part of an mqproj project, which will also include the server component.

The input parameters of the script allow you to specify the address of the service and the text of the message. The default is an unsecured connection. If you are going to launch the server *wsecho.js* with TLS support, you need to change the protocol to the secure *wss*. Keep in mind that establishing a secure connection takes longer (by a couple of seconds) than usual.

```
input string Server = "ws://localhost:9000/";
input string Message = "My outbound message";

#include <MQL5Book/AutoPtr.mqh>
#include <MQL5Book/ws/wsclient.mqh>
```

In the *OnStart* function, we create an instance of the WebSocket client (*wss*) for the given address and call the *open* method. In case of a successful connection, we wait for a welcome message from the service by calling *wss.readMessage* in blocking mode (wait up to 5 seconds, by default). We use an autopointer on the resulting object so as not to call *delete* manually at the end.

```
void OnStart()
{
   Print("\n");
   WebSocketClient<Hybi> wss(Server);
   Print("Opening...");
   if(wss.open())
   {
      Print("Waiting for welcome message (if any)");
      AutoPtr<IWebSocketMessage> welcome(wss.readMessage());
      ...
```

The *WebSocketClient* class contains event handler stubs, including the simple method *onMessage*, which will print the greeting to the log.

Then we send our message and again wait for a response from the server. The echo message will also be logged.

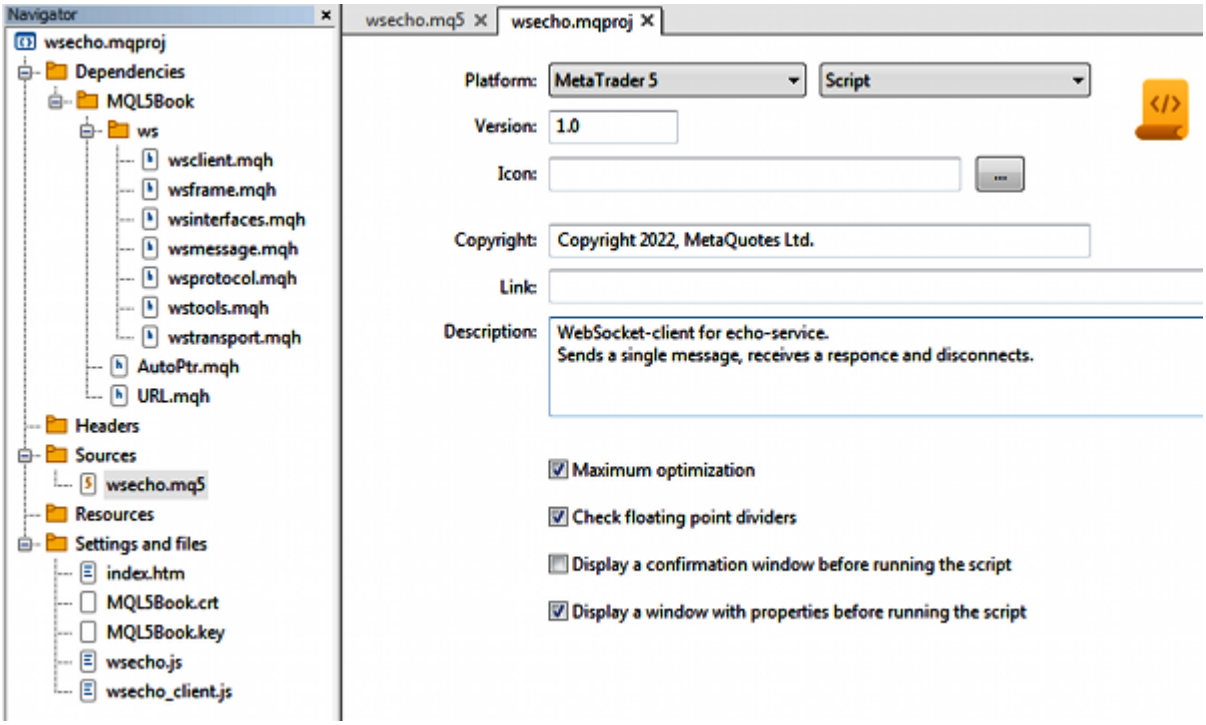
```
      Print("Sending message...");
      wss.send(Message);
      Print("Receiving echo...");
      AutoPtr<IWebSocketMessage> echo(wss.readMessage());
   }
   ...
```

Finally, we close the connection.

```
   if(wss.isConnected())
   {
      Print("Closing...");
      wss.close();
   }
}
```

Based on the script file, let's create a project file (*wsecho.mqproj*). We fill in the project properties with the version number (1.0), copyright, and description. Let's add echo service server files to the *Settings and Files* branch (this will at least remind the developer that there is a test server). After compilation, dependencies (header files) will appear in the hierarchy.

Everything should look like in the screenshot below.



Echo service project, client script and server

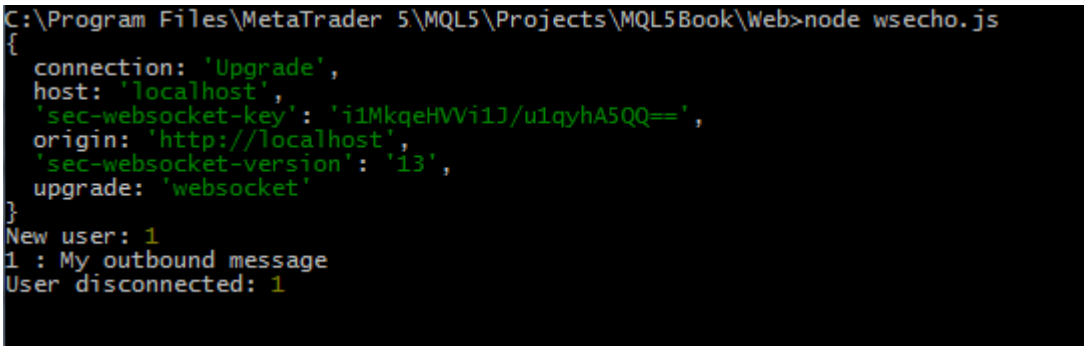
If the script was located inside the folder *Shared Projects*, for example, in *MQL5/Shared Projects/MQL5Book/wsEcho/*, then after successful compilation, its ex5 file would be automatically moved to the folder *MQL5/Scripts/Shared Projects/MQL5Book/wsEcho/*, and the corresponding entry would be displayed in the compilation log. This is the standard behavior for compiling any MQL programs in shared projects.

In all examples of this chapter, do not forget to start the server before testing the MQL script. In this case, run the command: *node.exe wsecho.js* while in the *web* folder.

Next, let's run the script *wsecho.ex5*. The log will show the actions that are taking place, as well as the message notifications.

```
Opening...
Connecting to localhost:9000
Buffer: 'HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: mIpas63g5xGMqJcKtreHKpSbY1w=
'
Headers:
                                [,0]                            [,1]
[0,] "upgrade"                      "websocket"
[1,] "connection"                   "Upgrade"
[2,] "sec-websocket-accept"         "mIpas63g5xGMqJcKtreHKpSbY1w="
 > Connected ws://localhost:9000/
Waiting for welcome message (if any)
 > Message ws://localhost:9000/ server#Hello, user1
Sending message...
Receiving echo...
 > Message ws://localhost:9000/ user1#My outbound message
Closing...
Close requested
Waiting...
SocketRead failed: 5273 Available: 1
 > Disconnected ws://localhost:9000/
Server close ack
```

The above HTTP headers are the server's response during the handshake process. If we look into the console window where the server is running, we will find the HTTP headers received by the server from our client.



Echo service server log

Also, the user's connection, message, and disconnection are indicated here.

Let's do a similar job for the chat service: create a WebSocket client in MQL5, a project for it, and test it. This time the type of the client program will be an Expert Advisor because the chat needs support for interactive events from the keyboard on the chart. The Expert Advisor is attached to the book in a folder *MQL5/MQL5Book/p7/wsChat/wschat.mq5*.

To demonstrate the technology of receiving events in handler methods, let's define our own class *MyWebSocket*, derived from *WebSocketClient*.

```
class MyWebSocket: public WebSocketClient<Hybi>
{
public:
   MyWebSocket(const string address, const bool compress = false):
      WebSocketClient(address, compress) { }

   /* void onConnected() override { } */

   void onDisconnect() override
   {
      // we can do something else and call (or not call) the legacy code
      WebSocketClient<Hybi>::onDisconnect();
   }

   void onMessage(IWebSocketMessage *msg) override
   {
     // TODO: we could truncate copies of our own messages,
     // but they are left for debugging
      Alert(msg.getString());
      delete msg;
   }
};
```

When a message is received, we will display it not in the log, but as an alert, after which the object should be deleted.

In the global context, we describe the object of our *wss* class and the *message* string where the user input from the keyboard will be accumulated.

```
MyWebSocket wss(Server);
string message = "";
```

The *OnInit* function contains the necessary preparation, in particular, starts a timer and opens a connection.

```
int OnInit()
{
  ChartSetInteger(0, CHART_QUICK_NAVIGATION, false);
  EventSetTimer(1);
  wss.setTimeOut(1000);
  Print("Opening...");
  return wss.open() ? INIT_SUCCEEDED : INIT_FAILED;
}
```

The timer is needed to check for new messages from other users.

```
void OnTimer()
{
   wss.checkMessages(false); // use a non-blocking check in the timer
}
```

In the *OnChartEvent* handler, we respond to keystrokes: all alphanumeric keys are translated into characters and attached to the *message* string. If necessary, you can press *Backspace* to remove the

last character. All typed text is updated in the chart comment. When the message is complete, press *Enter* to send it to the server.

```
void OnChartEvent(const int id, const long &lparam, const double &dparam,
   const string &sparam)
{
   if(id == CHARTEVENT_KEYDOWN)
   {
      if(lparam == VK_RETURN)
      {
         const static string longmessage = ...
         if(message == "long") wss.send(longmessage);
         else if(message == "bye") wss.close();
         else wss.send(message);
         message = "";
      }
      else if(lparam == VK_BACK)
      {
         StringSetLength(message, StringLen(message) - 1);
      }
      else
      {
         ResetLastError();
         const short c = TranslateKey((int)lparam);
         if(_LastError == 0)
         {
            message += ShortToString(c);
         }
      }
      Comment(message);
   }
}
```

If we enter the text "long", the program will send a specially prepared rather long text. If the message text is "bye", the program closes the connection. Also, the connection will be closed when the program exits.

```
void OnDeinit(const int)
{
   if(wss.isConnected())
   {
      Print("Closing...");
      wss.close();
   }
}
```

Let's create a project for the Expert Advisor (file *wschat.mqproj*), fill in its properties, and add the backend to the branch *Settings and Files*. This time we will show how the project file looks from the inside. In the mqproj file, the *Dependencies* branch is stored in the "files" property, and the *Settings and Files* branch is in the "tester" property.

      },
      {
        "type":"file",
        "path":"..\\Web\\wschat.js",
        "relative_to_project":true
      },
      {
        "type":"file",
        "path":"..\\Web\\wschat_client.js",
        "relative_to_project":true
      }
    ]
  }
```

If the Expert Advisor were inside the *Shared Projects* folder, for example, in *MQL5/Shared Projects/MQL5Book/wsChat/*, after successful compilation, its ex5 file would be automatically moved to the folder *MQL5/Experts/Shared Projects/MQL5Book/wsChat/*.

Starting the server *node.exe wschat.js*. Now you can run a couple of copies of the Expert Advisor on different charts. Basically, the service involves "communication" between different terminals and even different computers, but you can also test it from one terminal.

Here is an example of communication between the EURUSD and GBPUSD charts.

```
(EURUSD,H1)
(EURUSD,H1)   Opening...
(EURUSD,H1)   Connecting to localhost:9000
(EURUSD,H1)   Buffer: 'HTTP/1.1 101 Switching Protocols
(EURUSD,H1)   Upgrade: websocket
(EURUSD,H1)   Connection: Upgrade
(EURUSD,H1)   Sec-WebSocket-Accept: Dg+aQdCBwNExE5mEQsfk5w9J+uE=
(EURUSD,H1)
(EURUSD,H1)   '
(EURUSD,H1)   Headers:
(EURUSD,H1)                                   [,0]                            [,1]
(EURUSD,H1)   [0,] "upgrade"                       "websocket"
(EURUSD,H1)   [1,] "connection"                    "Upgrade"
(EURUSD,H1)   [2,] "sec-websocket-accept"          "Dg+aQdCBwNExE5mEQsfk5w9J+uE="
(EURUSD,H1)    > Connected ws://localhost:9000/

(GBPUSD,H1)
(GBPUSD,H1)   Opening...
(GBPUSD,H1)   Connecting to localhost:9000
(GBPUSD,H1)   Buffer: 'HTTP/1.1 101 Switching Protocols
(GBPUSD,H1)   Upgrade: websocket
(GBPUSD,H1)   Connection: Upgrade
(GBPUSD,H1)   Sec-WebSocket-Accept: NZENnc8p05T4amvngeop/e/+gFw=
(GBPUSD,H1)
(GBPUSD,H1)   '
(GBPUSD,H1)   Headers:
(GBPUSD,H1)                                   [,0]                            [,1]
(GBPUSD,H1)   [0,] "upgrade"                       "websocket"
(GBPUSD,H1)   [1,] "connection"                    "Upgrade"
(GBPUSD,H1)   [2,] "sec-websocket-accept"          "NZENnc8p05T4amvngeop/e/+gFw="
(GBPUSD,H1)    > Connected ws://localhost:9000/
(GBPUSD,H1)   Alert: server#Hello, user2
(EURUSD,H1)   Alert: user1#I'm typing this on EURUSD chart
(GBPUSD,H1)   Alert: user1#I'm typing this on EURUSD chart
(GBPUSD,H1)   Alert: user2#Got it on GBPUSD chart!
(EURUSD,H1)   Alert: user2#Got it on GBPUSD chart!
```

Since our messages are sent to everyone, including the sender, they are duplicated in the log, but on different charts.

Communication is visible on the server side as well.

```
C:\Program Files\MetaTrader 5\MQL5\Projects\MQL5Book\Web>node wschat.js
{
  connection: 'Upgrade',
  host: 'localhost',
  'sec-websocket-key': 'ZBiifDgZZxrYB3HDz5S6Vg==',
  origin: 'http://localhost',
  'sec-websocket-version': '13',
  upgrade: 'websocket'
}
New user: 1
{
  connection: 'Upgrade',
  host: 'localhost',
  'sec-websocket-key': 'a2UZhk69UluW1XblUtIqCw==',
  origin: 'http://localhost',
  'sec-websocket-version': '13',
  upgrade: 'websocket'
}
New user: 2
1 : I'm typing this on EURUSD chart
2 : Got it on GBPUSD chart!
```

Chat service server log

Now we have all the technical components for organizing the trading signals service.

7.8.8 Trading signal service and test web page

The trading signal service is technically identical to the chat service, however, its users (or rather client connections) must perform one of two roles:

- Message provider
- Message consumer

In addition, the information should not be available to everyone but work according to some subscription scheme.

To ensure this, when connecting to the service, users will be required to provide certain identifying information that differs depending on the role.

The provider must specify a public signal identifier (PUB_ID) that is unique among all signals. Basically, the same person could potentially generate more than one signal and should therefore be able to obtain multiple identifiers. In this sense, we will not complicate the service by introducing separate provider identifiers (as a specific person) and identifiers of its signals. Instead, only signal identifiers will be supported. For a real signal service, this issue needs to be worked out, along with authorization, which we left outside of this book.

The identifier will be required in order to advertise it or simply pass it on to persons interested in subscribing to this signal. But "everyone you meet" should not be able to access the signal knowing only the public identifier. In the simplest case, this would be acceptable for open account monitoring, but we will demonstrate the option of restricting access specifically in the context of signals.

For this purpose, the provider must provide the server with a secret key (PUB_KEY) known only to them but not to the public. This key will be required to generate a specific subscriber's access key.

The consumer (subscriber) must also have a unique identifier (SUB_ID, and here we will also do without authorization). To subscribe to the desired signal, the user must tell the signal provider the identifier (in practice, it is understood that at the same stage, it is necessary to confirm the payment, and usually this is all automated by the server). The provider forms a snapshot consisting of the provider's identifier, the subscriber's identifier, and the secret key. In our service, this will be done by calculating

the SHA256 hash from the PUB_ID:PUB_KEY:SUB_ID string, after which the resulting bytes are converted to a hexadecimal format string. This will be the access key (SUB_KEY or ACCESS_KEY) to the signal of a particular provider for a particular subscriber. The provider (and in real systems, the server itself automatically) forwards this key to the subscriber.

Thus, when connecting to the service, the subscriber will have to specify the subscriber identifier (SUB_ID), the identifier of the desired signal (PUB_ID), and the access key (SUB_KEY). Because the server knows the provider's secret key, it can recalculate the access key for the given combination of PUB_ID and SUB_ID, and compare it with the provided SUB_KEY. A match means the normal messaging process continues. The difference will result in an error message and disconnecting the pseudo-subscriber from the service.

It is important to note that in our demo, for the sake of simplicity, there is no normal registration of users and signals, and therefore the choice of identifiers is arbitrary. It is only important for us to keep track of the uniqueness of identifiers in order to know to whom and from whom to send information online. So, our service does not guarantee that the identifier, for example, "Super Trend" belongs to the same user yesterday, today, and tomorrow. Reservation of names is made according to the principle that the early bird catches the worm. As long as a provider is continuously connected under the given identifier, the signal is delivered. If the provider disconnects, then the identifier becomes available for selection in any next connection.

The only identifier that will always be busy is "Server": the server uses it to send out its connection status messages.

To generate access keys in the server folder, there is a simple JavaScript *access.js*. When you run it on the command line, you need to pass as the only parameter a string of the above type PUB_ID:PUB_KEY:SUB_ID (identifiers and the secret key between them, connected by the ':' symbol)

If the parameter is not specified, the script generates an access key for some demo identifiers (PUB_ID_001, SUB_ID_100) and a secret (PUB_KEY_FFF).

```
// JavaScript
const args = process.argv.slice(2);
const input = args.length > 0 ? args[0] : 'PUB_ID_001:PUB_KEY_FFF:SUB_ID_100';
console.log('Hashing "', input, '"');
const crypto = require('crypto');
console.log(crypto.createHash('sha256').update(input).digest('hex'));
```

Running the script with the command:

```
node access.js PUB_ID_001:PUB_KEY_FFF:SUB_ID_100
```

we get this result:

```
fd3f7a105eae8c2d9afce0a7a4e11bf267a40f04b7c216dd01cf78c7165a2a5a
```

By the way, you can check and repeat this algorithm in pure MQL5 using the *CryptEncode* function.

Having analyzed the conceptual part, let's proceed to practical implementation.

The server script of the signaling service will be placed in the file *MQL5/Experts/MQL5Book/p7/Web/wspubsub.js*. Setting up servers in it is the same as what we did earlier. However, in addition, you will need to connect the same "crypto" module that was used in *access.js*. The home page will be called *wspubsub.htm*.

```
// JavaScript
const crypto = require('crypto');
...
http1.createServer(options, function (req, res)
{
   ...
   if(req.url == '/')
   {
      req.url = "wspubsub.htm";
   }
   ...
});
```

Instead of one map of connected clients, we will define two maps, separately for signal providers and consumers.

```
// JavaScript
const publishers = new Map();
const subscribers = new Map();
```

In both maps, the key is the provider ID, but the first one stores the objects of the providers, and the second one stores the objects of subscribers subscribed to each provider (arrays of objects).

To transfer identifiers and keys during the handshake, we will use a special header allowed by the WebSockets specification, namely Sec-Websocket-Protocol. Let's agree that identifiers and keys will be glued together with the symbol '-': in the case of a provider, a string like X-MQL5-publisher-PUB_ID-PUB_KEY is expected, and in the case of a subscriber, we expect X-MQL5-subscriber-SUB_ID-PUB_ID-SUB_KEY.

Any attempts to connect to our service without the Sec-Websocket-Protocol: X-MQL5-... header will be stopped by immediate closure.

In the new client object (in the "connection" event handler parameter *onConnect(client)*) this title is easy to extract from the *client.protocol* property.

Let's show the procedure for registering and sending the signal provider's messages in a simplified form, without error handling (the full code is attached). It is important to note that the message text is generated in JSON format (which we will discuss in more detail in the next section). In particular, the sender of the message is passed in the "origin" property (moreover, when the message is sent by the service itself, this field contains the string "Server"), and the application data from the provider is placed in the "msg" property, and this may not be just text, but also nested structure of any content.

```
// JavaScript
const wsServer = new WebSocket.Server({ server });
wsServer.on('connection', function onConnect(client)
{
   console.log('New user:', ++count, client.protocol);
   if(client.protocol.startsWith('X-MQL5-publisher'))
   {
      const parts = client.protocol.split('-');
      client.id = parts[3];
      client.key = parts[4];
      publishers.set(client.id, client);
      client.send('{"origin":"Server", "msg":"Hello, publisher ' + client.id + '"}');
      client.on('message', function(message)
      {
         console.log('%s : %s', client.id, message);

         if(subscribers.get(client.id))
            subscribers.get(client.id).forEach(function(elem)
         {
            elem.send('{"origin":"publisher ' + client.id + '", "msg":'
               + message + '}');
         });
      });
      client.on('close', function()
      {
         console.log('Publisher disconnected:', client.id);
         if(subscribers.get(client.id))
            subscribers.get(client.id).forEach(function(elem)
         {
            elem.close();
         });
         publishers.delete(client.id);
      });
   }
   ...
```

Half of the algorithm for subscribers is similar, but here we have the calculation of the access key and its comparison with what the connecting client transmitted, as an addition.

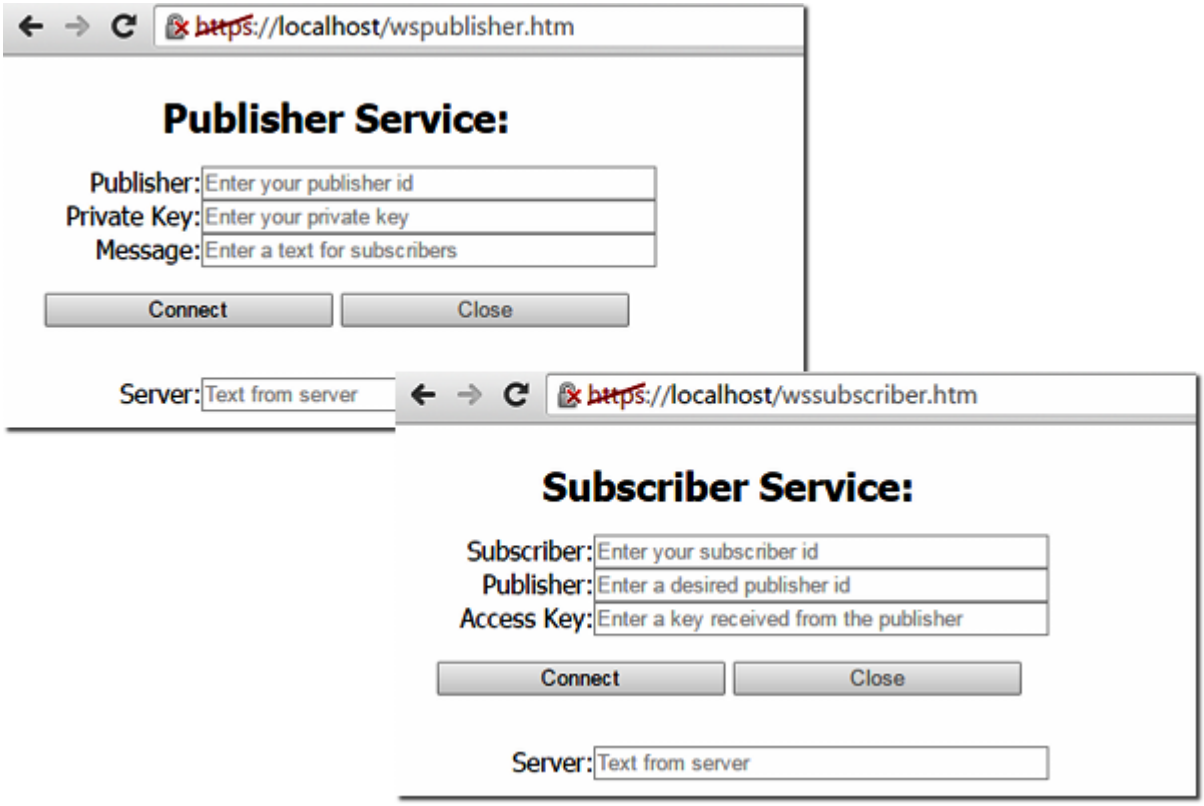
```
// JavaScript
   else if(client.protocol.startsWith('X-MQL5-subscriber'))
   {
      const parts = client.protocol.split('-');
      client.id = parts[3];
      client.pub_id = parts[4];
      client.access = parts[5];
      const id = client.pub_id;
      var p = publishers.get(id);
      if(p)
      {
         const check = crypto.createHash('sha256').update(id + ':' + p.key + ':'
            + client.id).digest('hex');
         if(check != client.access)
         {
            console.log(`Bad credentials: '${client.access}' vs '${check}'`);
            client.send('{"origin":"Server", "msg":"Bad credentials, subscriber '
               + client.id + '"}');
            client.close();
            return;
         }

         var list = subscribers.get(id);
         if(list == undefined)
         {
            list = [];
         }
         list.push(client);
         subscribers.set(id, list);
         client.send('{"origin":"Server", "msg":"Hello, subscriber '
            + client.id + '"}');
         p.send('{"origin":"Server", "msg":"New subscriber ' + client.id + '"}');
      }

      client.on('close', function()
      {
         console.log('Subscriber disconnected:', client.id);
         const list = subscribers.get(client.pub_id);
         if(list)
         {
            if(list.length > 1)
            {
               const filtered = list.filter(function(el) { return el !== client; });
               subscribers.set(client.pub_id, filtered);
            }
            else
            {
               subscribers.delete(client.pub_id);
            }
         }
      });
```

```
}
```

The user interface on the client page *wspubsub.htm* simply invites you to follow a link to one of the two pages with forms for suppliers (*wspublisher.htm* + *wspublisher_client.js*) or subscribers (*wssubscriber.htm* + *wssubscriber_client.js*).



Web pages of signal service test clients

Their implementation inherits the features of the previously considered JavaScript clients, but with respect to the customization of the Sec-Websocket-Protocol: X-MQL5- header and one more nuance.

Until now, we have exchanged simple text messages. But for a signaling service, you will need to transfer a lot of structured information, and JSON is better suited for this. Therefore, clients can parse JSON, although they do not use it for its intended purpose, because even if a command to buy or sell a specific ticker with a given amount is found in JSON, the browser does not know how to do this.

We will need to add JSON support to our signal service client in MQL5. Meanwhile, you can run on the server *wspubsub.js* and test the selective connection of signal providers and consumers in accordance with the details specified by them. We suggest you do it yourself, for your own benefit.

7.8.9 Signal service client program in MQL5

So, according to our decision, the text in the service messages will be in JSON format.

In the most common version, JSON is a text description of an object, similar to how it is done for structures in MQL5. The object is enclosed in curly brackets, inside which its properties are written separated by commas: each property has an identifier in quotes, followed by a colon and the value of the property. Here properties of several primitive types are supported: strings, integers and real numbers, booleans *true/false*, and empty value *null*. In addition, the property value can, in turn, be an

object or an array. Arrays are described using square brackets, within which the elements are separated by commas. For example,

```
{
   "string": "this is a text",
   "number": 0.1,
   "integer": 789735095,
   "enabled": true,
   "subobject" :
   {
      "option": null
   },
   "array":
   [
      1, 2, 3, 5, 8
   ]
}
```

Basically, the array at the top level is also valid JSON. For example,

```
[
   {
      "command": "buy",
      "volume": 0.1,
      "symbol": "EURUSD",
      "price": 1.0
   },
   {
      "command": "sell",
      "volume": 0.01,
      "symbol": "GBPUSD",
      "price": 1.5
   }
]
```

To reduce traffic in application protocols using JSON, it is customary to abbreviate field names to several letters (often to one).

Property names and string values are enclosed in double-quotes. If you want to specify a quote within a string, it must be escaped with a backslash.

The use of JSON makes the protocol versatile and extensible. For example, for the service being designed (trading signals and, in a more general case, account state copying), the following message structure can be assumed:

```
{
  "origin": "publisher_id",    // message sender ("Server" in technical message)
  "msg" :                      // message (text or JSON) as received from the sender
   {
     "trade" :                 // current trading commands (if there is a signal)
      {
        "operation": ...,      // buy/sell/close
         "symbol": "ticker",
         "volume": 0.1,
        ... // other signal parameters
      },
     "account":                // account status
      {
        "positions":           // positions
         {
           "n": 10,            // number of open positions
           [ { ... },{ ... } ] // array of properties of open positions
         },
        "pending_orders":      // pending orders
         {
            "n": ...
            [ { ... } ]
         }
         "drawdown": 2.56,
         "margin_level": 12345,
        ... // other status parameters
      },
     "hardware":               // remote control of the "health" of the PC
      {
         "memory": ...,
         "ping_to_broker": ...
      }
   }
}
```

Some of these features may or may not support specific implementations of client programs (everything that they do not "understand", they will simply ignore). In addition, subject to the condition that there are no conflicts in the names of properties at the same level, each information provider can add its own specific data to JSON. The messaging service will simply forward this information. Of course, the program on the receiving side must be able to interpret these specific data.

The book comes with a JSON parser called *ToyJson* ("toy" JSON, file *toyjson.mqh*) which is small and inefficient and does not support the full capabilities of the format specification (for example, in terms of processing of *escape* sequences). It was written specifically for this demo service, adjusted for the expected, not very complex, structure of information about trading signals. We will not describe it in detail here, and the principles of its use will become clear from the source code of the MQL client of the signal service.

For your projects and for the further development of this project, you can choose other JSON parsers available in the codebase on the *mql5.com* site.

One element (container or property) per *ToyJson* is described by the *JsValue* class object. There are several overloads of the method *put(key, value)* defined, that can be used for the addition of named internal properties as in a JSON object or *put(value)*, to add a value as in a JSON array. Also, this object can represent a single value of a primitive type. To read the properties of a JSON object, you can apply to *JsValue* a notation of the operator [] followed by the required property name in parentheses. Obviously, integer indexes are supported for accessing inside a JSON array.

Having formed the required configuration of related objects *JsValue*, you can serialize it into JSON text using the *stringify(string&buffer)* method.

The second class in *toyjson.mqh* – *JsParser* – allows you to perform the reverse operation: turn the text with the JSON description into a hierarchical structure of *JsValue* objects.

Taking into account the classes for working with JSON, let's start writing an Expert Advisor *MQL5/Experts/MQL5Book/p7/wsTradeCopier/wstradecopier.mq5*, which will be able to perform both roles in the transaction copy service: a provider of information about trades made on the account or a recipient of this information from the service to reproduce these trades.

The volume and content of the information sent is, from a political point of view, at the discretion of the provider and may differ significantly depending on the scenario (purpose) of using the service. In particular, it is possible to copy only ongoing transactions or the entire account balance along with pending orders and protective levels. In our example, we will only indicate the technical implementation of information transfer, and then you can choose a specific set of objects and properties at your discretion.

In the code, we will describe 3 structures which are inherited from built-in structures and which provide information "packing" in JSON:

- MqlTradeRequestWeb – MqlTradeRequest
- MqlTradeResultWeb – MqlTradeResult
- DealMonitorWeb – DealMonitor*

The last structure in the list, strictly speaking, is not built-in, but is defined by us in the file *DealMonitor.mqh*, yet it is filled on the standard set of deal properties.

The constructor of each of the derived structures populates the fields based on the transmitted primary source (trade request, its result, or deal). Each structure implements the *asJsValue* method, which returns a pointer to the *JsValue* object that reflects all the properties of the structure: they are added to the JSON object using the *JsValue::put* method. For example, here is how it is done in the case of *MqlTradeRequest*:

```
struct MqlTradeRequestWeb: public MqlTradeRequest
{
   MqlTradeRequestWeb(const MqlTradeRequest &r)
   {
      ZeroMemory(this);
      action = r.action;
      magic = r.magic;
      order = r.order;
      symbol = r.symbol;
      volume = r.volume;
      price = r.price;
      stoplimit = r.stoplimit;
      sl = r.sl;
      tp = r.tp;
      type = r.type;
      type_filling = r.type_filling;
      type_time = r.type_time;
      expiration = r.expiration;
      comment = r.comment;
      position = r.position;
      position_by = r.position_by;
   }

   JsValue *asJsValue() const
   {
      JsValue *req = new JsValue();
      // main block: action, symbol, type
      req.put("a", VerboseJson ? EnumToString(action) : (string)action);
      if(StringLen(symbol) != 0) req.put("s", symbol);
      req.put("t", VerboseJson ? EnumToString(type) : (string)type);

      // volumes
      if(volume != 0) req.put("v", TU::StringOf(volume));
      req.put("f", VerboseJson ? EnumToString(type_filling) : (string)type_filling);

      // block with prices
      if(price != 0) req.put("p", TU::StringOf(price));
      if(stoplimit != 0) req.put("x", TU::StringOf(stoplimit));
      if(sl != 0) req.put("sl", TU::StringOf(sl));
      if(tp != 0) req.put("tp", TU::StringOf(tp));

      // block of pending orders
      if(TU::IsPendingType(type))
      {
         req.put("t", VerboseJson ? EnumToString(type_time) : (string)type_time);
         if(expiration != 0) req.put("d", TimeToString(expiration));
      }

      // modification block
      if(order != 0) req.put("o", order);
      if(position != 0) req.put("q", position);
```

```
      if(position_by != 0) req.put("b", position_by);

      // helper block
      if(magic != 0) req.put("m", magic);
      if(StringLen(comment)) req.put("c", comment);

      return req;
   }
};
```

We transfer all properties to JSON (this is suitable for the account monitoring service), but you can leave only a limited set.

For properties that are enumerations, we have provided two ways to represent them in JSON: as an integer and as a string name of an enumeration element. The choice of method is made using the input parameter *VerboseJson* (ideally, it should be written in the structure code not directly but through a constructor parameter).

```
input bool VerboseJson = false;
```

Passing only numbers would simplify coding because, on the receiving side, it is enough to cast them to the desired enumeration type in order to perform "mirror" actions. However, numbers make it difficult for a person to perceive information, and they may need to analyze the situation (message). Therefore, it makes sense to support an option for the string representation, as being more "friendly", although it requires additional operations in the receiving algorithm.

The input parameters also specify the server address, the application role, and connection details separately for the provider and the subscriber.

```
enum TRADE_ROLE
{
   TRADE_PUBLISHER,  // Trade Publisher
   TRADE_SUBSCRIBER  // Trade Subscriber
};

input string Server = "ws://localhost:9000/";
input TRADE_ROLE Role = TRADE_PUBLISHER;
input bool VerboseJson = false;
input group "Publisher";
input string PublisherID = "PUB_ID_001";
input string PublisherPrivateKey = "PUB_KEY_FFF";
input string SymbolFilter = ""; // SymbolFilter (empty - current, '*' - any)
input ulong MagicFilter = 0;    // MagicFilter (0 - any)
input group "Subscriber";
input string SubscriberID = "SUB_ID_100";
input string SubscribeToPublisherID = "PUB_ID_001";
input string SubscriberAccessKey = "fd3f7a105eae8c2d9afce0a7a4e11bf267a40f04b7c216dd0
input string SymbolSubstitute = "EURUSD=GBPUSD"; // SymbolSubstitute (<from>=<to>,...
input ulong SubscriberMagic = 0;
```

Parameters *SymbolFilter* and *MagicFilter* in the provider group allow you to limit the monitored trading activity to a given symbol and magic number. An empty value in *SymbolFilter* means to control only the current symbol of the chart, to intercept any trades, enter the symbol '*'. The signal provider will use

for this purpose the *FilterMatched* function, which accepts the symbol and magic number of the transaction.

```
bool FilterMatched(const string s, const ulong m)
{
   if(MagicFilter != 0 && MagicFilter != m)
   {
      return false;
   }

   if(StringLen(SymbolFilter) == 0)
   {
      if(s != _Symbol)
      {
         return false;
      }
   }
   else if(SymbolFilter != s && SymbolFilter != "*")
   {
      return false;
   }

   return true;
}
```

The *SymbolSubstitute* parameter in the input group of the subscriber allows the substitution of the symbol received in messages with another one, which will be used for copy trading. This feature is useful if the names of tickers of the same financial instrument differ between brokers. But this parameter also performs the function of a permissive filter for repeating signals: only the symbols specified here will be traded. For example, to allow signal trading for the EURUSD symbol (even without ticker substitution), you need to set the string "EURUSD=EURUSD" in the parameter. The symbol from the signal messages is indicated to the left of the sign '=', and the symbol for trading is indicated to the right.

The character substitution list is processed by the *FillSubstitutes* function during initialization and then used to substitute and resolve the trade by the *FindSubstitute* function.

```
string Substitutes[][2];

void FillSubstitutes()
{
   string list[];
   const int n = StringSplit(SymbolSubstitute, ',', list);
   ArrayResize(Substitutes, n);
   for(int i = 0; i < n; ++i)
   {
      string pair[];
      if(StringSplit(list[i], '=', pair) == 2)
      {
         Substitutes[i][0] = pair[0];
         Substitutes[i][1] = pair[1];
      }
      else
      {
         Print("Wrong substitute: ", list[i]);
      }
   }
}

string FindSubstitute(const string s)
{
   for(int i = 0; i < ArrayRange(Substitutes, 0); ++i)
   {
      if(Substitutes[i][0] == s) return Substitutes[i][1];
   }
   return NULL;
}
```

To communicate with the service, we define a class derived from *WebSocketClient*. It is needed, first of all, to start trading on a signal when a message arrives in the *onMessage* handler. We will return to this issue a little later after we consider the formation and sending of signals on the provider side.

```
class MyWebSocket: public WebSocketClient<Hybi>
{
public:
   MyWebSocket(const string address): WebSocketClient(address) { }

   void onMessage(IWebSocketMessage *msg) override
   {
      ...
   }
};

MyWebSocket wss(Server);
```

Initialization in *OnInit* turns on the timer (for a periodic call *wss.checkMessages(false)*) and preparation of custom headers with user details, depending on the selected role. Then we open the connection with the *wss.open(custom)* call.

```
int OnInit()
{
   FillSubstitutes();
   EventSetTimer(1);
   wss.setTimeOut(1000);
   Print("Opening...");
   string custom;
   if(Role == TRADE_PUBLISHER)
   {
      custom = "Sec-Websocket-Protocol: X-MQL5-publisher-"
         + PublisherID + "-" + PublisherPrivateKey + "\r\n";
   }
   else
   {
      custom = "Sec-Websocket-Protocol: X-MQL5-subscriber-"
         + SubscriberID + "-" + SubscribeToPublisherID
         + "-" + SubscriberAccessKey + "\r\n";
   }
   return wss.open(custom) ? INIT_SUCCEEDED : INIT_FAILED;
}
```

The mechanism of copying, i.e., intercepting transactions and sending information about them to a web service, is launched in the *OnTradeTransaction* handler. As we know, this is not the only way and it would be possible to analyze the "snapshot" of the account state in *OnTrade*.

```
void OnTradeTransaction(const MqlTradeTransaction &transaction,
   const MqlTradeRequest &request,
   const MqlTradeResult &result)
{
   if(transaction.type == TRADE_TRANSACTION_REQUEST)
   {
      Print(TU::StringOf(request));
      Print(TU::StringOf(result));
      if(result.retcode == TRADE_RETCODE_PLACED           // successful action
         || result.retcode == TRADE_RETCODE_DONE
         || result.retcode == TRADE_RETCODE_DONE_PARTIAL)
      {
         if(FilterMatched(request.symbol, request.magic))
         {
            ... // see next block of code
         }
      }
   }
}
```

We track events about successfully completed trade requests that satisfy the conditions of the specified filters. Next, the structures of the request, the result of the request, and the deal are turned into JSON objects. All of them are placed in one common container *msg* under the names "req", "res", and "deal", respectively. Recall that the container itself will be included in the web service message as the "msg" property.

```
// container to attach to service message will be visible as "msg" propert
  // {"origin" : "this_publisher_id", "msg" : { our data is here }}
 JsValue msg;
 MqlTradeRequestWeb req(request);
 msg.put("req", req.asJsValue());

 MqlTradeResultWeb res(result);
 msg.put("res", res.asJsValue());

 if(result.deal != 0)
 {
    DealMonitorWeb deal(result.deal);
    msg.put("deal", deal.asJsValue());
 }
 ulong tickets[];
 Positions.select(tickets);
 JsValue pos;
 pos.put("n", ArraySize(tickets));
 msg.put("pos", &pos);
 string buffer;
 msg.stringify(buffer);

 Print(buffer);

 wss.send(buffer);
```

Once filled, the container is output as a string into *buffer*, printed to the log, and sent to the server.

We can add other information to this container: account status (drawdown, loading), the number and properties of pending orders, and so on. So, just to demonstrate the possibilities for expanding the content of messages, we have added the number of open positions above. To select positions according to filters, we used the *PositionFilter* class object (*PositionFilter.mqh*):

```
PositionFilter Positions;

int OnInit()
{
   ...
   if(MagicFilter) Positions.let(POSITION_MAGIC, MagicFilter);
   if(SymbolFilter == "") Positions.let(POSITION_SYMBOL, _Symbol);
   else if(SymbolFilter != "*") Positions.let(POSITION_SYMBOL, SymbolFilter);
   ...
}
```

Basically, in order to increase reliability, it makes sense for the copiers to analyze the state of positions, and not just intercept transactions.

This concludes the consideration of the part of the Expert Advisor that is involved in the role of the signal provider.

As a subscriber, as we have already announced, the Expert Advisor receives messages in the *MyWebSocket::onMessage* method. Here the incoming message is parsed with *JsParser::jsonify*, and the container that was formed by the transmitting side is retrieved from the *obj["msg"]* property.

```
class MyWebSocket: public WebSocketClient<Hybi>
{
public:
   void onMessage(IWebSocketMessage *msg) override
   {
      Alert(msg.getString());
      JsValue *obj = JsParser::jsonify(msg.getString());
      if(obj && obj["msg"])
      {
         obj["msg"].print();
         if(!RemoteTrade(obj["msg"])) { /* error processing */ }
         delete obj;
      }
      delete msg;
   }
};
```

The *RemoteTrade* function implements the signal analysis and trading operations. Here it is given with abbreviations, without handling potential errors. The function provides support for both ways of representing enumerations: as integer values or as string element names. The incoming JSON object is "examined" for the necessary properties (commands and signal attributes) by applying the operator [], including several times consecutively (to access nested JSON objects).

```
bool RemoteTrade(JsValue *obj)
{
   bool success = false;

   if(obj["req"]["a"] == TRADE_ACTION_DEAL
      || obj["req"]["a"] == "TRADE_ACTION_DEAL")
   {
      const string symbol = FindSubstitute(obj["req"]["s"].s);
      if(symbol == NULL)
      {
         Print("Suitable symbol not found for ", obj["req"]["s"].s);
         return false; // not found or forbidden
      }

      JsValue *pType = obj["req"]["t"];
      if(pType == ORDER_TYPE_BUY || pType == ORDER_TYPE_SELL
         || pType == "ORDER_TYPE_BUY" || pType == "ORDER_TYPE_SELL")
      {
         ENUM_ORDER_TYPE type;
         if(pType.detect() >= JS_STRING)
         {
            if(pType == "ORDER_TYPE_BUY") type = ORDER_TYPE_BUY;
            else type = ORDER_TYPE_SELL;
         }
         else
         {
            type = obj["req"]["t"].get<ENUM_ORDER_TYPE>();
         }

         MqlTradeRequestSync request;
         request.deviation = 10;
         request.magic = SubscriberMagic;
         request.type = type;

         const double lot = obj["req"]["v"].get<double>();
         JsValue *pDir = obj["deal"]["entry"];
         if(pDir == DEAL_ENTRY_IN || pDir == "DEAL_ENTRY_IN")
         {
            success = request._market(symbol, lot) && request.completed();
            Alert(StringFormat("Trade by subscription: market entry %s %s %s - %s",
               EnumToString(type), TU::StringOf(lot), symbol,
               success ? "Successful" : "Failed"));
         }
         else if(pDir == DEAL_ENTRY_OUT || pDir == "DEAL_ENTRY_OUT")
         {
            // closing action assumes the presence of a suitable position, look for i
            PositionFilter filter;
            int props[] = {POSITION_TICKET, POSITION_TYPE, POSITION_VOLUME};
            Tuple3<long,long,double> values[];
            filter.let(POSITION_SYMBOL, symbol).let(POSITION_MAGIC,
               SubscriberMagic).select(props, values);
```

```
            for(int i = 0; i < ArraySize(values); ++i)
            {
              // need a position that is opposite in direction to the deal
               if(!TU::IsSameType((ENUM_ORDER_TYPE)values[i]._2, type))
               {
                  // you need enough volume (exactly equal here!)
                  if(TU::Equal(values[i]._3, lot))
                  {
                     success = request.close(values[i]._1, lot) && request.completed(
                     Alert(StringFormat("Trade by subscription: market exit %s %s %s
                        EnumToString(type), TU::StringOf(lot), symbol,
                        success ? "Successful" : "Failed"));
                  }
               }
            }

            if(!success)
            {
               Print("No suitable position to close");
            }
         }
      }
   }
   return success;
}
```

This implementation does not analyze the transaction price, possible restrictions on the lot, stop levels, and other moments. We simply repeat the trade at the current local price. Also, when closing a position, a check is made for exact equality of the volume, which is suitable for hedging accounts, but not for netting, where partial closure is possible if the volume of the transaction is less than the position (and maybe more, in case of a reversal, but the DEAL_ENTRY_INOUT option is not here supported). All these points should be finalized for real application.

Let's start the server *node.exe wspubsub.js* and two copies of the Expert Advisor *wstradecopier.mq5* on different charts, in the same terminal. The usual scenario assumes that the Expert Advisor needs to be launched on different accounts, but a "paradoxical" option is also suitable for checking the performance: we will copy signals from one symbol to another.

In one copy of the Expert Advisor, we will leave the default settings, with the role of the publisher. It should be placed on the EURUSD chart. In the second copy that runs on the GBPUSD chart, we change the role to the subscriber. The string "EURUSD=GBPUSD" in the input parameter *SymbolSubstitute* allows GBPUSD trading on EURUSD signals.

The connection data will be logged, with the HTTP headers and greetings we've already seen, so we'll omit them.

Let's buy EURUSD and make sure that it is "duplicated" in the same volume for GBPUSD.

The following are fragments of the log (keep in mind that due to the fact that both Expert Advisors work in the same copy of the terminal, transaction messages will be sent to both charts and therefore, to facilitate the analysis of the log, you can alternately set the filters "EURUSD" and " USDUSD"):

```
(EURUSD,H1) TRADE_ACTION_DEAL, EURUSD, ORDER_TYPE_BUY, V=0.01, ORDER_FILLING_FOK, @ 0
(EURUSD,H1) DONE, D=1439023682, #=1461313378, V=0.01, @ 0.99886, Bid=0.99886, Ask=0.9
(EURUSD,H1) {"req" : {"a" : "TRADE_ACTION_DEAL", "s" : "EURUSD", "t" : "ORDER_TYPE_BU
»   "f" : "ORDER_FILLING_FOK", "p" : 0.99886, "o" : 1461313378}, "res" : {"code" : 10
»   "o" : 1461313378, "v" : 0.01, "p" : 0.99886, "b" : 0.99886, "a" : 0.99886}, "deal
»   "o" : 1461313378, "t" : "2022.09.19 16:45:50", "tmsc" : 1663605950086, "type" : "
»   "entry" : "DEAL_ENTRY_IN", "pid" : 1461313378, "r" : "DEAL_REASON_CLIENT", "v" :
»   "s" : "EURUSD"}, "pos" : {"n" : 1}}
```

This shows the content of the executed request and its result, as well as a buffer with a JSON string sent to the server.

Almost instantly, on the receiving side, on the GBPUSD chart, an alert is displayed with a message from the server in a "raw" form and formatted after successful parsing in *JsParser*. In the "raw" form, the "origin" property is stored, in which the server lets us know who is the source of the signal.

```
(GBPUSD,H1) Alert: {"origin":"publisher PUB_ID_001", "msg":{"req" : {"a" : "TRADE_ACT
»   "s" : "EURUSD", "t" : "ORDER_TYPE_BUY", "v" : 0.01, "f" : "ORDER_FILLING_FOK", "p

»   "p" : 0.99886, "s" : "EURUSD"}, "pos" : {"n" : 1}}}
(GBPUSD,H1)   {
(GBPUSD,H1)     req =
(GBPUSD,H1)     {
(GBPUSD,H1)       a = TRADE_ACTION_DEAL
(GBPUSD,H1)       s = EURUSD
(GBPUSD,H1)       t = ORDER_TYPE_BUY
(GBPUSD,H1)       v =  0.01
(GBPUSD,H1)       f = ORDER_FILLING_FOK
(GBPUSD,H1)       p =  0.99886
(GBPUSD,H1)       o =  1461313378
(GBPUSD,H1)     }
(GBPUSD,H1)     res =
(GBPUSD,H1)     {
(GBPUSD,H1)       code =  10009
(GBPUSD,H1)       d =  1439023682
(GBPUSD,H1)       o =  1461313378
(GBPUSD,H1)       v =  0.01
(GBPUSD,H1)       p =  0.99886
(GBPUSD,H1)       b =  0.99886
(GBPUSD,H1)       a =  0.99886
(GBPUSD,H1)     }
(GBPUSD,H1)     deal =
(GBPUSD,H1)     {
(GBPUSD,H1)       d =  1439023682
(GBPUSD,H1)       o =  1461313378
(GBPUSD,H1)       t = 2022.09.19 16:45:50
(GBPUSD,H1)       tmsc =  1663605950086
(GBPUSD,H1)       type = DEAL_TYPE_BUY
(GBPUSD,H1)       entry = DEAL_ENTRY_IN
(GBPUSD,H1)       pid =  1461313378
(GBPUSD,H1)       r = DEAL_REASON_CLIENT
(GBPUSD,H1)       v =  0.01
(GBPUSD,H1)       p =  0.99886
(GBPUSD,H1)       s = EURUSD
(GBPUSD,H1)     }
(GBPUSD,H1)     pos =
(GBPUSD,H1)     {
(GBPUSD,H1)       n =  1
(GBPUSD,H1)     }
(GBPUSD,H1)   }
(GBPUSD,H1)   Alert: Trade by subscription: market entry ORDER_TYPE_BUY 0.01 GBPUSD -
```

The last of the above entries indicates a successful transaction on GBPUSD. On the trading tab of the account, 2 positions should be displayed.

After some time, we close the EURUSD position, and the GBPUSD position should close automatically.

```
(EURUSD,H1) TRADE_ACTION_DEAL, EURUSD, ORDER_TYPE_SELL, V=0.01, ORDER_FILLING_FOK, @
(EURUSD,H1) DONE, D=1439025490, #=1461315206, V=0.01, @ 0.99881, Bid=0.99881, Ask=0.9
(EURUSD,H1) {"req" : {"a" : "TRADE_ACTION_DEAL", "s" : "EURUSD", "t" : "ORDER_TYPE_SE
»   "f" : "ORDER_FILLING_FOK", "p" : 0.99881, "o" : 1461315206, "q" : 1461313378}, "r
»   "d" : 1439025490, "o" : 1461315206, "v" : 0.01, "p" : 0.99881, "b" : 0.99881, "a"

```

Finally, next to the Expert Advisor *wstradecopier.mq5*, we create a project file *wstradecopier.mqproj* to add a description and necessary server files to it (in the old directory *MQL5/Experts/p7/MQL5Book/Web/*).

To summarize: we have organized a technically extensible, multi-user system for exchanging trading information via a socket server. Due to the technical features of web sockets (permanent open connection), this implementation of the signal service is more suitable for short-term and high-frequency trading, as well as for controlling arbitrage situations in quotes.

Solving the problem required combining several programs on different platforms and connecting a large number of dependencies, which is what usually characterizes the transition to the project level. The development environment is also expanded, going beyond the compiler and source code editor. In particular, the presence in the project of the client or server parts usually involves the work of different programmers responsible for them. In this case, shared projects in the cloud and with version control become indispensable.

Please note that when developing a project in the folder *MQL5/Shared Projects* via MetaEditor, header files from the standard directory *MQL5/Include* are not included in the shared storage. On the other hand, creating a dedicated folder *Include* inside your project and transferring the necessary standard mqh files to it will lead to duplication of information and potential discrepancies in the versions of header files. This behavior is likely to be improved in MetaEditor.

Another point for public projects is the need to administer users and authorize them. In our last example, this issue was only identified but not implemented. However, the mql5.com site provides a ready-made solution based on the well-known OAuth protocol. Anyone who has an mql5.com account can get familiar with the principle of OAuth and configure it for their web service: just find the section *Applications* (link looking like *https://www.mql5.com/en/users/<login> /apps*) in your profile. By registering a web service in mql5.com applications, you will be able to authorize users through the mql5.com website.

7.9 Native python support

The potential success of automated trading largely depends on the breadth of technology that is available in the implementation of the idea. As we have already seen in the previous sections, MQL5 allows you to go beyond strictly applied trading tasks and provides opportunities for integration with external services (for example, based on network functions and custom symbols), processing and storing data using relational databases, as well as connecting arbitrary libraries.

The last point allows you to ensure interaction with any software that provides API in the DLL format. Some developers use this method to connect to industrial distributed DBMSs (instead of the built-in SQLite), math packages like R or MATLAB, and other programming languages.

Python has become one of the most popular programming languages. Its feature is a compact core, which is complemented by packages which are ready-made collections of scripts for building application solutions. Traders benefit from the wide selection and functionality of the packages for fundamental market analysis (statistical calculations, data visualization) and testing of trading hypotheses, including machine learning.

Following this trend, MQ introduced Python support in MQL5 in 2019. This tighter "out-of-the-box" integration allows the complete transfer of technical analysis and trading algorithms to the Python environment.

From a technical point of view, integration is achieved by installing the "MetaTrader5" package in Python, which organizes interprocess interaction with the terminal (at the time of writing this, through the ipykernel/RPC mechanism).

Among the functions of the package, there are full analogs of the built-in MQL5 functions for obtaining information about the terminal, trading account, symbols in *Market Watch*, quotes, ticks, Depth of Market, orders, positions, and deals. In addition, the package allows you to switch trading accounts, send trade orders, check margin requirements, and evaluate potential profits/losses in real-time.

However, integration with Python has some limitations. In particular, it is not possible in Python to implement event handling such as *OnTick*, *OnBookEvent*, and others. Because of this, it is necessary to use an infinite loop to check new prices, much like we were forced to do in MQL5 scripts. The analysis of the execution of trade orders is just as difficult: in the absence of *OnTradeTransaction*, more code would be needed to know if a position was fully or partially closed. To bypass these restrictions, you can organize the interaction of the Python script and MQL5, for example, through sockets. The mql5.com site features articles with examples of the implementation of such a bridge.

Thus, it seems that it is only natural to use Python in conjunction with MetaTrader 5 for machine learning tasks that deal with quotes, ticks, or trading account history. Unfortunately, you can't get indicator readings in Python.

7.9.1 Installing Python and the MetaTrader5 package

To study the materials in this chapter, Python must be installed on your computer. If you haven't installed it yet, download the latest version of Python (e.g. 3.10 at the time of writing) from *https://www.python.org/downloads/windows*.

When installing Python, it is recommended to check the "Add Python to PATH" flag so that you can run Python scripts from the command line from any folder.

Once Python is downloaded and running, install the MetaTrader5 module from the command line (here *pip* is a standard Python package manager program):

```
pip install MetaTrader5
```

Subsequently, you can check the package update with the following command line:

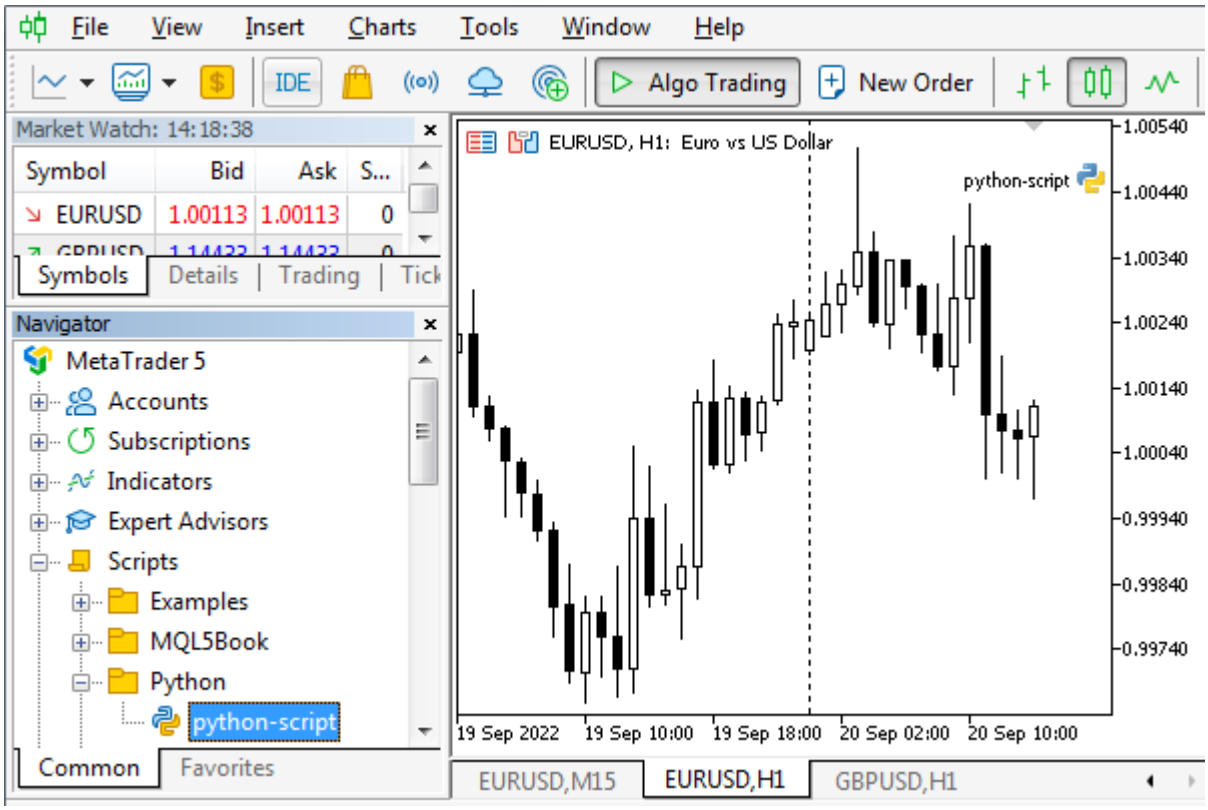
```
pip install --upgrade MetaTrader5
```

The syntax for adding other commonly used packages is similar. In particular, many scripts require data analysis and visualization packages: *pandas* and *matplotlib*, respectively.

```
pip install matplotlib
pip install pandas
```

You can create a new Python script directly from the MQL5 Wizard in MetaEditor. In addition to the script name, the user can select options for importing multiple packages, such as *TensorFlow*, *NumPy*, or *Datetime*.

Scripts by default are suggested to be placed in the folder *MQL5/Scripts*. Newly created and existing Python scripts are displayed in the MetaTrader 5 Navigator, marked with a special icon, and can be launched from the Navigator in the usual way. Python scripts can be executed on the chart in parallel with other MQL5 scripts and Expert Advisors. To stop a script if its execution is looped, simply remove it from the chart.



Running Python script in the terminal

The Python script launched from the terminal receives the name of the symbol and the timeframe of the chart through command line parameters. For example, we can run the following script on the EURUSD, H1 chart, in which the arguments are available as the *sys.argv* array:

```
import sys

print('The command line arguments are:')
for i in sys.argv:
   print(i)
```

It will output to the expert log:

```
The command line arguments are:
C:\Program Files\MetaTrader 5\MQL5\Scripts\MQL5Book\Python\python-args.py
EURUSD
60
```

In addition, a Python script can be run directly from MetaEditor by specifying the Python installation location in the editor *Settings* dialog, tab *Compilers* – then the compilation command for files with the extension **.py* becomes a run command.

Finally, Python scripts can also be run in their native environment by passing them as parameters in *python.exe* calls from the command line or from another IDE (Integrated Development Environment) adapted for Python, such as Jupyter Notebook.

If algorithmic trading is enabled in the terminal, then trading from Python is also enabled by default. To further protect accounts when using third-party Python libraries, the platform settings provide the option "Disable automatic trading via external Python API". Thus, Python scripts can selectively block trading, leaving it available to MQL programs. When this option is enabled, trading function calls in a Python script will return error 10027 (TRADE_RETCODE_CLIENT_DISABLES_AT) indicating that algorithmic trading is disabled by the client terminal.

MQL5 vs Python

Python is an interpreted language, unlike compiled MQL5. For us as developers, this makes life easier because we don't need a separate compilation phase to get a working program. However, the execution speed of scripts in Python is noticeably lower than those compiled in MQL5.

Python is a dynamically typed language: the type of a variable is determined by the value we put in it. On the one hand, this gives flexibility, but it also requires caution in order to avoid unforeseen errors. MQL5 uses static typing, that is, when describing variables, we must explicitly specify their type, and the compiler monitors type compatibility.

Python itself "cleans the garbage", that is, frees the memory allocated by the application program for objects. In MQL5 we have to follow up the timely call of *delete* for dynamic objects.

In Python syntax, source code indentation plays an important role. If you need to write a compound statement (for example, a loop or conditional) with a block of several nested statements, then Python uses spaces or tabs for this purpose (they must be equal in size within the block). Mixing tabs and spaces is not allowed. The wrong indentation will result in an error. In MQL5, we form blocks of compound statements by enclosing them in curly brackets { ... }, but formatting does not play a role, and you can apply any style you like without breaking the program's performance.

Python functions support two types of parameters: named and positional. The second type corresponds to what we are used to in MQL5: the value for each parameter must be passed strictly in its order in the list of arguments (according to the function prototype). In contrast, named parameters are passed as a combination of name and value (with '=' between them), and therefore they can be specified in any order, for example, *func(param2 = value2, param1 = value1)*.

7.9.2 Overview of functions of the MetaTrader5 package for Python

The API functions available in Python can be conditionally divided into 2 groups: functions that have full analogs in the MQL5 API and functions available only in Python. The presence of the second group is partly due to the fact that the connection between Python and MetaTrader 5 must be technically organized before application functions can be used. This explains the presence and purpose of a pair of functions *initialize* and *shutdown*: the first establishes a connection to the terminal, and the second one terminates it.

It is important that during the initialization process, the required copy of the terminal can be launched (if it has not been executed yet) and a specific trading account can be selected. In addition, it is possible to change the trading account in the context of an already opened connection to the terminal: this is done by the *login* function.

After connecting to the terminal, a Python script can get a summary of the terminal version using the *version* function. Full information about the terminal is available through *terminal_info* which is a complete analog of three *TerminalInfo* functions, as if they were united in one call.

The following table lists the Python application functions and their counterparts in the MQL5 API.

Python	MQL5
last_error	*GetLastError* (Attention! Python has its native error codes)
account_info	*AccountInfoInteger*, *AccountInfoDouble*, *AccountInfoString*
terminal_info	*TerminalInfoInteger*, *TerminalInfoDouble*, *TerminalInfoDouble*
symbols_total	*SymbolsTotal* (all symbols, including custom and disabled)
symbols_get	*SymbolsTotal* + *SymbolInfo* functions
symbol_info	*SymbolInfoInteger*, *SymbolInfoDouble*, *SymbolInfoString*
symbol_info_tick	*SymbolInfoTick*
symbol_select	*SymbolSelect*
market_book_add	*MarketBookAdd*
market_book_get	*MarketBookGet*
market_book_release	*MarketBookRelease*
copy_rates_from	*CopyRates* (by the number of bars, starting from date/time)
copy_rates_from_pos	*CopyRates* (by the number of bars, starting from the bar number)
copy_rates_range	*CopyRates* (in the date/time range)
copy_ticks_from	*CopyTicks* (by the number of ticks, starting from the specified time)
copy_ticks_range	*CopyTicksRange* (in the specified time range)
orders_total	*OrdersTotal*

Python	MQL5
orders_get	*OrdersTotal* + *OrderGet* functions
order_calc_margin	*OrderCalcMargin*
order_calc_profit	*OrderCalcProfit*
order_check	*OrderCheck*
order_send	*OrderSend*
positions_total	*PositionsTotal*
positions_get	*PositionsTotal* + *PositionGet* functions
history_orders_total	*HistoryOrdersTotal*
history_orders_get	*HistoryOrdersTotal* + *HistoryOrderGet* functions
history_deals_total	*HistoryDealsTotal*
history_deals_get	*HistoryDealsTotal* + *HistoryDealGet* functions

Functions from the Python API have several features.

As already noted, functions can have named parameters: when a function is called, such parameters are specified together with a name and value, in each pair of name and value they are combined with the equal sign '='. The order of specifying named parameters is not important (unlike positional parameters, which are used in MQL5 and must follow the strict order specified by the function prototype).

Python functions operate on data types native to Python. This includes not only the usual numbers and strings but also several composite types, somewhat similar to MQL5 arrays and structures.

For example, many functions return special Python data structures: *tuple* and *namedtuple*.

A tuple is a sequence of elements of an arbitrary type. It can be thought of as an array, but unlike an array, the elements of a tuple can be of different types. You can also think of a tuple as a set of structure fields.

An even closer resemblance to structure can be found with named tuples, where each element is given an ID. Only an index can be used to access an element in a common tuple (in square brackets, as in MQL5, that is, [i]). However, we can apply the dereference operator (dot '.') to a named tuple to get its "property " just like in the MQL5 structure (*tuple.field*).

Also, tuples and named tuples cannot be edited in code (that is, they are constants).

Another popular type is a dictionary: an associative array that stores key and value pairs, and the types of both can vary. The dictionary value is accessed using the operator [], and the key (whatever type it is, for example, a string) is indicated between the square brackets, which makes dictionaries similar to arrays. A dictionary cannot have two pairs with the same key, that is, the keys are always unique. In particular, a named tuple can easily be turned into a dictionary using the method *namedtuple._asdict()*.

7.9.3 Connecting a Python script to the terminal and account

The *initialize* function establishes a connection with the MetaTrader 5 terminal and has 2 forms: short (without parameters) and full (with several optional parameters, the first of them is *path* and it is positional, and all the rest are named).

```
bool initialize()
bool initialize(path, account = <ACCOUNT>, password = <"PASSWORD">,
  server = <"SERVER">, timeout = 60000, portable = False)
```

The *path* parameter sets the path to the terminal file (*metatrader64.exe*) (note that this is an unnamed parameter, unlike all the others, so if it is specified, it must come first in the list).

If the path is not specified, the module will try to find the executable file on its own (the developers do not disclose the exact algorithm). To eliminate ambiguities, use the second form of the function with parameters.

In the *account* parameter, you can specify the number of the trading account. If it is not specified, then the last trading account in the selected instance of the terminal will be used.

The password for the trading account is specified in the *password* parameter and can also be omitted: in this case, the password stored in the terminal database for the specified trading account is automatically substituted.

The *server* parameter is processed in a similar way with the trade server name (as it is specified in the terminal): if it is not specified, then the server saved in the terminal database for the specified trading account is automatically substituted.

The *timeout* parameter indicates the timeout in milliseconds that is given for the connection (if it is exceeded, an error will occur). The default value is 60000 (60 seconds).

The *portable* parameter contains a flag for launching the terminal in the portable mode (default is *False*).

The function returns *True* in case of successful connection to the MetaTrader 5 terminal and *False* otherwise.

If necessary, when making a call *initialize*, the MetaTrader 5 terminal can be launched.

For example, connection to a specific trading account is performed as follows.

```
import MetaTrader5 as mt5
if not mt5.initialize(login = 562175752, server = "MetaQuotes-Demo", password = "abc"
   print("initialize() failed, error code =", mt5.last_error())
   quit()
...
```

The *login* function also connects to the trading account with the specified parameters. But this implies that the connection with the terminal has already been established, that is, the function is usually used to change the account.

```
bool login(account, password = <"PASSWORD">, server = <"SERVER">, timeout = 60000)
```

The trading account number is provided in the *account* parameter. This is a required unnamed parameter, meaning it must come first in the list.

The *password*, *server*, and *timeout* parameters are identical to the relevant parameters of the *initialize* function.

The function returns *True* in case of successful connection to the trading account and *False* otherwise.

shutdown()

The *shutdown* function closes the previously established connection to the MetaTrader 5 terminal.

The example for the above functions will be provided in the next section.

When the connection is established, the script can find the version of the terminal.

tuple version()

The *version* function returns brief information about the version of the MetaTrader 5 terminal as a tuple of three values: version number, build number, and build date.

Field type	Description
integer	MetaTrader 5 terminal version (current, 500)
integer	Build number (for example, 3456)
string	Build date (e.g. '25 Feb 2022')

In case of an error, the function returns *None*, and the error code can be obtained using *last_error*.

More complete information about the terminal can be obtained using the *terminal_info* function.

7.9.4 Error checking: last_error

The *last_error* function returns information about the last Python error.

int last_error()

Integer error codes differ from the codes that are allocated for MQL5 errors and returned by the standard *GetLastError* function. In the following table, the abbreviation IPC refers to the term "Inter-Process Communication".

Constant	Meaning	Description
RES_S_OK	1	Success
RES_E_FAIL	-1	Common error
RES_E_INVALID_PARAMS	-2	Invalid arguments/parameters
RES_E_NO_MEMORY	-3	Memory allocation error
RES_E_NOT_FOUND	-4	Requested history not found
RES_E_INVALID_VERSION	-5	Version not supported
RES_E_AUTH_FAILED	-6	Authorization error
RES_E_UNSUPPORTED	-7	Method not supported
RES_E_AUTO_TRADING_DISABLED	-8	Algo trading is disabled
RES_E_INTERNAL_FAIL	-10000	General internal IPC error
RES_E_INTERNAL_FAIL_SEND	-10001	Internal error sending IPC data
RES_E_INTERNAL_FAIL_RECEIVE	-10002	Internal error sending IPC data
RES_E_INTERNAL_FAIL_INIT	-10003	IPC internal initialization error
RES_E_INTERNAL_FAIL_CONNECT	-10003	No IPC
RES_E_INTERNAL_FAIL_TIMEOUT	-10005	IPC timeout

In the following script (*MQL5/Scripts/MQL5Book/Python/init.py*), in the case of an error when connecting to the terminal, we display the error code and exit.

```
import MetaTrader5 as mt5
# show MetaTrader5 package version
print("MetaTrader5 package version: ", mt5.__version__)  #  5.0.37

# let's try to establish a connection or launch the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()
... # the working part of the script will be here
# terminate the connection to the terminal
mt5.shutdown()
```

7.9.5 Getting information about a trading account

The *account_info* function obtains full information about the current trading account.

namedtuple account_info()

The function returns information as a structure of named tuples (*namedtuple*). In case of an error, the result is *None*.

Using this function, you can use one call to get all the information that is provided by *AccountInfoInteger*, *AccountInfoDouble*, and *AccountInfoString* in MQL5, with all variants of supported properties. The names of the fields in the tuple correspond to the names of the enumeration elements without the "ACCOUNT_" prefix, reduced to lowercase.

The following script *MQL5/Scripts/MQL5Book/Python/accountinfo.py* is included with the book.

```
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

account_info = mt5.account_info()
if account_info != None:
   # display trading account data as is
   print(account_info)
   # display data about the trading account in the form of a dictionary
   print("Show account_info()._asdict():")
   account_info_dict = mt5.account_info()._asdict()
   for prop in account_info_dict:
      print("  {}={}".format(prop, account_info_dict[prop]))

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

The result should be something like this.

```
AccountInfo(login=25115284, trade_mode=0, leverage=100, limit_orders=200, margin_so_m
Show account_info()._asdict():
  login=25115284
  trade_mode=0
  leverage=100
  limit_orders=200
  margin_so_mode=0
  trade_allowed=True
  trade_expert=True
  margin_mode=2
  currency_digits=2
  fifo_close=False
  balance=99511.4
  credit=0.0
  profit=41.82
  equity=99553.22
  margin=98.18
  margin_free=99455.04
  margin_level=101398.67590140559
  margin_so_call=50.0
  margin_so_so=30.0
  margin_initial=0.0
  margin_maintenance=0.0
  assets=0.0
  liabilities=0.0
  commission_blocked=0.0
  name=MetaQuotes Dev Demo
  server=MetaQuotes-Demo
  currency=USD
  company=MetaQuotes Software Corp.
```

7.9.6 Getting information about the terminal

The *terminal_info* function allows you to get the status and parameters of the connected MetaTrader 5 terminal.

namedtuple terminal_info()

On success, the function returns the information as a structure of named tuples (*namedtuple*), and in case of an error, it returns *None*.

In one call of this function, you can get all the information that is provided by *TerminalInfoInteger*, *TerminalInfoDouble*, and *TerminalInfoDouble* in MQL5, with all variants of supported properties. The names of the fields in the tuple correspond to the names of the enumeration elements without the "TERMINAL_" prefix, reduced to lowercase.

For example (see *MQL5/Scripts/MQL5Book/Python/terminalinfo.py*):

```
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# display brief information about the MetaTrader 5 version
print(mt5.version())
# display full information about the settings and the state of the terminal
terminal_info = mt5.terminal_info()
if terminal_info != None:
   # display terminal data as is
   print(terminal_info)
   # display the data as a dictionary
   print("Show terminal_info()._asdict():")
   terminal_info_dict = mt5.terminal_info()._asdict()
   for prop in terminal_info_dict:
      print("  {}={}".format(prop, terminal_info_dict[prop]))

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

We should be something like the following.

```
[500, 3428, '14 Sep 2022']
TerminalInfo(community_account=True, community_connection=True, connected=True,....
Show terminal_info()._asdict():
  community_account=True
  community_connection=True
  connected=True
  dlls_allowed=False
  trade_allowed=False
  tradeapi_disabled=False
  email_enabled=False
  ftp_enabled=False
  notifications_enabled=False
  mqid=False
  build=2366
  maxbars=5000
  codepage=1251
  ping_last=77850
  community_balance=707.10668201585
  retransmission=0.0
  company=MetaQuotes Software Corp.
  name=MetaTrader 5
  language=Russian
  path=E:\ProgramFiles\MetaTrader 5
  data_path=E:\ProgramFiles\MetaTrader 5
  commondata_path=C:\Users\User\AppData\Roaming\MetaQuotes\Terminal\Common
```

7.9.7 Getting information about financial instruments

The group of functions of the MetaTrader5 package provides information about financial instruments.

The *symbol_info* function returns information about one financial instrument as a named tuple structure.

namedtuple symbol_info(symbol)

The name of the desired financial instrument is specified in the *symbol* parameter.

One call provides all the information that can be obtained using three MQL5 functions *SymbolInfoInteger*, *SymbolInfoDouble*, and *SymbolInfoString* with all properties. The names of the fields in the named tuple are the same as the names of the enumeration elements used in the specified functions but without the "SYMBOL_" prefix and in lowercase.

In case of an error, the function returns *None*.

> Attention! To ensure successful function execution, the requested symbol must be selected in *Market Watch*. This can be done from Python by calling *symbol_select* (see further).

Example (*MQL5/Scripts/MQL5Book/Python/eurjpy.py*):

```
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# make sure EURJPY is present in the Market Watch, or abort the algorithm
selected = mt5.symbol_select("EURJPY", True)
if not selected:
   print("Failed to select EURJPY")
   mt5.shutdown()
   quit()

# display the properties of the EURJPY symbol
symbol_info = mt5.symbol_info("EURJPY")
if symbol_info != None:
   # display the data as is (as a tuple)
   print(symbol_info)
   # output a couple of specific properties
   print("EURJPY: spread =", symbol_info.spread, ", digits =", symbol_info.digits)
   # output symbol properties as a dictionary
   print("Show symbol_info(\"EURJPY\")._asdict():")
   symbol_info_dict = mt5.symbol_info("EURJPY")._asdict()
   for prop in symbol_info_dict:
      print("  {}={}".format(prop, symbol_info_dict[prop]))

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

Result:

```
SymbolInfo(custom=False, chart_mode=0, select=True, visible=True, session_deals=0, se
EURJPY: spread = 17, digits = 3
Show symbol_info()._asdict():
  custom=False
  chart_mode=0
  select=True
  visible=True
  ...
  time=1585069682
  digits=3
  spread=17
  spread_float=True

  trade_tick_value_profit=0.8977708350166538
  trade_tick_value_loss=0.8978272580355541
  trade_tick_size=0.001
  trade_contract_size=100000.0
  ...
  volume_min=0.01
  volume_max=500.0
  volume_step=0.01
  volume_limit=0.0
  swap_long=-0.2
  swap_short=-1.2
  margin_initial=0.0
  margin_maintenance=0.0
  margin_hedged=100000.0
  ...
  currency_base=EUR
  currency_profit=JPY
  currency_margin=EUR
  ...
```

bool symbol_select(symbol, enable = None)

The *symbol_select* function adds the specified symbol to *Market Watch* or removes it. The symbol is specified in the first parameter. The second parameter is passed as *True* or *False*, which means showing or hiding the symbol, respectively.

If the second optional unnamed parameter is omitted, then by Python's type casting rules, *bool(none)* is equivalent to *False*.

The function is an analog of *SymbolSelect*.

int symbols_total()

The *symbols_total* function returns the number of all instruments in the MetaTrader 5 terminal, taking into account custom symbols and those not currently shown in the *Market Watch* window. This is the analog of the function *SymbolsTotal(false)*.

Next *symbols_get* function returns an array of tuples with information about all instruments or favorite instruments with names matching the specified filter in the optional named parameter *group*.

tuple[] symbols_get(group = "PATTERN")

Each element in the array tuple is a named tuple with a full set of symbol properties (we saw a similar tuple above in the context of the description of the *symbol_info* function).

Since there is only one parameter, its name can be omitted when calling the function.

In case of an error, the function will return a special value of *None*.

The *group* parameter allows you to select symbols by name, optionally using the substitution (wildcard) character '*' at the beginning and/or end of the searched string. '*' means 0 or any number of characters. Thus, you can organize a search for a substring that occurs in the name with an arbitrary number of other characters before or after the specified fragment. For example, "EUR*" means symbols that start with "EUR" and have any name extension (or just "EUR"). The "*EUR*" filter will return symbols with the names containing the "EUR" substring anywhere.

Also, the *group* parameter may contain multiple conditions separated by commas. Each condition can be specified as a mask using '*'. To exclude symbols, you can use the logical negation sign '!'. In this case, all conditions are applied sequentially, i.e., first you need to specify the inclusion conditions, and then the exclusion conditions. For example, group="*, !*EUR*" means that we need to select all symbols first and then exclude those that contain "EUR" in the name (anywhere).

For example, to display information about cross-currency rates, except for the 4 major Forex currencies, you can run the following query:

```
crosses = mt5.symbols_get(group = "*,!*USD*,!*EUR*,!*JPY*,!*GBP*")
print('len(*,!*USD*,!*EUR*,!*JPY*,!*GBP*):', len(crosses)) # the size of the resultin
for s in crosses:
   print(s.name, ":", s)
```

An example of the result:

```
len(*,!*USD*,!*EUR*,!*JPY*,!*GBP*):  10
AUDCAD : SymbolInfo(custom=False, chart_mode=0, select=True, visible=True, session_de
AUDCHF : SymbolInfo(custom=False, chart_mode=0, select=True, visible=True, session_de
AUDNZD : SymbolInfo(custom=False, chart_mode=0, select=True, visible=True, session_de
CADCHF : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
NZDCAD : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
NZDCHF : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
NZDSGD : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
CADMXN : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
CHFMXN : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
NZDMXN : SymbolInfo(custom=False, chart_mode=0, select=False, visible=False, session_
```

The *symbol_info_tick* function can be used to get the last tick for the specified financial instrument.

tuple symbol_info_tick(symbol)

The only mandatory parameter specifies the name of the financial instrument.

The information is returned as a tuple with the same fields as in the *MqlTick* structure. The function is an analog of *SymbolInfoTick*.

None is returned if an error occurs.

For the function to work properly, the symbol must be enabled in *Market Watch*. Let's demonstrate it in the script *MQL5/Scripts/MQL5Book/Python/gbpusdtick.py*.

```
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# try to include the GBPUSD symbol in the Market Watch
selected=mt5.symbol_select("GBPUSD", True)
if not selected:
   print("Failed to select GBPUSD")
   mt5.shutdown()
   quit()

# display the last tick of the GBPUSD symbol as a tuple
lasttick = mt5.symbol_info_tick("GBPUSD")
print(lasttick)
# display the values of the tick fields in the form of a dictionary
print("Show symbol_info_tick(\"GBPUSD\")._asdict():")
symbol_info_tick_dict = lasttick._asdict()
for prop in symbol_info_tick_dict:
   print("  {}={}".format(prop, symbol_info_tick_dict[prop]))

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

The result should be as follows:

```
Tick(time=1585070338, bid=1.17264, ask=1.17279, last=0.0, volume=0, time_msc=15850703
Show symbol_info_tick._asdict():
  time=1585070338
  bid=1.17264
  ask=1.17279
  last=0.0
  volume=0
  time_msc=1585070338728
  flags=2
  volume_real=0.0
```

7.9.8 Subscribing to order book changes

The Python API includes three functions for working with the order book.

bool market_book_add(symbol)

The *market_book_add* function subscribes to receive events about order book changes for the specified symbol. The name of the required financial instrument is indicated in a single unnamed parameter.

The function returns a boolean success indication.

The function is an analog of *MarketBookAdd*. After completing work with the order book, the subscription should be canceled by calling *market_book_release* (see further).

tuple[] market_book_get(symbol)

The *market_book_get* function requests the current contents of the order book for the specified symbol. The result is returned as a tuple (array) of *BookInfo* records. Each entry is an analog of the *MqlBookInfo* structure, and from the Python point of view, this is a named tuple with the fields "type", "price", "volume", "volume_real". In case of an error, the *None* value is returned.

> Note that for some reason in Python, the field is called *volume_dbl*, although in MQL5 the corresponding field is called *volume_real*.

To work with this function, you must first subscribe to receive order book events using the *market_book_add* function.

The function is an analog of *MarketBookGet*. Please note that a Python script cannot receive *OnBookEvent* events directly and should poll the contents of the glass in a loop.

bool market_book_release(symbol)

The *market_book_release* function cancels the subscription for order book change events for the specified symbol. On success, the function returns *True*. The function is an analog of *MarketBookRelease*.

Let's take a simple example (see *MQL5/Scripts/MQL5Book/Python/eurusdbook.py*).

```
import MetaTrader5 as mt5
import time               # connect a pack for the pause

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   mt5.shutdown()
   quit()

# subscribe to receive DOM updates for the EURUSD symbol
if mt5.market_book_add('EURUSD'):
   # run 10 times a loop to read data from the order book
   for i in range(10):
      # get the contents of the order book
      items = mt5.market_book_get('EURUSD')
      # display the entire order book in one line as is
      print(items)
      # now display each price level separately in the form of a dictionary, for clar
      for it in items or []:
         print(it._asdict())
      # let's pause for 5 seconds before the next request for data from the order boo
      time.sleep(5)
   # unsubscribe to order book changes
   mt5.market_book_release('EURUSD')
else:
   print("mt5.market_book_add('EURUSD') failed, error code =", mt5.last_error())

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

An example of the result:

```
(BookInfo(type=1, price=1.20036, volume=250, volume_dbl=250.0), BookInfo(type=1, pric
{'type': 1, 'price': 1.20036, 'volume': 250, 'volume_dbl': 250.0}
{'type': 1, 'price': 1.20029, 'volume': 100, 'volume_dbl': 100.0}
{'type': 1, 'price': 1.20028, 'volume': 50, 'volume_dbl': 50.0}
{'type': 1, 'price': 1.20026, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20023, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20022, 'volume': 50, 'volume_dbl': 50.0}
{'type': 2, 'price': 1.20021, 'volume': 100, 'volume_dbl': 100.0}
{'type': 2, 'price': 1.20014, 'volume': 250, 'volume_dbl': 250.0}
(BookInfo(type=1, price=1.20035, volume=250, volume_dbl=250.0), BookInfo(type=1, pric
{'type': 1, 'price': 1.20035, 'volume': 250, 'volume_dbl': 250.0}
{'type': 1, 'price': 1.20029, 'volume': 100, 'volume_dbl': 100.0}
{'type': 1, 'price': 1.20027, 'volume': 50, 'volume_dbl': 50.0}
{'type': 1, 'price': 1.20025, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20023, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20022, 'volume': 50, 'volume_dbl': 50.0}
{'type': 2, 'price': 1.20021, 'volume': 100, 'volume_dbl': 100.0}
{'type': 2, 'price': 1.20014, 'volume': 250, 'volume_dbl': 250.0}
(BookInfo(type=1, price=1.20037, volume=250, volume_dbl=250.0), BookInfo(type=1, pric
{'type': 1, 'price': 1.20037, 'volume': 250, 'volume_dbl': 250.0}
{'type': 1, 'price': 1.20031, 'volume': 100, 'volume_dbl': 100.0}
{'type': 1, 'price': 1.2003, 'volume': 50, 'volume_dbl': 50.0}
{'type': 1, 'price': 1.20028, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20025, 'volume': 36, 'volume_dbl': 36.0}
{'type': 2, 'price': 1.20023, 'volume': 50, 'volume_dbl': 50.0}
{'type': 2, 'price': 1.20022, 'volume': 100, 'volume_dbl': 100.0}
{'type': 2, 'price': 1.20016, 'volume': 250, 'volume_dbl': 250.0}
...
```

7.9.9 Reading quotes

The Python API allows you to get arrays of prices (bars) using three functions that differ in the way you specify the range of requested data: by bar numbers or by time. All functions are similar to different forms of *CopyRates*.

For all functions, the first two parameters are used to specify the name of the symbol and timeframe. The timeframes are listed in the TIMEFRAME enumeration, which is similar to the enumeration ENUM_TIMEFRAMES in MQL5.

> Please note: In Python, the elements of this enumeration are prefixed with TIMEFRAME_, while the elements of a similar enumeration in MQL5 are prefixed with PERIOD_.

Identifier	Description
TIMEFRAME_M1	1 minute
TIMEFRAME_M2	2 minutes
TIMEFRAME_M3	3 minutes
TIMEFRAME_M4	4 minutes
TIMEFRAME_M5	5 minutes

Identifier	Description
TIMEFRAME_M6	6 minutes
TIMEFRAME_M10	10 minutes
TIMEFRAME_M12	12 minutes
TIMEFRAME_M12	15 minutes
TIMEFRAME_M20	20 minutes
TIMEFRAME_M30	30 minutes
TIMEFRAME_H1	1 hour
TIMEFRAME_H2	2 hours
TIMEFRAME_H3	3 hours
TIMEFRAME_H4	4 hours
TIMEFRAME_H6	6 hours
TIMEFRAME_H8	8 hours
TIMEFRAME_H12	12 hours
TIMEFRAME_D1	1 day
TIMEFRAME_W1	1 week
TIMEFRAME_MN1	1 month

All three functions return bars as a *numpy* batch array with named columns *time*, *open*, *high*, *low*, *close*, *tick_volume*, *spread*, and *real_volume*. The *numpy.ndarray* array is a more efficient analog of named tuples. To access columns, use square bracket notation, *array['column']*.

None is returned if an error occurs.

All function parameters are mandatory and unnamed.

numpy.ndarray copy_rates_from(symbol, timeframe, date_from, count)

The *copy_rates_from* function requests bars starting from the specified date (*date_from*) in the number of *count* bars. The date can be set by the *datetime* object, or as the number of seconds since 1970.01.01.

When creating the *datetime* object, Python uses the local time zone, while the MetaTrader 5 terminal stores tick and bar open times in UTC (GMT, no offset). Therefore, to execute functions that use time, it is necessary to create *datetime* variables in UTC. To configure timezones, you can use the *pytz* package. For example (see *MQL5/Scripts/MQL5Book/Python/eurusdrates.py*):

```
from datetime import datetime
import MetaTrader5 as mt5
import pytz                    # import the pytz module to work with the timezone
# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   mt5.shutdown()
   quit()

# set the timezone to UTC
timezone = pytz.timezone("Etc/UTC")

# create a datetime object in the UTC timezone so that the local timezone offset is n
utc_from = datetime(2022, 1, 10, tzinfo = timezone)

# get 10 bars from EURUSD H1 starting from 10/01/2022 in the UTC timezone
rates = mt5.copy_rates_from("EURUSD", mt5.TIMEFRAME_H1, utc_from, 10)

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()

# display each element of the received data (tuple)
for rate in rates:
   print(rate)
```

A sample of received data:

```
(1641567600, 1.12975, 1.13226, 1.12922, 1.13017, 8325, 0, 0)
(1641571200, 1.13017, 1.13343, 1.1299, 1.13302, 7073, 0, 0)
(1641574800, 1.13302, 1.13491, 1.13293, 1.13468, 5920, 0, 0)
(1641578400, 1.13469, 1.13571, 1.13375, 1.13564, 3723, 0, 0)
(1641582000, 1.13564, 1.13582, 1.13494, 1.13564, 1990, 0, 0)
(1641585600, 1.1356, 1.13622, 1.13547, 1.13574, 1269, 0, 0)
(1641589200, 1.13572, 1.13647, 1.13568, 1.13627, 1031, 0, 0)
(1641592800, 1.13627, 1.13639, 1.13573, 1.13613, 982, 0, 0)
(1641596400, 1.1361, 1.13613, 1.1358, 1.1359, 692, 1, 0)
(1641772800, 1.1355, 1.13597, 1.13524, 1.1356, 1795, 10, 0)
```

numpy.ndarray copy_rates_from_pos(symbol, timeframe, start, count)

The *copy_rates_from_pos* function requests bars starting from the specified *start* index, in the quantity of *count*.

> The MetaTrader 5 terminal renders bars only within the limits of the history available to the user on the charts. The number of bars that are available to the user is set in the settings by the parameter "Max. bars in the window".

The following example (*MQL5/Scripts/MQL5Book/Python/ratescorr.py*) shows a graphic representation of the correlation matrix of several currencies based on quotes.

```
import MetaTrader5 as mt5
import pandas as pd              # connect the pandas module to output data
import matplotlib.pyplot as plt  # connect the matplotlib module for drawing

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   mt5.shutdown()
   quit()

# create a path in the sandbox for the image with the result
image = mt5.terminal_info().data_path + r'\MQL5\Files\MQL5Book\ratescorr'

# the list of working currencies for calculating correlation
sym = ['EURUSD','GBPUSD','USDJPY','USDCHF','AUDUSD','USDCAD','NZDUSD','XAUUSD']

# copy the closing prices of bars into DataFrame structures
d = pd.DataFrame()
for i in sym:        # last 1000 M1 bars for each symbol
   rates = mt5.copy_rates_from_pos(i, mt5.TIMEFRAME_M1, 0, 1000)
   d[i] = [y['close'] for y in rates]

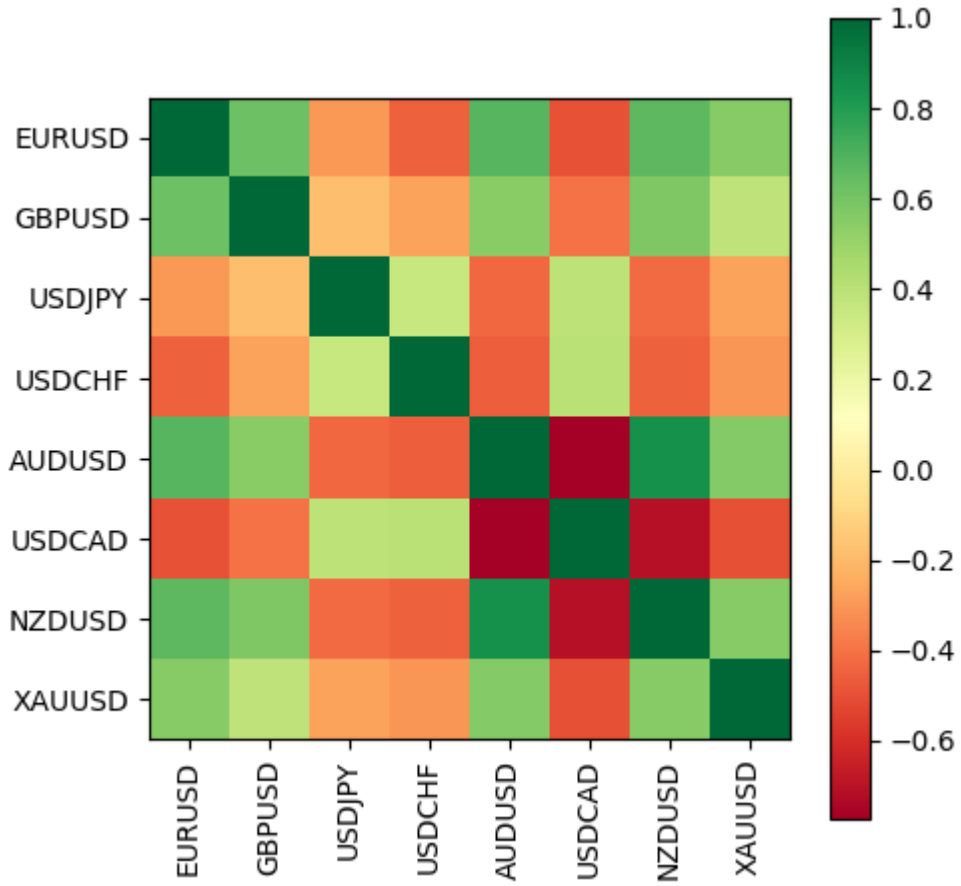
# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()

# calculate the price change as a percentage
rets = d.pct_change()

# compute correlations
corr = rets.corr()

# draw the correlation matrix
fig = plt.figure(figsize = (5, 5))
fig.add_axes([0.15, 0.1, 0.8, 0.8])
plt.imshow(corr, cmap = 'RdYlGn', interpolation = 'none', aspect = 'equal')
plt.colorbar()
plt.xticks(range(len(corr)), corr.columns, rotation = 'vertical')
plt.yticks(range(len(corr)), corr.columns)
plt.show()
plt.savefig(image)
```

The image file *ratescorr.png* is formed in the sandbox of the current working copy of MetaTrader 5. Interactive display of an image in a separate window using a call to *plt.show()* may not work if your Python installation does not include the Optional Features "tcl/tk and IDLE" or if you do not add the *pip install.tk* package.



Forex currency correlation matrix

numpy.ndarray copy_rates_range(symbol, timeframe, date_from, date_to)

The *copy_rates_range* function allows you to get bars in the specified date and time range, between *date_from* and *date_to*: both values are given as the number of seconds since the beginning of 1970, in the UTC time zone (because Python uses *datetime* local timezone, you should convert using the module *pytz*). The result includes bars with times of opening, *time* >= *date_from* and *time* <= *date_to*.

In the following script, we will request bars in a specific time range.

```
from datetime import datetime
import MetaTrader5 as mt5
import pytz             # connect the pytz module to work with the timezone
import pandas as pd     # connect the pandas module to display data in a tabular form

pd.set_option('display.max_columns', 500) # how many columns to show
pd.set_option('display.width', 1500)      # max. table width to display

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# set the timezone to UTC
timezone = pytz.timezone("Etc/UTC")
# create datetime objects in UTC timezone so that local timezone offset is not applie
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
utc_to = datetime(2020, 1, 10, minute = 30, tzinfo=timezone)

# get bars for USDJPY M5 for period 2020.01.10 00:00 - 2020.01.10 00:30 in UTC timezo
rates = mt5.copy_rates_range("USDJPY", mt5.TIMEFRAME_M5, utc_from, utc_to)

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()

# create a DataFrame from the received data
rates_frame = pd.DataFrame(rates)
# convert time from number of seconds to datetime format
rates_frame['time'] = pd.to_datetime(rates_frame['time'], unit = 's')

# output data
print(rates_frame)
```

An example of the result:

```
                 time     open     high      low    close  tick_volume  spread  real_
0 2020-01-10 00:00:00  109.513  109.527  109.505  109.521           43       2
1 2020-01-10 00:05:00  109.521  109.549  109.518  109.543          215       8
2 2020-01-10 00:10:00  109.543  109.543  109.466  109.505           98      10
3 2020-01-10 00:15:00  109.504  109.534  109.502  109.517          155       8

```

7.9.10 Reading tick history

The Python API includes two functions for reading the real tick history: *copy_ticks_from* with an indication of the number of ticks starting from the specified date, and *copy_ticks_range* for all ticks for the specified period.

Both functions have four required unnamed parameters, the first of which specifies the symbol. The second parameter specifies the initial time of the requested ticks. The third parameter indicates either the required number of ticks is passed (in the *copy_ticks_from* function) or the end time of ticks (in the *copy_ticks_range* function).

The last parameter determines what kind of ticks will be returned. It can contain one of the following flags (COPY_TICKS):

Identifier	Description
COPY_TICKS_ALL	All ticks
COPY_TICKS_INFO	Ticks containing Bid and/or Ask price changes
COPY_TICKS_TRADE	Ticks containing changes in the Last price and/or volume (Volume)

Both functions return ticks as an array *numpy.ndarray* (from the package *numpy*) with named columns *time*, *bid*, *ask*, *last*, and *flags*. The value of the field *flags* is a combination of bit flags from the TICK_FLAG enumeration: each bit means a change in the corresponding field with the tick property.

Identifier	Changed tick property
TICK_FLAG_BID	Bid price
TICK_FLAG_ASK	Ask price
TICK_FLAG_LAST	Last price
TICK_FLAG_VOLUME	Volume
TICK_FLAG_BUY	Last Buy price
TICK_FLAG_SELL	Last Sell price

numpy.ndarray copy_ticks_from(symbol, date_from, count, flags)

The *copy_ticks_from* function requests ticks starting from the specified time (*date_from*) in the given quantity (*count*).

The function is an analog of *CopyTicks*.

numpy.array copy_ticks_range(symbol, date_from, date_to, flags)

The *copy_ticks_range* function allows you to get ticks for the specified time range.

The function is an analog of *CopyTicksRange*.

In the following example (*MQL5/Scripts/MQL5Book/Python/copyticks.py*), we generate an interactive web page with a tick chart (note: the *plotly* package is used here; to install it in Python, run the command *pip install plotly*).

```
import MetaTrader5 as mt5
import pandas as pd
import pytz
from datetime import datetime

# connect to terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# set the name of the file to save to the sandbox
path = mt5.terminal_info().data_path + r'\MQL5\Files\MQL5Book\copyticks.html'

# copy 1000 EURUSD ticks from a specific moment in history
utc = pytz.timezone("Etc/UTC")
rates = mt5.copy_ticks_from("EURUSD", \
datetime(2022, 5, 25, 1, 15, tzinfo = utc), 1000, mt5.COPY_TICKS_ALL)
bid = [x['bid'] for x in rates]
ask = [x['ask'] for x in rates]
time = [x['time'] for x in rates]
time = pd.to_datetime(time, unit = 's')

# terminate the connection to the terminal
mt5.shutdown()

# connect the graphics package and draw 2 rows of ask and bid prices on the web page
import plotly.graph_objs as go
from plotly.offline import download_plotlyjs, init_notebook_mode, plot, iplot
data = [go.Scatter(x = time, y = bid), go.Scatter(x = time, y = ask)]
plot(data, filename = path)
```

Here's what the result might look like.

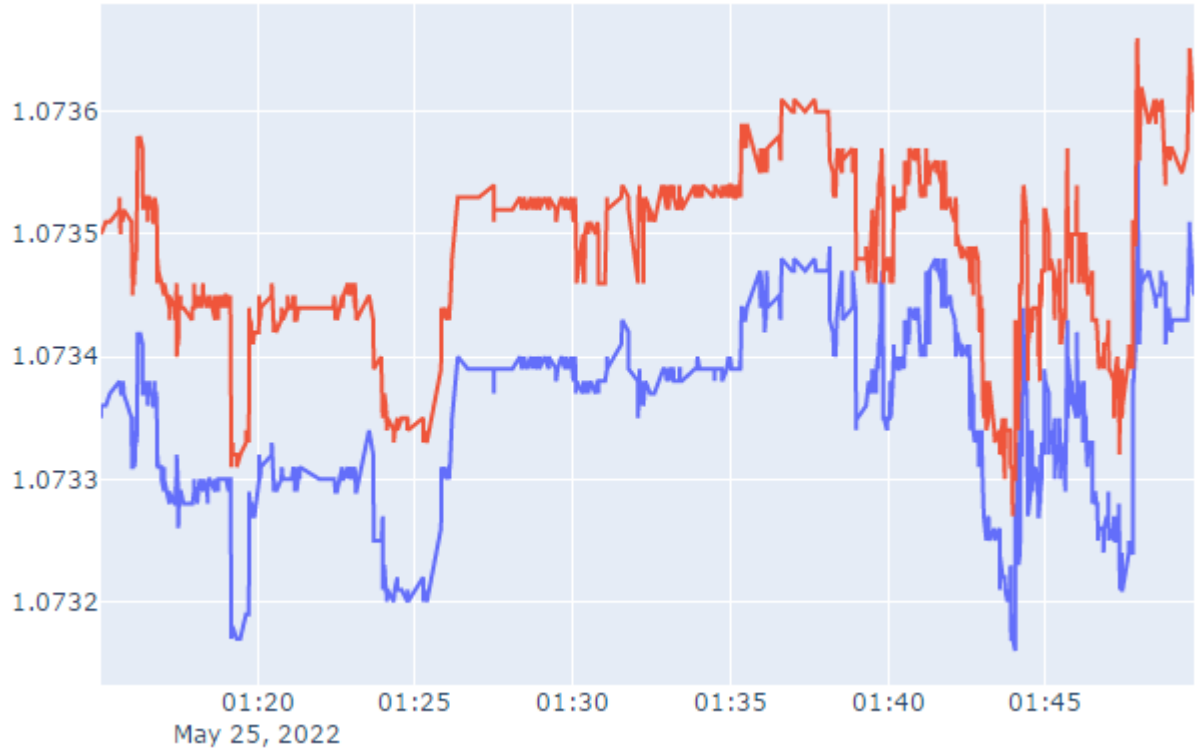

Chart with ticks received in a Python script

Webpage *copyticks.html* is generated in the subdirectory *MQL5/Files/MQL5Book*.

7.9.11 Calculating margin requirements and evaluating profits

A Python developer can directly calculate the margin and potential profit or loss of the proposed trading operation in the script using the *order_calc_margin* and *order_calc_profit* functions. In the case of successful execution, the result of any function is a real number; otherwise, it's *None*.

float order_calc_margin(action, symbol, volume, price)

The *order_calc_margin* function returns the margin amount (in the account currency) required to complete the specified trade operation *action* which can be one of the two elements of the ENUM_ORDER_TYPE enumeration: ORDER_TYPE_BUY or ORDER_TYPE_SELL. The following parameters specify the name of the financial instrument, the volume of the trade operation, and the opening price.

The function is an analog of *OrderCalcMargin*.

float order_calc_profit(action, symbol, volume, price_open, price_close)

The *order_calc_profit* function returns the amount of profit or loss (in the account currency) for the specified type of trade, symbol, and volume, as well as the difference between market entry and exit prices.

The function is an analog of *OrderCalcProfit*.

It is recommended to check the margin and the expected result of the trading operation before sending an order.

7.9.12 Checking and sending a trade order

If necessary, you can trade directly from a Python script. The pair of functions *order_check* and *order_send* allows you to pre-check and then execute a trading operation.

For both functions, the only parameter is the request structure *TradeRequest* (it can be initialized as a dictionary in Python, see an example). The structure fields are exactly the same as for *MqlTradeRequest*.

OrderCheckResult order_check(request)

The *order_check* function checks the correctness of trade request fields and the sufficiency of funds to complete the required trading operation.

The result of the function is returned as the *OrderCheckResult* structure. It repeats the structure of *MqlTradeCheckResult* but additionally contains the *request* field with a copy of the original request.

The *order_check* function is an analog of *OrderCheck*.

Example (*MQL5/Scripts/MQL5Book/python/ordercheck.py*):

```
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
...
# get account currency for information
account_currency=mt5.account_info().currency
print("Account currency:", account_currency)

# get the necessary properties of the deal symbol
symbol = "USDJPY"
symbol_info = mt5.symbol_info(symbol)
if symbol_info is None:
   print(symbol, "not found, can not call order_check()")
   mt5.shutdown()
   quit()

point = mt5.symbol_info(symbol).point
# if the symbol is not available in the Market Watch, add it
if not symbol_info.visible:
   print(symbol, "is not visible, trying to switch on")
   if not mt5.symbol_select(symbol, True):
      print("symbol_select({}) failed, exit", symbol)
      mt5.shutdown()
      quit()

# prepare the query structure as a dictionary
request = \
{
   "action": mt5.TRADE_ACTION_DEAL,
   "symbol": symbol,
   "volume": 1.0,
   "type": mt5.ORDER_TYPE_BUY,
   "price": mt5.symbol_info_tick(symbol).ask,
   "sl": mt5.symbol_info_tick(symbol).ask - 100 * point,
   "tp": mt5.symbol_info_tick(symbol).ask + 100 * point,
   "deviation": 10,
   "magic": 234000,
   "comment": "python script",
   "type_time": mt5.ORDER_TIME_GTC,
   "type_filling": mt5.ORDER_FILLING_RETURN,
}

# run the test and display the result as is
result = mt5.order_check(request)
print(result)                        # [?this is not in the help log?]

# convert the result to a dictionary and output element by element
result_dict = result._asdict()
for field in result_dict.keys():
   print("   {}={}".format(field, result_dict[field]))
   # if this is the structure of a trade request, then output it element by element a
```

```
      if field == "request":
         traderequest_dict = result_dict[field]._asdict()
         for tradereq_filed in traderequest_dict:
            print("       traderequest: {}={}".format(tradereq_filed,
            traderequest_dict[tradereq_filed]))

   # terminate the connection to the terminal
   mt5.shutdown()
```

Result:

```
   Account currency: USD
   OrderCheckResult(retcode=0, balance=10000.17, equity=10000.17, profit=0.0, margin=100
      retcode=0
      balance=10000.17
      equity=10000.17
      profit=0.0
      margin=1000.0
      margin_free=9000.17
      margin_level=1000.017
      comment=Done
      request=TradeRequest(action=1, magic=234000, order=0, symbol='USDJPY', volume=1.0,
          traderequest: action=1
          traderequest: magic=234000
          traderequest: order=0
          traderequest: symbol=USDJPY
          traderequest: volume=1.0
          traderequest: price=144.128
          traderequest: stoplimit=0.0
          traderequest: sl=144.028
          traderequest: tp=144.228
          traderequest: deviation=10
          traderequest: type=0
          traderequest: type_filling=2
          traderequest: type_time=0
          traderequest: expiration=0
          traderequest: comment=python script
          traderequest: position=0
          traderequest: position_by=0
```

OrderSendResult order_send(request)

The *order_send* function sends a request from the terminal to the trading server to make a trade operation.

The result of the function is returned as the *OrderSendResult* structure. It repeats the structure of *MqlTradeResult* but additionally contains the *request* field with a copy of the original request.

The function is an analog of *OrderSend*.

Example (*MQL5/Scripts/MQL5Book/python/ordersend.py*):

```
import time
import MetaTrader5 as mt5

# let's establish a connection to the MetaTrader 5 terminal
...
# assign the properties of the working symbol
symbol = "USDJPY"
symbol_info = mt5.symbol_info(symbol)
if symbol_info is None:
   print(symbol, "not found, can not trade")
   mt5.shutdown()
   quit()

# if the symbol is not available in the Market Watch, add it
if not symbol_info.visible:
   print(symbol, "is not visible, trying to switch on")
   if not mt5.symbol_select(symbol, True):
      print("symbol_select({}) failed, exit", symbol)
      mt5.shutdown()
      quit()

# let's prepare the request structure for the purchase
lot = 0.1
point = mt5.symbol_info(symbol).point
price = mt5.symbol_info_tick(symbol).ask
deviation = 20
request = \
{
   "action": mt5.TRADE_ACTION_DEAL,
   "symbol": symbol,
   "volume": lot,
   "type": mt5.ORDER_TYPE_BUY,
   "price": price,
   "sl": price - 100 * point,

```

7.9.13 Getting the number and list of active orders

The Python API provides the following functions for working with active orders.

int orders_total()

The *orders_total* function returns the number of active orders.

The function is an analog of *Orders Total*.

Detailed information about each order can be obtained using the *orders_get* function, which has several options with the ability to filter by symbol or ticket. Either way, the function returns the array of named

tuples *TradeOrder* (field names match ENUM_ORDER_PROPERTY_enumerations without the "ORDER_" prefix and reduced to lowercase). In case of an error, the result is *None*.

```
namedtuple[] orders_get()
namedtuple[] orders_get(symbol = <"SYMBOL">)
namedtuple[] orders_get(group = <"PATTERN">)
namedtuple[] orders_get(ticket = <TICKET>)
```

The *orders_get* function without parameters returns orders for all symbols.

The optional named parameter *symbol* makes it possible to specify a specific symbol name for order selection.

The optional named parameter *group* is intended for specifying a search pattern using the wildcard character '*' (as a substitute for an arbitrary number of any characters, including zero characters in the given place of the pattern) and the condition logical negation character '!'. The filter template operation principle was described in the section Getting information about financial instruments.

If the *ticket* parameter is specified, a certain order is searched.

In one function call, you can get all active orders. It is an analog of the combined use of *OrdersTotal*, *OrderSelect*, and *OrderGet* functions.

In the next example (*MQL5/Scripts/MQL5Book/Python/ordersget.py*), we request information about orders using different ways.

```
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # how many columns to show
pd.set_option('display.width', 1500)      # max. table width to display

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# display information about active orders on the GBPUSD symbol
orders = mt5.orders_get(symbol = "GBPUSD")
if orders is None:
   print("No orders on GBPUSD, error code={}".format(mt5.last_error()))
else:
   print("Total orders on GBPUSD:", len(orders))
   # display all active orders
   for order in orders:
      print(order)
print()

# getting a list of orders on symbols whose names contain "*GBP*"
gbp_orders = mt5.orders_get(group="*GBP*")
if gbp_orders is None:
   print("No orders with group=\"*GBP*\", error code={}".format(mt5.last_error()))
else:
   print("orders_get(group=\"*GBP*\")={}".format(len(gbp_orders)))
   # display orders as a table using pandas.DataFrame
   df = pd.DataFrame(list(gbp_orders), columns = gbp_orders[0]._asdict().keys())
   df.drop(['time_done', 'time_done_msc', 'position_id', 'position_by_id',
   'reason', 'volume_initial', 'price_stoplimit'], axis = 1, inplace = True)
   df['time_setup'] = pd.to_datetime(df['time_setup'], unit = 's')
   print(df)

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

The sample result is below:

```
Total orders on GBPUSD: 2
TradeOrder(ticket=554733548, time_setup=1585153667, time_setup_msc=1585153667718, tim
TradeOrder(ticket=554733621, time_setup=1585153671, time_setup_msc=1585153671419, tim

orders_get(group="*GBP*")=4
      ticket           time_setup  time_setup_msc  type ... volume_current  price_open
0  554733548 2020-03-25 16:27:47   1585153667718     3 ...            0.2     1.25379
1  554733621 2020-03-25 16:27:51   1585153671419     2 ...            0.2     1.14370
2  554746664 2020-03-25 16:38:14   1585154294401     3 ...            0.2     0.93851
3  554746710 2020-03-25 16:38:17   1585154297022     2 ...            0.2     0.90527
```

7.9.14 Getting the number and list of open positions

The *positions_total* function returns the number of open positions.

```
int positions_total()
```

The function is an analog of *PositionsTotal*.

To get detailed information about each position, use the *positions_get* function which has multiple options. All variants return an array of named tuples *TradePosition* with keys corresponding to position properties (see elements of ENUM_POSITION_PROPERTY_enumerations, without the "POSITION_" prefix, in lowercase). In case of an error, the result is *None*.

```
namedtuple[] positions_get()
namedtuple[] positions_get(symbol = <"SYMBOL">)
namedtuple[] positions_get(group = <"PATTERN">)
namedtuple[] positions_get(ticket = <TICKET>)
```

The function without parameters returns all open positions.

The function with the *symbol* parameter allows the selection of positions for the specified symbol.

The function with the *group* parameter provides filtering by search mask with wildcards '*' (any characters are replaced) and logical negation of the condition '!'. For details see the section Getting information about financial instruments.

A version with the *ticket* parameters selects a position with a specific ticket (POSITION_TICKET property).

The *positions_get* function can be used to get all positions and their properties in one call, which makes it similar to a bunch of *PositionsTotal*, *PositionSelect*, and *PositionGet* functions.

In the script *MQL5/Scripts/MQL5Book/Python/positionsget.py*, we request positions for a specific symbol and search mask.

```
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # how many columns to show
pd.set_option('display.width', 1500)      # max. table width to display

# let's establish a connection to the MetaTrader 5 terminal
if not mt5.initialize():
   print("initialize() failed, error code =", mt5.last_error())
   quit()

# get open positions on USDCHF
positions = mt5.positions_get(symbol = "USDCHF")
if positions == None:
   print("No positions on USDCHF, error code={}".format(mt5.last_error()))
elif len(positions) > 0:
   print("Total positions on USDCHF =", len(positions))
 # display all open positions
   for position in positions:
      print(position)

# get a list of positions on symbols whose names contain "*USD*"
usd_positions = mt5.positions_get(group = "*USD*")
if usd_positions == None:
    print("No positions with group=\"*USD*\", error code={}".format(mt5.last_error())
elif len(usd_positions) > 0:
   print("positions_get(group=\"*USD*\") = {}".format(len(usd_positions)))
   # display the positions as a table using pandas.DataFrame
   df=pd.DataFrame(list(usd_positions), columns = usd_positions[0]._asdict().keys())
   df['time'] = pd.to_datetime(df['time'], unit='s')
   df.drop(['time_update', 'time_msc', 'time_update_msc', 'external_id'],
   axis=1, inplace=True)
   print(df)

# complete the connection to the MetaTrader 5 terminal
mt5.shutdown()
```

Here's what the result might be:

```
Total positions on USDCHF = 1
TradePosition(ticket=1468454363, time=1664217233, time_msc=1664217233239, time_update
   time_update_msc=1664217233239, type=1, magic=0, identifier=1468454363, reason=0, v
   sl=0.0, tp=0.0, price_current=0.9853, swap=-0.01, profit=6.24, symbol='USDCHF', co
positions_get(group="*USD*") = 2
       ticket                time  type  ...  identifier  volume  price_open  ... _cu
0  1468454363 2022-09-26 18:33:53     1  ...  1468454363    0.01     0.99145  ...  0.
1  1468475849 2022-09-26 18:44:00     0  ...  1468475849    0.01     1.06740  ...  1.
```

7.9.15 Reading the history of orders and deals

Working with orders and deals in the account history using Python scripts is also possible. For these purposes, there are functions *history_orders_total*, *history_orders_get*, *history_deals_total*, and *history_deals_get*.

int history_orders_total(date_from, date_to)

The *history_orders_total* function returns the number of orders in the trading history in the specified time interval. Each of the parameters is set by the *datetime* object or as the number of seconds since 1970.01.01.

The function is an analog of *HistoryOrdersTotal*.

The *history_orders_get* function is available in several versions and supports order filtering by substring in symbol name, ticket, or position ID. All variants return an array of named tuples *TradeOrder* (field names match ENUM_ORDER_PROPERTY_enumerations without the "ORDER_" prefix and in lowercase). If there are no matching orders, the array will be empty. In case of an error, the function will return *None*.

namedtuple[] history_orders_get(date_from, date_to, group = <"PATTERN">)
namedtuple[] history_orders_get(ticket = <ORDER_TICKET>)
namedtuple[] history_orders_get(position = <POSITION_ID>)

The first version selects orders within the specified time range (similar to *history_orders_total*). In the optional named parameter *group*, you can specify a search pattern for a substring of the symbol name (you can use the wildcard characters '*' and negation '!' in it, see the section Getting information about financial instruments).

The second version is designed to search for a specific order by its ticket.

The last version selects orders by position ID (ORDER_POSITION_ID property).

Either option is equivalent to calling several MQL5 functions: *HistoryOrdersTotal*, *HistoryOrderSelect*, and *HistoryOrderGet*-functions.

Let's see on an example of the script *historyordersget.py* how to get the number and list of historical orders for different conditions.

```
from datetime import datetime
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # how many columns to show
pd.set_option('display.width', 1500)      # max. table width for display
...
# get the number of orders in the history for the period (total and *GBP*)
from_date = datetime(2022, 9, 1)
to_date = datetime.now()
total = mt5.history_orders_total(from_date, to_date)
history_orders=mt5.history_orders_get(from_date, to_date, group="*GBP*")
# print(history_orders)
if history_orders == None:
   print("No history orders with group=\"*GBP*\", error code={}".format(mt5.last_erro
else :
   print("history_orders_get({}, {}, group=\"*GBP*\")={} of total {}".format(from_dat
   to_date, len(history_orders), total))

# display all canceled historical orders for ticket position 0
position_id = 0
position_history_orders = mt5.history_orders_get(position = position_id)
if position_history_orders == None:
   print("No orders with position #{}".format(position_id))
   print("error code =", mt5.last_error())
elif len(position_history_orders) > 0:
   print("Total history orders on position #{}: {}".format(position_id,
   len(position_history_orders)))
   # display received orders as is
   for position_order in position_history_orders:
      print(position_order)
   # display these orders as a table using pandas.DataFrame
   df = pd.DataFrame(list(position_history_orders),
   columns = position_history_orders[0]._asdict().keys())
   df.drop(['time_expiration', 'type_time', 'state', 'position_by_id', 'reason', 'vol
   'price_stoplimit','sl','tp', 'time_setup_msc', 'time_done_msc', 'type_filling', 'e
   axis = 1, inplace = True)
   df['time_setup'] = pd.to_datetime(df['time_setup'], unit='s')
   df['time_done'] = pd.to_datetime(df['time_done'], unit='s')
   print(df)
...
```

The result of the script (given with abbreviations):

```
history_orders_get(2022-09-01 00:00:00, 2022-09-26 21:50:04, group="*GBP*")=15 of total 44

Total history orders on position #0: 14
TradeOrder(ticket=1437318706, time_setup=1661348065, time_setup_msc=1661348065049, time_done=166134
   time_done_msc=1661348083632, time_expiration=0, type=2, type_time=0, type_filling=2, state=2, ma

0   1437318706 2022-08-24 13:34:25 2022-08-24 13:34:43     2          0.01     0.99301        0.993
1   1437331579 2022-08-24 13:42:25 2022-08-24 13:42:31     2          0.01     0.99281        0.992
2   1437331739 2022-08-24 13:42:33 2022-08-24 13:42:43     2          0.01     0.99285        0.992
...
```

We can see that in September, there were only 44 orders, 15 of which included the GBP currency (an odd number due to the open position). The history contains 14 canceled orders.

int history_deals_total(date_from, date_to)

The *history_deals_total* function returns the number of deals in history for the specified period.

The function is an analog of *HistoryDealsTotal*.

The *history_deals_get* function has several forms and is designed to select trades with the ability to filter by order ticket or position ID. All forms of the function return an array of named tuples *TradeDeal*, with fields reflecting properties from the ENUM_DEAL_PROPERTY_enumerations (the prefix "DEAL_" has been removed from the field names and lowercase has been applied). In case of an error, we get *None*.

namedtuple[] history_deals_get(date_from, date_to, group = <"PATTERN">)
namedtuple[] history_deals_get(ticket = <ORDER_TICKET>)
namedtuple[] history_deals_get(position = <POSITION_ID>)

The first form of the function is similar to requesting historical orders using *history_orders_get*.

The second form allows the selection of deals generated by a specific order by its ticket (the DEAL_ORDER property).

Finally, the third form requests deals that have formed a position with a given ID (the DEAL_POSITION_ID property).

The function allows you to get all transactions together with their properties in one call, which is analogous to the bunch of *HistoryDealsTotal*, *HistoryDealSelect*, and *HistoryDealGet*-functions.

Here is the main part of the test script *historydealsget.py*.

```
# set the time range
from_date = datetime(2020, 1, 1)
to_date = datetime.now()

# get trades for symbols whose names do not contain either "EUR" or "GBP"
deals = mt5.history_deals_get(from_date, to_date, group="*,!*EUR*,!*GBP*")
if deals == None:
   print("No deals, error code={}".format(mt5.last_error()))
elif len(deals) > 0:
   print("history_deals_get(from_date, to_date, group=\"*,!*EUR*,!*GBP*\") =",
   len(deals))
   # display all received deals as they are
   for deal in deals:
      print("  ",deal)
   # display these trades as a table using pandas.DataFrame
   df = pd.DataFrame(list(deals), columns = deals[0]._asdict().keys())
   df['time'] = pd.to_datetime(df['time'], unit='s')
   df.drop(['time_msc','commission','fee'], axis = 1, inplace = True)
   print(df)
```

An example of result:

```
history_deals_get(from_date, to_date, group="*,!*EUR*,!*GBP*") = 12
   TradeDeal(ticket=1109160642, order=0, time=1632188460, time_msc=1632188460852, typ
   TradeDeal(ticket=1250629232, order=1268074569, time=1645709385, time_msc=164570938
   TradeDeal(ticket=1250639814, order=1268085019, time=1645709950, time_msc=164570995
   TradeDeal(ticket=1250639928, order=1268085129, time=1645709955, time_msc=164570995
   TradeDeal(ticket=1250640111, order=1268085315, time=1645709965, time_msc=164570996
   TradeDeal(ticket=1250640309, order=1268085512, time=1645709973, time_msc=164570997
   TradeDeal(ticket=1250640400, order=1268085611, time=1645709978, time_msc=164570997
   TradeDeal(ticket=1250640616, order=1268085826, time=1645709988, time_msc=164570998

7.10 Built-in support for parallel computing: OpenCL

OpenCL is an open parallel programming standard that allows you to create applications for simultaneous execution on many cores of modern processors, different in architecture, in particular, graphic (GPU) or central (CPU).

In other words, OpenCL allows you to use all the cores of the central processor or all the computing power of the video card for computing one task, which ultimately reduces the program execution time. Therefore, the use of OpenCL is very useful for computationally intensive tasks, but it is important to note that the algorithms for solving these tasks must be divisible into parallel threads. These include, for example, training neural networks, Fourier transform, or solving systems of equations of large dimensions.

For example, in relation to the trading specifics, an increase in performance can be achieved with a script, indicator, or Expert Advisor that performs a complex and lengthy analysis of historical data for several symbols and timeframes, and the calculation for each of which does not depend on others.

> At the same time, beginners often have a question whether it is possible to speed up the testing and optimization of Expert Advisors using OpenCL. The answers to both questions are no. Testing reproduces the real process of sequential trading, and therefore each next bar or tick depends on the results of the previous ones, which makes it impossible to parallelize the calculations of one pass. As for optimization, the tester's agents only support CPU cores. This is due to the complexity of a full-fledged analysis of quotes or ticks, tracking positions and calculating balance and equity. However, if complexity doesn't scare you, you can implement your own optimization engine on the graphics card cores by transferring all the calculations that emulate the trading environment with the required reliability to OpenCL.

OpenCL means Open Computing Language. It is similar to the C and C++ languages, and therefore, to MQL5. However, in order to prepare ("compile") an OpenCL program, pass input data to it, run it in parallel on several cores, and obtain calculation results, a special programming interface (a set of functions) is used. This OpenCL API is also available for MQL programs that wish to implement parallel execution.

To use OpenCL, it is not necessary to have a video card on your PC as the presence of a central processor is enough. In any case, special drivers from the manufacturer are required (OpenCL version 1.1 and higher is required). If your computer has games or other software (for example, scientific, video editor, etc.) that work directly with video cards, then the necessary software layer is most likely already available. This can be checked by trying to run an MQL program in the terminal with an OpenCL call (at least a simple example from the terminal delivery, see further).

If there is no OpenCL support, you will see an error in the log.

```
OpenCL OpenCL not found, please install OpenCL drivers
```

If there is a suitable device on your computer and OpenCL support has been enabled for it, the terminal will display a message with the name and type of this device (there may be several devices). For example:

```
OpenCL Device #0: CPU GenuineIntel Intel(R) Core(TM) i7-2700K CPU @ 3.50GHz with Open
OpenCL Device #1: GPU Intel(R) Corporation Intel(R) UHD Graphics 630 with OpenCL 2.1
```

The procedure for installing drivers for various devices is described in the article on mql5.com. Support extends to the most popular devices from Intel, AMD, ATI, and Nvidia.

In terms of the number of cores and the speed of distributed computing, central processors are significantly inferior to graphics cards, but a good multi-core central processor will be quite enough to significantly increase performance.

> Important: If your computer has a video card with OpenCL support, then you do not need to install OpenCL software emulation on the CPU!

OpenCL device drivers automate the distribution of calculations across cores. For example, if you need to perform a million of calculations of the same type with different vectors, and there are only a thousand cores at your disposal, then the drivers will automatically start each next task as the previous ones are ready and the cores are released.

Preparatory operations for setting up the OpenCL runtime environment in an MQL program are performed only once using the functions of the above OpenCL API.

1. Creating a context for an OpenCL program (selecting a device, such as a video card, CPU, or any available): *CLContextCreate(CL_USE_ANY)*. The function will return a context descriptor (an integer, let's denote it conditionally *ContextHandle*).

2. Creating an OpenCL program in the received context: it is compiled based on the source code in the OpenCL language using the *CLProgramCreate* function call, to which the text of the code is passed through the parameter *Source*:*CLProgramCreate(ContextHandle, Source, BuildLog)*. The function will return the program handle (integer *ProgramHandle*). It is important to note here that inside the source code of this program, there must be functions (at least one) marked with a special keyword *__kernel* (or simply *kernel*): they contain the parts of the algorithm to be parallelized (see example below). Of course, in order to simplify (decompose the source code), the programmer can divide the logical subtasks of the kernel function into other auxiliary functions and call them from the kernel: at the same time, there is no need to mark the auxiliary functions with the word *kernel*.

3. Registering a kernel to execute by the name of one of those functions that are marked in the code of the OpenCL program as kernel-forming: *CLKernelCreate(ProgramHandle, KernelName)*. Calling this function will return a handle to the kernel (an integer, let's say, *KernelHandle*). You can prepare many different functions in OpenCL code and register them as different kernels.

4. If necessary, creating buffers for data arrays passed by reference to the kernel and for returned values/arrays: *CLBufferCreate(ContextHandle, Size * sizeof(double), CL_MEM_READ_WRITE),* etc. Buffers are also identified and managed with descriptors.

Next, once or several times, if necessary, (for example, in indicator or Expert Advisor event handlers), calculations are performed directly according to the following scheme:

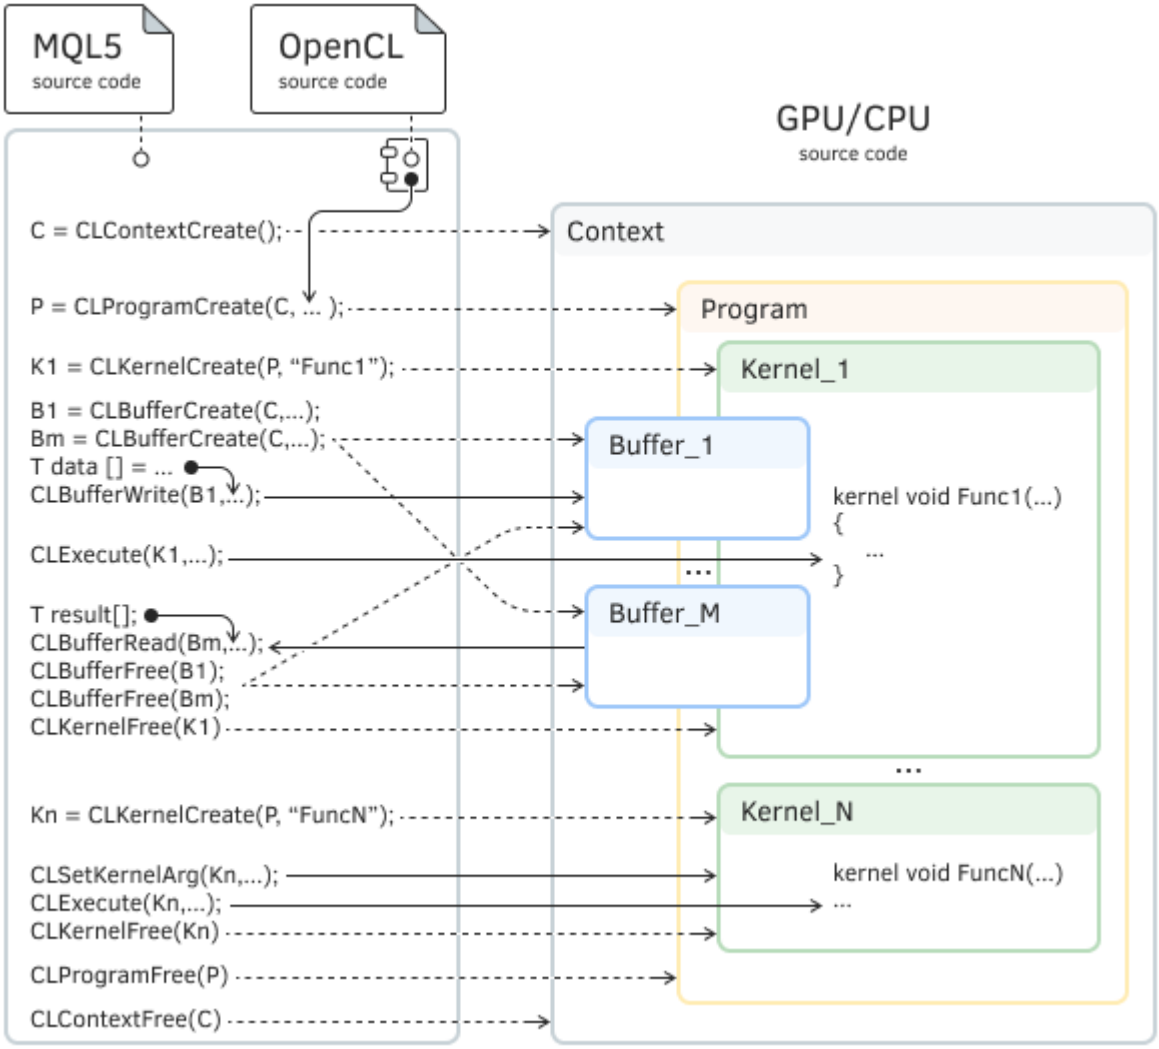
I. Passing input data and/or binding input/output buffers with *CLSetKernelArg(KernelHandle,...)* and/or *CLSetKernelArgMem(KernelHandle,..., BufferHandle)*. The first function provides the setting of a scalar value, and the second is equivalent to passing or receiving a value (or an array of values) by reference. At this stage, data is moved from MQL5 to the OpenCL execution core. *CLBufferWrite(BufferHandle,...)* writes data to the buffer. Parameters and buffers will become available to the OpenCL program during kernel execution.

II. Performing Parallel Computations by Calling a Specific Kernel *CLExecute(KernelHandle,...)*. The kernel function will be able to write the results of its work to the output buffer.

III. Getting results with *CLBufferRead(BufferHandle)*. At this stage, data is moved back from OpenCL to MQL5.

After completion of calculations, all descriptors should be released: *CLBufferFree(BufferHandle)*,*CLKernelFree(KernelHandle)*, *CLProgramFree(ProgramHandle)*, and *CLContextFree(ContextHandle)*.

This sequence is conventionally indicated in the following diagram.



Scheme of interaction between an MQL program and an OpenCL attachment

It is recommended to write the OpenCL source code in separate text files, which can then be connected to the MQL5 program using resource variables.

The standard header library supplied with the terminal contains a wrapper class for working with OpenCL: *MQL5/Include/OpenCL/OpenCL.mqh*.

Examples of using OpenCL can be found in the folder *MQL5/Scripts/Examples/OpenCL/*. In particular, there is the *MQL5/Scripts/Examples/OpenCL/Double/Wavelet.mq5* script, which produces a wavelet transform of the time series (you can take an artificial curve according to the stochastic Weierstrass model or the increment in prices of the current financial instrument). In any case, the initial data for the algorithm is an array which is a two-dimensional image of a series.

When running this script, same as when running any other MQL program with OpenCL code, the terminal will select the fastest device (if there are several of them, and the specific device was not

selected in the program itself or was not already defined earlier). Information about this is displayed in the *Journal* tab (terminal log, not experts).

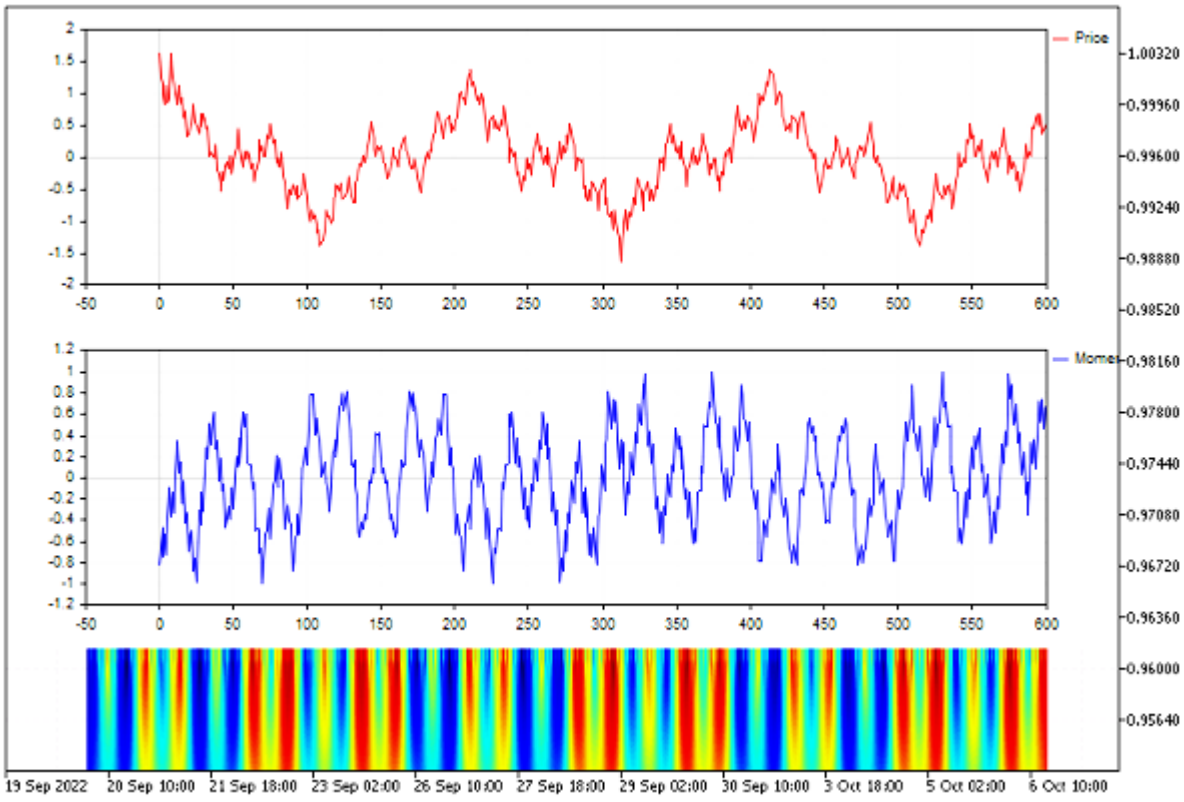
```
Scripts script Wavelet (EURUSD,H1) loaded successfully
OpenCL  device #0: GPU NVIDIA Corporation NVIDIA GeForce GTX 1650 with OpenCL 3.0 (16
OpenCL  device #1: GPU Intel(R) Corporation Intel(R) UHD Graphics 630 with OpenCL 3.0
OpenCL  device performance test started
OpenCL  device performance test successfully finished
OpenCL  device #0: GPU NVIDIA Corporation NVIDIA GeForce GTX 1650 with OpenCL 3.0 (16
OpenCL  device #1: GPU Intel(R) Corporation Intel(R) UHD Graphics 630 with OpenCL 3.0
Scripts script Wavelet (EURUSD,H1) removed
```

As a result of execution, the script displays in the *Experts* tab records with calculation speed measurements in the usual way (in series, on the CPU) and in parallel (on OpenCL cores).

```
OpenCL: GPU device 'Intel(R) UHD Graphics 630' selected
time CPU=5235 ms, time GPU=125 ms, CPU/GPU ratio: 41.880000
```

The ratio of speeds, depending on the specifics of the task, can reach tens.

The script displays on the chart the original image, its derivative in the form of increments, and the result of the wavelet transform.



The original simulated series, its increments and wavelet transform

Please note that the graphic objects remain on the chart after the script finished working. They will need to be removed manually.

Here is how the source OpenCL code of the wavelet transform looks like, implemented in a separate file *MQL5/Scripts/Examples/OpenCL/Double/Kernels/wavelet.cl*.

```
// increased calculation accuracy double is required
// (by default, without this directive we get float)
#pragma OPENCL EXTENSION cl_khr_fp64 : enable

// Helper function Morlet
double Morlet(const double t)
{
   return exp(-t * t * 0.5) * cos(M_2_PI * t);
}

// OpenCL kernel function
__kernel void Wavelet_GPU(__global double *data, int datacount,
   int x_size, int y_size, __global double *result)
{
   size_t i = get_global_id(0);
   size_t j = get_global_id(1);
   double a1 = (double)10e-10;
   double a2 = (double)15.0;
   double da = (a2 - a1) / (double)y_size;
   double db = ((double)datacount - (double)0.0) / x_size;
   double a = a1 + j * da;
   double b = 0 + i * db;
   double B = (double)1.0;
   double B_inv = (double)1.0 / B;
   double a_inv = (double)1.0 / a;
   double dt = (double)1.0;
   double coef = (double)0.0;

   for(int k = 0; k < datacount; k++)
   {
      double arg = (dt * k - b) * a_inv;
      arg = -B_inv * arg * arg;
      coef = coef + exp(arg);
   }

   double sum = (float)0.0;
   for(int k = 0; k < datacount; k++)
   {
      double arg = (dt * k - b) * a_inv;
      sum += data[k] * Morlet(arg);
   }
   sum = sum / coef;
   uint pos = (int)(j * x_size + i);
   result[pos] = sum;
}
```

Full information about the OpenCL syntax, built-in functions and principles of operation can be found on the official website of Khronos Group.

In particular, it is interesting to note that OpenCL supports not only the usual scalar numeric data types (starting from *char* and ending with *double*) but also vector *(u)charN*, *(u)shortN*, *(u)intN*, *(u)longN*,

floatN, doubleN, where N = {2|3|4|8|16} and denotes the length of the vector. In this example, this is not used.

In addition to the mentioned keyword *kernel*, an important role in the organization of parallel computing is played by the *get_global_id* function: it allows you to find in the code the number of the computational subtask that is currently running. Obviously, the calculations in different subtasks should be different (otherwise it would not make sense to use many cores). In this example, since the task involves the analysis of a two-dimensional image, it is more convenient to identify its fragments using two orthogonal coordinates. In the above code, we get them using two calls, *get_global_id(0)* and *get_global_id(1)*.

Actually, we set the data dimension for the task ourselves when calling the MQL5 function *CLExecute* (see further).

In the file *Wavelet.mq5*, the OpenCL source code is included using the directive:

```
#resource "Kernels/wavelet.cl" as string cl_program
```

The image size is set by macros:

```
#define SIZE_X 600
#define SIZE_Y 200
```

To manage OpenCL, the standard library with the class *COpenCL* is used. Its methods have similar names and internally use the corresponding built-in OpenCL functions from the MQL5 API. It is suggested that you familiarize yourself with it.

```
#include <OpenCL/OpenCL.mqh>
```

In a simplified form (without error checking and visualization), the MQL code that launches the transformation is shown below. Wavelet transform-related actions are summarized in the *CWavelet* class.

```
class CWavelet
{
protected:
   ...
   int        m_xsize;              // image dimensions along the axes
   int        m_ysize;
   double     m_wavelet_data_GPU[]; // result goes here
   COpenCL    m_OpenCL;             // wrapper object
   ...
};
```

The main parallel computing is organized by its method *CalculateWavelet_GPU*.

```
bool CWavelet::CalculateWavelet_GPU(double &data[], uint &time)
{
   int datacount = ArraySize(data); // image size (number of dots)

   // compile the cl-program according to its source code
   m_OpenCL.Initialize(cl_program, true);

   // register a single kernel function from the cl file
   m_OpenCL.SetKernelsCount(1);
   m_OpenCL.KernelCreate(0, "Wavelet_GPU");

   // register 2 buffers for input and output data, write the input array
   m_OpenCL.SetBuffersCount(2);
   m_OpenCL.BufferFromArray(0, data, 0, datacount, CL_MEM_READ_ONLY);
   m_OpenCL.BufferCreate(1, m_xsize * m_ysize * sizeof(double), CL_MEM_READ_WRITE);
   m_OpenCL.SetArgumentBuffer(0, 0, 0);
   m_OpenCL.SetArgumentBuffer(0, 4, 1);

   ArrayResize(m_wavelet_data_GPU, m_xsize * m_ysize);
   uint work[2];              // task of analyzing a two-dimensional image - hence th
   uint offset[2] = {0, 0};   // start from the very beginning (or you can skip somet
   work[0] = m_xsize;
   work[1] = m_ysize;

   // set input data
   m_OpenCL.SetArgument(0, 1, datacount);
   m_OpenCL.SetArgument(0, 2, m_xsize);
   m_OpenCL.SetArgument(0, 3, m_ysize);

   time = GetTickCount();     // cutoff time for speed measurement
   // start computing on the GPU, two-dimensional task
   m_OpenCL.Execute(0, 2, offset, work);

   // get results into output buffer
   m_OpenCL.BufferRead(1, m_wavelet_data_GPU, 0, 0, m_xsize * m_ysize);

   time = GetTickCount() - time;

   m_OpenCL.Shutdown(); // free all resources - call all necessary functions CL***Fre
   return true;
}
```

In the source code of the example, there is a commented out line calling *PreparePriceData* to prepare an input array based on real prices: you can activate it instead of the previous line with the *PrepareModelData* call (which generates an artificial number).

```
void OnStart()
{
   int momentum_period = 8;
   double price_data[];
   double momentum_data[];
   PrepareModelData(price_data, SIZE_X + momentum_period);

   // PreparePriceData("EURUSD", PERIOD_M1, price_data, SIZE_X + momentum_period);

   PrepareMomentumData(price_data, momentum_data, momentum_period);
   ... // visualization of the series and increments
   CWavelet wavelet;
   uint time_gpu = 0;
   wavelet.CalculateWavelet_GPU(momentum_data, time_gpu);
   ... // visualization of the result of the wavelet transform
}
```

A special set of error codes (with the ERR_OPENCL_ prefix, starting with code 5100, ERR_OPENCL_NOT_SUPPORTED) has been allocated for operations with OpenCL. The codes are described in the help. If there are problems with the execution of OpenCL programs, the terminal outputs detailed diagnostics to the log, indicating error codes.

Conclusion

This section concludes the book. Throughout severn parts and numerous chapters, we have explored various aspects of MQL5 programming, starting from the language basics and advancing to related sophisticated technologies that enable a gradual transition from creating individual trader-specific tools to complex trading systems and products.

The knowledge you gain will assist you in bringing various ideas to life and achieving success in the world of professional algorithmic trading.

- Develop applications and sell them through the Market, the largest store of programs for MetaTrader with a ready infrastructure for authors. The Market provides access to a huge audience, offering product protection and licensing along with an integrated system for accepting payments.
- Develop custom applications via Freelance. Access the entire array of development orders and benefit from a convenient working system and payment protection.
- Share your experience by publishing your code in the Code Base. Present your programs to thousands of traders from the MQL5.community.

And, of course, keep learning. The www.mql5.com website features a wealth of information and ready-made algorithms:

- Programming articles, in which professional authors address practical problems.
- Forum where you can exchange experiences and seek advice from other developers.
- Code Base with program source codes to aid in learning the capabilities of the MQL5 languages and creating your own programs.

Finally, I would like to remind you that software development involves not only programming but also many other equally important areas: writing technical specifications (even if only for yourself), designing, prototyping, creating user interface design, providing documentation, and further support. All these aspects significantly influence the efficiency of your work as a programmer and the quality of the final result.

In particular, most practical tasks can be broken down into standard algorithms and principles that different language programmers have been using for a long time. This includes design patterns, collections of data structures optimized for specific tasks, and tools for automating development. All of this should be applied in the MetaTrader 5 platform with the help of MQL5 and in addition to it. While the book is just the first step on the path to professional growth.
