```

© 2000-2025, MetaQuotes Ltd.

CorrCoef

Compute the Pearson correlation coefficient (linear correlation coefficient).

```
matrix matrix::CorrCoef(
  const bool    rowvar=true  // rows or cols vectors of observations
);

scalar vector::CorrCoef(
  const vector&  b           // second vector
);
```

Return Value

Pearson product-moment correlation coefficients.

Note

The correlation coefficient is in the range [-1, 1].

Due to floating point rounding the resulting array may not be Hermitian, the diagonal elements may not be 1, and the elements may not satisfy the inequality abs(a) <= 1. The real and imaginary parts are clipped to the interval [-1, 1] in an attempt to improve on that situation but is not much help in the complex case.

A simple algorithm for calculating the correlation coefficient of two vectors using MQL5:

```
double VectorCorrelation(const vector& vector_x,const vector& vector_y)
  {
   ulong n=vector_x.Size()<vector_y.Size() ? vector_x.Size() : vector_y.Size();
   if(n<=1)
      return(0);

   ulong  i;
   double xmean=0;
   double ymean=0;
   for(i=0; i<n; i++)
     {
      if(!MathIsValidNumber(vector_x[i]))
         return(0);
      if(!MathIsValidNumber(vector_y[i]))
         return(0);
      xmean+=vector_x[i];
      ymean+=vector_y[i];
     }
   xmean/=(double)n;
   ymean/=(double)n;
```

© 2000-2025, MetaQuotes Ltd.

```
   double s=0;
   double xv=0;
   double yv=0;
   double t1=0;
   double t2=0;
//--- calculation
   s=0;
   for(i=0; i<n; i++)
     {
      t1=vector_x[i]-xmean;
      t2=vector_y[i]-ymean;
      xv+=t1*t1;
      yv+=t2*t2;
      s+=t1*t2;
     }
//--- check
   if(xv==0 || yv==0)
      return(0);
//--- return result
   return(s/(MathSqrt(xv)*MathSqrt(yv)));
  }
```

MQL5 example:

```
   vectorf vector_a={1,2,3,4,5};
   vectorf vector_b={0,1,0.5,2,2.5};
   Print("vectors correlation ",vector_a.CorrCoef(vector_b));
//---
   matrixf matrix_a={{1,2,3,4,5},
                     {0,1,0.5,2,2.5}};
   Print("matrix rows correlation\n",matrix_a.CorrCoef());
   matrixf matrix_a2=matrix_a.Transpose();
   Print("transposed matrix cols correlation\n",matrix_a2.CorrCoef(false));
   matrixf matrix_a3={{1.0f, 2.0f, 3.0f, 4.0f, 5.0f},
                      {0.0f, 1.0f, 0.5f, 2.0f, 2.5f},
                      {0.1f, 1.0f, 2.0f, 1.0f, 0.3f}};
   Print("rows correlation\n",matrix_a3.CorrCoef());
   Print("cols correlation\n",matrix_a3.CorrCoef(false));

Cov

Compute the covariance matrix.

```
matrix matrix::Cov(
  const bool     rowvar=true  // rows or cols vectors of observations
);

matrix matrix::Cov(
  const bool     rowvar,      // rows or cols vectors of observations
  const int      ddof         // delta degrees of freedom
);

matrix vector::Cov(
  const vector& b             // second vector
);

matrix vector::Cov(
  const vector& b,            // second vector
  const int      ddof         // delta degrees of freedom
);
```

Parameters

rowwar

[in] If rowvar is true (default), then each row represents a variable, with observations in the columns. Otherwise, the relationship is transposed: each column represents a variable, while the rows contain observations.

b

[in] Second vector of observations.

ddof

[in] "Delta Degrees of Freedom": the divisor used in the calculation is N - ddof, where N represents the number of elements. By default ddof is 1.

Note

Compute the covariance matrix.

A simple algorithm for calculating the covariance matrix of two vectors using MQL5:

```
bool VectorCovariation(const vector& vector_a,const vector& vector_b,matrix& matrix_c)
  {
   int i,j;
   int m=2;
   int n=(int)(vector_a.Size()<vector_b.Size()?vector_a.Size():vector_b.Size());
//--- checks
   if(n<=1)
      return(false);
```

© 2000-2025, MetaQuotes Ltd.

```
   for(i=0; i<n; i++)
     {
      if(!MathIsValidNumber(vector_a[i]))
         return(false);
      if(!MathIsValidNumber(vector_b[i]))
         return(false);
     }
//---
   matrix matrix_x(2,n);
   matrix_x.Row(vector_a,0);
   matrix_x.Row(vector_b,1);
   vector t=vector::Zeros(m);
//--- calculation
   for(i=0; i<m; i++)
      for(j=0; j<n; j++)
         t[i]+=matrix_x[i][j]/double(n);
   for(i=0; i<m; i++)
      for(j=0; j<n; j++)
         matrix_x[i][j]-=t[i];
//--- syrk C=alpha*A^H*A+beta*C (beta=0 and not considered)
   matrix_c=matrix::Zeros(m,m);
   for(i=0; i<m; i++)
     {
      for(j=0; j<n; j++)
        {
         double v=matrix_x[i][j]/(n-1);
         for(int i_=i; i_<m; i_++)
            matrix_c[i][i_]+=v*matrix_x[i_][j];
        }
     }
//--- force symmetricity
   for(i=0; i<m-1; i++)
      for(j=i+1; j<m; j++)
         matrix_c[j][i]=matrix_c[i][j];
//---
   return(true);
  }
```

MQL5 example:

```
   matrix matrix_a={{3,-2.1},{1.1,-1},{0.12,4.3}};
   Print("covariation cols\n",matrix_a.Cov(false));
   Print("covariation rows\n",matrix_a.Cov());

   vector vector_a=matrix_a.Col(0);
   vector vector_b=matrix_a.Col(1);
   Print("covariation vectors\n",vector_a.Cov(vector_b));
```

 [-10.659   -4.389    8.7362]]
covariation vectors
 [[ 2.14413333 -4.286     ]
 [-4.286      11.71      ]]
```

© 2000-2025, MetaQuotes Ltd.

Correlate

Compute the cross-correlation of two vectors.

```
vector vector::Correlate(
  const vector&           v,        // vector
  ENUM_VECTOR_CONVOLVE    mode      // mode
   );
```

Parameters

v

[in] Second vector.

mode

[in] The 'mode' parameter determines the linear convolution calculation mode. Value from the ENUM_VECTOR_CONVOLVE enumeration.

Return Value

Cross-correlation of two vectors.

Note

The 'mode' parameter determines the linear convolution calculation mode.

A simple algorithm for calculating the correlation coefficient of two vectors using MQL5:

```
vector VectorCrossCorrelationFull(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=m+n-1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
      for(int i_=i; i_<i+m; i_++)
         c[i_]+=b[n-i-1]*a[i_-i];

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorCrossCorrelationSame(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n);
   vector c=vector::Zeros(size);
```

© 2000-2025, MetaQuotes Ltd.

```
   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-size/2+1;
         if(k>=0 && k<size)
            c[k]+=b[n-i-1]*a[i_-i];
        }
     }

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorCrossCorrelationValid(const vector& a,const vector& b)
  {
   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n)-MathMin(m,n)+1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-n+1;
         if(k>=0 && k<size)
            c[k]+=b[n-i-1]*a[i_-i];
        }
     }

   return(c);
  }
```

MQL5 example:

```
   vector a={1,2,3,4,5};
   vector b={0,1,0.5};

   Print("full\n",a.Correlate(b,VECTOR_CONVOLVE_FULL));
   Print("same\n",a.Correlate(b,VECTOR_CONVOLVE_SAME));
   Print("valid\n",a.Correlate(b,VECTOR_CONVOLVE_VALID));
   Print("full\n",b.Correlate(a,VECTOR_CONVOLVE_FULL));

Convolve

Return the discrete, linear convolution of two vectors

```
vector vector::Convolve(
  const vector&            v,         // vector
  ENUM_VECTOR_CONVOLVE     mode       // mode
   );
```

Parameters

v

[out] Second vector.

mode

[in] The 'mode' parameter determines the linear convolution calculation mode ENUM_VECTOR_CONVOLVE.

Return Value

Discrete, linear convolution of two vectors.

A simple algorithm for calculating the convolution of two vectors in MQL5:

```
vector VectorConvolutionFull(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionFull(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=m+n-1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
      for(int i_=i; i_<i+m; i_++)
         c[i_]+=b[i]*a[i_-i];

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorConvolutionSame(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionSame(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
```

© 2000-2025, MetaQuotes Ltd.

```
   int    size=MathMax(m,n);
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-size/2+1;
         if(k>=0 && k<size)
            c[k]+=b[i]*a[i_-i];
        }
     }

   return(c);
  }
//+------------------------------------------------------------------+
//|                                                                  |
//+------------------------------------------------------------------+
vector VectorConvolutionValid(const vector& a,const vector& b)
  {
   if(a.Size()<b.Size())
      return(VectorConvolutionValid(b,a));

   int    m=(int)a.Size();
   int    n=(int)b.Size();
   int    size=MathMax(m,n)-MathMin(m,n)+1;
   vector c=vector::Zeros(size);

   for(int i=0; i<n; i++)
     {
      for(int i_=i; i_<i+m; i_++)
        {
         int k=i_-n+1;
         if(k>=0 && k<size)
            c[k]+=b[i]*a[i_-i];
        }
     }

   return(c);
  }
```

MQL5 example:

```
  vector a= {1, 2, 3, 4, 5};
  vector b= {0, 1, 0.5};

  Print("full\n", a.Convolve(b, VECTOR_CONVOLVE_FULL));

Matrix transformations

Matrix decomposition can be used in the following cases:

- as an intermediate step when solving systems of linear equations
- for matrix inversion
- when calculating determinants
- when finding eigenvalues and eigenvectors of a matrix
- when computing analytic functions of matrices
- when using the least squares method
- in the numerical solution of differential equations

Different matrix decomposition types are used depending on the problem.

Function	Action
Cholesky	Computes the Cholesky decomposition
Eig	Computes the eigenvalues and right eigenvectors of a square matrix
EigVals	Computes the eigenvalues of a general matrix
LU	LU factorization of a matrix as the product of a lower triangular matrix and an upper triangular matrix
LUP	LUP factorization with partial pivoting, which refers to LU decomposition with row permutations only: PA=LU
QR	Compute the qr factorization of a matrix
SVD	Singular Value Decomposition

© 2000-2025, MetaQuotes Ltd.

Cholesky

Compute the Cholesky decomposition.

```
bool matrix::Cholesky(
  matrix&  L      // matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

Return Value

Returns true on success, false otherwise.

Note

Return the Cholesky decomposition, L * L.H, of the square matrix a, where L is lower-triangular and .H is the conjugate transpose operator (which is the ordinary transpose if a is real-valued). a must be Hermitian (symmetric if real-valued) and positive-definite. No checking is performed to verify whether a is Hermitian or not. In addition, only the lower-triangular and diagonal elements of a are used. Only L is actually returned.

Example

```
matrix matrix_a= {{5.7998084, -2.1825367}, {-2.1825367, 9.85910595}};
matrix matrix_l;
Print("matrix_a\n", matrix_a);

matrix_a.Cholesky(matrix_l);
Print("matrix_l\n", matrix_l);
Print("check\n", matrix_l.MatMul(matrix_l.Transpose()));

/*
matrix_a

Eig

Compute the eigenvalues and right eigenvectors of a square matrix.

```
bool matrix::Eig(
  matrix&  eigen_vectors,         // matrix of eigenvectors
  vector&  eigen_values           // vector of eigenvalues
   );
```

Complex solution of eigenvalues and eigenvectors

```
bool matrix::Eig(
  matrix<complex>& eigen_vectors, // matrix of eigenvectors
  vector<complex>& eigen_values   // vector of eigenvalues
   );
```

Parameters

eigen_vectors

[out] Matrix of vertical eigenvectors.

eigen_values

[out] Vector of eigenvalues.

Return Value

Returns true on success, false otherwise.

Note

If a complex solution is encountered when calculating eigenvalues, the calculation is stopped and the error code is set to 4019 (ERR_MATH_OVERFLOW). Use the complex overload of the Eig method to obtain a complete solution in complex space

If a complex eigenvalue has an imaginary part equal to zero, then it is a real eigenvalue. This can be seen in the example below.

Example

```
void OnStart()
  {
   matrix matrix_a =
     {
        {-3.474589, 1.106384, -9.091977,-3.925227 },
        {-5.522139, 2.366887,-15.162351,-6.357512 },
        { 8.394926,-2.960067, 22.292115, 9.524129 },
        { 7.803242,-2.080287, 19.217706, 8.186645 }
     };

   matrix eigen_vectors;
   vector eigen_values;

   bool res=matrix_a.Eig(eigen_vectors, eigen_values);
```

© 2000-2025, MetaQuotes Ltd.

```
   Print("res=",res,"  error=",GetLastError());
   Print("Eigen vectors:\n",eigen_vectors, "\nEigen Values:\n",eigen_values);

//--- check correctness A * v = lambda * v
   int vectors=0;
   for(ulong n=0; n<eigen_values.Size(); n++)
     {
      vector eigen_vector=eigen_vectors.Col(n);
      vector vector_d1   =eigen_vector*eigen_values[n];
      vector vector_d2   =matrix_a.MatMul(eigen_vector);

      ulong errors=vector_d1.Compare(vector_d2,1e-13);
      if(errors==0)
         vectors++;
     }
   Print("vectors=",vectors);

//--- complex solution

EigVals

Compute the eigenvalues of a general matrix.

```
bool matrix::EigVals(
  vector&  eigen_values      // vector of eigenvalues
   );
```

Parameters

eigen_values

[out] Vector of right eigenvalues.

Return Value

Returns true on success, false otherwise.

Note

The only difference between EigVals and Eig is that EigVals does not calculate eigenvectors, while it only calculates eigenvalues.

© 2000-2025, MetaQuotes Ltd.

LU

LU factorization of a matrix as the product of a lower triangular matrix and an upper triangular matrix.

```
bool matrix::LU(
  matrix&  L,      // lower triangular matrix
  matrix&  U       // upper triangular matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

U

[out] Upper triangular matrix.

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,2,6,7},
                    {8,9,3,10},
                    {11,12,14,4}};
   matrix matrix_l,matrix_u;
//--- LU decomposition
   matrix_a.LU(matrix_l,matrix_u);
   Print("matrix_l\n",matrix_l);
   Print("matrix_u\n",matrix_u);
//--- check if A = L * U
   Print("check\n",matrix_l.MatMul(matrix_u));

LUP

LUP factorization with partial pivoting, which refers to LU decomposition with row permutations only: PA=LU.

```
bool  LUP(
  matrix&  L,      // lower triangular matrix
  matrix&  U,      // upper triangular matrix
  matrix&  P       // permutations matrix
   );
```

Parameters

L key

[out] Lower triangular matrix.

U

[out] Upper triangular matrix.

P

[out] Permutations matrix

Return Value

Returns true on success, false otherwise.

Example

```
   matrix matrix_a={{1,2,3,4},
                    {5,2,6,7},
                    {8,9,3,10},
                    {11,12,14,4}};
   matrix matrix_l,matrix_u,matrix_p;
//--- LUP decomposition
   matrix_a.LUP(matrix_l,matrix_u,matrix_p);
   Print("matrix_l\n",matrix_l);
   Print("matrix_u\n",matrix_u);
   Print("matrix_p\n",matrix_p);
//--- check if P * A = L * U
   Print("P * A\n",matrix_p.MatMul(matrix_a));

QR

Compute the qr factorization of a matrix.

```
bool  QR(
  matrix&  Q,      // matrix with orthonormal columns
  matrix&  R       // upper-triangular matrix
   );
```

Parameters

Q

[out] A matrix with orthonormal columns. When mode = 'complete' the result is an orthogonal/unitary matrix depending on whether or not a is real/complex. The determinant may be either +/- 1 in that case. In case the number of dimensions in the input array is greater than 2 then a stack of the matrices with above properties is returned.

R key

[out] Upper triangular matrix.

Return Value

Returns true on success, false otherwise.

Example

```
//---  A*x = b
  matrix A = {{0, 1}, {1, 1}, {1, 1}, {2, 1}};
  Print("A \n", A);
  vector b = {1, 2, 2, 3};
  Print("b \n", b);
//--- A = Q*R
  matrix q, r;
  A.QR(q, r);
  Print("q \n", q);
  Print("r \n", r);
  matrix qr=q.MatMul(r);
  Print("qr \n", qr);

SVD

Singular Value Decomposition.

```
bool matrix::SVD(
  matrix&  U,                    // unitary matrix
  matrix&  V,                    // unitary matrix
  vector&  singular_values       // singular values vector
   );
```

Parameters

U

[out] Unitary matrix of order m, consisting of left singular vectors.

V

[out] Unitary matrix of order n, consisting of right singular vectors.

singular_values

[out] Singular values

Return Value

Returns true on success, false otherwise.

Example

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a=a-4;
  Print("matrix a \n", a);
  a.Reshape(3, 3);
  matrix b=a;
  Print("matrix b \n", b);
//--- execute SVD decomposition

Statistical methods

Methods for computing descriptive statistics of matrices and vectors.

Function	Action
ArgMax	Return the index of the maximum value
ArgMin	Return the index of the minimum value
Max	Return the maximum value in a matrix/vector
Min	Return the minimum value in a matrix/vector
Ptp	Return the range of values of a matrix/vector or of the given matrix axis
Sum	Return the sum of the matrix/vector elements which can also be performed for the given axis (axes)
Prod	Return the product of the matrix/vector elements which can also be performed for the given axis
CumSum	Return the cumulative sum of matrix/vector elements, including those along the given axis
CumProd	Return the cumulative product of matrix/vector elements, including those along the given axis
Percentile	Return the specified percentile of values of matrix/vector elements or elements along the specified axis
Quantile	Return the specified quantile of values of matrix/vector elements or elements along the specified axis
Median	Compute the median of the matrix/vector elements
Mean	Compute the arithmetic mean of element values
Average	Compute the weighted mean of matrix/vector values
Std	Return the standard deviation of values of matrix/vector elements or of elements along the given axis
Var	Compute the variance of values of matrix/vector elements
LinearRegression	Calculate a vector/matrix with calculated linear regression values

© 2000-2025, MetaQuotes Ltd.

ArgMax

Return the index of the maximum value.

```
ulong vector::ArgMax();

ulong matrix::ArgMax();

vector matrix::ArgMax(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Index of the maximum value.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_max=matrix_a.ArgMax(0);
   vector rows_max=matrix_a.ArgMax(1);
   ulong  matrix_max=matrix_a.ArgMax();

   Print("cols_max=",cols_max);
   Print("rows_max=",rows_max);
   Print("max index ",matrix_max,"  max value ",matrix_a.Flat(matrix_max));

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_max=[0,3,1]
   rows_max=[0,2,0,1]
   max index 5  max value 12.0
   */
```

© 2000-2025, MetaQuotes Ltd.

ArgMin

Return the index of the minimum value.

```
ulong vector::ArgMin();

ulong matrix::ArgMin();

vector matrix::ArgMin(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Index of the minimum value.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_min=matrix_a.ArgMin(0);
   vector rows_min=matrix_a.ArgMin(1);
   ulong  matrix_min=matrix_a.ArgMin();

   Print("cols_min=",cols_min);
   Print("rows_min=",rows_min);
   Print("min index ",matrix_min,"  min value ",matrix_a.Flat(matrix_min));

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_min=[1,0,0]
   rows_min=[2,0,2,0]
   min index 3  min value 1.0
   */
```

© 2000-2025, MetaQuotes Ltd.

Max

Return the maximum value in a matrix/vector.

```
double vector::Max();

double matrix::Max();

vector matrix::Max(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Maximum value in a matrix/vector.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_max=matrix_a.Max(0);
   vector rows_max=matrix_a.Max(1);
   double matrix_max=matrix_a.Max();

   Print("cols_max=",cols_max);
   Print("rows_max=",rows_max);
   Print("max value ",matrix_max);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_max=[10,11,12]
   rows_max=[10,12,6,11]
   max value 12.0
   */
```

© 2000-2025, MetaQuotes Ltd.

Min

Return the minimum value in a matrix/vector.

```
double vector::Min();

double matrix::Min();

vector matrix::Min(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Minimum value in a matrix/vector.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_min=matrix_a.Min(0);
   vector rows_min=matrix_a.Min(1);
   double matrix_min=matrix_a.Min();

   Print("cols_min=",cols_min);
   Print("rows_min=",rows_min);
   Print("min value ",matrix_min);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_min=[1,3,2]
   rows_min=[2,1,4,7]
   min value 1.0
   */
```

© 2000-2025, MetaQuotes Ltd.

Ptp

Return the range of values of a matrix/vector or of the given matrix axis, equivalent to Max() - Min(). Ptp - Peak to peak.

```
double vector::Ptp();

double matrix::Ptp();

vector matrix::Ptp(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Vector with ranges of values (maximum - minimum) .

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_ptp=matrix_a.Ptp(0);
   vector rows_ptp=matrix_a.Ptp(1);
   double matrix_ptp=matrix_a.Ptp();

   Print("cols_ptp  ",cols_ptp);
   Print("rows_ptp  ",rows_ptp);
   Print("ptp value  ",matrix_ptp);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_ptp [9,8,10]
   rows_ptp [8,11,2,4]
   ptp value  11.0
   */
```

© 2000-2025, MetaQuotes Ltd.

Sum

Return the sum of the matrix/vector elements which can also be performed for the given axis (axes).

```
double vector::Sum();

double matrix::Sum();

vector matrix::Sum(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Sum of the matrix/vector elements which can also be performed for the given axis (axes).

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_sum=matrix_a.Sum(0);
   vector rows_sum=matrix_a.Sum(1);
   double matrix_sum=matrix_a.Sum();

   Print("cols_sum=",cols_sum);
   Print("rows_sum=",rows_sum);
   Print("sum value ",matrix_sum);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_sum=[24,27,27]
   rows_sum=[15,21,15,27]
   sum value 78.0
   */
```

© 2000-2025, MetaQuotes Ltd.

Prod

Return the product of the matrix/vector elements which can also be performed for the given axis.

```
double vector::Prod(
  const double  initial=1      // initial multiplier
   );

double matrix::Prod(
  const double  initial=1      // initial multiplier
   );

vector matrix::Prod(
  const int     axis,          // axis
  const double  initial=1      // initial multiplier
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

initial=1

[in] Initial multiplier.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vector cols_prod=matrix_a.Prod(0);
   vector rows_prod=matrix_a.Prod(1);
   double matrix_prod=matrix_a.Prod();

   Print("cols_prod=",cols_prod);
   cols_prod=matrix_a.Prod(0,0.1);
   Print("cols_prod=",cols_prod);
   Print("rows_prod=",rows_prod);
   Print("prod value ",matrix_prod);

  /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_prod=[420,1320,864]
   cols_prod=[42,132,86.40000000000001]
   rows_prod=[60,96,120,693]
```

© 2000-2025, MetaQuotes Ltd.

```
   prod value 479001600.0
*/
```

© 2000-2025, MetaQuotes Ltd.

CumSum

Return the cumulative sum of matrix/vector elements, including those along the given axis.

```
vector vector::CumSum();

vector matrix::CumSum();

matrix matrix::CumSum(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Cumulative sum of the elements along the given axis.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   matrix cols_cumsum=matrix_a.CumSum(0);
   matrix rows_cumsum=matrix_a.CumSum(1);
   vector cumsum_values=matrix_a.CumSum();

   Print("cols_cumsum\n",cols_cumsum);
   Print("rows_cumsum\n",rows_cumsum);
   Print("cumsum values  ",cumsum_values);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_cumsum
   [[10,3,2]
    [11,11,14]
    [17,16,18]
    [24,27,27]]
   rows_cumsum
   [[10,13,15]
    [1,9,21]
    [6,11,15]
```

© 2000-2025, MetaQuotes Ltd.

```
    [7,18,27]]
   cumsum values  [10,13,15,16,24,36,42,47,51,58,69,78]
   */
```

© 2000-2025, MetaQuotes Ltd.

CumProd

Return the cumulative product of matrix/vector elements, including those along the given axis.

```
vector vector::CumProd();

vector matrix::CumProd();

matrix matrix::CumProd(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis for each column (i.e., over the rows), 1 — vertical axis for each row (i.e. over the columns)

Return Value

Cumulative product of the elements along the given axis.

Example

```
   matrix matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   matrix cols_cumprod=matrix_a.CumProd(0);
   matrix rows_cumprod=matrix_a.CumProd(1);
   vector cumprod_values=matrix_a.CumProd();

   Print("cols_cumprod\n",cols_cumprod);
   Print("rows_cumprod\n",rows_cumprod);
   Print("cumprod values  ",cumprod_values);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_cumprod
   [[10,3,2]
    [10,24,24]
    [60,120,96]
    [420,1320,864]]
   rows_cumprod
   [[10,30,60]
    [1,8,96]
```

© 2000-2025, MetaQuotes Ltd.

```
   [6,30,120]
   [7,77,693]]
  cumprod values  [10,30,60,60,480,5760,34560,172800,691200,4838400,53222400,47900160
  */
```

© 2000-2025, MetaQuotes Ltd.

Percentile

Return the specified percentile of values of matrix/vector elements or elements along the specified axis.

```
double vector::Percentile(
  const int  percent      //
   );

double matrix::Percentile(
  const int  percent      //
   );

vector matrix::Percentile(
  const int  percent,     //
  const int  axis         // axis
   );
```

Parameters

percent

[in] Percentiles to compute, which must be between 0 and 100 inclusive.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Percentile: scalar or vector.

Note

Valid values of the 'percent' parameter are in the range [0, 100]. A linear algorithm is used to calculate percentiles. The correct calculation of percentiles requires the sequence to be sorted.

Example

```
   matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_percentile=matrix_a.Percentile(50,0);
   vectorf rows_percentile=matrix_a.Percentile(50,1);
   float matrix_percentile=matrix_a.Percentile(50);

   Print("cols_percentile ",cols_percentile);
   Print("rows_percentile ",rows_percentile);
   Print("percentile value  ",matrix_percentile);

   /*
```

© 2000-2025, MetaQuotes Ltd.

```
   matrix_a
   [[1,2,3]
    [4,5,6]
    [7,8,9]
    [10,11,12]]
   cols_percentile [5.5,6.5,7.5]
   rows_percentile [2,5,8,11]
   percentile value  6.5
   */
```

© 2000-2025, MetaQuotes Ltd.

Quantile

Return the specified quantile of values of matrix/vector elements or elements along the specified axis.

```
double vector::Quantile(
  const double quantile      // quantile
   );

double matrix::Quantile(
  const double quantile      // quantile
   );

vector matrix::Quantile(
  const double quantile,     // quantile
  const int    axis          // axis
   );
```

Parameters

quantile

[in] Quantile to compute, which must be between 0 and 1 inclusive.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Quantile: scalar or vector.

Note

The 'quantile' parameter takes values in the range [0, 1]. A linear algorithm is used to calculate quantiles. The correct calculation of quantiles requires the sequence to be sorted.

Example

```
   matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_quantile=matrix_a.Quantile(0.5,0);
   vectorf rows_quantile=matrix_a.Quantile(0.5,1);
   float matrix_quantile=matrix_a.Quantile(0.5);

   Print("cols_quantile ",cols_quantile);
   Print("rows_quantile ",rows_quantile);
   Print("quantile value  ",matrix_quantile);

   /*
   matrix_a
```

© 2000-2025, MetaQuotes Ltd.

```
   [[1,2,3]
    [4,5,6]
    [7,8,9]
    [10,11,12]]
   cols_quantile [5.5,6.5,7.5]
   rows_quantile [2,5,8,11]
   quantile value  6.5
   */
```

© 2000-2025, MetaQuotes Ltd.

Median

Compute the median of the matrix/vector elements.

```
double vector::Median();

double matrix::Median();

vector matrix::Median(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Median: scalar or vector.

Note

The median is the middle value that separates the highest half of the array/vector elements from the lowest half of elements. Same as Quantile(0.5) and Percentile(50). The correct calculation of median requires the sequence to be sorted.

Example

```
matrixf matrix_a={{1,2,3},{4,5,6},{7,8,9},{10,11,12}};
Print("matrix_a\n",matrix_a);

vectorf cols_median=matrix_a.Median(0);
vectorf rows_median=matrix_a.Median(1);
float matrix_median=matrix_a.Median();

Print("cols_median ",cols_median);
Print("rows_median ",rows_median);
Print("median value  ",matrix_median);

/*
matrix_a
[[1,2,3]
 [4,5,6]
 [7,8,9]
 [10,11,12]]
cols_median [5.5,6.5,7.5]
```

© 2000-2025, MetaQuotes Ltd.

```
   rows_median [2,5,8,11]
   median value  6.5
   */
```

© 2000-2025, MetaQuotes Ltd.

Mean

Compute the arithmetic mean of element values.

```
double vector::Mean();

double matrix::Mean();

vector matrix::Mean(
  const int  axis      // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Arithmetic mean of element values.

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   Print("matrix_a\n",matrix_a);

   vectorf cols_mean=matrix_a.Mean(0);
   vectorf rows_mean=matrix_a.Mean(1);
   float matrix_mean=matrix_a.Mean();

   Print("cols_mean ",cols_mean);
   Print("rows_mean ",rows_mean);
   Print("mean value  ",matrix_mean);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_mean [6,6.75,6.75]
   rows_mean [5,7,5,9]
   mean value  6.5
   */
```

© 2000-2025, MetaQuotes Ltd.

Average

Compute the weighted mean of matrix/vector values.

```
double vector::Average(
  const vector& weigts      // weights vector
   );

double matrix::Average(
  const matrix& weigts      // weights matrix
);

vector matrix::Average(
  const matrix& weigts,     // weights matrix
  const int     axis        // axis
   );
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

Weighted mean: scalar or vector.

Note

The weight matrix/vector is associated with the main matrix/vector.

Example

```
   matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
   matrixf matrix_w=matrixf::Ones(4,3);
   Print("matrix_a\n",matrix_a);

   vectorf cols_average=matrix_a.Average(matrix_w,0);
   vectorf rows_average=matrix_a.Average(matrix_w,1);
   float matrix_average=matrix_a.Average(matrix_w);

   Print("cols_average ",cols_average);
   Print("rows_average ",rows_average);
   Print("average value  ",matrix_average);

   /*
   matrix_a
   [[10,3,2]
```

© 2000-2025, MetaQuotes Ltd.

```
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_average [6,6.75,6.75]
   rows_average [5,7,5,9]
   average value  6.5
   */ value  6.5
```

© 2000-2025, MetaQuotes Ltd.

Std

Return the standard deviation of values of matrix/vector elements or of elements along the given axis.

```
double vector::Std();

double vector::Std(
  const int  ddof      // delta degrees of freedom
);

double matrix::Std();

vector matrix::Std(
  const int  axis      // axis
);

vector matrix::Std(
  const int  axis,     // axis
  const int  ddof      // delta degrees of freedom
);
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

ddof

[in] "Delta Degrees of Freedom": the divisor used in the calculation is N - ddof, where N represents the number of elements. By default ddof is zero.

Return Value

Standard_deviation: scalar or vector.

Note

The standard deviation is the square root of the average of the squared deviations from the mean, i. e., std = sqrt(mean(x)), where x = abs(a - a.mean())**2.

The average squared deviation is typically calculated as x.sum() / (N - ddof), where N = len(x).

Expression with ddof=0 sometimes called the "population standard deviation". If ddof>0 (most commonly used 1), the resulting quantity is sometimes called the "sample standard deviation".

Example

```
matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
Print("matrix_a\n",matrix_a);
```

© 2000-2025, MetaQuotes Ltd.

```
vectorf cols_std=matrix_a.Std(0);
vectorf rows_std=matrix_a.Std(1);
float matrix_std=matrix_a.Std();

Print("cols_std ",cols_std);
Print("rows_std ",rows_std);
Print("std value  ",matrix_std);

/*
matrix_a
[[10,3,2]
 [1,8,12]
 [6,5,4]
 [7,11,9]]
cols_std [3.2403703,3.0310888,3.9607449]
rows_std [3.5590262,4.5460606,0.81649661,1.6329932]
std value  3.452052593231201
*/
```

© 2000-2025, MetaQuotes Ltd.

Var

Compute the variance of values of matrix/vector elements.

```
double vector::Var();

double vector::Var(
  const int  ddof      // delta degrees of freedom
);

double matrix::Var();

vector matrix::Var(
  const int  axis      // axis
);

vector matrix::Var(
  const int  axis,     // axis
  const int  ddof      // delta degrees of freedom
);
```

Parameters

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

ddof

[in] "Delta Degrees of Freedom": the divisor used in the calculation is N - ddof, where N represents the number of elements. By default ddof is zero.

Return Value

Variance: scalar or vector.

Note

The variance is the average of the squared deviations from the mean, i.e., var = mean(x), where x = abs(a - a.mean())**2.

The mean is typically calculated as x.sum() / (N - ddof), where N = len(x).

Expression with ddof=0 sometimes called the "population variance". If ddof>0 (most commonly used 1), the resulting quantity is sometimes called the "sample variance".

Example

```
matrixf matrix_a={{10,3,2},{1,8,12},{6,5,4},{7,11,9}};
Print("matrix_a\n",matrix_a);

vectorf cols_var=matrix_a.Var(0);
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf rows_var=matrix_a.Var(1);
   float matrix_var=matrix_a.Var();

   Print("cols_var ",cols_var);
   Print("rows_var ",rows_var);
   Print("var value  ",matrix_var);

   /*
   matrix_a
   [[10,3,2]
    [1,8,12]
    [6,5,4]
    [7,11,9]]
   cols_var [10.5,9.1875,15.6875]
   rows_var [12.666667,20.666666,0.66666669,2.6666667]
   var value  11.916666984558105
   */
```

© 2000-2025, MetaQuotes Ltd.

LinearRegression

Calculate a vector/matrix with calculated linear regression values.

```
vector vector::LinearRegression();

matrix matrix::LinearRegression(
  ENUM_MATRIX_AXIS  axis=AXIS_NONE      // axis along which regression is calculated
   );
```

Parameters

axis

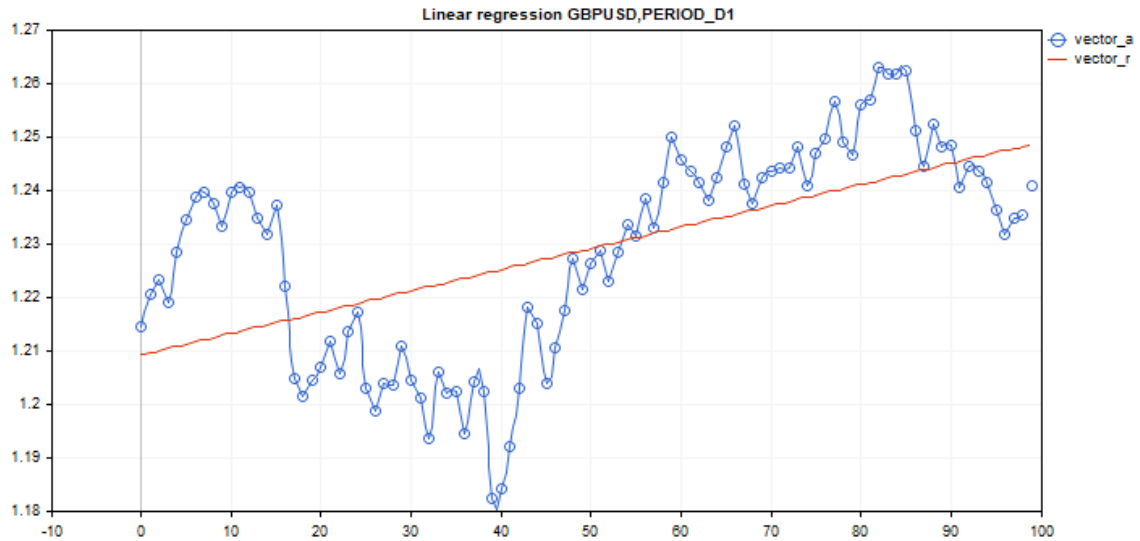
[in] Specifying the axis along which the regression is calculated. ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

Return Value

Vector or matrix with calculated linear regression values.

Note

Linear regression is calculated using the standard regression equation: y (x) = a * x + b, where a is the line slope, while b is its Y axis shift.



Example:

```
#include <Graphics\Graphic.mqh>

#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

//+------------------------------------------------------------------+
```

© 2000-2025, MetaQuotes Ltd.

```
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector vector_a;
   vector_a.CopyRates(_Symbol,_Period,COPY_RATES_CLOSE,1,100);
   vector vector_r=vector_a.LinearRegression();

//--- switch off chart show
   ChartSetInteger(0,CHART_SHOW,false);

//--- arrays for drawing a graph
   double x[];
   double y1[];
   double y2[];
   ArrayResize(x,uint(vector_a.Size()));
   ArrayResize(y1,uint(vector_a.Size()));
   ArrayResize(y2,uint(vector_a.Size()));
   for(ulong i=0; i<vector_a.Size(); i++)
     {
      x[i]=(double)i;
      y1[i]=vector_a[i];
      y2[i]=vector_r[i];
     }

//--- graph title
   string title="Linear regression "+_Symbol+","+EnumToString(_Period);

   long   chart=0;
   string name="LinearRegression";

//--- create graph
   CGraphic graphic;
   graphic.Create(chart,name,0,0,0,GRAPH_WIDTH,GRAPH_HEIGHT);
   graphic.BackgroundMain(title);
   graphic.BackgroundMainSize(12);

//--- activation function graph
   CCurve *curvef=graphic.CurveAdd(x,y1,CURVE_POINTS_AND_LINES);
   curvef.Name("vector_a");
   curvef.LinesWidth(2);

   graphic.Destroy();
   ObjectDelete(chart,name);
   ChartSetInteger(0,CHART_SHOW,true);
  }
```

ENUM_MATRIX_AXIS

Enumeration for specifying the axis in all statistical functions for matrices.

ID	Description
AXIS_NONE	The axis is not specified. Calculation is performed over all matrix elements, as if it were a vector (see the Flat method).
AXIS_HORZ	Horizontal axis
AXIS_VERT	Vertical axis

© 2000-2025, MetaQuotes Ltd.

Feature methods

These methods enable the receiving of matrix features, such as:

- number of rows
- number of columns
- norm
- condition number
- determinant
- matrix rank
- trace
- spectrum

Function	Action
Rows	Return the number of rows in a matrix
Cols	Return the number of columns in a matrix
Size	Return the size of vector
Norm	Return matrix or vector norm
Cond	Compute the condition number of a matrix
Det	Compute the determinant of a square invertible matrix
SLogDet	Compute the sign and logarithm of the determinant of an matrix
Rank	Return matrix rank using the Gaussian method
Trace	Return the sum along diagonals of the matrix
Spectrum	Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A

© 2000-2025, MetaQuotes Ltd.

Rows

Return the number of rows in a matrix.

```
ulong matrix::Rows()
```

Return Value

Integer.

Example

```
matrix m= {{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}};
m.Reshape(3, 4);
Print("matrix m \n" , m);
Print("m.Rows()=", m.Rows());
Print("m.Cols()=", m.Cols());

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 m.Rows()=3
 m.Cols()=4
*/
```

© 2000-2025, MetaQuotes Ltd.

Cols

Return the number of columns in a matrix.

```
ulong matrix::Cols()
```

Return Value

Integer.

Example

```
matrix m= {{1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}};
m.Reshape(3, 4);
Print("matrix m \n" , m);
Print("m.Cols()=", m.Cols());
Print("m.Rows()=", m.Rows());

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 m.Cols()=4
 m.Rows()=3
*/
```

© 2000-2025, MetaQuotes Ltd.

Size

Return the size of vector.

```
ulong vector::Size()
```

Return Value

Integer.

Example

```
matrix m={{1,2,3,4,5,6,7,8,9,10,11,12}};
m.Reshape(3,4);
Print("matrix m\n",m);
vector v=m.Row(1);
Print("v.Size()=",v.Size());
Print("v=",v);

/*
 matrix m
 [[1,2,3,4]
  [5,6,7,8]
  [9,10,11,12]]
 v.Size()=4
 v=[5,6,7,8]
*/
```

© 2000-2025, MetaQuotes Ltd.

Norm

Return matrix or vector norm.

```
double vector::Norm(
  const ENUM_VECTOR_NORM  norm,     // vector norm
  const int               norm_p=2  // number of p-norm in case of VECTOR_NORM_P
   );

double matrix::Norm(
  const ENUM_MATRIX_NORM  norm      // matrix norm
   );
```

Parameters

norm

[in] Norm order

Return Value

Matrix or vector norm.

Note

- VECTOR_NORM_INF is the maximum absolute value among vector elements.
- VECTOR_NORM_MINUS_INF is the minimum absolute value of a vector.
- VECTOR_NORM_P is the P-norm of the vector. If norm_p=0, then this is the number of non-zero vector elements. norm_p=1 is the sum of absolute values of vector elements. norm_p=2 is the square root of the sum of squares of vector element values. The value of the norm_p parameter can be negative.
- MATRIX_NORM_FROBENIUS is the square root of the sum of the squares of the matrix element values. The Frobenius norm and the vector P2-norm are consistent.
- MATRIX_NORM_SPECTRAL is the maximum value of the matrix spectrum.
- MATRIX_NORM_NUCLEAR is the sum of the singular values of the matrix.
- MATRIX_NORM_INF is the maximum vector p1-norm among the vertical vectors of the matrix. The matrix inf-norm and the vector inf-norm are consistent.
- MATRIX_NORM_MINUS_INF is the minimum vector p1-norm among the vertical vectors of the matrix.
- MATRIX_NORM_P1 is the maximum vector p1-norm among horizontal matrix vectors.
- MATRIX_NORM_MINUS_P1 is the minimum vector p1-norm among horizontal matrix vectors.
- MATRIX_NORM_P2 is the highest singular value of the matrix.
- MATRIX_NORM_MINUS_P2 is the lowest singular value of a matrix.

A simple algorithm for calculating the P-norm of a vector in MQL5:

```
double VectorNormP(const vector& v,int norm_value)
  {
   ulong  i;
```

© 2000-2025, MetaQuotes Ltd.

```
   double norm=0.0;
//---
   switch(norm_value)
     {
      case 0 :
         for(i=0; i<v.Size(); i++)
            if(v[i]!=0)
               norm+=1.0;
         break;
      case 1 :
         for(i=0; i<v.Size(); i++)
            norm+=MathAbs(v[i]);
         break;
      case 2 :
         for(i=0; i<v.Size(); i++)
            norm+=v[i]*v[i];
         norm=MathSqrt(norm);
         break;
      default :
         for(i=0; i<v.Size(); i++)
            norm+=MathPow(MathAbs(v[i]),norm_value);
         norm=MathPow(norm,1.0/norm_value);
     }
//---
   return(norm);
  }
```

MQL5 example:

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a=a-4;
  Print("matrix a \n", a);
  a.Reshape(3, 3);
  matrix b=a;
  Print("matrix b \n", b);
  Print("b.Norm(MATRIX_NORM_P2)=", b.Norm(MATRIX_NORM_FROBENIUS));
  Print("b.Norm(MATRIX_NORM_FROBENIUS)=", b.Norm(MATRIX_NORM_FROBENIUS));
  Print("b.Norm(MATRIX_NORM_INF)", b.Norm(MATRIX_NORM_INF));
  Print("b.Norm(MATRIX_NORM_MINUS_INF)", b.Norm(MATRIX_NORM_MINUS_INF));
  Print("b.Norm(MATRIX_NORM_P1)=)", b.Norm(MATRIX_NORM_P1));
  Print("b.Norm(MATRIX_NORM_MINUS_P1)=", b.Norm(MATRIX_NORM_MINUS_P1));
  Print("b.Norm(MATRIX_NORM_P2)=", b.Norm(MATRIX_NORM_P2));
  Print("b.Norm(MATRIX_NORM_MINUS_P2)=", b.Norm(MATRIX_NORM_MINUS_P2));

  /*
  matrix a
  [[-4,-3,-2,-1,0,1,2,3,4]]
  matrix b
  [[-4,-3,-2]
```

© 2000-2025, MetaQuotes Ltd.

```
  [-1,0,1]
  [2,3,4]]
  b.Norm(MATRIX_NORM_P2)=7.745966692414834
  b.Norm(MATRIX_NORM_FROBENIUS)=7.745966692414834
  b.Norm(MATRIX_NORM_INF)9.0
  b.Norm(MATRIX_NORM_MINUS_INF)2.0
  b.Norm(MATRIX_NORM_P1)=)7.0
  b.Norm(MATRIX_NORM_MINUS_P1)=6.0
  b.Norm(MATRIX_NORM_P2)=7.348469228349533
  b.Norm(MATRIX_NORM_MINUS_P2)=1.857033188519056e-16
  */
```

Python example:

```
import numpy as np
from numpy import linalg as LA
a = np.arange(9) - 4
print("a \n",a)
b = a.reshape((3, 3))
print("b \n",b)
print("LA.norm(b)=",LA.norm(b))
print("LA.norm(b, 'fro')=",LA.norm(b, 'fro'))
print("LA.norm(b, np.inf)=",LA.norm(b, np.inf))
print("LA.norm(b, -np.inf)=",LA.norm(b, -np.inf))
print("LA.norm(b, 1)=",LA.norm(b, 1))
print("LA.norm(b, -1)=",LA.norm(b, -1))
print("LA.norm(b, 2)=",LA.norm(b, 2))
print("LA.norm(b, -2)=",LA.norm(b, -2))

a
 [-4 -3 -2 -1  0  1  2  3  4]
b
 [[-4 -3 -2]
 [-1  0  1]
 [ 2  3  4]]
LA.norm(b)= 7.745966692414834
LA.norm(b, 'fro')= 7.745966692414834
LA.norm(b, np.inf)= 9.0
LA.norm(b, -np.inf)= 2.0
LA.norm(b, 1)= 7.0
LA.norm(b, -1)= 6.0
LA.norm(b, 2)= 7.3484692283495345
LA.norm(b, -2)= 1.857033188519056e-16
```

© 2000-2025, MetaQuotes Ltd.

Cond

Compute the condition number of a matrix.

```
double matrix::Cond(
  const ENUM_MATRIX_NORM  norm      // matrix norm
   );
```

Parameters

norm

[in] Order of the norm from ENUM_MATRIX_NORM

Return Value

The condition number of the matrix. May be infinite.

Note

The condition number of x is defined as the norm of x times the norm of the inverse of x [1]. The norm can be the usual L2-norm (root-of-sum-of-squares) or one of a number of other matrix norms.

The condition umber is the K value equal to the product of the matrix A norms and its inverse. Matrices with a high condition number are called ill-conditioned. Those with a low condition number are called well-conditioned. The inverse matrix is obtained using pseudo-inversion, so as not to be limited by the condition of squareness and non-singularity of the matrix.

An exception is the spectral condition number.

A simple algorithm for calculating the spectral condition number in MQL5:

```
double MatrixCondSpectral(matrix& a)
  {
   double norm=0.0;
   vector v=a.Spectrum();

   if(v.Size()>0)
     {
      double max_norm=v[0];
      double min_norm=v[0];
      for(ulong i=1; i<v.Size(); i++)
        {
         double real=MathAbs(v[i]);
         if(max_norm<real)
            max_norm=real;
         if(min_norm>real)
            min_norm=real;
        }
      max_norm=MathSqrt(max_norm);
```

© 2000-2025, MetaQuotes Ltd.

```
      min_norm=MathSqrt(min_norm);
      if(min_norm>0.0)
         norm=max_norm/min_norm;
     }

  return(norm);
 }
```

MQL5 example:

```
 matrix a= {{1, 0, -1}, {0, 1, 0}, { 1, 0, 1}};
 Print("a.Cond(MATRIX_NORM_P2)=", a.Cond(MATRIX_NORM_P2));
 Print("a.Cond(MATRIX_NORM_FROBENIUS)=", a.Cond(MATRIX_NORM_FROBENIUS));
 Print("a.Cond(MATRIX_NORM_INF)=", a.Cond(MATRIX_NORM_INF));
 Print("a.Cond(MATRIX_NORM_MINUS_INF)=", a.Cond(MATRIX_NORM_MINUS_INF));
 Print("a.Cond(MATRIX_NORM_P1)=)", a.Cond(MATRIX_NORM_P1));
 Print("a.Cond(MATRIX_NORM_MINUS_P1)=", a.Cond(MATRIX_NORM_MINUS_P1));
 Print("a.Cond(MATRIX_NORM_P2)=", a.Cond(MATRIX_NORM_P2));
 Print("a.Cond(MATRIX_NORM_MINUS_P2)=", a.Cond(MATRIX_NORM_MINUS_P2));

 /*
 matrix a
 [[1,0,-1]
 [0,1,0]
 [1,0,1]]
 a.Cond(MATRIX_NORM_P2)=1.414213562373095
 a.Cond(MATRIX_NORM_FROBENIUS)=3.162277660168379
 a.Cond(MATRIX_NORM_INF)=2.0
 a.Cond(MATRIX_NORM_MINUS_INF)=0.9999999999999997
 a.Cond(MATRIX_NORM_P1)=)2.0
 a.Cond(MATRIX_NORM_MINUS_P1)=0.9999999999999998
 a.Cond(MATRIX_NORM_P2)=1.414213562373095
 a.Cond(MATRIX_NORM_MINUS_P2)=0.7071067811865472
 */
```

Python example:

```
import numpy as np
from numpy import linalg as LA
a = np.array([[1, 0, -1], [0, 1, 0], [1, 0, 1]])
print("a \n",a)
print("LA.cond(a)=",LA.cond(a))
print("LA.cond(a, 'fro')=",LA.cond(a, 'fro'))
print("LA.cond(a, np.inf)=",LA.cond(a, np.inf))
print("LA.cond(a, -np.inf)=",LA.cond(a, -np.inf))
print("LA.cond(a, 1)=",LA.cond(a, 1))
print("LA.cond(a, -1)=",LA.cond(a, -1))
```

© 2000-2025, MetaQuotes Ltd.

```
print("LA.cond(a, 2)=",LA.cond(a, 2))
print("LA.cond(a, -2)=",LA.cond(a, -2))

a
 [[ 1  0 -1]
 [ 0  1  0]
 [ 1  0  1]]
LA.cond(a)= 1.4142135623730951
LA.cond(a, 'fro')= 3.1622776601683795
LA.cond(a, np.inf)= 2.0
LA.cond(a, -np.inf)= 1.0
LA.cond(a, 1)= 2.0
LA.cond(a, -1)= 1.0
LA.cond(a, 2)= 1.4142135623730951
LA.cond(a, -2)= 0.7071067811865475
```

© 2000-2025, MetaQuotes Ltd.

Det

Compute the determinant of a square invertible matrix.

```
double matrix::Det()
```

Return Value

Determinant of matrix.

Note

2nd and 3rd order matrix determinants are calculated according to the Sarrus rule. d2=a11*a22-a12*a21; d3=a11*a22*a33+a12*a23*a31+a13*a21*a32-a13*a22*a31-a11*a23*a32-a12*a21*a33

The determinant is calculated by the Gaussian method by reducing the matrix to an upper triangular form. The determinant of an upper triangular matrix is equal to the product of the main diagonal elements.

If at least one matrix row or column is zero, the determinant is zero.

If two or more matrix rows or columns are linearly dependent, its determinant is zero.

The determinant of a matrix is equal to the product of its eigenvalues.

MQL5 example:

```
matrix m={{1,2},{3,4}};
double det=m.Det();
Print("matrix m\n",m);
Print("det(m)=",det);
/*
matrix m
[[1,2]
 [3,4]]
det(m)=-2.0
*/
```

Python example:

```
import numpy as np

a = np.array([[1, 2], [3, 4]])
print('a \n',a)
print('nnp.linalg.det(a) \n',np.linalg.det(a))

a
 [[1 2]
 [3 4]]
```

© 2000-2025, MetaQuotes Ltd.

```
np.linalg.det(a)
 -2.0000000000000004
```

© 2000-2025, MetaQuotes Ltd.

SLogDet

Compute the sign and logarithm of a matrix determinant.

```
double matrix::SLogDet(
  int&  sign      // sign
   );
```

Parameters

sign

[out] The sign of the determinant. If the sign is even, the determinant is positive.

Return Value

A number representing the sign of the determinant.

Note

The determinant is calculated by the Gaussian method by reducing the matrix to an upper triangular form. The determinant of an upper triangular matrix is equal to the product of the main diagonal elements. The logarithm of a product is equal to the sum of the logarithms. Therefore, in case of an overflow when calculating the determinant, you can use the SLogDet method.

If the sign is even, the determinant is positive.

Example

```
a = np.array([[1, 2], [3, 4]])
(sign, logdet) = np.linalg.slogdet(a)
(sign, logdet) (-1, 0.69314718055994529) # may vary  sign * np.exp(logdet) -2.0
```

© 2000-2025, MetaQuotes Ltd.

Rank

Return matrix rank using the Gaussian method.

```
int  Rank()
```

Return Value

Rank of matrix.

Note

The rank of a system of rows (or columns) of a matrix A that has m rows and n columns is the maximum number of linearly independent rows (or columns). Several rows (columns) are called linearly independent if none of them can be expressed linearly in terms of others. The rank of the row system is always equal to the rank of the column system. This value is called the rank of the matrix.

MQL5 example:

```
matrix a=matrix::Eye(4, 4);;
Print("matrix a \n", a);
Print("a.Rank()=", a.Rank());

matrix I=matrix::Eye(4, 4);
I[3, 3] = 0.;    // rank deficient matrix
Print("I \n", I);
Print("I.Rank()=", I.Rank());

matrix b=matrix::Ones(1, 4);
Print("b \n", b);
Print("b.Rank()=", b.Rank());;// 1 dimension - rank 1 unless all 0

matrix  zeros=matrix::Zeros(4, 1);
Print("zeros \n", zeros);
Print("zeros.Rank()=", zeros.Rank());

/*
matrix a
[[1,0,0,0]
[0,1,0,0]
[0,0,1,0]
[0,0,0,1]]
a.Rank()=4

I
[[1,0,0,0]
[0,1,0,0]
```

© 2000-2025, MetaQuotes Ltd.

```
  [0,0,1,0]
  [0,0,0,0]]
  I.Rank()=3

  b
  [[1,1,1,1]]
  b.Rank()=1

  zeros
  [[0]
  [0]
  [0]
  [0]]
  zeros.Rank()=0
  */
```

Python example:

```
import numpy as np
from numpy.linalg import matrix_rank
a=(np.eye(4)) # Full rank matrix
print("a \n", a)
print("matrix_rank(a)=",matrix_rank(a))
I=np.eye(4)
I[-1,-1] = 0. # rank deficient matrix
print("I \n",I)
print("matrix_rank(I)=",matrix_rank(I))

b=np.ones((4,))
print("b \n",b)
print("matrix_rank(b)=",matrix_rank(b)) # 1 dimension - rank 1 unless all 0

zeros=np.zeros((4,))
print("zeroes \n",zeros)
print("matrix_rank(zeros)=",matrix_rank(zeros))

a
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]
 [0. 0. 0. 1.]]
matrix_rank(a)= 4

I
 [[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]
 [0. 0. 0. 0.]]
```

© 2000-2025, MetaQuotes Ltd.

```
matrix_rank(I)= 3

b
 [1. 1. 1. 1.]
matrix_rank(b)= 1

zeroes
 [0. 0. 0. 0.]
matrix_rank(zeros)= 0
```

© 2000-2025, MetaQuotes Ltd.

Trace

Return the sum along diagonals of the matrix.

```
double matrix::Trace()
```

Return Value

The sum along the diagonal.

Note

The trace of a matrix is equal to the sum of its eigenvalues.

MQL5 example:

```
  matrix a= {{0, 1, 2, 3, 4, 5, 6, 7, 8}};
  a.Reshape(3, 3);
  Print("matrix a \n", a);
  Print("a.Trace() \n", a.Trace());

  /*
  matrix a
  [[0,1,2]
  [3,4,5]
  [6,7,8]]
  a.Trace()
  12.0
  */
```

Python example:

```
a = np.arange(9).reshape((3,3))
print('a \n',a)
print('np.trace(a) \n',np.trace(a))

a
 [[0 1 2]
 [3 4 5]
 [6 7 8]]

np.trace(a)
 12
```

© 2000-2025, MetaQuotes Ltd.

Spectrum

Compute spectrum of a matrix as the set of its eigenvalues from the product AT*A.

```
vector matrix::Spectrum()
```

Return Value

Spectrum of a matrix as a vector of matrix eigenvalues.

Example

```
double MatrixCondSpectral(matrix& a)
  {
   double norm=0.0;
   vector v=a.Spectrum();

   if(v.Size()>0)
     {
      double max_norm=v[0];
      double min_norm=v[0];
      for(ulong i=1; i<v.Size(); i++)
        {
         double real=MathAbs(v[i]);
         if(max_norm<real)
            max_norm=real;
         if(min_norm>real)
            min_norm=real;
        }
      max_norm=MathSqrt(max_norm);
      min_norm=MathSqrt(min_norm);
      if(min_norm>0.0)
         norm=max_norm/min_norm;
     }

   return(norm);
  }
```

© 2000-2025, MetaQuotes Ltd.

Matrix methods for solving systems of linear equations

Methods for solving systems of linear equations and calculating the inverse matrix.

Function	Action
Solve	Solve a linear matrix equation, or system of linear algebraic equations
LstSq	Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices)
Inv	Compute the (multiplicative) inverse of a square non-degenerate matrix by the Jordan-Gauss method
PInv	Compute the pseudo-inverse of a matrix by the Moore-Penrose method

© 2000-2025, MetaQuotes Ltd.

Solve

Solve a linear matrix equation, or system of linear algebraic equations.

```
vector matrix::Solve(
  const vector  b      // ordinate or 'dependent variable' values
   );
```

Parameters

b

[in] Ordinate or 'dependent variable' values. (Vector of free terms).

Return Value

Vector with solution to the system a * x = b.

Note

If at least one matrix row or column is zero, the system has no solution.

If two or more matrix rows or columns are linearly dependent, the system has no solution.

Example

```
//--- SLAE solution
   vector_x=matrix_a.Solve(vector_b);
//--- check if a * x = b
   result_vector=matrix_a.MatMul(vector_x);
   errors=vector_b.Compare(result_vector,1e-12);
```

© 2000-2025, MetaQuotes Ltd.

LstSq

Return the least-squares solution of linear algebraic equations (for non-square or degenerate matrices).

```
vector matrix::LstSq(
  const vector  b      // ordinate or 'dependent variable' values
   );
```

Parameters

b

[in] Ordinate or 'dependent variable' values. (Vector of free terms)

Return Value

Vector with solution to the system a * x = b. This is true only for systems that have an exact solution.

Example

```
   matrix a={{3, 2},
             {4,-5},
             {3, 3}};
   vector b={7,40,3};
//---
   vector x=a.LstSq(b);
//--- check, must be [5, -4]
   Print("x=", x);
//--- check, must be [7, 40, 3]
   vector b1=a.MatMul(x);
   Print("b1=",b1);

/*
  x=[5.000000000000002,-4]
  b1=[7.000000000000005,40.00000000000001,3.000000000000005]
*/
```

© 2000-2025, MetaQuotes Ltd.

Inv

Compute the multiplicative inverse of a square invertible matrix by the Jordan-Gauss method.

```
matrix matrix::Inv()
```

Return Value

Multiplicative inverse of the matrix.

Note

The product of the original matrix and the inverse matrix is the identity matrix.

If at least one matrix row or column is zero, the inverse matrix cannot be obtained.

If two or more matrix rows or columns are linearly dependent, the inverse matrix cannot be obtained.

Example

```
int TestInverse(const int size_m)
  {
   int    i,j,errors=0;
   matrix matrix_a(size_m,size_m);
//--- populate the square matrix
   MatrixTestFirst(matrix_a);
//--- microseconds will be measured
   ulong t1=GetMicrosecondCount();
//--- get the inverse matrix
   matrix inverse=matrix_a.Inv();
//--- measure
   ulong t2=GetMicrosecondCount();
//--- check the correctness
   matrix identity=matrix_a.MatMul(inverse);
//---
   for(i=0; i<size_m; i++)
     {
      for(j=0; j<size_m; j++)
        {
         double value;
         //--- ones must be along the diagonal
         if(i==j)
            value=1.0;
         else
            value=0.0;
         if(MathClassify(identity[i][j])>FP_ZERO)
            errors++;
         else
```

© 2000-2025, MetaQuotes Ltd.

```
            {
             if(identity[i][j]!=value)
               {
                double diff=MathAbs(identity[i][j]-value);
                //--- too many multiplications and devisions, so reduce the check accu
                if(diff>1e-9)
                   errors++;
               }
            }
         }
      }
//---
   double elapsed_time=double(t2-t1)/1000.0;
   printf("Inversion of matrix %d x %d  %s  errors=%d  time=%.3f ms",size_m,size_m,er
   return(errors);
  }
```

© 2000-2025, MetaQuotes Ltd.

PInv

Compute the pseudo-inverse of a matrix by the Moore-Penrose method.

```
matrix matrix::PInv()
```

Return Value

The pseudo-inverse of matrix.

Example

```
int TestPseudoInverse(const int size_m, const int size_k)
  {
   matrix matrix_a(size_m,size_k);
   matrix matrix_inverted(size_k,size_m);
   matrix matrix_temp;
   matrix matrix_a2;
//--- fill the matrix
   MatrixTestFirst(matrix_a);
//--- invert
   matrix_inverted=matrix_a.PInv();
//--- check the correctness
   int errors=0;
//--- A * A+ * A = A   (A+ is a pseudo-inverse of A)
   matrix_temp=matrix_a.MatMul(matrix_inverted);
   matrix_a2=matrix_temp.MatMul(matrix_a);
   errors=(int)matrix_a.CompareByDigits(matrix_a2,10);

   printf("PseudoInversion %s matrix_size  %d x %d  errors=%d",errors==0?"passed":"fa
//---
   return(errors);
  }
```

Machine learning

These methods are used in machine learning.

The neural network activation function determines the output value of a neuron depending on the weighted sum of inputs. The selection of the activation function has a big impact on the neural network performance. Different model parts (layers) can use different activation functions.

In addition to all known activation functions, MQL5 also offers their derivatives. Function derivatives enable an efficient update of model parameters based on the error received in learning.

A neural network aims at finding an algorithm that minimizes the error in learning, for which the loss function is used. The value of the loss function indicates by how much the value predicted by the model deviates from the real one. Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Function	Action
Activation	Compute activation function values and write them to the passed vector/matrix
Derivative	Compute activation function derivative values and write them to the passed vector/matrix
Loss	Compute loss function values and write them to the passed vector/matrix
LossGradient	Compute a vector or matrix of loss function gradients
RegressionMetric	Compute the regression metric as the deviation error from the regression line constructed on the specified data array
ConfusionMatrix	Compute confusion matrix. The method is applied to the vector of predicted values
ConfusionMatrixMultilabel	Compute confusion matrix for each label. The method is applied to the vector of predicted values
ClassificationMetric	Compute the classification metric to evaluate the quality of the predicted data compared to the true data The method is applied to the vector of predicted values
ClassificationScore	Compute the classification metric to evaluate the quality of the predicted data compared to the true data
PrecisionRecall	Compute values to construct a precision-recall curve. Similarly to ClassificationScore, this method is applied to the vector of true values
ReceiverOperatingCharacteristic	Compute values to construct the Receiver Operating Characteristic (ROC) curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

Example

© 2000-2025, MetaQuotes Ltd.

This example demonstrates the training of a model using matrix operations. The model is trained for the function (a + b + c)^2 / (a^2 + b^2 + c^2). We input the initial data matrix, in which a, b and c are contained in different columns. The function result is obtained at the model output.

```
matrix weights1, weights2, weights3;                // matrices of weights
matrix output1, output2, result;                    // matrices of neural layer outputs
input int layer1 = 200;                             // the size of the first hidden lay
input int layer2 = 200;                             // the size of the second hidden la
input int Epochs = 20000;                           // the number of training epochs
input double lr = 3e-6;                             // learning rate

Activation

Compute activation function values and write them to the passed vector/matrix.

```
bool vector::Activation(
  vector&                    vect_out,      // vector to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   ...                                     // additional parameters
   );

bool matrix::Activation(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation      // activation function
   );

bool matrix::Activation(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
  ENUM_MATRIX_AXIS           axis,          // axis
   ...                                     // additional parameters
   );
```

Parameters

vect_out/matrix_out

[out] Vector or matrix to get the computed values of the activation function.

activation

[in] Activation function from the ENUM_ACTIVATION_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameters required for some activation functions. If no parameters are specified, default values are used.

Return Value

Returns true if successful, otherwise - false.

Additional Parameters

Some activation functions accept additional parameters. If no parameters are specified, default values are used

© 2000-2025, MetaQuotes Ltd.

```
AF_ELU  (Exponential Linear Unit)
  double alpha=1.0

Activation function: if(x>=0) f(x) = x
                     else f(x) = alpha * (exp(x)-1)

AF_LINEAR
  double alpha=1.0
  double beta=0.0

Activation function: f(x) = alpha*x + beta

AF_LRELU   (Leaky REctified Linear Unit)
  double alpha=0.3

Activation function: if(x>=0) f(x)=x
                     else f(x) = alpha*x

AF_RELU  (REctified Linear Unit)
  double alpha=0.0
  double max_value=0.0
  double treshold=0.0

Activation function: if(alpha==0) f(x) = max(x,0)
                     else if(x>max_value) f(x) = x
                     else f(x) = alpha*(x - treshold)

```
   Activation function: if(x[i]>=0) f(x)[i] = x[i]
                        else f(x)[i] = alpha[i] * x[i]
```

Note

In artificial neural networks, the activation function of a neuron determines the output signal, which is defined by an input signal or a set of input signals. The selection of the activation function has a big impact on the neural network performance. Different model parts (layers) can use different activation functions.

Examples of using additional parameters:

```
vector x={0.1, 0.4, 0.9, 2.0, -5.0, 0.0, -0.1};
vector y;

x.Activation(y,AF_ELU);
Print(y);
x.Activation(y,AF_ELU,2.0);
Print(y);

Print("");
x.Activation(y,AF_LINEAR);
Print(y);
x.Activation(y,AF_LINEAR,2.0);
Print(y);
x.Activation(y,AF_LINEAR,2.0,5.0);
Print(y);

Print("");
x.Activation(y,AF_LRELU);
Print(y);
x.Activation(y,AF_LRELU,1.0);
Print(y);
x.Activation(y,AF_LRELU,0.1);
Print(y);

Print("");
x.Activation(y,AF_RELU);
Print(y);
x.Activation(y,AF_RELU,2.0,0.5);
Print(y);
x.Activation(y,AF_RELU,2.0,0.5,1.0);
Print(y);

Print("");
x.Activation(y,AF_SWISH);
Print(y);
```

© 2000-2025, MetaQuotes Ltd.

```
   x.Activation(y,AF_SWISH,2.0);
   Print(y);

   Print("");
   x.Activation(y,AF_TRELU);
   Print(y);
   x.Activation(y,AF_TRELU,0.3);
   Print(y);

   Print("");
   vector a=vector::Full(x.Size(),2.0);
   x.Activation(y,AF_PRELU,a);
   Print(y);

Derivative

Compute activation function derivative values and write them to the passed vector/matrix

```
bool vector::Derivative(
  vector&                    vect_out,      // vector to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   ...                                      // additional parameters
   );

bool matrix::Derivative(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
   );

bool matrix::Derivative(
  matrix&                    matrix_out,    // matrix to get values
  ENUM_ACTIVATION_FUNCTION   activation,    // activation function
  ENUM_MATRIX_AXIS           axis,          // axis
   ...                                      // additional parameters
   );
```

Parameters

vect_out/matrix_out

[out] Vector or matrix to get the computed values of the derivative of the activation function.

activation

[in] Activation function from the ENUM_ACTIVATION_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameters are the same as that of the activation functions. Only some activation functions accept additional parameters. If no parameters are specified, default values are used.

Return Value

Returns true if successful, otherwise - false.

Note

Function derivatives enable an efficient update of model parameters based on the error received in learning during the error backpropagation.

© 2000-2025, MetaQuotes Ltd.

© 2000-2025, MetaQuotes Ltd.

Loss

Compute the value of the loss function.

```
double vector::Loss(
  const vector&       vect_true,     // vector of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   ...                               // additional parameter
   );

double matrix::Loss(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   );

double matrix::Loss(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
  ENUM_MATRIX_AXIS    axis,          // axis
   ...                               // additional parameter
   );
```

Parameters

vect_true/matrix_true

[in] Vector or matrix of true values.

loss

[in] Loss function from the ENUM_LOSS_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameter 'delta' can only be used by the Hubert loss function (LOSS_HUBER)

Return Value

double value.

How the 'delta' parameter is used in the Hubert loss function (LOSS_HUBER)

```
   double delta = 1.0;
   double error = fabs(y - x);
   if(error<delta)
      loss = 0.5 * error^2;
   else
```

© 2000-2025, MetaQuotes Ltd.

```
      loss = 0.5 * delta^2 + delta * (error - delta);
```

Note

A neural network aims at finding the algorithms that minimize the error on the training sample, for which the loss function is used.

The value of the loss function indicates by how much the value predicted by the model deviates from the real one.

Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Example of calling the Hubert loss function:

```
   vector y_true = {0.0, 1.0, 0.0, 0.0};
   vector y_pred = {0.6, 0.4, 0.4, 0.6};
   double loss=y_pred.Loss(y_true,LOSS_HUBER);
   Print(loss);
   double loss2=y_pred.Loss(y_true,LOSS_HUBER,0.5);
   Print(loss2);

/* Result
   0.155
   0.15125
*/
```

© 2000-2025, MetaQuotes Ltd.

LossGradient

Compute a vector or matrix of loss function gradients.

```
vector vector::LossGradient(
  const vector&       vect_true,     // vector of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function type
   ...                               // additional parameter
   );

matrix matrix::LossGradient(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
   );

matrix matrix::LossGradient(
  const matrix&       matrix_true,   // matrix of true values
  ENUM_LOSS_FUNCTION  loss,          // loss function
  ENUM_MATRIX_AXIS    axis,          // axis
   ...                               // additional parameter
   );
```

Parameters

vect_true/matrix_true

[in] Vector or matrix of true values.

loss

[in] Loss function from the ENUM_LOSS_FUNCTION enumeration.

axis

[in] ENUM_MATRIX_AXIS enumeration value (AXIS_HORZ — horizontal axis, AXIS_VERT — vertical axis).

...

[in] Additional parameter 'delta' can only be used by the Hubert loss function (LOSS_HUBER)

Return Value

Vector or matrix of loss function gradient values. The gradient is the partial derivative with respect to dx (x is the predicted value) of the loss function at a given point.

Note

Gradients are used in neural networks to adjust the weight matrix weights during backpropagation, when training the model.

© 2000-2025, MetaQuotes Ltd.

A neural network aims at finding the algorithms that minimize the error on the training sample, for which the loss function is used.

Different loss functions are used depending on the problem. For example, Mean Squared Error (MSE) is used for regression problems, and Binary Cross-Entropy (BCE) is used for binary classification purposes.

Example of calculating loss function gradients

```
   matrixf y_true={{ 1, 2, 3, 4 },
                   { 5, 6, 7, 8 },
                   { 9,10,11,12 }};
   matrixf y_pred={{ 1, 2, 3, 4 },
                   {11,10, 9, 8 },
                   { 5, 6, 7,12 }};
   matrixf loss_gradient =y_pred.LossGradient(y_true,LOSS_MAE);
   matrixf loss_gradienth=y_pred.LossGradient(y_true,LOSS_MAE,AXIS_HORZ);
   matrixf loss_gradientv=y_pred.LossGradient(y_true,LOSS_MAE,AXIS_VERT);
   Print("loss gradients\n",loss_gradient);
   Print("loss gradients on horizontal axis\n",loss_gradienth);
   Print("loss gradients on vertical axis\n",loss_gradientv);

/* Result
   loss gradients
   [[0,0,0,0]
    [0.083333336,0.083333336,0.083333336,0]
    [-0.083333336,-0.083333336,-0.083333336,0]]
   loss gradients on horizontal axis
   [[0,0,0,0]
    [0.33333334,0.33333334,0.33333334,0]
    [-0.33333334,-0.33333334,-0.33333334,0]]
   loss gradients on vertical axis
   [[0,0,0,0]
    [0.25,0.25,0.25,0]
    [-0.25,-0.25,-0.25,0]]
*/
```

© 2000-2025, MetaQuotes Ltd.

RegressionMetric

Compute the regression metric to evaluate the quality of the predicted data compared to the true data

```
double vector::RegressionMetric(
   const vector&           vector_true,   // vector of true values
   ENUM_REGRESSION_METRIC  metric         // metric type
   );

double matrix::RegressionMetric(
   const matrix&           matrix_true,   // matrix of true values
   ENUM_REGRESSION_METRIC  metric         // metric type
);

vector matrix::RegressionMetric(
   const matrix&           matrix_true,   // matrix of true values
   ENUM_REGRESSION_METRIC  metric,        // metric type
   int                     axis           // axis
   );
```

Parameters

vector_true/matrix_true

[in] Vector or matrix of true values.

metric

[in] Metric type from the ENUM_REGRESSION_METRIC enumeration.

axis

[in] Axis. 0 — horizontal axis, 1 — vertical axis.

Return Value

The calculated metric which evaluates the quality of the predicted data compared to the true data.

Note

- REGRESSION_MAE — mean absolute error which represents the absolute differences between predicted values and corresponding true values
- REGRESSION_MSE — mean square error which represents the squared differences between predicted values and corresponding true values
- REGRESSION_RMSE — square root of MSE
- REGRESSION_R2 - 1 — MSE(regression) / MSE(mean)
- REGRESSION_MAPE — MAE as a percentage
- REGRESSION_MSPE — MSE as a percentage
- REGRESSION_RMSLE — RMSE computed on a logarithmic scale

Example:

© 2000-2025, MetaQuotes Ltd.

```
   vector y_true = {3, -0.5, 2, 7};
   vector y_pred = {2.5, 0.0, 2, 8};
//---
   double mse=y_pred.RegressionMetric(y_true,REGRESSION_MSE);
   Print("mse=",mse);
//---
   double mae=y_pred.RegressionMetric(y_true,REGRESSION_MAE);
   Print("mae=",mae);
//---
   double r2=y_pred.RegressionMetric(y_true,REGRESSION_R2);
   Print("r2=",r2);

  /* Result
   mae=0.375
   mse=0.5
   r2=0.9486081370449679
   */
```

© 2000-2025, MetaQuotes Ltd.

ConfusionMatrix

Compute confusion matrix. The method is applied to the vector of predicted values.

```
matrix vector::ConfusionMatrix(
   const vector&        vect_true      // vector of true values
   );

matrix vector::ConfusionMatrix(
   const vector&        vect_true,     // vector of true values
   uint                 label          // label value
   );
```

Parameters

vect_true

[in] Vector of true values.

label

[in] Label value for calculating the confusion matrix.

Return Value

Confusion matrix. If a label value is not specified, a multi-class confusion matrix is returned, where each label is matched to each other label individually. If a label value is specified, a 2 x 2 matrix is returned, in which the specified label is considered positive, while all other labels are negative (ovr, one vs rest).

Note

Confusion matrix C is such that Cij is equal to the number of observations known to be in group i and predicted to be in group j. Thus in binary classification, the count of true negatives (TN) is C00, false negatives (FN) is C10, true positives (TP) is C11 and false positives (FP) is C01.

In other words, the matrix can be graphically represented as follows:

TN	FP
FN	TP

The sizes of the vector of true values and the vector of predicted values should be the same.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};
   matrix confusion=y_pred.ConfusionMatrix(y_true);
```

© 2000-2025, MetaQuotes Ltd.

```
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,0);
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,1);
   Print(confusion);
   confusion=y_pred.ConfusionMatrix(y_true,2);
   Print(confusion);

/*

  [[25,2]
   [2,1]]
*/
```

© 2000-2025, MetaQuotes Ltd.

ConfusionMatrixMultilabel

Compute confusion matrix for each label. The method is applied to the vector of predicted values.

```
uint vector::ConfusionMatrixMultiLabel(
   const vector&       vect_true,     // vector of true values
   matrix&             confusions[]   // array of calculated confusion matrices
   );
```

Parameters

vect_true

[in] Vector of true values.

confusions

[out] An array of 2 x 2 matrices with computed confusion matrices for each label.

Return Value

Size of the array of calculated confusion matrices. In case of failure, it returns 0

Note

The result array can be dynamic or static. If the array is static, then it must be no less in size than the number of classes.

The sizes of the vector of true values and the vector of predicted values should be the same.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};
   matrix label_confusions[12];

   uint   res=y_pred.ConfusionMatrixMultiLabel(y_true,label_confusions);
   Print("res=",res,"  size=",label_confusions.Size());
   for(uint i=0; i<res; i++)
      Print(label_confusions[i]);

/*
  res=10  size=12
  [[26,1]
   [0,3]]
  [[27,0]
   [0,3]]
  [[25,2]
   [2,1]]
```

```
   [[28,0]
    [1,1]]
   [[24,1]
    [2,3]]
   [[27,1]
    [0,2]]
   [[27,0]
    [2,1]]
   [[25,2]
    [1,2]]
   [[28,0]
    [2,0]]
   [[23,3]
    [0,4]]
*/
```

© 2000-2025, MetaQuotes Ltd.

ClassificationMetric

Compute the classification metric to evaluate the quality of the predicted data compared to the true data. The method is applied to the vector of predicted values.

```
vector vector::ClassificationMetric(
   const vector&               vect_true,     // vector of true values
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   );

vector vector::ClassificationMetric(
   const vector&               vect_true,     // vector of true values
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   ENUM_AVERAGE_MODE           mode           // averaging mode
   );
```

Parameters

vect_true

[in] Vector of true values.

metric

[in] Metric type from the ENUM_CLASSIFICATION_METRIC enumeration. Values other than CLASSIFICATION_TOP_K_ACCURACY, CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC (used in the ClassificationScore method) are applied.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Used for the CLASSIFICATION_F1, CLASSIFICATION_JACCARD, CLASSIFICATION_PRECISION and CLASSIFICATION_RECALL metrics.

Return Value

A vector containing the calculated metric. In the case of the AVERAGE_NONE averaging mode, the vector contains metric values for each class without averaging. (For example, in case of the binary classification, this would be two metrics for 'false' and 'true' respectively).

Note about averaging modes

AVERAGE_BINARY is only meaningful for binary classification.

AVERAGE_MICRO — calculate metrics globally by counting the total true positives, false negatives and false positives.

AVERAGE_MACRO — calculate metrics for each label and find their unweighted mean. This does not take label imbalance into account.

AVERAGE_WEIGHTED — calculate metrics for each label and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

© 2000-2025, MetaQuotes Ltd.

Note

In case of binary classification, we can input not only an n x 2 matrix, where the first column contains probabilities for a negative label, and the second column contains probabilities for a positive label, but also a matrix consisting of one column with positive probabilities. This is because binary classification models can return either two probabilities or one probability for a positive label.

Example:

```
vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};

ClassificationScore

Compute the classification metric to evaluate the quality of the predicted data compared to the true data.

Unlike other methods in the Machine Learning section, this one applies to the vector of true values rather than the vector of predicted values.

```
vector vector::ClassificationScore(
   const matrix&               pred_scores,   // matrix containing probability distribu
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   ENUM_AVERAGE_MODE           mode          // averaging mode
   );

vector vector::ClassificationScore(
   const matrix&               pred_scores,   // matrix containing probability distribu
   ENUM_CLASSIFICATION_METRIC metric         // metric type
   int                         param         // additional parameter
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows should correspond to the size of the vector of true values.

metric

[in] Metric type from the ENUM_CLASSIFICATION_METRIC enumeration. The CLASSIFICATION_TOP_K_ACCURACY, CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC values are used.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Used for the CLASSIFICATION_AVERAGE_PRECISION and CLASSIFICATION_ROC_AUC metrics.

param

[in] In case of the CLASSIFICATION_TOP_K_ACCURACY metric, the integer K value should be specified instead of the averaging mode.

Return Value

A vector containing the calculated metric. In the case of the AVERAGE_NONE averaging mode, the vector contains metric values for each class without averaging. (For example, in case of the binary classification, this would be two metrics for 'false' and 'true' respectively).

Note about averaging modes

AVERAGE_BINARY is only meaningful for binary classification.

© 2000-2025, MetaQuotes Ltd.

AVERAGE_MICRO — calculate metrics globally by considering each element of the label indicator matrix as a label. The label indicator matrix refers to a matrix with a set of probabilities for each label.

AVERAGE_MACRO — calculate metrics for each label and find their unweighted mean. This does not take label imbalance into account.

AVERAGE_WEIGHTED — calculate metrics for each label and find their average weighted by support (the number of true instances for each label).

Note

In case of binary classification, we can input not only an n x 2 matrix, where the first column contains probabilities for a negative label, and the second column contains probabilities for a positive label, but also a matrix consisting of one column with positive probabilities. This is because binary classification models can return either two probabilities or one probability for a positive label.

Example:

```
   vector y_true={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,8,4,2,7,6,8,4,2,3,6};
   //vector y_pred={7,2,1,0,4,1,4,9,5,9,0,6,9,0,1,5,9,7,3,4,2,9,4,9,5,9,2,7,7,0};

//--- label scores          0         1         2         3         4         5
   matrix y_scores={{0.000109, 0.000186, 0.000449, 0.000052, 0.000002, 0.000022, 0.000
                    {0.000091, 0.081956, 0.916816, 0.001106, 0.000006, 0.000002, 0.000

PrecisionRecall

Compute values to construct a precision-recall curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

```
bool vector::PrecisionRecall(
   const matrix&                 pred_scores,   // matrix containing the probability
   const ENUM_ENUM_AVERAGE_MODE  mode           // averaging mode
   matrix&                       precision,     // calculated precision values for ea
   matrix&                       recall,        // calculated recall values for each
   matrix&                       thresholds,    // threshold values sorted in descend
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows must correspond to the size of the vector of true values.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Only AVERAGE_NONE, AVERAGE_BINARY and AVERAGE_MICRO are used.

precision

[out] A matrix with calculated precision curve values. If no averaging is applied (AVERAGE_NONE), the number of rows in the matrix corresponds to the number of model classes. The number of columns corresponds to the size of the vector of true values (or the number of rows in the probability distribution matrix pred_score). In the case of microaveraging, the number of rows in the matrix corresponds to the total number of threshold values, excluding duplicates.

recall

[out] A matrix with calculated recall curve values.

threshold

[out] Threshold matrix obtained by sorting the probability matrix

Note

See notes for the ClassificationScore method.

Example

An example of collecting statistics from the mnist.onnx model (99% accuracy).

```
//--- data for classification metrics
   vectorf y_true(images);
   vectorf y_pred(images);
   matrixf y_scores(images,10);
//--- input-output
   matrixf image(28,28);
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf result(10);

//--- testing
   for(int test=0; test<images; test++)
     {
      image=test_data[test].image;
      if(!OnnxRun(model,ONNX_DEFAULT,image,result))
        {
         Print("OnnxRun error ",GetLastError());
         break;
        }
      result.Activation(result,AF_SOFTMAX);
      //--- collect data
      y_true[test]=(float)test_data[test].label;
      y_pred[test]=(float)result.ArgMax();
      y_scores.Row(result,test);
     }    }
```

Accuracy calculation

```
   vectorf accuracy=y_pred.ClassificationMetric(y_true,CLASSIFICATION_ACCURACY);
   PrintFormat("accuracy=%f",accuracy[0]);

accuracy=0.989000
```

An example of plotting precision-recall graphs, where precision values are plotted on the y-axis and recall values are plotted on the x-axis. Also precision and recall graphs are plotted separately, with threshold values plotted on the x-axis

```
   if(y_true.PrecisionRecall(y_scores,AVERAGE_MICRO,mat_precision,mat_recall,mat_thres
     {
      double precision[],recall[],thres[];
      ArrayResize(precision,mat_thres.Cols());
      ArrayResize(recall,mat_thres.Cols());
      ArrayResize(thres,mat_thres.Cols());

      for(uint i=0; i<thres.Size(); i++)
        {
         precision[i]=mat_precision[0][i];
         recall[i]=mat_recall[0][i];
         thres[i]=mat_thres[0][i];
        }
      thres[0]=thres[1]+0.001;

      PlotCurve("Precision-Recall curve (micro average)","p-r","",recall,precision);
      Plot2Curves("Precision-Recall (micro average)","precision","recall",thres,precis
     }
```

© 2000-2025, MetaQuotes Ltd.

ReceiverOperatingCharacteristic

Compute values to construct the Receiver Operating Characteristic (ROC) curve. Similarly to ClassificationScore, this method is applied to the vector of true values.

```
bool vector::ReceiverOperatingCharacteristic(
   const matrix&                 pred_scores,   // matrix containing the probability c
   const ENUM_ENUM_AVERAGE_MODE  mode           // averaging mode
   matrix&                       fpr,           // calculated false positive rate valu
   matrix&                       tpr,           // calculated true positive rate value
   matrix&                       thresholds,    // threshold values sorted in descendi
   );
```

Parameters

pred_scores

[in] A matrix containing a set of horizontal vectors with probabilities for each class. The number of matrix rows must correspond to the size of the vector of true values.

mode

[in] Averaging mode from the ENUM_AVERAGE_MODE enumeration. Only AVERAGE_NONE, AVERAGE_BINARY and AVERAGE_MICRO are used.

fpr

[out] A matrix with calculated values of the false positive rate curve. If no averaging is applied (AVERAGE_NONE), the number of rows in the matrix corresponds to the number of model classes. The number of columns corresponds to the size of the vector of true values (or the number of rows in the probability distribution matrix pred_score). In the case of microaveraging, the number of rows in the matrix corresponds to the total number of threshold values, excluding duplicates.

tpr

[out] A matrix with calculated values of the true positive rate curve.

threshold

[out] Threshold matrix obtained by sorting the probability matrix

Note

See notes for the ClassificationScore method.

Example

An example of plotting ROC graphs, where tpr values are plotted on the y-axis and fpr values are plotted on the x-axis. Also fpr and tpr graphs are plotted separately, with threshold values plotted on the x-axis

```
   matrixf mat_thres;
   matrixf mat_fpr;
   matrixf mat_tpr;
```

© 2000-2025, MetaQuotes Ltd.

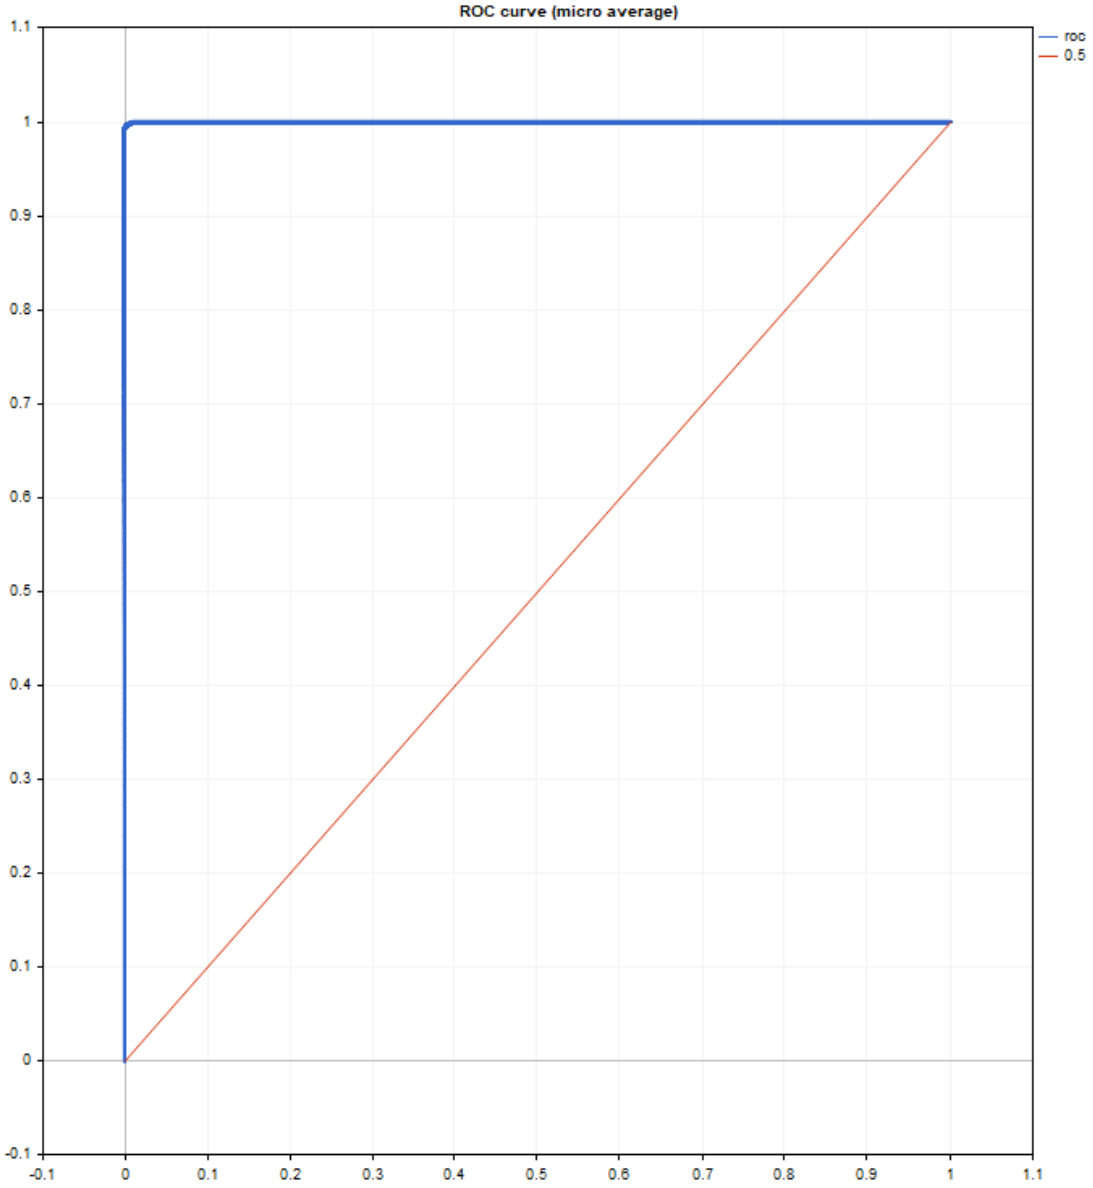
```
   if(y_true.ReceiverOperatingCharacteristic(y_scores,AVERAGE_MICRO,mat_fpr,mat_tpr,ma
     {
      double fpr[],tpr[],thres[];
      ArrayResize(fpr,mat_thres.Cols());
      ArrayResize(tpr,mat_thres.Cols());
      ArrayResize(thres,mat_thres.Cols());

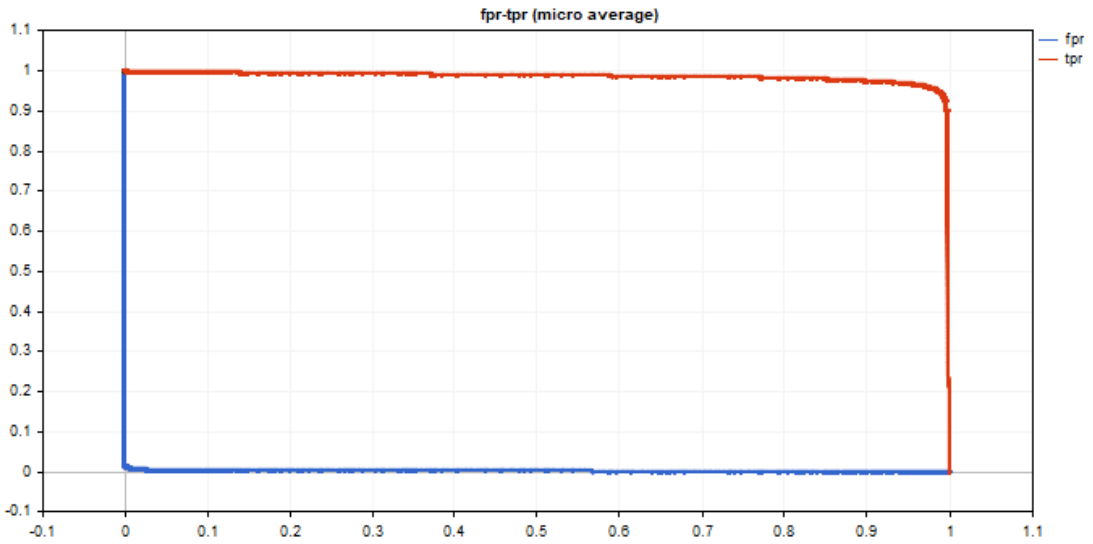
      for(uint i=0; i<fpr.Size(); i++)
        {
         fpr[i]=mat_fpr[0][i];
         tpr[i]=mat_tpr[0][i];
         thres[i]=mat_thres[0][i];
        }
      thres[0]=thres[1]+0.001;

      PlotCurve("ROC curve (micro average)","roc","0.5",fpr,tpr);
      Plot2Curves("fpr-tpr (micro average)","fpr","tpr",thres,fpr,tpr);
     }
```

Resulting curves:

© 2000-2025, MetaQuotes Ltd.





© 2000-2025, MetaQuotes Ltd.

The graph output code is simple and based on the <Graphics/Graphic.mqh> standard library.

The examples use the data of the mnist.onnx model. The code is presented in the PrecisionRecall method description.

ROC AUC is close to ideal.

```
roc auc score micro = [0.99991]
```

© 2000-2025, MetaQuotes Ltd.

OpenBLAS Methods

OpenBLAS is a high-performance open-source linear algebra library that implements BLAS (Basic Linear Algebra Subprograms) and some LAPACK functions. OpenBLAS is designed to improve computational performance, particularly in matrix and vector operations, which are often used in scientific and engineering tasks such as machine learning, numerical methods, and simulations.

Key features of OpenBLAS:

- Multithreading support: OpenBLAS can efficiently use multiple processor cores for parallel computations, significantly accelerating operations on multiprocessor systems.
- Optimization for processor architectures: OpenBLAS includes optimized builds for various processors such as Intel, AMD, ARM and others. The library automatically detects processor characteristics and selects the most suitable function implementations.
- Extensive BLAS operation support: OpenBLAS implements core BLAS functions, including vector operations (e.g., vector addition and dot product), matrix operations (multiplication), and vector-matrix operations.
- LAPACK compatibility: The library supports LAPACK (Linear Algebra PACKage) functions for more complex linear algebra operations, such as solving systems of linear equations, calculating matrix eigenvalues, and others.
- High performance: Compared to other BLAS libraries, OpenBLAS often shows better results due to hand-optimization for specific processor architectures.

Applications

OpenBLAS is widely used in applications involving numerical computations:

- Training neural networks and other machine learning tasks.
- Scientific computing (e.g. modeling of physical processes).
- Processing and analyzing large amounts of data.

The library is integrated into many popular scientific software packages such as NumPy, SciPy, and TensorFlow, which rely on high-performance linear algebra operations.

OpenBLAS is an excellent choice for those seeking an open-source solution for high-performance computing, particularly when working with large matrices and vectors.

Function	Action
SingularValueDecompositionDC	Singular Value Decomposition, "divide-and-conquer" algorithm. This algorithm is considered the fastest among other SVD algorithms (lapack function GESDD).
SingularValueDecompositionQR	Singular Value Decomposition, QR algorithm. This algorithm is considered a classical SVD algorithm (lapack function GESVD).

© 2000-2025, MetaQuotes Ltd.

Function	Action
SingularValueDecompositionQRPivot	Singular Value Decomposition, QR with pivoting algorithm (lapack function GESVDQ).
SingularValueDecompositionBisect	Singular Value Decomposition, bisection algorithm (lapack function GESVDX).
SingularValueDecompositionJacobiHigh	Singular Value Decomposition, Jacobi high level algorithm (lapack function GEJSV).
SingularValueDecompositionJacobiLow	Singular Value Decomposition, Jacobi low level algorithm (lapack function GESVJ). The method computes small singular values and their singular vectors with much greater accuracy than other SVD routines in certain cases.
SingularValueDecompositionBidiagDC	Singular Value Decomposition, divide-and-conquer algorithm for bidiagonal matrices (lapack function BDSVDX).
SingularValueDecompositionBidiagBisect	Singular Value Decomposition, bisection algorithm for bidiagonal matrices (lapack function BDSVDX).
EigenSolver	Compute eigenvalues and eigenvectors of a regular square matrix using the classical algorithm (lapack function GEEV).
EigenSolver2	Compute generalized eigenvalues and eigenvectors for a pair of ordinary square matrices (lapack function GGEV).
EigenSolverX	Compute eigenvalues and eigenvectors of a regular square matrix in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GEEVX).
EigenSolverShur	Compute eigenvalues, upper triangular matrix in Schur form, and matrix of Schur vectors (lapack function GEES). See also Schur decomposition.
EigenSymmetricDC	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the divide-and-conquer algorithm (lapack functions SYEVD, HEEVD).
EigenSymmetricQR	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex

Singular value decomposition

This section features functions for decomposing a matrix into three components: orthogonal matrices and a diagonal matrix of singular values. SVD is applied to solve various linear algebra problems such as data dimensionality reduction, image compression, solving systems of equations, and data analysis and optimization. The main functions allow you to compute singular values and vectors, reconstruct matrices, and approximate matrices with reduced rank accuracy.

Function	Action
SingularValueDecompositionDC	Singular Value Decomposition, "divide-and-conquer" algorithm. This algorithm is considered the fastest among other SVD algorithms (lapack function GESDD).
SingularValueDecompositionQR	Singular Value Decomposition, QR algorithm. This algorithm is considered a classical SVD algorithm (lapack function GESVD).
SingularValueDecompositionQRPivot	Singular Value Decomposition, QR with pivoting algorithm (lapack function GESVDQ).
SingularValueDecompositionBisect	Singular Value Decomposition, bisection algorithm (lapack function GESVDX).
SingularValueDecompositionJacobiHigh	Singular Value Decomposition, Jacobi high level algorithm (lapack function GEJSV).
SingularValueDecompositionJacobiLow	Singular Value Decomposition, Jacobi low level algorithm (lapack function GESVJ). The method computes small singular values and their singular vectors with much greater accuracy than other SVD routines in certain cases.
SingularValueDecompositionBidiagDC	Singular Value Decomposition, divide-and-conquer algorithm for bidiagonal matrices (lapack function BDSVDX).
SingularValueDecompositionBidiagBisect	Singular Value Decomposition, bisection algorithm for bidiagonal matrices (lapack function BDSVDX).

SingularValueDecompositionDC

Singular Value Decomposition, "divide-and-conquer" algorithm. This algorithm is considered the fastest among other SVD algorithms (lapack function GESDD).

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionDC(
   ENUM_SVD_Z      jobz,     // how to computed
   vector&         S,        // vector of computed singular values
   matrix&         U,        // matrix of computed left vectors U
   matrix&         VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionDC(
   ENUM_SVD_Z      jobz,     // how to computed
   vectorf&        S,        // vector of computed singular values
   matrixf&        U,        // matrix of computed left vectors U
   matrixf&        VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complex>

```
bool  matrix::SingularValueDecompositionDC(
   ENUM_SVD_Z      jobz,     // how to computed
   vector&         S,        // vector of computed singular values
   matrixc&        U,        // matrix of computed left vectors U
   matrixc&        VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complexf>

```
bool  matrix::SingularValueDecompositionDC(
   ENUM_SVD_Z      jobz,                  // how to computed
   vectorf&        singular_values,       // vector of computed singular values
   matrixcf&       U,                     // matrix of computed left vectors U
   matrixcf&       VT                     // transposed matrix of right vectors VT
   );
```

Parameters

jobz

[in] ENUM_SVD_Z enumeration value which determines the method for computing left and singular eigenvectors.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

© 2000-2025, MetaQuotes Ltd.

VT

[out] Matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobz parameter.

When jobv is set to SVDZ_N, the left and right vectors are not computed. Only singular values are computed.

When jobv is set to SVDZ_A, the full matrices of the U and VT vectors are computed.

When the value is SVDZ_S, truncated matrices of vectors U and VT are computed.

ENUM_SVD_Z

An enumeration defining the way to compute left and right singular vectors.

ID	Description
SVDZ_N	Columns U or rows VT are not computed
SVDZ_A	All M columns of U or all N columns of VT are returned in arrays U and VT
SVDZ_S	The first min(M,N) columns of U or the first min(M,N) columns of VT are returned in arrays U and VT

SingularValueDecompositionQR

Singular Value Decomposition, QR algorithm. Considered a classical SVD algorithm (lapack function GESVD).

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionQR(
   ENUM_SVD_Z      jobu,     // how to compute left vectors
   ENUM_SVD_Z      jobv,     // how to compute right vectors
   vector&         S,        // vector of computed singular values
   matrix&         U,        // matrix of computed left vectors U
   matrix&         VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionQR(
   ENUM_SVD_Z      jobu,     // how to compute left vectors
   ENUM_SVD_Z      jobv,     // how to compute right vectors
   vectorf&        S,        // vector of computed singular values
   matrixf&        U,        // matrix of computed left vectors U
   matrixf&        VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complex>

```
bool  matrix::SingularValueDecompositionQR(
   ENUM_SVD_Z      jobu,     // how to compute left vectors
   ENUM_SVD_Z      jobv,     // how to compute right vectors
   vector          S,        // vector of computed singular values
   matrixc         U,        // matrix of computed left vectors U
   matrixc         VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complexf>

```
bool  matrix::SingularValueDecompositionQR(
   ENUM_SVD_Z      jobu,                  // how to compute left vectors
   ENUM_SVD_Z      jobv,                  // how to compute right vectors
   vectorf&        singular_values,       // vector of computed singular values
   matrixcf&       u,                     // matrix of computed left vectors U
   matrixcf&       vt                     // transposed matrix of right vectors VT
   );
```

Parameters

jobu

[in] ENUM_SVD_Z enumeration value defining how the left singular vectors should be computed.

jobv

© 2000-2025, MetaQuotes Ltd.

[in] ENUM_SVD_Z enumeration value defining how the right singular vectors should be computed.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

VT

[out] Matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobu and jobv parameters.

When set to SVDZ_N, the left (jobu) and right (jobv) vectors are not computed. Singular values are always computed.

When set to SVDZ_A, the full matrices of vectors U (jobu) or VT (jobv) are computed.

With the value SVDZ_S, truncated matrices of vectors U (jobu) or VT (jobv) are computed.

ENUM_SVD_Z

An enumeration defining the way to compute left and right singular vectors.

ID	Description
SVDZ_N	Columns U or rows VT are not computed
SVDZ_A	All M columns of U or all N columns of VT are returned in arrays U and VT
SVDZ_S	The first min(M,N) columns of U or the first min(M,N) columns of VT are returned in arrays U and VT

SingularValueDecompositionQRPivot

Singular Value Decomposition, QR with pivoting algorithm (lapack function GESVDQ).

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionQRPivot(
   ENUM_SVDQRP_A   joba,     // computation accuracy level
   ENUM_SVDQRP_P   jobp,     // use row reversal to compute
   ENUM_SVDQRP_R   jobr,     // use triangular matrix R to compute
   ENUM_SVDQRP_U   jobu,     // how to compute left vectors
   ENUM_SVDQRP_V   jobv,     // how to compute right vectors
   vector&         S,        // vector of computed singular values
   matrix&         U,        // matrix of computed left vectors U
   matrix&         VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionQRPivot(
   ENUM_SVDQRP_A   joba,     // computation accuracy level
   ENUM_SVDQRP_P   jobp,     // use row reversal to compute
   ENUM_SVDQRP_R   jobr,     // use triangular matrix R to compute
   ENUM_SVDQRP_U   jobu,     // how to compute left vectors
   ENUM_SVDQRP_V   jobv,     // how to compute right vectors
   vectorf&        S,        // vector of computed singular values
   matrixf&        U,        // matrix of computed left vectors U
   matrixf&        VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complex>

```
bool  matrix::SingularValueDecompositionQRPivot(
   ENUM_SVDQRP_A   joba,     // computation accuracy level
   ENUM_SVDQRP_P   jobp,     // use row reversal to compute
   ENUM_SVDQRP_R   jobr,     // use triangular matrix R to compute
   ENUM_SVDQRP_U   jobu,     // how to compute left vectors
   ENUM_SVDQRP_V   jobv,     // how to compute right vectors
   vector&         S,        // vector of computed singular values
   matrixc&        U,        // matrix of computed left vectors U
   matrixc&        VT        // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complexf>

```
bool  matrix::SingularValueDecompositionQRPivot(
   ENUM_SVDQRP_A   joba,                  // computation accuracy level
   ENUM_SVDQRP_P   jobp,                  // use row reversal to compute
   ENUM_SVDQRP_R   jobr,                  // use triangular matrix R to compute
   ENUM_SVDQRP_U   jobu,                  // how to compute left vectors
```

© 2000-2025, MetaQuotes Ltd.

```
   ENUM_SVDQRP_V   jobv,                  // how to compute right vectors
   vectorf&        singular_values,       // vector of computed singular values
   matrixcf&       u,                     // matrix of computed left vectors U
   matrixcf&       vt                     // transposed matrix of right vectors VT
   );
```

Parameters

joba

[in] ENUM_SVDQRP_A enumeration value defining the accuracy level of the SVD computation.

jobp

[in] ENUM_SVDQRP_P enumeration value defining the use of row reversal during the computation process.

jobr

[in] ENUM_SVDQRP_R enumeration value defining whether to transpose the triangular matrix R obtained as a result of the initial QR factorization.

jobu

[in] ENUM_SVDQRP_U enumeration value that determines how the left singular vectors should be computed.

jobv

[in] ENUM_SVDQRP_V enumeration value defining how the right singular vectors should be computed.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

VT

[out] Matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The number of matrix rows must not be less than the number of columns.

If both left and right singular vectors are computed, jobv must be set to SVDQRPV_R when jobu=SVDQRPU_R.

ENUM_SVDQRP_A

An enumeration that specifies the level of accuracy of the SVD computation.

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDQRP_A	The requested accuracy corresponds to the inverse error limited by epsilon. This is an aggressive level of truncation.
SVDQRPA_M	Similar to SVDQRP_A, but the truncation is softer. This is the average level of truncation.
SVDQRPA_H	High accuracy is required.

ENUM_SVDQRP_P

An enumeration that specifies whether to use row reversal during calculation.

ID	Description
SVDQRPP_P	The rows of A are ordered in descending order. Recommended for numerical reliability.
SVDQRPP_N	No row reversal.

ENUM_SVDQRP_R

An enumeration that specifies whether to transpose the triangular matrix R obtained as a result of the initial QR factorization.

ID	Description
SVDQRPR_T	After the initial rotated QR factorization, GESVD is applied to the transpose R**T of the calculated triangular factor R.
SVDQRPR_N	The triangular factor R is given as input to GESVD.

ENUM_SVDQRP_U

An enumeration defining how left singular vectors should be computed.

ID	Description
SVDQRPU_A	All M left singular vectors are computed.
SVDQRPU_S	The min(M,N) left singular vectors are computed.
SVDQRPU_R	The numerical rank NUMRANK is determined and only the NUMRANK of the left singular vectors is computed.
SVDQRPU_F	N left singular vectors are returned.
SVDQRPU_N	Left singular vectors are not computed.

ENUM_SVDQRP_V

An enumeration defining how right singular vectors should be computed.

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDQRPV_A	All N right singular vectors are computed.
SVDQRPV_R	The numerical rank NUMRANK is defined and only the NUMRANK of right singular vectors are computed.
SVDQRPV_N	Right singular vectors are not computed.

SingularValueDecompositionBisect

Singular Value Decomposition, bisection algorithm (lapack function GESVDX).

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionBisect(
   ENUM_SVD_VECTORS     jobv,      // computation accuracy level
   ENUM_BLAS_RANGE      range,     // subset of computable singular values
   double               lower,     // lower limit of the subset
   double               upper,     // upper limit of the subset
   vector&              S,         // vector of computed singular values
   matrix&              U,         // matrix of computed left vectors U
   matrix&              VT         // transposed matrix of right vectors VT
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionBisect(
   ENUM_SVD_VECTORS     jobv,      // computation accuracy level
   ENUM_BLAS_RANGE      range,     // subset of computable singular values
   double               lower,     // lower limit of the subset
   double               upper,     // upper limit of the subset
   vectorf&             S,         // vector of computed singular values
   matrixf&             U,         // matrix of computed left vectors U
   matrixf&             VT         // ransposed matrix of right vectors VT
   );
```

Computing for type matrix<complex>

```
bool  matrix::SingularValueDecompositionBisect(
   ENUM_SVD_VECTORS     jobv,      // computation accuracy level
   ENUM_BLAS_RANGE      range,     // subset of computable singular values
   double               lower,     // lower limit of the subset
   double               upper,     // upper limit of the subset
   vector&              S,         // vector of computed singular values
   matrixc&             U,         // matrix of computed left vectors U
   matrixc&             VT         // transposed matrix of right vectors VT
   );
```

Computing for type matrix<complexf>

```
bool  matrix::SingularValueDecompositionBisect(
   ENUM_SVD_VECTORS     jobv,               // computation accuracy level
   ENUM_BLAS_RANGE      range,              // subset of computable singular values
   double               lower,              // lower limit of the subset
   double               upper,              // upper limit of the subset
   vectorf&             singular_values,    // vector of computed singular values
   matrixcf&            u,                  // matrix of computed left vectors U
   matrixcf&            vt                  // transposed matrix of right vectors VT
```

© 2000-2025, MetaQuotes Ltd.

```
   );
```

Parameters

jobv

[in] ENUM_SVD_VECTORS enumeration value which determines the method for computing left and singular eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable singular values and vectors.

lower

[in] The lower limit of singular values subset; specified depending on the value of the range parameter.

upper

[in] The upper limit of singular values subset; specified depending on the value of the range parameter.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

VT

[out] Matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobuv* and *range* parameters.

When BLASRANGE_A is set, all singular values are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those singular values (and their vectors) that fall within the range of real values specified by the 'lower' and 'upper' parameters are computed.

With the BLASRANGE_I value, only those singular values (and their vectors) that fall within the range of integer indices specified by the 'lower' and 'upper' parameters are computed. For example, with lower=0 and upper=2, only the first three singular values are computed.

ENUM_SVD_VECTORS

An enumeration defining the way to compute left and right singular vectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDVECTORS_N	Only singular values are computed, without vectors.
SVDVECTORS_U	Left singular vectors are computed.
SVDVECTORS_V	Right singular vectors are computed.
SVDVECTORS_UV	Left and right singular vectors are computed.

ENUM_BLAS_RANGE

An enumeration defining a subset of computable singular values and vectors.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	Singular or eigenvalues from IL to IU will be found

   ENUM_SVDJH_V    jobv,                  // how to compute right vectors
   ENUM_SVDJH_R    jobr,                  // define range of computable singular valu
   ENUM_SVDJH_T    jobt,                  // define whether to transpose when computi
   ENUM_SVDJH_P    jobp,                  // the possibility of structured perturbati
   vectorf&        singular_values,       // vector of computed singular values S
   matrixcf&       u,                     // matrix of computed left vectors U
   matrixcf&       v,                     // matrix of computed left vectors V
   vectorf&        work_results           // additional computation results
   );
```

Parameters

joba

[in] ENUM_SVDJH_A enumeration value determining the accuracy level of the SVD computation.

jobu

[in] ENUM_SVDJH_U enumeration value that determines how the left singular vectors should be computed.

jobv

[in] ENUM_SVDJH_V enumeration value that determines how the right singular vectors should be computed.

jobr

[in] ENUM_SVDJH_R enumeration value defining the range of computable values

jobt

[in] ENUM_SVDJH_T enumeration value defining whether to transpose the matrix of it is square. If the matrix is non-square, this parameter is ignored.

jobp

[in] ENUM_SVDJH_P enumeration value defining the possibility of structured perturbations to remove denormalized values.

S

[out] Vector of singular values.

For work(1)/work(2) = one: the singular values of A. During the computation S contains Euclidean column norms of the iterated matrices in the array a.

For work(1)≠work(2): the singular values of A are (work(1)/work(2)) * S(1:n). This factored form is used if sigma_max(A) overflows or if small singular values have been saved from underflow by scaling the input matrix A.

jobr = 'R', some of the singular values may be returned as exact zeros obtained by 'setting to zero' because they are below the numerical rank threshold or are denormalized numbers.

U

© 2000-2025, MetaQuotes Ltd.

[out] Matrix of left singular vectors.

V

[out] Matrix of right singular vectors.

work_results

[out] Vector consisting of 7 statistics obtained as a result of the computation.

work(1) = scale = work(2)/work(1) is the scaling factor such that scale*sva(1:n) are the computed singular values of A. See the description of S.

work(2) = see the description of work(1).

work(3) = sconda is an estimate for the condition number of column equilibrated A. If joba = 'E' or 'G', sconda is an estimate of sqrt(||(R**t * R)**(-1)||_1). It is computed using ?pocon. It holds n**(-1/4) * sconda ≤ ||R**(-1)||_2 ≤ n**(1/4) * sconda, where R is the triangular factor from the QRF of A. However, if R is truncated and the numerical rank is determined to be strictly smaller than n, sconda is returned as -1, indicating that the smallest singular values might be lost.

If full SVD is needed, the following two condition numbers are useful for the analysis of the algorithm. They are provied for a user who is familiar with the details of the method.

work(4) = an estimate of the scaled condition number of the triangular factor in the first QR factorization.

work(5) = an estimate of the scaled condition number of the triangular factor in the second QR factorization.

The following two parameters are computed if jobt = 'T'. They are provided for a user who is familiar with the details of the method.

work(6) = the entropy of A**t*A :: this is the Shannon entropy of diag(A**t*A) / Trace(A**t*A) taken as point in the probability simplex.

work(7) = the entropy of A*A**t.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The number of matrix rows must not be less than the number of columns.

ENUM_SVDJH_A

An enumeration that specifies the level of accuracy of the SVD computation.

ID	Description
SVDJHA_C	Computation as with 'C' with an additional estimate of the condition number. It provides a realistic error bound.
SVDJHA_E	Computation as with SVDJHA_C' with an additional estimate of the condition number. It provides a realistic error bound.

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDJHA_F	Higher accuracy than the SVDJHA_C option.
SVDJHA_G	Computation as with SVDJHA_F with an additional estimate of the condition number.
SVDJHA_A	Small singular values are the noise and the matrix is treated as numerically rank deficient.
SVDJHA_R	Similar as in SVDJHA_A, but more accuracy.

ENUM_SVDJH_U

An enumeration defining how left singular vectors should be computed.

ID	Description
SVDJHU_U	N columns of U are returned in the array U.
SVDJHU_F	Full set of M left singular vectors is returned in the array U.
SVDJHU_N	U is not computed.

ENUM_SVDJH_V

An enumeration defining how right singular vectors should be computed.

ID	Description
SVDJHV_V	N columns of V are returned in the array V
SVDJHV_J	N columns of V are returned in the array V, but they are computed as the product of Jacobi rotations
SVDJHV_N	V is not computed

ENUM_SVDJH_R

An enumeration that defines the range of values to be computed.

ID	Description
SVDJHR_N	Do not kill small columns of c*A.
SVDJHR_R	RESTRICTED range for sigma(c*A). This option is recommended.

ENUM_SVDJH_T

An enumeration that specifies whether a matrix should be transposed if it is square.

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDJHT_T	Transpose if entropy test indicates possibly faster convergence of Jacobi process.
SVDJHT_N	Do not use transposition. Do not speculate.

ENUM_SVDJH_P

An enumeration that specifies the possibility of structured perturbations to remove denormalized values.

ID	Description
SVDJHP_P	Introduce perturbation.
SVDJHP_N	Do not perturb.

SingularValueDecompositionJacobiLow

Singular Value Decomposition, Jacobi low level algorithm (lapack function GESVJ). The method computes small singular values and their singular vectors with much greater accuracy than other SVD routines in certain cases.

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionJacobiLow(
   ENUM_SVDJH_U   jobu,            // how to compute left vectors
   ENUM_SVDJH_V   jobv,            // how to compute right vectors
   double         ctol,            // threshold for convergence if jobu='C'
   ulong          mv,              // number of first rows of matrix V if jobv='A'
   vector&        S,               // vector of computed singular values
   matrix&        U,               // matrix of computed left vectors U
   matrix&        V,               // matrix of computed left vectors V
   vector&        work_results     // additional computation results
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionJacobiLow(
   ENUM_SVDJH_U   jobu,            // how to compute left vectors
   ENUM_SVDJH_V   jobv,            // how to compute right vectors
   double         ctol,            // threshold for convergence if jobu='C'
   ulong          mv,              // number of first rows of matrix V if jobv='A'
   vectorf&       S,               // vector of computed singular values
   matrixf&       U,               // U matrix of computed left vectors
   matrixf&       V,               // V matrix of computed left vectors
   vector&        work_results     // additional computation results
   );
```

Computing for type matrix<complex>

```
bool  matrix::SingularValueDecompositionJacobiLow(
   ENUM_SVDJH_U   jobu,            // how to compute left vectors
   ENUM_SVDJH_V   jobv,            // how to compute right vectors
   double         ctol,            // threshold for convergence if jobu='C'
   ulong          mv,              // number of first rows of matrix V if jobv='A'
   vector&        S,               // vector of computed singular values
   matrixc&       U,               // U matrix of computed left vectors
   matrixc&       V,               // V matrix of computed left vectors
   vector&        work_results     // additional computation results
   );
```

Computing for type matrix<complexf>

```
bool  matrix::SingularValueDecompositionJacobiLow(
   ENUM_SVDJH_U    jobu,                  // how to compute left vectors
   ENUM_SVDJH_V    jobv,                  // how to compute right vectors
```

© 2000-2025, MetaQuotes Ltd.

```
   double          ctol,                  // threshold for convergence if jobu='C'
   ulong           mv,                    // number of first rows of matrix V if jobv
   vectorf&        singular_values,       // vector of computed singular values S
   matrixcf&       u,                     // matrix of computed left vectors U
   matrixcf&       v,                     // matrix of computed left vectors V
   vectorf&        work_results           // additional computation results
   );
```

Parameters

jobu

[in] ENUM_SVDJL_U enumeration value that determines how the left singular vectors should be computed.

jobv

[in] ENUM_SVDJL_V enumeration value defining how the right singular vectors should be computed.

ctol

[in] Convergence threshold if jobu=SVDJLU_C. For other values of 'jobu' the parameter is ignored.

mv

[in] Number of rows of matrix V to be computed if jobv=SVDJLV_A. For other values of 'jobv' the parameter is ignored.

S

[out] Vector of singular values.

Depending on the value scale = work(1), where scale is the scaling factor:

if scale = 1, S(1:n) contains the computed singular values of a. During the computation, sva contains the Euclidean column norms of the iterated matrices in the array a.

if scale ≠ 1, the singular values of a are scale*S(1:n), and this factored representation is due to the fact that some of the singular values of a might underflow or overflow.

U

[out] Matrix of left singular vectors.

V

[out] Matrix of right singular vectors (non-transposed).

work_results

[out] Vector consisting of 7 statistics obtained as a result of the computation.

work(1) = scale is the scaling factor such that scale*S(1:n) are the computed singular values of A. See the description of S).

work(2) is the number of the computed nonzero singular value.

work(3) is the number of the computed singular values that are larger than the underflow threshold.

work(4) is the number of sweeps of Jacobi rotations needed for numerical convergence.

© 2000-2025, MetaQuotes Ltd.

work(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep. This is useful information in cases when ?gesvj did not converge, as it can be used to estimate whether the output is still useful and for post festum analysis.

work(6) is the largest absolute value over all sines of the Jacobi rotation angles in the last sweep. It can be useful in a post festum analysis.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The number of matrix rows must not be less than the number of columns.

ENUM_SVDJL_U

An enumeration defining how left singular vectors should be computed.

ID	Description
SVDJLU_U	The left singular vectors corresponding to the nonzero singular values are computed and returned in the leading columns of A
SVDJLU_C	Analogous to SVDJLU_U, except that user can control the level of numerical orthogonality of the computed left singular vectors.
SVDJLU_N	The matrix U is not computed.

ENUM_SVDJL_V

An enumeration defining how right singular vectors should be computed.

ID	Description
SVDJLV_V	The matrix V is computed
SVDJLV_A	The Jacobi rotations are applied to the MV-by-N matrix V.
SVDJLV_N	The matrix V is not computed.

SingularValueDecompositionBidiagDC

Singular Value Decomposition, divide-and-conquer algorithm for bidiagonal matrices (lapack function BDSDC).

Computing for type matrix<double>

```
bool  matrix::SingularValueDecompositionBidiagDC(
   ENUM_SVDBIDIAG_Z     jobz,        // how to compute left vectors
   ENUM_BLAS_RANGE      range,       // subset of computed singular values
   double               lower,       // lower limit of the subset
   double               upper,       // upper limit of the subset
   vector&              S,           // vector of computed singular values
   matrix&              U,           // U matrix of computed left vectors
   matrix&              VT           // VT transposed matrix of right vectors
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionBidiagDC(
   ENUM_SVDBIDIAG_Z     jobz,        // how to compute left vectors
   ENUM_BLAS_RANGE      range,       // subset of computed singular values
   double               lower,       // lower limit of the subset
   double               upper,       // upper limit of the subset
   vectorf&             S,           // vector of computed singular values
   matrixf&             U,           // U matrix of computed left vectors
   matrixf&             VT           // VT transposed matrix of right vectors
   );
```

Parameters

jobz

[in] ENUM_SVDBIDIAG_Z enumeration value that determines how the left singular vectors should be computed.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable singular values and vectors.

lower

[in] The lower limit of singular values subset; specified depending on the value of the range parameter.

upper

[in] The upper limit of singular values subset; specified depending on the value of the range parameter.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

© 2000-2025, MetaQuotes Ltd.

V

[out] Transposed matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the jobz and range parameters.

When BLASRANGE_A is set, all singular values are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those singular values (and their vectors) that fall within the range of real values specified by the 'lower' and 'upper' parameters are computed.

With the BLASRANGE_I value, only those singular values (and their vectors) that fall within the range of integer indices specified by the 'lower' and 'upper' parameters are computed. For example, with lower=0 and upper=2, only the first three singular values are computed.

A bidiagonal matrix is a square matrix with non-zero main diagonal and one of the sub-diagonals.

Upper bidiagonal matrix

```
[[x, x, 0, 0, 0],
 [0, x, x, 0, 0],
 [0, 0, x, x, 0],
 [0, 0, 0, x, x],
 [0, 0, 0, 0, x]]
```

Lower bidiagonal matrix

```
[[x, 0, 0, 0, 0],
 [x, x, 0, 0, 0],
 [0, x, x, 0, 0],
 [0, 0, x, x, 0],
 [0, 0, 0, x, x]]
```

ENUM_SVDBIDIAG_Z

An enumeration defining how left singular vectors should be computed.

ID	Description
SVDJOBZ_V	Compute singular values and singular vectors.
SVDJOBZ_N	Compute singular values only.

ENUM_BLAS_RANGE

© 2000-2025, MetaQuotes Ltd.

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

   double              upper,      // upper limit of the subset
   vector&             S,          // vector of computed singular values
   matrix&             U,          // U matrix of computed left vectors
   matrix&             VT          // VT transposed matrix of right vectors
   );
```

Computing for type matrix<float>

```
bool  matrix::SingularValueDecompositionBidiagBisect(
   ENUM_SVDBIDIAG_Z    jobz,       // how to compute left vectors
   ENUM_BLAS_RANGE     range,      // subset of computed singular values
   double              lower,      // lower limit of the subset
   double              upper,      // upper limit of the subset
   vectorf&            S,          // vector of computed singular values
   matrixf&            U,          // U matrix of computed left vectors
   matrixf&            VT          // VT transposed matrix of right vectors
   );
```

Parameters

jobz

[in] ENUM_SVDBIDIAG_Z enumeration value that determines how the left singular vectors should be computed.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable singular values and vectors.

lower

[in] The lower limit of singular values subset; specified depending on the value of the range parameter.

upper

[in] The upper limit of singular values subset; specified depending on the value of the range parameter.

S

[out] Vector of singular values.

U

[out] Matrix of left singular vectors.

© 2000-2025, MetaQuotes Ltd.

V

[out] Transposed matrix of right singular vectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

When BLASRANGE_A is set, all singular values are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those singular values (and their vectors) that fall within the range of real values specified by the 'lower' and 'upper' parameters are computed.

Eigen Values

The section features functions for computing eigenvalues and eigenvectors. It describes methods for solving standard linear algebra problems using the LAPACK library algorithms. These functions are efficient for matrix analysis, diagonalization, system stabilization, and other tasks.

- **EigenSolver**: The function is designed to compute the eigenvalues and eigenvectors of an arbitrary square matrix using the classical algorithm represented by the GEEV lapack function. This method is applied to a wide range of matrices, allowing the decomposition of matrices into their eigenvalues and eigenvectors.
- **EigenSymmetricDC**: The function for computing eigenvalues and eigenvectors of symmetric or Hermitian matrices using the divide-and-conquer algorithm. The lapack functions SYEVD and HEEVD enable the efficient handling of symmetric or Hermitian matrices, providing faster and more accurate processing of such matrices.

Function	Action
EigenSolver	Compute eigenvalues and eigenvectors of a regular square matrix using the classical algorithm (lapack function GEEV).
EigenSolverX	Compute eigenvalues and eigenvectors of a regular square matrix in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GEEVX).
EigenSolverShur	Compute eigenvalues, upper triangular matrix in Schur form, and matrix of Schur vectors (lapack function GEES). See also Schur decomposition.
EigenSolver2	Compute generalized eigenvalues and eigenvectors for a pair of ordinary square matrices (lapack function GGEV).
EigenSolver2X	Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GGEVX). Both matrices must be the same size.
EigenSolver2Shur	Compute a pair of ordinary square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES).
EigenSolver2Blocked	Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices using a block algorithm (lapack function GGEV3). Both matrices must be the same size. The method parameters are exactly the same as EigenSolver2.

© 2000-2025, MetaQuotes Ltd.

Function	Action
EigenSolver2ShurBlocked	Compute a pair of regular square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES3).
EigenSymmetricDC	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the divide-and-conquer algorithm (lapack functions SYEVD, HEEVD).
EigenSymmetricQR	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the QR algorithm (lapack functions SYEV, HEEV).
EigenSymmetricRobust	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR, HEEVR).
EigenSymmetricBisect	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the bisection algorithm (lapack functions SYEVX, HEEVX).
EigenSymmetricDC2s	Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm (lapack functions SYEVD_2STAGE, HEEVD_2STAGE).
EigenSymmetricQR2s	Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal (lapack functions SYEV_2STAGE, HEEV_2STAGE).
EigenSymmetricRobust2s	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal then using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR_2STAGE, HEEVR_2STAGE).
EigenSymmetricBisect2s	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal then using the bisection algorithm (lapack functions SYEVX_2STAGE, HEEVX_2STAGE).

© 2000-2025, MetaQuotes Ltd.

Function	Action
EigenSymmetric2DC	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.
EigenSymmetric2QR	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.
EigenSymmetric2Bisect	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.
EigenTridiagonalDC	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEVD).
EigenTridiagonalQR	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEV).
EigenTridiagonalRobust	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack function STEVR).
EigenTridiagonalBisect	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the bisection algorithm (lapack function STEVX).
EigenTridiagonalQL	Compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm (lapack function STERF).
EigenTridiagonalDCQ	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEDC).
EigenTridiagonalQRQ	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEQR).
EigenTridiagonalPosDefQ	Compute eigenvalues and eigenvectors of a symmetric positive definite (положительно определённая) tridiagonal matrix using the QR algorithm (lapack function PTEQR).

© 2000-2025, MetaQuotes Ltd.

General Matrices

Functions for calculating eigenvalues and eigenvectors of a square matrix using classical algorithms. It provides various methods for working with both real and complex matrices, allowing you to solve linear algebra problems with a choice of methods for calculating eigenvectors.

Function	Action
EigenSolver	Compute eigenvalues and eigenvectors of a regular square matrix using the classical algorithm (lapack function GEEV).
EigenSolverX	Compute eigenvalues and eigenvectors of a regular square matrix in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GEEVX).
EigenSolverShur	Compute eigenvalues, upper triangular matrix in Schur form, and matrix of Schur vectors (lapack function GEES). See also Schur decomposition.
EigenSolver2	Compute generalized eigenvalues and eigenvectors for a pair of ordinary square matrices (lapack function GGEV).
EigenSolver2X	Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GGEVX). Both matrices must be the same size.
EigenSolver2Shur	Compute a pair of ordinary square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES).
EigenSolver2Blocked	Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices using a block algorithm (lapack function GGEV3). Both matrices must be the same size. The method parameters are exactly the same as EigenSolver2.
EigenSolver2ShurBlocked	Compute a pair of regular square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES3).

© 2000-2025, MetaQuotes Ltd.

EigenSolver

Compute eigenvalues and eigenvectors of a regular square matrix using the classical algorithm (lapack function GEEV).

Computing for type matrix<double>

```
bool  matrix::EigenSolver(
   ENUM_EIG_VECTORS      jobv,                 // compute left and right eigenvecto
   vectorc&              eigen_values,         // vector of computed eigenvalues
   matrix&               left_eigenvectors,    // matrix of computed left vectors
   matrix&               right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolver(
   ENUM_EIG_VECTORS      jobv,                 // compute left and right eigenvecto
   vectorcf&             eigen_values,         // vector of computed eigenvalues
   matrixf&              left_eigenvectors,    // matrix of computed left vectors
   matrixf&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSolver(
   ENUM_EIG_VECTORS      jobv,                 // compute left and right vectors
   vectorc&              eigen_values,         // vector of computed eigenvalues
   matrixc&              left_eigenvectors,    // matrix of computed left vectors
   matrixc&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolver(
   ENUM_EIG_VECTORS      jobv,                 // compute left and right vectors
   vectorcf&             eigen_values,         // vector of computed eigenvalues
   matrixcf&             left_eigenvectors,    // matrix of computed left vectors
   matrixcf&             right_eigenvectors    // matrix of computed right vectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

EV

[out] Vector of eigenvalues.

left_eigenvectors

[out] Matrix of left eigenvectors.

© 2000-2025, MetaQuotes Ltd.

right_eigenvectors

[out] Matrix of right eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobv parameter.

If EIGVECTORS_N is set, the left and right vectors are not computed. Only eigenvalues are computed.

With EIGVECTORS_L, only left eigenvectors are computed, right eigenvectors are not computed.

When EIGVECTORS_R is set, only the right eigenvectors are computed, the left vectors are not computed.

With EIGVECTORS_LR, the left and right eigenvectors are computed, Eigenvalues are always computed.

Real (non-complex) matrices can have a complex solution. Therefore, the vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

ENUM_EIG_VECTORS

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are calculated, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

© 2000-2025, MetaQuotes Ltd.

EigenSolverX

Compute eigenvalues and eigenvectors of a regular square matrix in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GEEVX).

Computing for type matrix<double>

```
bool  matrix::EigenSolverX(
   ENUM_EIG_BALANCE      balance,                // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                   // determines computation of right a
   ENUM_EIG_SENSE        sense,                  // determines computation of recipr
   vectorc&              eigen_values,           // vector of computed eigenvalues
   matrix&               left_eigenvectors,      // matrix of computed left vectors
   matrix&               right_eigenvectors      // matrix of computed right vectors
   matrix&               shur_matrix,            // balanced matrix in Schur form
   long&                 ilo,                    // subscript of balanced matrix
   long&                 ihi,                    // superscript of balanced matrix
   vector&               scale,                  // details of permutations and scali
   double&               ab_norm,                // 1-norm of balanced matrix
   vector&               rconde,                 // vector of reciprocal condition nu
   vector&               rcondv                  // vector of reciprocal condition nu
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolverX(
   ENUM_EIG_BALANCE      balance,                // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                   // determines computation of right a
   ENUM_EIG_SENSE        sense,                  // determines computation of recipr
   vectorcf&             eigen_values,           // vector of computed eigenvalues
   matrixf&              left_eigenvectors,      // matrix of computed left vectors
   matrixf&              right_eigenvectors      // matrix of computed right vectors
   matrixf&              shur_matrix,            // balanced matrix in Schur form
   long&                 ilo,                    // subscript of balanced matrix
   long&                 ihi,                    // superscript of balanced matrix
   vectorf&              scale,                  // details of permutations and scali
   float&                ab_norm,                // 1-norm of balanced matrix
   vectorf&              rconde,                 // vector of reciprocal condition nu
   vectorf&              rcondv                  // vector of reciprocal condition nu
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSolverX(
   ENUM_EIG_BALANCE      balance,                // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                   // determines computation of right a
   ENUM_EIG_SENSE        sense,                  // determines computation of recipr
   vectorc&              eigen_values,           // vector of computed eigenvalues
```

© 2000-2025, MetaQuotes Ltd.

```
   matrixc&              left_eigenvectors,       // matrix of computed left vectors
   matrixc&              right_eigenvectors       // matrix of computed right vectors
   matrixc&              shur_matrix,             // balanced matrix in Schur form
   long&                 ilo,                     // subscript of balanced matrix
   long&                 ihi,                     // superscript of balanced matrix
   vector&               scale,                   // details of permutations and scali
   double&               ab_norm,                 // 1-norm of balanced matrix
   vector&               rconde,                  // vector of reciprocal condition nu
   vector&               rcondv                   // vector of reciprocal condition nu
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolverX(
   ENUM_EIG_BALANCE      balance,                 // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                    // determines computation of right a
   ENUM_EIG_SENSE        sense,                   // determines computation of recipro
   vectorcf&             eigen_values,            // vector of computed eigenvalues
   matrixcf&             left_eigenvectors,       // matrix of computed left vectors
   matrixcf&             right_eigenvectors       // matrix of computed right vectors
   matrixcf&             shur_matrix,             // balanced matrix in Schur form
   long&                 ilo,                     // subscript of balanced matrix
   long&                 ihi,                     // superscript of balanced matrix
   vectorf&              scale,                   // details of permutations and scali
   float&                ab_norm,                 // 1-norm of balanced matrix
   vectorf&              rconde,                  // vector of reciprocal condition nu
   vectorf&              rcondv                   // vector of reciprocal condition nu
   );
```

Parameters

balance

[in] Value from the ENUM_EIG_BALANCE enumeration which determines the need and method for balancing the input matrix; it is used to improve the conditioning of the eigenvalues and eigenvectors.

jobv

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

sense

[in] Value from the ENUM_EIG_SENSE enumeration determining the need to compute reciprocal condition numbers.

eigen_values

[out] Vector of eigenvalues.

left_eigenvectors

[out] Matrix of left eigenvectors.

right_eigenvectors

© 2000-2025, MetaQuotes Ltd.

[out] Matrix of right eigenvectors.

shur_matrix

[out] Balanced matrix in Schur form; the matrix is not filled if neither left nor right eigenvectors are computed.

ilo

[out] Subscript of the balanced matrix; the matrix is not filled if no balancing is applied.

ihi

[out] Superscript of the balanced matrix; the matrix is not filled if no balancing is applied.

scale

[out] Vector of details of permutations and scaling when balancing the input matrix.

Details of the permutations and scaling factors applied when balancing A.

If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then

scale(j) = P(j), for j = 1,...,ilo-1

= D(j), for j = ilo,...,ihi

= P(j) for j = ihi+1,..., n.

The order in which the interchanges are made is n to ihi+1, then 1 to ilo-1.

ab_norm

[out] 1-norm of the balanced matrix (the maximum of the sum of absolute values of elements in any of the matrix columns).

rconde

[out] Vector of reciprocal condition numbers for each eigenvalue; it is computed if the 'sense' parameter is set to 'E' or 'B'.

rcondv

[out] Vector of reciprocal condition numbers for each eigenvector; it is computed if the 'sense' parameter is set to 'V' or 'B.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Input matrix balancing depends on the value of the '*balance*' parameter.

ENUM_EIG_BALANCE

An enumeration defining the need to compute eigenvectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGBALANCE_N	Do not diagonally scale or permute
EIGBALANCE_P	Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale
EIGBALANCE_S	Diagonally scale the matrix. Do not permute
EIGBALANCE_B	Both diagonally scale and permute

ENUM_EIG_VECTORS

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

ENUM_EIG_SENSE

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGSENSE_N	None of reciprocal condition numbers are computed
EIGSENSE_E	Computed for eigenvalues only
EIGSENSE_V	Computed for right eigenvectors only
EIGSENSE_B	Computed for eigenvalues and right eigenvectors

© 2000-2025, MetaQuotes Ltd.

EigenSolverShur

Compute eigenvalues, upper triangular matrix in Schur form, and matrix of Schur vectors (lapack function GEES). See also Schur decomposition.

Computing for type matrix<double>

```
bool  matrix::EigenSolverShur(
   ENUM_EIG_VECTORS      jobvs,                  // method to compute Shur vectors
   vectorc&              eigen_values,           // vector of computed eigenvalues
   matrix&               shur_matrix,            // matrix in Schur form
   matrix&               shur_vectors            // matrix of Schur vectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolverShur(
   ENUM_EIG_VECTORS      jobvs,                  // method to compute Shur vectors
   vectorcf&             eigen_values,           // vector of computed eigenvalues
   matrixf&              shur_matrix,            // matrix in Schur form
   matrixf&              shur_vectors            // matrix of Schur vectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSolverShur(
   ENUM_EIG_VECTORS      jobvs,                  // method to compute Shur vectors
   vectorc&              eigen_values,           // vector of computed eigenvalues
   matrixc&              shur_matrix,            // matrix in Schur form
   matrixc&              shur_vectors            // matrix of Schur vectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolverShur(
   ENUM_EIG_VECTORS      jobvs,                  // method to compute Shur vectors
   vectorcf&             eigen_values,           // vector of computed eigenvalues
   matrixcf&             shur_matrix,            // matrix in Schur form
   matrixcf&             shur_vectors            // matrix of Schur vectors
   );
```

Parameters

jobvs

[in] Value from the ENUM_EIG_SHUR enumeration, which defines the method for computing Shur vectors.

eigen_values

[out] Vector of eigenvalues.

shur_matrix

[out] Upper triangular Schur matrix (Schur form for the input matrix).

© 2000-2025, MetaQuotes Ltd.

shur_vectors

[out] Matrix of Schur vectors; it is not computed if the *jobvs* parameter is set to N.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the *jobvs* parameter values.

Real (non-complex) matrices can have a complex solution. Therefore, the input vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

EigenSolverShur

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGSHUR_N	Schur vectors are not computed
EIGSHUR_V	Schur vectors are computed

© 2000-2025, MetaQuotes Ltd.

EigenSolver2

Compute generalized eigenvalues and eigenvectors for a pair of ordinary square matrices (lapack function GGEV). Both matrices must be the same size.

Computing for type matrix<double>

```
bool  matrix::EigenSolver2(
   matrix&               B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorc&              alpha,                // vector of computed eigenvalues
   vector&               beta,                 // vector of eigenvalue divisors
   matrix&               left_eigenvectors,    // matrix of computed left vectors
   matrix&               right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolver2(
   matrix&               B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorcf&             alpha,                // vector of computed eigenvalues
   vectorf&              beta,                 // vector of eigenvalue divisors
   matrixf&              left_eigenvectors,    // matrix of computed left vectors
   matrixf&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSolver2(
   matrixc&              B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorc&              alpha,                // vector of computed eigenvalues
   vectorc&              beta,                 // vector of eigenvalue divisors
   matrixc&              left_eigenvectors,    // matrix of computed left vectors
   matrixc&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolver2(
   matrixcf&             B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorcf&             alpha,                // vector of computed eigenvalues
   vectorcf&             beta,                 // vector of eigenvalue divisors
   matrixcf&             left_eigenvectors,    // matrix of computed left vectors
   matrixcf&             right_eigenvectors    // matrix of computed right vectors
   );
```

Parameters

© 2000-2025, MetaQuotes Ltd.

B

[in] The second matrix in the pair.

jobv

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

alpha

[out] Vector of eigenvalues.

beta

[out] Vector of eigen value divisors.

left_eigenvectors

[out] Matrix of left eigenvectors.

right_eigenvectors

[out] Matrix of right eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobv parameter.

ENUM_EIG_VECTORS

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

A * v(j) = lambda(j) * B * v(j).

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

u(j)**H * A = lambda(j) * u(j)**H * B .

© 2000-2025, MetaQuotes Ltd.

where u(j)**H is the conjugate-transpose of u(j).

Real (non-complex) matrices can have a complex solution. Therefore, the input vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

© 2000-2025, MetaQuotes Ltd.

EigenSolver2X

Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices in Expert mode, i.e. with the ability to influence the computation algorithm and the ability to obtain accompanying computation data (lapack function GGEVX). Both matrices must be the same size.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

Computing for type matrix<double>

```
bool  matrix::EigenSolver2X(
   matrix&               B,                    // second matrix in the pair
   ENUM_EIG_BALANCE      balance,              // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                 // determines computation of right a
   ENUM_EIG_SENSE        sense,                // determines computation of recipro
   vectorc&              alpha,                // vector of computed eigenvalues
   vector&               beta,                 // vector of eigenvalue divisors
   matrix&               left_eigenvectors,    // matrix of computed left vectors
   matrix&               right_eigenvectors    // matrix of computed right vectors
   matrix&               shur_matrix1,         // the first part of the real Schur
   matrix&               shur_matrix2,         // the second part of the real Schu
   long&                 ilo,                  // subscript of balanced matrix
   long&                 ihi,                  // superscript of balanced matrix
   vector&               lscale,               // details of the permutations and s
   vector&               rscale,               // details of the permutations and s
   double&               ab_norm,              // one-norm of balanced input matri
   double&               bb_norm,              // one-norm of balanced second matr
   vector&               rconde,               // vector of reciprocal condition nu
   vector&               rcondv                // vector of reciprocal condition nu
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolver2X(
   matrixf&              B,                    // second matrix in the pair
   ENUM_EIG_BALANCE      balance,              // input matrix balancing method
   ENUM_EIG_VECTORS      jobv,                 // determines computation of right a
   ENUM_EIG_SENSE        sense,                // determines computation of recipro
   vectorcf&             alpha,                // vector of computed eigenvalues
   vectorf&              beta,                 // vector of eigenvalue divisors
   matrixf&              left_eigenvectors,    // matrix of computed left vectors
   matrixf&              right_eigenvectors    // matrix of computed right vectors
   matrixf&              shur_matrix1,         // the first part of the real Schur
   matrixf&              shur_matrix2,         // the second part of the real Schu
   long&                 ilo,                  // subscript of balanced matrix
   long&                 ihi,                  // superscript of balanced matrix
   vectorf&              lscale,               // details of the permutations and s
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf&              rscale,                 // details of the permutations and s
   float&                ab_norm,                // one-norm of balanced input matrix
   float&                bb_norm,                // one-norm of balanced second matri
   vectorf&              rconde,                 // vector of reciprocal condition nu

   );
```

Parameters

B

[in] The second matrix in the pair.

balance

[in] Value from the ENUM_EIG_BALANCE enumeration which determines the need and method for balancing the input matrix; it is used to improve the conditioning of the eigenvalues and eigenvectors.

jobv

[in] Value from the ENUM_EIG_VECTORS enumeration which determines the method for computing left and right eigenvectors.

sense

[in] Value from the ENUM_EIG_SENSE enumeration which determines the need to compute reciprocal condition numbers.

eigen_values

[out] Vector of eigenvalues.

left_eigenvectors

[out] Matrix of left eigenvectors.

right_eigenvectors

[out] Matrix of right eigenvectors.

shur_matrix1, shur_matrix2

[out] 2 parts of balanced matrix in Schur form; the matrix is not filled if neither left nor right eigenvectors are computed.

ilo

[out] Subscript of the balanced matrix; the matrix is not filled if no balancing is applied.

ihi

[out] Superscript of the balanced matrix; the matrix is not filled if no balancing is applied.

lscale

[out] Vector contains details of the permutations and scaling factors applied to the left side of A and B.

If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then

lscale(j) = PL(j), for j = 1,..., ilo-1

= DL(j), for j = ilo,...,ihi

= PL(j) for j = ihi+1,..., n.

© 2000-2025, MetaQuotes Ltd.

The order in which the interchanges are made is n to ihi+1, then 1 to ilo-1.

rscale

[out] Vector contains details of the permutations and scaling factors applied to the right side of A and B.

If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then

rscale(j) = PR(j), for j = 1,..., ilo-1

= DR(j), for j = ilo,...,ihi

= PR(j) for j = ihi+1,..., n.

The order in which the interchanges are made is n to ihi+1, then 1 to ilo-1.

ab_norm

[out] One-norm of the balanced input matrix (the maximum of the sum of absolute values of elements in any of the matrix columns).

bb_norm

[out] One-norm of balanced second matrix B.

rconde

[out] Vector of reciprocal condition numbers for each eigenvalue; it is computed if the 'sense' parameter is set to 'E' or 'B'.

rcondv

[out] Vector of reciprocal condition numbers for each eigenvector; it is computed if the 'sense' parameter is set to 'V' or 'B'.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

Input matrices balancing depends on the value of the *balance* parameter.

ENUM_EIG_BALANCE

An enumeration that specifies whether the matrices should be balanced.

ID	Description
EIGBALANCE_N	Do not diagonally scale or permute.
EIGBALANCE_P	Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale.
EIGBALANCE_S	Diagonally scale the matrix. Do not permute.
EIGBALANCE_B	Both diagonally scale and permute.

© 2000-2025, MetaQuotes Ltd.

ENUM_EIG_VECTORS

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

ENUM_EIG_SENSE

An enumeration determining the need to compute reciprocal condition numbers.

ID	Description
EIGSENSE_N	None of reciprocal condition numbers are computed.
EIGSENSE_E	Computed for eigenvalues only.
EIGSENSE_V	Computed for right eigenvectors only.
EIGSENSE_B	Computed for eigenvalues and right eigenvectors.

© 2000-2025, MetaQuotes Ltd.

EigenSolver2Shur

Compute a pair of ordinary square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES).

Computes the generalized eigenvalues, the generalized real/complex Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (vsl and vsr) for a pair of n-by-n real/complex nonsymmetric matrices (A,B). This gives the generalized Schur factorization:

(A,B) = (vsl*S *vsrH, vsl*T*vsrH)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

Computing for type matrix<double>

```
bool  matrix::EigenSolver2Shur(
   matrix&                 B,         // second matrix in the pair
   ENUM_EIG_VECTORS        jobvs,     // method to compute left and right vectors
   vector&                 alpha,     // vector of computed eigenvalues
   vector&                 beta,      // vector of eigenvalue divisors
   matrix&                 shur_s,    // matrix S in Schur form
   matrix&                 shur_t,    // matrix T in Schur form
   matrix&                 vsl,       // matrix of left Schur vectors vsl
   matrix&                 vsr        // matrix of right Schur vectors vsr
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolver2Shur(
   matrixf&                B,         // second matrix in the pair
   ENUM_EIG_VECTORS        jobvs,     // method to compute left and right vectors
   vectorcf&               alpha,     // vector of computed eigenvalues
   vectorf&                beta,      // vector of eigenvalue divisors
   matrixf&                shur_s,    // matrix S in Schur form
   matrixf&                shur_t,    // matrix T in Schur form
   matrixf&                vsl,       // matrix of left Schur vectors vsl
   matrixf&                vsr        // matrix of right Schur vectors vsr
   );
```

Computing for type matrix<complex>

```
bool  matrix::EigenSolver2Shur(
   matrixc&                B,         // second matrix in the pair
   ENUM_EIG_VECTORS        jobvs,     // method to compute left and right vectors
   vectorc&                alpha,     // vector of computed eigenvalues
   vectorc&                beta,      // vector of eigenvalue divisors
   matrixc&                shur_s,    // matrix S in Schur form
   matrixc&                shur_t,    // matrix T in Schur form
```

© 2000-2025, MetaQuotes Ltd.

```
   matrixc&                vsl,       // matrix of left Schur vectors vsl
   matrixc&                vsr        // matrix of right Schur vectors vsr
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolver2Shur(
   matrixcf&               B,         // second matrix in the pair
   ENUM_EIG_VECTORS        jobvs,     // method to compute left and right vectors
   vectorcf&               alpha,     // vector of computed eigenvalues
   vectorcf&               beta,      // vector of eigenvalue divisors
   matrixcf&               shur_s,    // matrix S in Schur form
   matrixcf&               shur_t,    // matrix T in Schur form
   matrixcf&               vsl,       // matrix of left Schur vectors vsl
   matrixcf&               vsr        // matrix of right Schur vectors vsr
   );
```

Parameters

B

[out] The second matrix in the pair.

jobvs

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

alpha

[out] Vector of eigenvalues.

beta

[out] Vector of eigenvalue divisors.

shur_s

[out] Matrix S, block upper triangular Schur matrix (Schur form for the input matrix).

shur_t

[out] Matrix T, block upper triangular Schur matrix (Schur form for the second matrix in the pair).

vsl

[out] Matrix of left Schur vectors.

vsr

[out] Matrix of right Schur vectors.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

Computation depends on the *jobvs* parameter values.

© 2000-2025, MetaQuotes Ltd.

The second matrix in the pair must be the same size as the first (input) one.

Real (non-complex) matrices can have a complex solution. Therefore, the vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

EigenSolverShur

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

© 2000-2025, MetaQuotes Ltd.

EigenSolver2Blocked

Compute generalized eigenvalues and eigenvectors for a pair of regular square matrices using a block algorithm (lapack function GGEV3). Both matrices must be the same size. The method parameters are exactly the same as EigenSolver2.

Computing for type matrix<double>

```
bool  matrix::EigenSolver2Blocked(
   matrix&               B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorc&              alpha,                // vector of computed eigenvalues
   vector&               beta,                 // vector of eigenvalue divisors
   matrix&               left_eigenvectors,    // matrix of computed left vectors
   matrix&               right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSolver2Blocked(
   matrix&               B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorcf&             alpha,                // vector of computed eigenvalues
   vectorf&              beta,                 // vector of eigenvalue divisors
   matrixf&              left_eigenvectors,    // matrix of computed left vectors
   matrixf&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complex>

```
bool  matrix::EigenSolver2Blocked(
   matrixc&              B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorc&              alpha,                // vector of computed eigenvalues
   vectorc&              beta,                 // vector of eigenvalue divisors
   matrixc&              left_eigenvectors,    // matrix of computed left vectors
   matrixc&              right_eigenvectors    // matrix of computed right vectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSolver2(
   matrixcf&             B,                    // second matrix in the pair
   ENUM_EIG_VECTORS      jobv,                 // method to compute right and left
   vectorcf&             alpha,                // vector of computed eigenvalues
   vectorcf&             beta,                 // vector of eigenvalue divisors
   matrixcf&             left_eigenvectors,    // matrix of computed left vectors
   matrixcf&             right_eigenvectors    // matrix of computed right vectors
   );
```

Parameters

© 2000-2025, MetaQuotes Ltd.

B

[out] The second matrix in the pair.

jobv

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

alpha

[out] Vector of eigenvalues.

beta

[out] Vector of eigenvalue divisors.

left_eigenvectors

[out] Matrix of left eigenvectors.

righeft_eigenvectors

[out] Matrix of right eigenvectors.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

Computation depends on the value of the jobv parameter.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies:

A * v(j) = lambda(j) * B * v(j).

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies:

u(j)**H * A = lambda(j) * u(j)**H * B .

where u(j)**H is the conjugate-transpose of u(j).

Real (non-complex) matrices can have a complex solution. Therefore, the input vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

ENUM_EIG_VECTORS

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

© 2000-2025, MetaQuotes Ltd.

EigenSolver2ShurBlocked

Compute a pair of regular square matrices of generalized eigenvalues, generalized eigenvectors, generalized Schur forms, as well as left and right Schur vectors (lapack function GGES3).

Computes the generalized eigenvalues, the generalized real/complex Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR) for a pair of n-by-n real/complex nonsymmetric matrices (A,B). This gives the generalized Schur factorization:

(A,B) = (vsl*S *vsrH, vsl*T*vsrH)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of vsl and vsr then form an orthonormal/unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

Computing for type matrix<double>

```
bool  matrix::EigenSolver2ShurBlocked(
   matrix&                B,         // second matrix in the pair
   ENUM_EIG_VECTORS       jobvs,     // method to compute left and right vectors
   vectorc&               alpha,     // vector of computed eigenvalues
   vector&                beta,      // vector of eigenvalue divisors
   matrix&                shur_s,    // matrix S in Schur form
   matrix&                shur_t,    // matrix T in Schur form
   matrix&                vsl,       // matrix of left Schur vectors VSL
   matrix&                vsr        // matrix of right Schur vectors VSR
   );
```

Computing for type matrix<float>

```
bool  matrix::EigenSolver2ShurBlocked(
   matrixf&               B,         // second matrix in the pair
   ENUM_EIG_VECTORS       jobvs,     // method to compute left and right vectors
   vectorcf&              alpha,     // vector of computed eigenvalues
   vectorf&               beta,      // vector of eigenvalue divisors
   matrixf&               shur_s,    // matrix S in Schur form
   matrixf&               shur_t,    // matrix T in Schur form
   matrixf&               vsl,       // matrix of left Schur vectors VSL
   matrixf&               vsr        // matrix of right Schur vectors VSR
   );
```

Computing for type matrix<complex>

```
bool  matrix::EigenSolver2ShurBlocked(
   matrixc&               B,         // second matrix in the pair
   ENUM_EIG_VECTORS       jobvs,     // method to compute left and right vectors
   vectorc&               alpha,     // vector of computed eigenvalues
   vectorc&               beta,      // vector of eigenvalue divisors
   matrixc&               shur_s,    // matrix S in Schur form
   matrixc&               shur_t,    // matrix T in Schur form
```

© 2000-2025, MetaQuotes Ltd.

```
   matrixc&                vsl,       // matrix of left Schur vectors VSL
   matrixc&                vsr        // matrix of right Schur vectors VSR
   );
```

Computing for type matrix<complexf>

```
bool  matrix::EigenSolver2ShurBlocked(
   matrixcf&               B,         // second matrix in the pair
   ENUM_EIG_VECTORS        jobvs,     // method to compute left and right vectors
   vectorcf&               alpha,     // vector of computed eigenvalues
   vectorcf&               beta,      // vector of eigenvalue divisors
   matrixcf&               shur_s,    // matrix S in Schur form
   matrixcf&               shur_t,    // matrix T in Schur form
   matrixcf&               vsl,       // matrix of left Schur vectors VSL
   matrixcf&               vsr        // matrix of right Schur vectors VSR
   );
```

Parameters

B

[in] The second matrix in the pair.

jobvs

[in] ENUM_EIG_VECTORS enumeration value which determines the method for computing left and right eigenvectors.

alpha

[out] Vector of eigenvalues.

beta

[out] Vector of eigenvalue divisors.

shur_s

[out] Matrix S, block upper triangular Schur matrix (Schur form for the input matrix).

shur_t

[out] Matrix T, block upper triangular Schur matrix (Schur form for the second matrix in the pair).

vsl

[out] Matrix of left Schur vectors VSL.

vsr

[out] Matrix of right Schur vectors VSR.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

Computation depends on the *jobvs* parameter values.

© 2000-2025, MetaQuotes Ltd.

The second matrix in the pair must be the same size as the first (input) one.

Real (non-complex) matrices can have a complex solution. Therefore, the vector of eigenvalues must be complex. In case of a complex solution, the error code is set to 4019 (ERR_MATH_OVERFLOW). Otherwise, only the real parts of the complex values of the eigenvalue vector should be used.

EigenSolverShur

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVECTORS_N	Only eigenvalues are computed, without vectors.
EIGVECTORS_L	Only left eigenvectors are computed.
EIGVECTORS_R	Only right eigenvectors are computed.
EIGVECTORS_LR	Left and right eigenvectors are computed, eigenvalues are always computed.

© 2000-2025, MetaQuotes Ltd.

Symmetric Matrices

Functions for computing eigenvalues and eigenvectors of symmetric or Hermitian matrices using the divide and conquer algorithm, making the process efficient and fast. These methods can be applied to matrices of different data types, including real and complex numbers.

Function	Action
EigenSymmetricDC	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the divide-and-conquer algorithm (lapack functions SYEVD, HEEVD).
EigenSymmetricQR	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the QR algorithm (lapack functions SYEV, HEEV).
EigenSymmetricRobust	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR, HEEVR).
EigenSymmetricBisect	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugate) matrix using the bisection algorithm (lapack functions SYEVX, HEEVX).
EigenSymmetricDC2s	Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm (lapack functions SYEVD_2STAGE, HEEVD_2STAGE).
EigenSymmetricQR2s	Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal (lapack functions SYEV_2STAGE, HEEV_2STAGE).
EigenSymmetricRobust2s	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal then using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR_2STAGE, HEEVR_2STAGE).
EigenSymmetricBisect2s	Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction

© 2000-2025, MetaQuotes Ltd.

Function	Action
	to tridiagonal then using the bisection algorithm (lapack functions SYEVX_2STAGE, HEEVX_2STAGE).
EigenSymmetric2DC	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.
EigenSymmetric2QR	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.
EigenSymmetric2Bisect	Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricDC

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the divide-and-conquer algorithm (lapack functions SYEVD, HEEVD).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricDC(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricDC(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricDC(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricDC(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixcf&             eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated.

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricQR

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the QR algorithm (lapack functions SYEV, HEEV).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricQR(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricQR(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricQR(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricQR(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixcf&             eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated.

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricRobust

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR, HEEVR).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // Upper bound of the subset
   float                 abstol,            // absolute error tolerance
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf&              eigen_values,       // vector of computed eigenvectors
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

© 2000-2025, MetaQuotes Ltd.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricBisect

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the bisection algorithm (lapack functions SYEVX, HEEVX).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // Upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
```

© 2000-2025, MetaQuotes Ltd.

```
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

V

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

© 2000-2025, MetaQuotes Ltd.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricDC2s

Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal. If eigenvectors are desired, it uses a divide and conquer algorithm (lapack functions SYEVD_2STAGE, HEEVD_2STAGE).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricDC2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricDC2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricDC2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricDC2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixcf&             eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated. In the current OpenBLAS implementation, this value is not supported. Attempting to use it will result in error 4003 (ERR_INVALID_PARAMETER).

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated. Not available in this release.
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricQR2s

Compute all eigenvalues and, optionally, eigenvectors of a real symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal (lapack functions SYEV_2STAGE, HEEV_2STAGE).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricQR2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricQR2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricQR2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vector&               eigen_values,      // vector of computed eigenvalues
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricQR2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   vectorf&              eigen_values,      // vector of computed eigenvalues
   matrixcf&             eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated. In the current OpenBLAS implementation, this value is not supported. Attempting to use it will result in error 4003 (ERR_INVALID_PARAMETER).

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated. Not available in this release.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricRobust2s

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal then using the Multiple Relatively Robust Representations, MRRR algorithm (lapack functions SYEVR_2STAGE, HEEVR_2STAGE).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricRobust2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricRobust2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricRobust2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricRobust2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf&              eigen_values,       // vector of computed eigenvectors
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated. In the current OpenBLAS implementation, this value is not supported. Attempting to use it will result in error 4003 (ERR_INVALID_PARAMETER).

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

© 2000-2025, MetaQuotes Ltd.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated. Not available in this release.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetricBisect2s

Compute eigenvalues and eigenvectors of a symmetric or Hermitian (complex conjugated) matrix using the 2stage technique for the reduction to tridiagonal then using the bisection algorithm (lapack functions SYEVX_2STAGE, HEEVX_2STAGE).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetricBisect2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetricBisect2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetricBisect2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrixc&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetricBisect2s(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorf&             eigen_values,       // vector of computed eigenvectors
   matrixcf&            eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

V

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated. In the current OpenBLAS implementation, this value is not supported. Attempting to use it will result in error 4003 (ERR_INVALID_PARAMETER).

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

EigenSymmetric2DC

Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

Here A and B are assumed to be symmetric (Hermitian) and B is also positive definite. If eigenvectors are desired, it uses a divide-and-conquer algorithm (lapack functions SYGVD, HEGVD).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetric2DC(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrix&               B,                  // second matrix
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors,      // matrix of computed eigenvectors
   matrix&               triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetric2DC(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixf&              B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors,      // matrix of computed eigenvectors
   matrixf&              triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetric2DC(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixc&              B,                  // second matrix
   vector&               eigen_values,       // vector of computed eigenvalues
   matrixc&              eigen_vectors,      // matrix of computed eigenvectors
   matrixc&              triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetric2DC(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixcf&             B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors,      // matrix of computed eigenvectors
   matrixcf&             triangular_factor   // triangular factor from the Cholesky fa
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

itype

[in] ENUM_EIGS2_TYPE enumeration value which specified the problem type to be solved : A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

B

[in] Second matrix B. Must be positive definite symmetric (or Hermitian conjugated) matrix.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

triangular_factor

[out] The triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated). Second matrix B must be positive definite symmetric. If the input matrix and second matrix B are triangular, then both must be the same triangular, upper or lower.

ENUM_EIGS2_TYPE

An enumeration that specifies the problem type to be solved.

ID	Description
EIGS2TYPE_1	1: A*x = (lambda)*B*x
EIGS2TYPE_2	2: A*B*x = (lambda)*x
EIGS2TYPE_3	3: B*A*x = (lambda)*x

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetric2QR

Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

Here A and B are assumed to be symmetric (Hermitian) and B is also positive definite. This method uses QR algorithm (lapack functions SYGV, HEGV).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetric2QR(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrix&               B,                  // second matrix
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors,      // matrix of computed eigenvectors
   matrix&               triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetric2QR(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixf&              B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors,      // matrix of computed eigenvectors
   matrixf&              triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenSymmetric2QR(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixc&              B,                  // second matrix
   vector&               eigen_values,       // vector of computed eigenvalues
   matrixc&              eigen_vectors,      // matrix of computed eigenvectors
   matrixc&              triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetric2QR(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   matrixcf&             B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors,      // matrix of computed eigenvectors
   matrixcf&             triangular_factor   // triangular factor from the Cholesky fa
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

itype

[in] ENUM_EIGS2_TYPE enumeration value which specified the problem type to be solved : A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

B

[in] Second matrix B. Must be positive definite symmetric (or Hermitian conjugated) matrix.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

triangular_factor

[out] The triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated). Second matrix B must be positive definite symmetric. If the input matrix and second matrix B are triangular, then both must be the same triangular, upper or lower.

ENUM_EIGS2_TYPE

An enumeration that specifies the problem type to be solved.

ID	Description
EIGS2TYPE_1	1: A*x = (lambda)*B*x
EIGS2TYPE_2	2: A*B*x = (lambda)*x
EIGS2TYPE_3	3: B*A*x = (lambda)*x

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenSymmetric2Bisect

Compute all the eigenvalues, and optionally, the eigenvectors of a generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

Here A and B are assumed to be symmetric (Hermitian) and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues. This method uses bisection algorithm (lapack functions SYGVX, HEGVX).

Computing for type matrix<double>

```
bool  matrix::EigenSymmetric2Bisect(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,              // subset of eigenvalues to compute
   double                lower,              // lower bound of the subset
   double                upper,              // Upper bound of the subset
   double                abstol,             // absolute error tolerance
   matrix&               B,                  // second matrix
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors,      // matrix of computed eigenvectors
   matrix&               triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenSymmetric2Bisect(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,              // subset of eigenvalues to compute
   float                 lower,              // lower bound of the subset
   float                 upper,              // upper bound of the subset
   float                 abstol,             // absolute error tolerance
   matrixf&              B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors,      // matrix of computed eigenvectors

```

© 2000-2025, MetaQuotes Ltd.

```
   matrixc&              eigen_vectors,      // matrix of computed eigenvectors
   matrixc&              triangular_factor   // triangular factor from the Cholesky fa
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenSymmetric2Bisect(
   ENUM_EIGS2_TYPE       itype,              // the problem type to be solved
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,              // subset of eigenvalues to compute
   float                 lower,              // lower bound of the subset
   float                 upper,              // Upper bound of the subset
   float                 abstol,             // absolute error tolerance
   matrixcf&             B,                  // second matrix
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors,      // matrix of computed eigenvectors
   matrixcf&             triangular_factor   // triangular factor from the Cholesky fa
   );
```

Parameters

itype

[in] ENUM_EIGS2_TYPE enumeration value which specified the problem type to be solved : A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x.

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

© 2000-2025, MetaQuotes Ltd.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

B

[in] Second matrix B. Must be positive definite symmetric (or Hermitian conjugated) matrix.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

triangular_factor

[out] The triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input can be a symmetric (Hermitian), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated). Second matrix B must be positive definite symmetric. If the input matrix and second matrix B are triangular, then both must be the same triangular, upper or lower.

ENUM_EIGS2_TYPE

An enumeration that specifies the problem type to be solved.

ID	Description
EIGS2TYPE_1	1: A*x = (lambda)*B*x
EIGS2TYPE_2	2: A*B*x = (lambda)*x
EIGS2TYPE_3	3: B*A*x = (lambda)*x

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

Tridiagonal Matrices

Functions for computing eigenvalues and eigenvectors of symmetric tridiagonal matrices using various algorithms. Each function implements a specific solution method and supports matrix types double and float.

Common Parameters:

- jobv — Determines whether to compute eigenvectors (EIGVALUES_V) or only eigenvalues (EIGVALUES_N).
- range — Specifies the range of computed eigenvalues (BLASRANGE_A, BLASRANGE_V, BLASRANGE_I).
- lower and upper — Lower and upper bounds for computing a subset of the spectrum.
- abstol — Absolute error tolerance.

All functions operate on symmetric tridiagonal matrices and allow selecting the most suitable algorithm depending on performance and accuracy requirements.

Function	Action
EigenTridiagonalDC	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEVD).
EigenTridiagonalQR	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEV).
EigenTridiagonalRobust	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack function STEVR).
EigenTridiagonalBisect	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the bisection algorithm (lapack function STEVX).
EigenTridiagonalQL	Compute all eigenvalues of a symmetric tridiagonal matrix using the square-root-free variant of the QL or QR algorithm (lapack function STERF).
EigenTridiagonalDCQ	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEDC).
EigenTridiagonalQRQ	Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEQR).
EigenTridiagonalPosDefQ	Compute eigenvalues and eigenvectors of a symmetric positive definite (положительно

© 2000-2025, MetaQuotes Ltd.

Function	Action
	определённая) tridiagonal matrix using the QR algorithm (lapack function PTEQR).

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalDC

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEVD).

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalDC(
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalDC(
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated.

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalQR

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEV).

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalQR(
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalQR(
   ENUM_EIG_VALUES       jobv,               // compute eigenvectors or not
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the jobv parameter.

When jobv = EIGVALUES_V, eigenvectors and eigenvalues are calculated.

If EIGVALUES_N is set, eigenvectors are not calculated. Only eigenvalues are computed.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIG_VALUES

An enumeration that specifies whether to calculate eigenvectors.

© 2000-2025, MetaQuotes Ltd.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are calculated, without vectors.

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalRobust

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the Multiple Relatively Robust Representations, MRRR algorithm (lapack function STEVR).

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalRobust(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

© 2000-2025, MetaQuotes Ltd.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

ID	Description
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalBisect

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the bisection algorithm (lapack function STEVX).

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   double                lower,             // lower bound of the subset
   double                upper,             // Upper bound of the subset
   double                abstol,            // absolute error tolerance
   vector&               eigen_values,      // vector of computed eigenvectors
   matrix&               eigen_vectors      // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalBisect(
   ENUM_EIG_VALUES       jobv,              // compute eigenvectors or not
   ENUM_BLAS_RANGE       range,             // subset of eigenvalues to compute
   float                 lower,             // lower bound of the subset
   float                 upper,             // upper bound of the subset
   float                 abstol,            // absolute error tolerance
   vectorf&              eigen_values,      // vector of computed eigenvectors
   matrixf&              eigen_vectors      // matrix of computed eigenvectors
   );
```

Parameters

jobv

[in] ENUM_EIG_VALUES enumeration value which determines the method for computing eigenvectors.

range

[in] ENUM_BLAS_RANGE enumeration value that defines a subset of computable eigenvalues and vectors.

lower

[in] The lower bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

upper

[in] The upper bound of eigenvalues subset; it is specified depending on the value of the '*range*' parameter.

abstol

[in] Absolute error tolerance.

The absolute error tolerance to which each eigenvalue/eigenvector is required.

© 2000-2025, MetaQuotes Ltd.

If jobv = 'V', the eigenvalues and eigenvectors output have residual norms bounded by abstol, and the dot products between different eigenvectors are bounded by abstol.

If abstol < n *eps*|T|, then n *eps*|T| is used instead, where eps is the machine precision, and |T| is the 1-norm of the matrix T. The eigenvalues are computed to an accuracy of eps*|T| irrespective of abstol.

If high relative precision is important, 'abstol' should be set to a safe minimum value X such that 1.0/X does not overflow.

eigen_values

[out] Vector of eigenvalues.

V

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the values of the *jobv* and *range* parameters.

When BLASRANGE_A is set, all eigenvalues are computed, and the lower and upper parameters are ignored.

With the BLASRANGE_V value, only those eigenvalues (and their vectors) are computed, which fall within the range of real values specified by the 'lower' and 'upper' parameters.

With the BLASRANGE_I value, only those eigenvalues (and their vectors) are computed, which fall within the range of integer indices specified by the 'lower' and 'upper' parameters. For example, with lower=0 and upper=2, only the first three eigenvalues are computed.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIG_VALUES

An enumeration defining the need to compute eigenvectors.

ID	Description
EIGVALUES_V	Eigenvectors and eigenvalues are calculated.
EIGVALUES_N	Only eigenvalues are computed, without vectors.

ENUM_BLAS_RANGE

An enumeration defining how right singular vectors should be computed.

ID	Description
BLASRANGE_A	All singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

ID	Description
BLASRANGE_V	All singular or eigenvalues in the half-open interval (VL,VU] will be found.
BLASRANGE_I	The IL-th through IU-th singular or eigenvalues will be found.

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalQL

Compute all eigenvalues of a symmetric tridiagonal matrix using the square-root-free variant of the QL or QR algorithm (lapack function STERF).

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalQL(
   vector&               eigen_values        // vector of computed eigenvalues
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalQL(
   vectorf&              eigen_values        // vector of computed eigenvalues
   );
```

Parameters

eigen_values

[out] Vector of eigenvalues.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The input must be a symmetric matrix in the tridiagonal form.

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalDCQ

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide-and-conquer algorithm (lapack function STEDC). Unlike EigenTridiagonalDC, this method can be used to compute the eigenvectors of the original symmetric matrix. A symmetric matrix can be reduced to tridiagonal form using the ReduceSymmetricToTridiagonal method. The orthogonal matrix Q obtained from this transformation is then used to compute the eigenvectors of the original symmetric matrix.

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalDCQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrix&               Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalDCQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixf&              Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenTridiagonalDCQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixc&              Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrixc&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenTridiagonalDCQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixcf&             Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

compv

[in] ENUM_EIGTRIDIAG_Z enumeration value which determines the method for computing eigenvectors.

Q

[in] Orthogonal matrix Q produced by method ReflectTridiagonalToQ.

© 2000-2025, MetaQuotes Ltd.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the compv parameter.

When compv = EIGCOMPZ_N, compute eigenvalues only, eigenvectors are not calculated.

If EIGCOMPZ_V is set, eigenvalues are computed and eigenvectors of original symmetric matrix are calculated also.

If EIGCOMPZ_I is set, eigenvalues are computed and eigenvectors of tridiagonal matrix are calculated also.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIGTRIDIAG_Z

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGCOMPZ_N	'N': Compute eigenvalues only
EIGCOMPZ_V	'V': Compute eigenvectors of original symmetric matrix also
EIGCOMPZ_I	'I': Compute eigenvectors of tridiagonal matrix also

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalQRQ

Compute eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the QR algorithm (lapack function STEQR). Unlike EigenTridiagonalQR, this method can be used to compute the eigenvectors of the original symmetric matrix. A symmetric matrix can be reduced to tridiagonal form using the ReduceSymmetricToTridiagonal method. The orthogonal matrix Q obtained from this transformation is then used to compute the eigenvectors of the original symmetric matrix.

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalQRQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrix&               Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalQRQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixf&              Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenTridiagonalQRQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixc&              Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrixc&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenTridiagonalQRQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixcf&             Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

compv

[in] ENUM_EIGTRIDIAG_Z enumeration value which determines the method for computing eigenvectors.

Q

[in] Orthogonal matrix Q produced by method ReflectTridiagonalToQ.

© 2000-2025, MetaQuotes Ltd.

eigen_values

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the compv parameter.

When compv = EIGCOMPZ_N, compute eigenvalues only, eigenvectors are not calculated.

If EIGCOMPZ_V is set, eigenvalues are computed and eigenvectors of original symmetric matrix are calculated also.

If EIGCOMPZ_I is set, eigenvalues are computed and eigenvectors of tridiagonal matrix are calculated also.

The input must be a symmetric matrix in the tridiagonal form.

ENUM_EIGTRIDIAG_Z

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGCOMPZ_N	'N': Compute eigenvalues only
EIGCOMPZ_V	'V': Compute eigenvectors of original symmetric matrix also
EIGCOMPZ_I	'I': Compute eigenvectors of tridiagonal matrix also

© 2000-2025, MetaQuotes Ltd.

EigenTridiagonalPosDefQ

Compute eigenvalues and eigenvectors of a symmetric positive definite tridiagonal matrix using the QR algorithm (lapack function PTEQR). This method can be used to compute the eigenvectors of both the input tridiagonal matrix and the original positive definite symmetric matrix. This is achieved using the orthogonal matrix Q obtained during the reduction to tridiagonal form.

Computing for type matrix<double>

```
bool  matrix::EigenTridiagonalPosDefQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrix&               Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrix&               eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<float>

```
bool  matrixf::EigenTridiagonalPosDefQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixf&              Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixf&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complex>

```
bool  matrixc::EigenTridiagonalPosDefQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixc&              Q,                  // orthogonal matrix used in the reductio
   vector&               eigen_values,       // vector of computed eigenvalues
   matrixc&              eigen_vectors       // matrix of computed eigenvectors
   );
```

Computing for type matrix<complexf>

```
bool  matrixcf::EigenTridiagonalPosDefQ(
   ENUM_EIGTRIDIAG_Z     compv,              // compute eigenvectors or not
   matrixcf&             Q,                  // orthogonal matrix used in the reductio
   vectorf&              eigen_values,       // vector of computed eigenvalues
   matrixcf&             eigen_vectors       // matrix of computed eigenvectors
   );
```

Parameters

compv

[in] ENUM_EIGTRIDIAG_Z enumeration value which determines the method for computing eigenvectors.

Q

[in] Orthogonal matrix Q produced by method ReflectTridiagonalToQ.

eigen_values

© 2000-2025, MetaQuotes Ltd.

[out] Vector of eigenvalues.

eigen_vectors

[out] Matrix of eigenvectors.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Computation depends on the value of the compv parameter.

When compv = EIGCOMPZ_N, compute eigenvalues only, eigenvectors are not calculated.

If EIGCOMPZ_V is set, eigenvalues are computed and eigenvectors of original symmetric matrix are calculated also.

If EIGCOMPZ_I is set, eigenvalues are computed and eigenvectors of tridiagonal matrix are calculated also.

The input must be a symmetric positive definite tridiagonal matrix.

ENUM_EIGTRIDIAG_Z

An enumeration that specifies whether to calculate eigenvectors.

ID	Description
EIGCOMPZ_N	'N': Compute eigenvalues only
EIGCOMPZ_V	'V': Compute eigenvectors of original symmetric matrix also
EIGCOMPZ_I	'I': Compute eigenvectors of tridiagonal matrix also

Orthoghonal Factorizations

OpenBLAS provides a number of routines for factorizing a general rectangular m-by-n matrix A, as the product of an orthogonal matrix (unitary if complex) and a triangular (or possibly trapezoidal) matrix.

A real matrix Q is orthogonal if $Q^T Q = I$; a complex matrix Q is unitary if $Q^H Q = I$. Orthogonal or unitary matrices have the important property that they leave the two-norm of a vector invariant:

$||x||_2 = ||Qx||_2$, if Q is orthogonal or unitary

As a result, they help to maintain numerical stability because they do not amplify rounding errors.

Orthogonal factorizations are used in the solution of linear least squares problems. They may also be used to perform preliminary steps in the solution of eigenvalue or singular value problems.

Function	Action
FactorizationQR	Computes the QR factorization of a general m-by-n matrix: A = Q * R. Lapack function GEQRF.
FactorizationQRNonNeg	Computes the QR factorization of a general m-by-n matrix: A = Q * R. R is an upper triangular matrix with nonnegative diagonal entries. Lapack function GEQRFP.
FactorizationQRPivot	Computes the QR factorization of a general m-by-n matrix with column pivoting: A * P = Q * R. Lapack function GEQP3.

© 2000-2025, MetaQuotes Ltd.

FactorizationQR

Computes the QR factorization of a general m-by-n matrix: A = Q * R. Lapack function GEQRF.

Computing for type matrix<double>

```
bool  matrix::FactorizationQR(
   bool            reduced,      // calculation mode reduced or complete
   matrix&         Q,            // orthogonal matrix Q
   matrix&         R             // upper triangular matrix R
   );
```

Computing for type matrix<float>

```
bool  matrix::FactorizationQR(
   bool            reduced,      // calculation mode reduced or complete
   matrixf&        Q,            // orthogonal matrix Q
   matrixf&        R             // upper triangular matrix R
   );
```

Computing for type matrix<complex>

```
bool  matrix::FactorizationQR(
   bool            reduced,      // calculation mode reduced or complete
   matrixc&        Q,            // unitary matrix Q
   matrixc&        R             // upper triangular matrix R
   );
```

Computing for type matrix<complexf>

```
bool  matrix::FactorizationQR(
   bool            reduced,      // calculation mode reduced or complete
   matrixcf&       Q,            // unitary matrix Q
   matrixcf&       R             // upper triangular matrix R
   );
```

Parameters

reduced

[in] Calculation mode. If reduced is true then matrices Q, R calculated with dimensions (M, K), (K, N). If reduced is false it means complete calculation of matrices Q, R with dimensions (M,M), (M,N).

Q

[out] Orthogonal or unitary matrix Q.

R

[out] Upper triangular matrix R.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Note

If *reduced* is true

If m >= n, matrix Q is of m-by-n sizes, matrix R is of n-by-n sizes.

If m < n, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

If *reduced* is false, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

© 2000-2025, MetaQuotes Ltd.

FactorizationQRNonNeg

Computes the QR factorization of a general m-by-n matrix: A = Q * R. R is an upper triangular matrix with nonnegative diagonal entries. Lapack function GEQRFP.

Computing for type matrix<double>

```
bool  matrix::FactorizationQRNonNeg(
   bool             reduced,       // calculation mode reduced or complete
   matrix&          Q,             // orthogonal matrix Q
   matrix&          R              // upper triangular matrix R
   );
```

Computing for type matrix<float>

```
bool  matrix::FactorizationQRNonNeg(
   bool             reduced,       // calculation mode reduced or complete
   matrixf&         Q,             // orthogonal matrix Q
   matrixf&         R              // upper triangular matrix R
   );
```

Computing for type matrix<complex>

```
bool  matrix::FactorizationQRNonNeg(
   bool             reduced,       // calculation mode reduced or complete
   matrixc&         Q,             // unitary matrix Q
   matrixc&         R              // upper triangular matrix R
   );
```

Computing for type matrix<complexf>

```
bool  matrix::FactorizationQRNonNeg(
   bool             reduced,       // calculation mode reduced or complete
   matrixcf&        Q,             // unitary matrix Q
   matrixcf&        R              // upper triangular matrix R
   );
```

Parameters

reduced

[in] Calculation mode. If reduced is true then matrices Q, R calculated with dimensions (M, K), (K, N). If reduced is false it means complete calculation of matrices Q, R with dimensions (M,M), (M,N).

Q

[out] Orthogonal or unitary matrix Q.

R

[out] Upper triangular matrix R.

Return Value

© 2000-2025, MetaQuotes Ltd.

Return true if successful, otherwise false in case of an error.

Note

If *reduced* is true

If m >= n, matrix Q is of m-by-n sizes, matrix R is of n-by-n sizes.

If m < n, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

If *reduced* is false, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

© 2000-2025, MetaQuotes Ltd.

FactorizationQRPivot

Computes the QR factorization of a general m-by-n matrix with column pivoting: A * P = Q * R. Lapack function GEQP3.

Computing for type matrix<double>

```
bool  matrix::FactorizationQRPivot(
   bool             reduced,       // calculation mode reduced or complete
   long[]&          jpvt,          // array with predefined permutations
   matrix&          Q,             // orthogonal matrix Q
   matrix&          R,             // upper triangular matrix R
   matrix&          P              // permutation matrix
   );
```

Computing for type matrix<float>

```
bool  matrix::FactorizationQRPivot(
   bool             reduced,       // calculation mode reduced or complete
   long[]&          jpvt,          // array with predefined permutations
   matrixf&         Q,             // orthogonal matrix Q
   matrixf&         R,             // upper triangular matrix R
   matrixf&         P              // permutation matrix
   );
```

Computing for type matrix<complex>

```
bool  matrix::FactorizationQRPivot(
   bool             reduced,       // calculation mode reduced or complete
   long[]&          jpvt,          // array with predefined permutations
   matrixc&         Q,             // unitary matrix Q
   matrixc&         R,             // upper triangular matrix R
   matrixc&         P              // permutation matrix
   );
```

Computing for type matrix<complexf>

```
bool  matrix::FactorizationQRPivot(
   bool             reduced,       // calculation mode reduced or complete
   long[]&          jpvt,          // array with predefined permutations
   matrixcf&        Q,             // unitary matrix Q
   matrixcf&        R,             // upper triangular matrix R
   matrixcf&        P              // permutation matrix
   );
```

Parameters

reduced

[in] Calculation mode. If reduced is true then matrices Q, R calculated with dimensions (M, K), (K, N). If reduced is false it means complete calculation of matrices Q, R with dimensions (M,M), (M,N).

© 2000-2025, MetaQuotes Ltd.

jpvt

[in] Integer array of dimension n. if jpvt(i) ≠ 0, the i-th column of A is moved to the beginning of AP before the computation, and fixed in place during the computation. If jpvt(i) = 0, the i-th column of A is a free column (that is, it may be interchanged during the computation with any other free column). If array has zero size (or not initialized), then all the columns of A assumed to be free.

Q

[out] Orthogonal or unitary matrix Q.

R

[out] Upper triangular matrix R.

P

[out] Permutation matrix P of n-by-n sizes.

Return Value

Return true if successful, otherwise false in case of an error.

Note

If *reduced* is true

If m >= n, matrix Q is of m-by-n sizes, matrix R is of n-by-n sizes.

If m < n, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

If *reduced* is false, matrix Q is of m-by-m sizes, matrix R is of m-by-n sizes.

Linear Equations

This section provides functions for solving systems of linear equations of the form A·X = B, where A is a square coefficient matrix, B is the right-hand side, and X is the solution matrix or vector. The methods support various data types (double, float, complex, complexf) and are based on LAPACK functions to ensure high precision and performance.

The functions are categorized based on the type of the coefficient matrix A. Each function is overloaded to support both matrix and vector forms for the right-hand side (B) and the solution (X).

Function	Action
LinearEquationsSolution	Computes the solution to the system of linear equations with a square coefficient matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n general matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function GESV.
LinearEquationsSolution	Computes the solution to the system of linear equations with a symmetric or Hermitian conjugated matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n symmetric or unitary matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack functions SYSV, HESV.
LinearEquationsSolutionComplexSy	Computes the solution to the system of linear equations with a complex symmetric (not Hermitian conjugated!) matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n complex symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function SYSV.
LinearEquationsSolutionSyPD	Computes the solution to the system of linear equations with a symmetric or Hermitian conjugated positive-definite matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n symmetric or unitary positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function POSV.
LinearEquationsSolutionGeTri	Computes the solution to the system of linear equations with a general (nonsymmetric) tridiagonal coefficient matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n general tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function GESV.

© 2000-2025, MetaQuotes Ltd.

Function	Action
LinearEquationsSolutionSyTriPD	Computes the solution to the system of linear equations with a symmetric tridiagonal positive-definite coefficient matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n symmetric tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function GESV.

LinearEquationsSolution

Computes the solution to the system of linear equations with a square coefficient matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n general matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function GESV.

Computing for type matrix<double>

```
bool  matrix::LinearEquationsSolution(
   matrix&          B,             // right hand side matrix B
   matrix&          X              // solution matrix X
   );

bool  matrix::LinearEquationsSolution(
   vector&          B,             // right hand side vector B
   vector&          X              // solution vector X
   );
```

Computing for type matrix<float>

```
bool  matrix::LinearEquationsSolution(
   matrixf&         B,             // right hand side matrix B
   matrixf&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolution(
   vectorf&          B,             // right hand side vector B
   vectorf&          X              // solution vector X
   );
```

Computing for type matrix<complex>

```
bool  matrix::LinearEquationsSolution(
   matrixc&         B,             // right hand side matrix B
   matrixc&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolution(
   vectorc&         B,             // right hand side vector B
   vectorc&         X              // solution vector X
   );
```

Computing for type matrix<complexf>

```
bool  matrix::LinearEquationsSolution(
   matrixcf&        B,             // right hand side matrix B
   matrixcf&        X              // solution matrix X
   );

bool  matrix::LinearEquationsSolution(
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorcf&       B,              // right hand side vector B
   vectorcf&       X               // solution vector X
   );
```

Parameters

B

[in] Matrix B whose columns are the right-hand sides for the systems of equations. Vector B contains one column of right-hand side.

X

[out] Matrix or vector X with solutions of linear equations system.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Output matrix X has the same sizes as input matrix B. Output vector X has the same size as input vector B.

© 2000-2025, MetaQuotes Ltd.

LinearEquationsSolutionSy

Computes the solution to the system of linear equations with a symmetric or Hermitian conjugated matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n symmetric or unitary matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack functions SYSV, HESV.

Computing for type matrix<double>

```
bool  matrix::LinearEquationsSolutionSy(
   matrix&          B,             // right hand side matrix B
   matrix&          X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSy(
   vector&          B,             // right hand side vector B
   vector&          X              // solution vector X
   );
```

Computing for type matrix<float>

```
bool  matrix::LinearEquationsSolutionSy(
   matrixf&         B,             // right hand side matrix B
   matrixf&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSy(
   vectorf&          B,             // right hand side vector B
   vectorf&          X              // solution vector X
   );
```

Computing for type matrix<complex>

```
bool  matrix::LinearEquationsSolutionSy(
   matrixc&         B,             // right hand side matrix B
   matrixc&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSy(
   vectorc&         B,             // right hand side vector B
   vectorc&         X              // solution vector X
   );
```

Computing for type matrix<complexf>

```
bool  matrix::LinearEquationsSolutionSy(
   matrixcf&        B,             // right hand side matrix B
   matrixcf&        X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSy(
```

© 2000-2025, MetaQuotes Ltd.

```
   vectorcf&       B,              // right hand side vector B
   vectorcf&       X               // solution vector X
   );
```

Parameters

B

[in] Matrix B whose columns are the right-hand sides for the systems of equations. Vector B contains one column of right-hand side.

X

[out] Matrix or vector X with solutions of linear equations system.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Output matrix X has the same sizes as input matrix B. Output vector X has the same size as input vector B.

The input can be a symmetric (Hermitian conjugated), upper triangular or lower triangular matrix. Triangular matrices are assumed to be symmetric (Hermitian conjugated).

© 2000-2025, MetaQuotes Ltd.

LinearEquationsSolutionComplexSy

Computes the solution to the system of linear equations with a complex symmetric (not Hermitian conjugated!) matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n complex symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function SYSV.

Computing for type matrix<complex>

```
bool  matrix::LinearEquationsSolutionComplexSy(
   matrixc&        B,             // right hand side matrix B
   matrixc&        X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionComplexSy(
   vectorc&        B,             // right hand side vector B
   vectorc&        X              // solution vector X
   );
```

Computing for type matrix<complexf>

```
bool  matrix::LinearEquationsSolutionComplexSy(
   matrixcf&       B,             // right hand side matrix B
   matrixcf&       X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionComplexSy(
   vectorcf&       B,             // right hand side vector B
   vectorcf&       X              // solution vector X
   );
```

Parameters

B

[in] Matrix B whose columns are the right-hand sides for the systems of equations. Vector B contains one column of right-hand side.

X

[out] Matrix or vector X with solutions of linear equations system.

Return Value

Return true if successful, otherwise false in case of an error.

Note

Output matrix X has the same sizes as input matrix B. Output vector X has the same size as input vector B.

The input can be a complex symmetric, upper triangular or lower triangular matrix. Triangular matrices are assumed to be complex symmetric.

LinearEquationsSolutionSyPD

Computes the solution to the system of linear equations with a symmetric or Hermitian conjugated positive-definite matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n symmetric or unitary positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function POSV.

Computing for type matrix<double>

```
bool  matrix::LinearEquationsSolutionSyPD(
   matrix&          B,             // right hand side matrix B
   matrix&          X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSyPD(
   vector&          B,             // right hand side vector B
   vector&          X              // solution vector X
   );
```

Computing for type matrix<float>

```
bool  matrix::LinearEquationsSolutionSyPD(
   matrixf&         B,             // right hand side matrix B
   matrixf&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionSyPD(
   vectorf&          B,             // right hand side vector B
   vectorf&          X              // solution vector X
   );
```

Computing for type matrix<complex>

```

LinearEquationsSolutionGeTri

Computes the solution to the system of linear equations with a general (nonsymmetric) tridiagonal coefficient matrix A and multiple right-hand sides. A*X = B, where A is an n-by-n general tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. Lapack function GESV.

Computing for type matrix<double>

```
bool  matrix::LinearEquationsSolutionGeTri(
   matrix&          B,             // right hand side matrix B
   matrix&          X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionGeTri(
   vector&          B,             // right hand side vector B
   vector&          X              // solution vector X
   );
```

Computing for type matrix<float>

```
bool  matrix::LinearEquationsSolutionGeTri(
   matrixf&         B,             // right hand side matrix B
   matrixf&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionGeTri(
   vectorf&          B,             // right hand side vector B
   vectorf&          X              // solution vector X
   );
```

Computing for type matrix<complex>

```
bool  matrix::LinearEquationsSolutionGeTri(
   matrixc&         B,             // right hand side matrix B
   matrixc&         X              // solution matrix X
   );

bool  matrix::LinearEquationsSolutionGeTri(
   vectorc&         B,             // right hand side vector B

Dynamic Mode Decomposition

The Dynamic Mode Decomposition (DMD) functions are designed to compute an evolution operator from data snapshots, enabling efficient analysis of linear dynamics in extended phase spaces. The methods provide memory-efficient representations of evolution operators, with DynamicModeDecompositionQR incorporating QR-based data compression for improved computational efficiency.

Function	Action
DynamicModeDecomposition	Compute the Dynamic Mode Decomposition (DMD) for a pair of data snapshot matrices. Lapack function GEDMD.
DynamicModeDecompositionQR	Compute the Dynamic Mode Decomposition (DMD) for a pair of data snapshot matrices, using a QR factorization based compression of the data. Lapack function GEDMDQ.

The Dynamic mode decomposition (DMD) method is an algorithm for searching for an evolution operator (inverse operator problem solutions) in a finite-dimensional problem solution space (numerical or experimentally obtained) in a set of solutions (slices, "snapshots") in some consecutive moments of time. Expansion of the phase space due to the use of a nonlinear basis (relative to the variables of the problem) allows us to construct a global linear operator describing a linear evolution in the extended "rectifying space" (the Coopman operator) and the Perron-Frobenius operator that is its adjoint one. The DMD method is equivalent to a compressed representation of a linear evolution operator in the form of a product of rectangular matrices, which provides significant savings in the required memory during calculations.

© 2000-2025, MetaQuotes Ltd.

DynamicModeDecomposition

Compute the Dynamic Mode Decomposition (DMD) for a pair of data snapshot matrices. Lapack function GEDMD. For the input matrices X and Y such that Y = A*X with an unaccessible matrix A, GEDMD computes a certain number of Ritz pairs of A using the standard Rayleigh-Ritz extraction from a subspace of range(X) that is determined using the leading left singular vectors of X. Optionally, GEDMD returns the residuals of the computed Ritz pairs, the information needed for a refinement of the Ritz vectors, or the eigenvectors of the Exact DMD. Both matrices must be the same size.

Computing for type matrix<double>

```
bool  matrix::DynamicModeDecomposition(
   matrix&               B,                  // second snapshot matrix in the pai
   ENUM_DMD_SCALE        jobs,               // determines whether the initial da
   ENUM_DMD_EIGV         jobz,               // determines whether the eigenvecto
   ENUM_DMD_RESIDUALS    jobr,               // determines whether to compute the

   matrixcf&             S                     // computed vectors
   );
```

Parameters

Y

[in] The second snapshot matrix in the pair.

jobs

© 2000-2025, MetaQuotes Ltd.

[in] Value from the ENUM_DMD_SCALE enumeration which determines whether the initial data snapshots are scaled by a diagonal matrix.

jobz

[in] Value from the ENUM_DMD_EIGV enumeration which determines whether the eigenvectors (Koopman modes) will be computed.

jobr

[in] Value from the ENUM_DMD_RESIDUALS enumeration which determines whether to compute the residuals.

jobf

[in] Value from the ENUM_DMD_REFINE enumeration which specifies whether to store information needed for post-processing (e.g. computing refined Ritz vectors).

whtsvd

[in] Value from the ENUM_SVD_ALG enumeration which allows for a selection of the SVD algorithm from the LAPACK library.

nrnk

[in] Value determines the mode how to compute the numerical rank, i.e. how to truncate small singular values of the input matrix X. If

NRNK = -1 :: i-th singular value sigma(i) is truncated if sigma(i) <= TOL*sigma(1). This option is recommended.

NRNK = -2 :: i-th singular value sigma(i) is truncated if sigma(i) <= TOL*sigma(i-1). This option is included for R&D purposes. It requires highly accurate SVD, which may not be feasible.

The numerical rank can be enforced by using positive value of NRNK as follows: 0 < NRNK <= N :: at most NRNK largest singular values will be used. If the number of the computed nonzero singular values is less than NRNK, then only those nonzero values will be used and the actually used dimension is less than NRNK.

tol

[in] The tolerance for truncating small singular values. 0 <= TOL < 1

eigen_values

[out] Vector of eigenvalues of size K. The leading K (K<=N) entries of EIGS contain the computed eigenvalues (Ritz values).

left_vectors

[out] Matrix of left singular vectors. The leading K columns contain a POD basis (POD - Proper Orthogonal Decomposition, правильная ортогональная декомпозиция), i.e. the leading K left singular vectors of the input data matrix X All N columns of contain all left singular vectors of the input matrix X.

Z

[out] Matrix of Ritz vectors. If JOBZ =='V' then Z contains the Ritz vectors. Z(:,i) is an eigenvector of the i-th Ritz value; ||Z(:,i)||_2=1. If JOBZ == 'F', then the Z(:,i)'s are given implicitly as the columns of X(:,1:K)*W(1:K,1:K), i.e. X(:,1:K)*W(:,i) is an eigenvector corresponding to EIGS(i). The columns of W(1:k,1:K) are the computed eigenvectors of the K-by-K Rayleigh quotient.

residuals

© 2000-2025, MetaQuotes Ltd.

[out] Residuals for the K computed Ritz pairs.

res_vectors

[out] Residual vectors for the K computed Ritz pairs.

B

[out] M-by-K matrix (K<=N).

If JOBF =='R', B(1:M,1:K) contains A*U(:,1:K), and can be used for computing the refined vectors; see further details in the provided references.

If JOBF == 'E', B(1:M,1:K) contains A*U(:,1:K)*W(1:K,1:K), which are the vectors from the Exact DMD, up to scaling by the inverse eigenvalues.

If JOBF =='N', then B is not referenced.

W

[out] K-by-K matrix (K<=N). Contains the K computed eigenvectors of the matrix Rayleigh quotient. The Ritz vectors (returned in Z) are the product of X (containing a POD basis for the input matrix X) and W.

S

[out] K-by-K matrix (K<=N). The array S(1:K,1:K) is used for the matrix Rayleigh quotient. This content is overwritten during the eigenvalue decomposition by GEEV.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The number of matrices rows (M) must not be less than the number of columns (N).

ENUM_DMD_SCALE

An enumeration that determines whether the initial data snapshots are scaled by a diagonal matrix.

ID	Description
DMDSCALE_S	'S': The data snapshots matrices X and Y are multiplied with a diagonal matrix D so that X*D has unit nonzero columns
DMDSCALE_C	'C': The snapshots are scaled as with the 'S' option.If it is found that an i-th column of X is zero vector and the corresponding i-th column of Y is non-zero, then the i-th column of Y is set to zero
DMDSCALE_Y	'Y': The data snapshots matrices X and Y are multiplied with a diagonal matrix D so that Y*D has unit nonzero columns
DMDSCALE_N	'N': No data scaling

© 2000-2025, MetaQuotes Ltd.

ENUM_DMD_EIGV

An enumeration which determines whether the eigenvectors (Koopman modes) will be computed.

ID	Description
DMDEIGV_V	'V': The eigenvectors (Koopman modes) will be computed
DMDEIGV_F	'F': The eigenvectors (Koopman modes) will be returned in factored form
DMDEIGV_N	'N': The eigenvectors are not computed

ENUM_DMD_RESIDUALS

An enumeration which determines whether to compute the residuals.

ID	Description
DMDRESIDUALS_R	'R': The residuals for the computed eigenpairs will be computed
DMDRESIDUALS_N	'N': The residuals are not computed

ENUM_DMD_REFINE

An enumeration which specifies whether to store information needed for post-processing.

ID	Description
DMDREFINE_R	'R': The matrix needed for the refinement of the Ritz vectors is computed and stored in the array B
DMDREFINE_E	'E': The unscaled eigenvectors of the Exact DMD are computed and returned in the array B
DMDREFINE_N	'N': No eigenvector refinement data is computed

ENUM_SVD_ALG

An enumeration selecting the SVD algorythm.

ID	Description
SVDALG_1	1: GESVD (the QR SVD algorithm)
SVDALG_2	2: GESDD (the Divide and Conquer algorithm)

© 2000-2025, MetaQuotes Ltd.

ID	Description
SVDALG_3	3: GESVDQ (the preconditioned QR SVD; this and 4 are the most accurate options)
SVDALG_4	4: GEJSV (the preconditioned Jacobi SVD; this and 3 are the most accurate options)

DynamicModeDecompositionQR

Compute the Dynamic Mode Decomposition (DMD) for a pair of data snapshot matrices, using a QR factorization based compression of the data. Lapack function GEDMDQ. For the input matrices X and Y such that Y = A*X with an unaccessible matrix A, GEDMDQ computes a certain number of Ritz pairs of A using the standard Rayleigh-Ritz extraction from a subspace of range(X) that is determined using the leading left singular vectors of X. Optionally, GEDMDQ returns the residuals of the computed Ritz pairs, the information needed for a refinement of the Ritz vectors, or the eigenvectors of the Exact DMD.

The input M-by-N matrix F. The columns of F are the sequence of data snapshots from a single trajectory, taken at equidistant discrete times. It is assumed that the column norms of F are in the range of the normalized floating point numbers.

Computing for type matrix<double>

```
bool  matrix::DynamicModeDecompositionQR(
   ENUM_DMD_SCALE        jobs,                 // determines whether the initial da
   ENUM_DMDQ_EIGV        jobz,                 // determines whether the eigenvecto
   ENUM_DMD_RESIDUALS    jobr,                 // determines whether to compute the
   ENUM_DMDQ_Q           jobq,                 // specifies whether to explicitly c
   ENUM_DMDQ_R           jobt,                 // specifies whether to return the u

   matrixcf&            S                   // computed vectors
   );
```

Parameters

jobs

[in] Value from the ENUM_DMD_SCALE enumeration which determines whether the initial data snapshots are scaled by a diagonal matrix. The data snapshots are the columns of F. The leading N-1 columns of F are denoted X and the trailing N-1 columns are denoted Y.

jobz

[in] Value from the ENUM_DMDQ_EIGV enumeration which determines whether the eigenvectors (Koopman modes) will be computed.

jobr

[in] Value from the ENUM_DMD_RESIDUALS enumeration which determines whether to compute the residuals.

jobq

[in] Value from the ENUM_DMDQ_Q enumeration which specifies whether to explicitly compute and return the unitary matrix from the QR factorization of the data snapshot matrix.

jobt

[in] Value from the ENUM_DMDQ_R enumeration which specifies whether to return the upper triangular factor from the QR factorization of the data snapshot matrix.

jobf

[in] Value from the ENUM_DMD_REFINE enumeration which specifies whether to store information needed for post-processing (e.g. computing refined Ritz vectors).

whtsvd

[in] Value from the ENUM_SVD_ALG enumeration which allows for a selection of the SVD algorithm from the LAPACK library.

nrnk

[in] Value determines the mode how to compute the numerical rank, i.e. how to truncate small singular values of the input matrix X. If

NRNK = -1 :: i-th singular value sigma(i) is truncated if sigma(i) <= TOL*sigma(1). This option is recommended.

NRNK = -2 :: i-th singular value sigma(i) is truncated if sigma(i) <= TOL*sigma(i-1). This option is included for R&D purposes. It requires highly accurate SVD, which may not be feasible.

The numerical rank can be enforced by using positive value of NRNK as follows: 0 < NRNK <= N-1 :: at most NRNK largest singular values will be used. If the number of the computed nonzero

© 2000-2025, MetaQuotes Ltd.

singular values is less than NRNK, then only those nonzero values will be used and the actually used dimension is less than NRNK.

tol

[in] The tolerance for truncating small singular values. 0 <= TOL < 1

eigen_values

[out] Vector of eigenvalues of size K. The leading K (K<N) entries of EIGS contain the computed eigenvalues (Ritz values).

Q

[out] Orthogonal matrix/factor of the QR factorization of the initial data snapshots matrix F.

R key

[out] N-by-N upper triangular factor from the QR factorization of the data snapshot matrix F.

left_vectors

[out] Matrix of left singular vectors. The leading K columns of X contain the leading K left singular vectors of the hold representations of the leading N-1 snapshots in the orthonormal basis computed in the QR factorization of F. To lift them to the space of the left singular vectors U(:,1:K) of the input data, pre-multiply with the Q factor from the initial QR factorization.

Z

[out] M-by-K matrix

If JOBZ =='V' then Z contains the Ritz vectors. Z(:,i) is an eigenvector of the i-th Ritz value; ||Z(:,i)||_2=1.

If JOBZ == 'F', then the Z(:,i)'s are given implicitly as Z*V, where Z contains orthonormal matrix (the product of Q from the initial QR factorization and the SVD/POD_basis returned by GEDMD in X) and the second factor (the eigenvectors of the Rayleigh quotient) is in the matrix V, as returned by GEDMD. That is, X(:,1:K)*V(:,i) is an eigenvector corresponding to EIGS(i). The columns of V(1:K,1:K) are the computed eigenvectors of the K-by-K Rayleigh quotient.

residuals

[out] Residuals for the K computed Ritz pairs.

B

[out] N-by-K matrix (K<N).

If JOBF =='R', B(1:N,1:K) contains A*U(:,1:K), and can be used for computing the refined vectors.

If JOBF == 'E', B(1:N,1;K) contains A*U(:,1:K)*W(1:K,1:K), which are the vectors from the Exact DMD, up to scaling by the inverse eigenvalues.

In both cases, the content of B can be lifted to the original dimension of the input data by pre-multiplying with the Q factor from the initial QR factorization. Here A denotes a compression of the underlying operator.

If JOBF =='N', then B is not referenced.

V

[out] K-by-K matrix (K<N). Contains the the K eigenvectors of the Rayleigh quotient. The Ritz vectors (returned in Z) are the product of Q from the initial QR factorization.

© 2000-2025, MetaQuotes Ltd.

S

[out] K-by-K matrix (K<N). The array S(1:K,1:K) is used for the matrix Rayleigh quotient. This content is overwritten during the eigenvalue decomposition by GEEV.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The number of matrices rows (M) must not be less than the number of columns (N).

ENUM_DMD_SCALE

An enumeration that determines whether the initial data snapshots are scaled by a diagonal matrix.

ID	Description
DMDSCALE_S	'S': The data snapshots matrices X and Y are multiplied with a diagonal matrix D so that X*D has unit nonzero columns
DMDSCALE_C	'C': The snapshots are scaled as with the 'S' option.If it is found that an i-th column of X is zero vector and the corresponding i-th column of Y is non-zero, then the i-th column of Y is set to zero
DMDSCALE_Y	'Y': The data snapshots matrices X and Y are multiplied with a diagonal matrix D so that Y*D has unit nonzero columns
DMDSCALE_N	'N': No data scaling

ENUM_DMDQ_EIGV

An enumeration which determines whether the eigenvectors (Koopman modes) will be computed.

ID	Description
DMDQEIGV_V	'V': The eigenvectors (Koopman modes) will be computed
DMDQEIGV_F	'F': The eigenvectors (Koopman modes) will be returned in factored form as the product Z*V
DMDQEIGV_Q	'Q': The eigenvectors (Koopman modes) will be returned in factored form as the product Q*Z
DMDQEIGV_N	'N': The eigenvectors are not computed

ENUM_DMD_RESIDUALS

© 2000-2025, MetaQuotes Ltd.

An enumeration which determines whether to compute the residuals.

ID	Description
DMDRESIDUALS_R	'R': The residuals for the computed eigenpairs will be computed
DMDRESIDUALS_N	'N': The residuals are not computed

ENUM_DMDQ_Q

An enumeration which specifies whether to explicitly compute and return the unitary matrix from the QR factorization.

ID	Description
DMDQQ_Q	'Q': The matrix Q of the QR factorization of the data snapshot matrix is computed
DMDQQ_N	'N': The matrix Q is not explicitly computed

ENUM_DMDQ_R

An enumeration whichspecifies whether to return the upper triangular factor from the QR factorization.

ID	Description
DMDQR_R	'R': The matrix R of the QR factorization of the data snapshot matrix is computed
DMDQR_N	'N': The matrix R is not explicitly computed

ENUM_DMD_REFINE

An enumeration which specifies whether to store information needed for post-processing.

ID	Description
DMDREFINE_R	'R': The matrix needed for the refinement of the Ritz vectors is computed and stored in the array B
DMDREFINE_E	'E': The unscaled eigenvectors of the Exact DMD are computed and returned in the array B
DMDREFINE_N	'N': No eigenvector refinement data is computed

© 2000-2025, MetaQuotes Ltd.

ENUM_SVD_ALG

An enumeration selecting the SVD algorythm.

ID	Description
SVDALG_1	1: GESVD (the QR SVD algorithm)
SVDALG_2	2: GESDD (the Divide and Conquer algorithm)
SVDALG_3	3: GESVDQ (the preconditioned QR SVD; this and 4 are the most accurate options)
SVDALG_4	4: GEJSV (the preconditioned Jacobi SVD; this and 3 are the most accurate options)

© 2000-2025, MetaQuotes Ltd.

Singular Spectrum Analysis

The section contains functions for decomposing a matrix into three components: orthogonal matrices and a diagonal matrix of singular values. SVD is applied to solve various linear algebra problems such as data dimensionality reduction, image compression, solving systems of equations, as well as data analysis and optimization. The main functions allow calculating singular values and vectors, reconstruct matrices, as well as approximate them with reduced rank accuracy.

Function	Action
SingularSpectrumAnalysisSpectrum	A method function for calculating the relative contributions of spectral components based on their eigenvalues.
SingularSpectrumAnalysisForecast	A method function for calculating reconstructed and predicted data using spectral components of the input time series.
SingularSpectrumAnalysisReconstructComponents	A method function for calculating reconstructed components of the input time series and their contributions.
SingularSpectrumAnalysisReconstructSeries	A method function for calculating the reconstructed time series using the first component_count components.

© 2000-2025, MetaQuotes Ltd.

SingularSpectrumAnalysisSpectrum

A method function for calculating the relative contributions of spectral components based on their eigenvalues.

Calculations for vector<double> type

```
bool  vector::SingularSpectrumAnalysisSpectrum(
   ulong   window_length,      // window size for constructing the trajectory matrix
   vector& spectrum            // vector of component contributions to the input serie
   );
```

Calculations for vector<complex> type

```
bool  vector::SingularSpectrumAnalysisSpectrum(
   ulong   window_length,      // window size for constructing the trajectory matrix
   vectorc& spectrum           // vector of component contributions to the input serie
   );
```

Parameters

window_length

[in] Window size for constructing the trajectory matrix, the number of components the input time series should be decomposed into.

spectrum

[out] Vector of component contributions to the input series - eigenvalues of the covariance matrix of the input time series.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The *window_length* parameter value should be less than the size of the input time series. To construct a full-fledged trajectory matrix, the optimal size is considered to be approximately equal to half the size of the input time series.

© 2000-2025, MetaQuotes Ltd.

SingularSpectrumAnalysisForecast

A method function for calculating reconstructed and predicted data using spectral components of the input time series.

Calculations for vector<double> type

```
bool  vector::SingularSpectrumAnalysisForecast(
   ulong    window_length,         // window size for constructing the trajectory mati
   ulong    component_count,       // number of components used for forecasting
   ulong    forecast_horizon,      // number of points to forecast
   vector&  forecast               // vector consisting of reconstructed and predicted
   );
```

Calculations for vector<complex> type

```
bool  vector::SingularSpectrumAnalysisForecast(
   ulong    window_length,         // window size for constructing the trajectory mati
   ulong    component_count,       // number of components used for forecasting
   ulong    forecast_horizon,      // number of points to forecast
   vectorc& forecast               // vector consisting of reconstructed and predicted
   );
```

Parameters

window_length

[in] Window size for constructing the trajectory matrix, the number of components the input time series should be decomposed into.

component_count

[in] Number of components used for forecasting.

forecast_horizon

[in] Number of points to forecast.

forecast

[out] Combining points reconstructed by *component_count* plus *forecast_horizon* points predicted using the first *component_count* components. Thus, the *forecast* vector has the size of (T+forecast_horizon), where T is the input series length.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The *window_length* parameter value should be less than the size of the input time series. To construct a full-fledged trajectory matrix, the optimal size is considered to be approximately equal to half the size of the input time series.

© 2000-2025, MetaQuotes Ltd.

SingularSpectrumAnalysisReconstructComponents

A method function for calculating reconstructed components of the input time series and their contributions.

Calculations for vector<double> and matrix<double> types

```
bool  vector::SingularSpectrumAnalysisReconstructComponents(
   ulong    window_length,      // window size for constructing the trajectory matrix
   matrix&  components,         // matrix of reconstructed components
   vector&  contributions       // vector of component contributions to the input seri
   );
```

Calculations for vector<complex> and matrix<complex> types

```
bool  vector::SingularSpectrumAnalysisReconstructComponents(
   ulong    window_length,      // window size for constructing the trajectory matrix
   matrixc& components,         // matrix of reconstructed components
   vectorc& contributions       // vector of component contributions to the input seri
   );
```

Parameters

window_length

[in] Window size for constructing the trajectory matrix, the number of components the input time series should be decomposed into.

components

[out] A matrix of reconstructed components, where each column describes a separate component.

contributions

[out] Vector of component contributions to the input series (eigenvalues of the covariance matrix of the input time series).

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The *window_length* parameter value should be less than the size of the input time series. To construct a full-fledged trajectory matrix, the optimal size is considered to be approximately equal to half the size of the input time series.

© 2000-2025, MetaQuotes Ltd.

SingularSpectrumAnalysisReconstructSeries

A method function for calculating the reconstructed time series using the first *component_count* components.

Calculations for vector<double> type

```
bool  vector::SingularSpectrumAnalysisReconstructSeries(
   ulong    window_length,       // window size for constructing the trajectory matri
   ulong    component_count,     // number of components used for reconstruction
   vector&  reconstructed        // reconstructed time series
   );
```

Calculations for vector<complex> type

```
bool  vector::SingularSpectrumAnalysisReconstructSeries(
   ulong    window_length,       // window size for constructing the trajectory matri
   ulong    component_count,     // number of components used for reconstruction
   vectorc& reconstructed        // reconstructed time series
   );
```

Parameters

window_length

[in] Window size for constructing the trajectory matrix, the number of components the input time series should be decomposed into.

component_count

[out] Number of components used for time series reconstruction.

reconstructed

[out] Vector containing the reconstructed output series.

Return Value

The function returns 'true' on success or 'false' if an error occurs.

Note

The *window_length* parameter value should be less than the size of the input time series. To construct a full-fledged trajectory matrix, the optimal size is considered to be approximately equal to half the size of the input time series.

Reductions

Functions designed to transform matrices into special forms using orthogonal transformations. These methods are widely used in numerical computations, such as spectral analysis, eigenvalue problems, and singular value decomposition (SVD) of matrices.

These functions enable efficient matrix transformations essential for solving linear algebra problems, including computing Singular Value Decomposition (SVD) and finding eigenvalues of symmetric matrices. The use of LAPACK functions ensures high performance and computational accuracy.

Function	Action
ReduceToBidiagonal	Reduces a general real or complex m-by-n matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q**T * A * P = B. If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal. Lapack function GEBRD.
ReflectBidiagonalToQP	Generates orthogonal matrices Q and P**T (or P**H for complex types) determined by ReduceToBidiagonal method when reducing a real or complex matrix A to bidiagonal form: A = Q * B * P**T. Q and P**T are defined as products of elementary reflectors H(i) or G(i) respectively. Lapack functions ORGBR, UNGBR.
ReduceSymmetricToTridiagonal	Reduces a real symmetric or complex Hermitian matrix A to tridiagonal form B by an orthogonal similarity transformation: Q**T * A * Q = B. Lapack functions SYTRD, HETRD.
ReflectTridiagonalToQ	Generates orthogonal matrix Q, which is defined as the product of n-1 elementary reflectors of order n, as returned by ReduceSymmetricToTridiagonal

© 2000-2025, MetaQuotes Ltd.

ReduceToBidiagonal

Reduces a general real or complex m-by-n matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q**T * A * P = B. If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal. Lapack function GEBRD.

Computing for type matrix<double>

```
bool  matrix::ReduceToBidiagonal(
   matrix&          B,             // bidiagonal matrix
   matrix&          reflect_qp,    // q and p-reflectors
   vector&          tau_q,         // scalar factors of the elementary reflectors Q
   vector&          tau_p          // scalar factors of the elementary reflectors P
   );
```

Computing for type matrix<float>

```
bool  matrix::ReduceToBidiagonal(
   matrixf&         B,             // bidiagonal matrix
   matrixf&         reflect_qp,    // q and p-reflectors
   vectorf&         tau_q,         // scalar factors of the elementary reflectors Q
   vectorf&         tau_p          // scalar factors of the elementary reflectors P
   );
```

Computing for type matrix<complex>

```
bool  matrix::ReduceToBidiagonal(
   matrixc&         B,             // bidiagonal matrix
   matrixc&         reflect_qp,    // q and p-reflectors
   vectorc&         tau_q,         // scalar factors of the elementary reflectors Q
   vectorc&         tau_p          // scalar factors of the elementary reflectors P
   );
```

Computing for type matrix<complexf>

```
bool  matrix::ReduceToBidiagonal(
   matrixcf&        B,             // bidiagonal matrix
   matrixcf&        reflect_qp,    // q and p-reflectors
   vectorcf&        tau_q,         // scalar factors of the elementary reflectors Q
   vectorcf&        tau_p          // scalar factors of the elementary reflectors P
   );
```

Parameters

B

[out] Upper or lower bidiagonal matrix.

reflect_qp

[out] Transformed matrix A. If m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the vector tau_q, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the vector tau_p, represent the orthogonal matrix P as a product of

© 2000-2025, MetaQuotes Ltd.

elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the vector tau_q, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the vector tau_p, represent the orthogonal matrix P as a product of elementary reflectors.

tau_q

[out] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix Q.

tau_p

[out] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix P.

Return Value

Return true if successful, otherwise false in case of an error.

Note

The matrices Q and P are represented as products of elementary reflectors:

If m >= n,

Q = H(1) H(2) . . . H(n) and P = G(1) G(2) . . . G(n-1)

Each H(i) and G(i) has the form:

H(i) = I - tauq * v * v**T and G(i) = I - taup * u * u**T

where tauq and taup are scalars, and v and u are vectors;

v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i);

u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);

tauq is stored in *tau_q*(i) and taup in *tau_p*(i).

If m < n,

Q = H(1) H(2) . . . H(m-1) and P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

H(i) = I - tauq * v * v**T and G(i) = I - taup * u * u**T

where tauq and taup are scalars, and v and u are vectors;

v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);

u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);

tauq is stored in *tau_q*(i) and taup in *tau_p*(i).

The contents of A on exit (output matrix *reflect_qp*) are illustrated by the following examples:

© 2000-2025, MetaQuotes Ltd.

```
m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):
   (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
   (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
   (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
   (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
   (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
   (  v1  v2  v3  v4  v5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

Matrices Q and P can be produced with ReflectBidiagonalToQP method.

© 2000-2025, MetaQuotes Ltd.

ReflectBidiagonalToQP

Generates orthogonal matrices Q and P**T (or P**H for complex types) determined by ReduceToBidiagonal method when reducing a real or complex matrix A to bidiagonal form: A = Q * B * P**T. Q and P**T are defined as products of elementary reflectors H(i) or G(i) respectively. Lapack functions ORGBR, UNGBR.

As input is used transformed matrix reflect_qp with the same sizes m-by-n as in original matrix A.

Computing for type matrix<double>

```
bool  matrix::ReflectBidiagonalToQP(
   vector&          tau_q,         // scalar factors of the elementary reflectors Q
   vector&          tau_p,         // scalar factors of the elementary reflectors P
   matrix&          Q,             // matrix Q
   matrix&          PT             // transposed matrix P
   );
```

Computing for type matrix<float>

```
bool  matrix::ReflectBidiagonalToQP(
   vectorf&         tau_q,         // scalar factors of the elementary reflectors Q
   vectorf&         tau_p,         // scalar factors of the elementary reflectors P
   matrixf&         Q,             // matrix Q
   matrixf&         PT             // transposed matrix P
   );
```

Computing for type matrix<complex>

```
bool  matrix::ReflectBidiagonalToQP(
   vectorc&         tau_q,         // scalar factors of the elementary reflectors Q
   vectorc&         tau_p,         // scalar factors of the elementary reflectors P
   matrixc&         Q,             // matrix Q
   matrixc&         PH             // hermitian conjugated matrix P
   );
```

Computing for type matrix<complexf>

```
bool  matrix::ReflectBidiagonalToQP(
   vectorcf&        tau_q,         // scalar factors of the elementary reflectors Q
   vectorcf&        tau_p,         // scalar factors of the elementary reflectors P
   matrixcf&        Q,             // matrix Q
   matrixcf&        PH             // hermitian conjugated matrix P
   );
```

Parameters

tau_q

[in] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix Q.

tau_p

© 2000-2025, MetaQuotes Ltd.

[in] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix P.

Q

[out] Orthogonal matrix Q.

PT (PH)

[out] Transposed (or hermitian conjugated) matrix P.

Return Value

Return true if successful, otherwise false in case of an error.

Note

If m >= n, matrix Q is of m-by-n sizes, matrix PT is of n-by-n sizes.

If m < n, matrix Q is of m-by-m sizes, matrix PT is of m-by-n sizes.

© 2000-2025, MetaQuotes Ltd.

ReduceSymmetricToTridiagonal

Reduces a real symmetric or complex Hermitian matrix A to trdiagonal form B by an orthogonal similarity transformation: Q**T * A * Q = B. Lapack functions SYTRD, HETRD.

Computing for type matrix<double>

```
bool  matrix::ReduceSymmetricToTridiagonal(
   matrix&         B,             // tridiagonal matrix
   matrix&         reflect_q,     // q-reflectors
   vector&         tau_q          // scalar factors of the elementary reflectors Q
   );
```

Computing for type matrix<float>

```
bool  matrix::ReduceSymmetricToTridiagonal(
   matrixf&        B,             // tridiagonal matrix
   matrixf&        reflect_q,     // q-reflectors
   vectorf&        tau_q          // scalar factors of the elementary reflectors Q
   );
```

Computing for type matrix<complex>

```
bool  matrix::ReduceSymmetricToTridiagonal(
   matrixc&        B,             // tridiagonal matrix
   matrixc&        reflect_q,     // q-reflectors
   vectorc&        tau_q          // scalar factors of the elementary reflectors Q
   );
```

Computing for type matrix<complexf>

```
bool  matrix::ReduceSymmetricToTridiagonal(
   matrixcf&       B,             // tridiagonal matrix
   matrixcf&       reflect_q,     // q and p-reflectors
   vectorcf&       tau_q          // scalar factors of the elementary reflectors Q
   );
```

Parameters

B

[out] Symmetric (or Hermitian) tridiagonal matrix.

reflect_q

[out] Upper or lower triangular matrix, it depends on the input matrix A. In upper case the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix B, and the elements above the first superdiagonal, with the array *tau_q*, represent the orthogonal matrix Q as a product of elementary reflectors; in lower case the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix B, and the elements below the first subdiagonal, with the array *tau_q*, represent the orthogonal matrix Q as a product of elementary reflectors.

tau_q

© 2000-2025, MetaQuotes Ltd.

[out] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix Q.

Return Value

Return true if successful, otherwise false in case of an error.

Note

In upper case the matrix Q is represented as a product of elementary reflectors

Q = H(n-1) . . . H(2) H(1)

Each H(i) has the form

H(i) = I - tau * v * v**T

where tau is a scalar, and v is a vector with v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in A(1:i-1,i+1), and tau in *tau_q*(i).

In lower case the matrix Q is represented as a product of elementary reflectors

Q = H(1) H(2) . . . H(n-1)

Each H(i) has the form

H(i) = I - tau * v * v**T

where tau is a scalar, and v is a vector with v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i), and tau in *tau_q*(i). */

The contents of A on exit (output matrix *reflect_q*) are illustrated by the following examples with n = 5:

```
      upper case:                          lower case:

      (  d   e   v2  v3  v4 )              (  d                   )
      (      d   e   v3  v4 )              (  e   d               )
      (          d   e   v4 )              (  v1  e   d           )
      (              d   e  )              (  v1  v2  e   d       )
      (                  d  )              (  v1  v2  v3  e   d   )
```

where d and e denote diagonal and off-diagonal elements of B and vi denotes an element of the vector defining H(i).

Matrix Q can be produced with ReflectTridiagonalToQ method.

© 2000-2025, MetaQuotes Ltd.

ReflectTridiagonalToQ

Generates orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order n, as returned by ReduceSymmetricToTridiagonal:

in upper case Q = H(n-1) . . . H(2) H(1),

in lower case Q = H(1) H(2) . . . H(n-1).

Lapack functions ORGTR, UNGTR.

As input is used transformed matrix reflect_q with the same sizes n-by-n as in original matrix A.

Computing for type matrix<double>

```
bool  matrix::ReflectTridiagonalToQ(
   vector&          tau_q,         // scalar factors of the elementary reflectors Q
   matrix&          Q              // matrix Q
   );
```

Computing for type matrix<float>

```
bool  matrix::ReflectTridiagonalToQ(
   vectorf&         tau_q,         // scalar factors of the elementary reflectors Q
   matrixf&         Q              // matrix Q
   );
```

Computing for type matrix<complex>

```
bool  matrix::ReflectTridiagonalToQ(
   vectorc&         tau_q,         // scalar factors of the elementary reflectors Q
   matrixc&         Q              // matrix Q
   );
```

Computing for type matrix<complexf>

```
bool  matrix::ReflectTridiagonalToQ(
   vectorcf&        tau_q,         // scalar factors of the elementary reflectors Q
   matrixcf&        Q              // matrix Q
   );
```

Parameters

tau_q

[in] Vector of the scalar factors of the elementary reflectors which represent the orthogonal matrix Q.

Q

[out] Orthogonal matrix Q.

Return Value

Return true if successful, otherwise false in case of an error.

© 2000-2025, MetaQuotes Ltd.

Conversion Functions

This is a group of functions that provide conversion of data from one format into another.

The NormalizeDouble() function must be specially noted as it provides the necessary accuracy of the price presentation. In trading operations, no unnormalized prices may be used if their accuracy even a digit exceeds that required by the trade server.

Function	Action
CharToString	Converting a symbol code into a one-character string
DoubleToString	Converting a numeric value to a text line with a specified accuracy
EnumToString	Converting an enumeration value of any type to string
NormalizeDouble	Rounding of a floating point number to a specified accuracy
StringToDouble	Converting a string containing a symbol representation of number into number of double type
StringToInteger	Converting a string containing a symbol representation of number into number of long type
StringToTime	Converting a string containing time or date in "yyyy.mm.dd [hh:mi]" format into datetime type
TimeToString	Converting a value containing time in seconds elapsed since 01.01.1970 into a string of "yyyy.mm.dd hh:mi" format
IntegerToString	Converting int into a string of preset length
ShortToString	Converting symbol code (unicode) into one-symbol string
ShortArrayToString	Copying array part into a string
StringToShortArray	Symbol-wise copying a string to a selected part of array of ushort type
CharArrayToString	Converting symbol code (ansi) into one-symbol array
StringToCharArray	Symbol-wise copying a string converted from Unicode to ANSI, to a selected place of array of uchar type
CharArrayToStruct	Copy uchar type array to POD structure
StructToCharArray	Copy POD structure to uchar type array
ColorToARGB	Converting color type to uint type to receive ARGB representation of the color.
ColorToString	Converting color value into string as "R,G,B"
StringToColor	Converting "R,G,B" string or string with color name into color type value
StringFormat	Converting number into string according to preset format

CharToString

Converting a symbol code into a one-character string.

```
string  CharToString(
   uchar  char_code      // numeric code of symbol
   );
```

Parameters

char_code

[in] Code of ANSI symbol.

Return Value

String with a ANSI symbol.

Example:

```
string ExtStrArray[224];

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- in the loop from the symbol code 32 (space) to 255(UCHAR_MAX),
//--- fill the array with symbol codes converted to a string in accordance with the cu
   for(int i=32; i<=UCHAR_MAX; i++)
      ExtStrArray[i-32]=CharToString((uchar)i);

//--- print the header and the symbol table in the journal
   Print("Table of symbols:");
   ArrayPrint(ExtStrArray,_Digits," | ");
   /*
   result:
   Table of symbols:
   [  0] " " | "!" | """ | "#" | "$" | "%" | "&" | "'" | "(" | ")" | "*" | "+" | ","
   [ 25] "9" | ":" | ";" | "<" | "=" | ">" | "?" | "@" | "A" | "B" | "C" | "D" | "E"
   [ 50] "R" | "S" | "T" | "U" | "V" | "W" | "X" | "Y" | "Z" | "[" | "\" | "]" | "^"
   [ 75] "k" | "l" | "m" | "n" | "o" | "p" | "q" | "r" | "s" | "t" | "u" | "v" | "w"
   [100] "„" | "…" | "†" | "‡" | "€" | "‰" | "Љ" | "‹" | "Њ" | "Ќ" | "Ћ" | "Џ" | "ђ"
   [125] "ќ" | "ћ" | "џ" | " " | "ў" | "Ў" | "Ј" | "¤" | "Ґ" | "¦" | "§" | "Ё" | "©"
   [150] "¶" | "·" | "ё" | "№" | "є" | "»" | "ј" | "S" | "s" | "ї" | "A" | "Б" | "В"
   [175] "П" | "Р" | "С" | "Т" | "У" | "Ф" | "Х" | "Ц" | "Ч" | "Ш" | "Щ" | "Ъ" | "Ы"
   [200] "и" | "й" | "к" | "л" | "м" | "н" | "о" | "п" | "р" | "с" | "т" | "у" | "ф"
   */
  }
```

StringToCharArray, ShortToString, StringGetCharacter

© 2000-2025, MetaQuotes Ltd.

CharArrayToString

It copies and converts part of array of uchar type into a returned string.

```
string  CharArrayToString(
   uchar  array[],              // array
   int    start=0,              // starting position in the array
   int    count=-1              // number of symbols
   uint    codepage=CP_ACP      // code page
   );
```

Parameters

array[]

[in] Array of uchar type.

start=0

[in] Position from which copying starts. by default 0 is used.

count=-1

[in] Number of array elements for copying. Defines the length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.

codepage=CP_ACP

[in] The value of the code page. There is a number of built-in constants for the most used code pages.

Return Value

String.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create an array with symbol codes
   uchar array[]= { 84, 104, 105, 115,  32, 105, 115,  32,  97,  32,
                    116, 101, 115, 116,  32, 111, 102,  32, 116, 104,
                    101,  32,  67, 104,  97, 114,  65, 114, 114,  97,
                    121,  84, 111,  83, 116, 114, 105, 110, 103,  40,
                     41,  32, 102, 117, 110,  99, 116, 105, 111, 110
                   };
//--- print an array of codes converted into a string in the journal
   Print(CharArrayToString(array));

//--- create an array with symbol codes and terminal zero
   uchar array_z[]= { 84, 104, 105, 115,  32, 105, 115,  32,  97,  32,
```

© 2000-2025, MetaQuotes Ltd.

```
                     116, 101, 115, 116,   0,  32, 111, 102,  32, 116,
                     104, 101,  32,  67, 104,  97, 114,  65, 114, 114,
                      97, 121,  84, 111,  83, 116, 114, 105, 110, 103,
                      40,  41,  32, 102, 117, 110,  99, 116, 105, 111, 110
                    };
//--- print the second array of codes with terminal zero in the journal
   PrintFormat("%s ...", CharArrayToString(array_z));

   /*
   result:
   This is a test of the CharArrayToString() function
   This is a test ...
   */
  }
```

See also

StringToCharArray, ShortArrayToString, Use of a Codepage

© 2000-2025, MetaQuotes Ltd.

CharArrayToStruct

Copy uchar type array to POD structure.

```
bool  CharArrayToStruct(
   void&          struct_object,     // structure
   const uchar&   char_array[],      // array
   uint           start_pos=0        // starting position in the array
   );
```

Parameters

struct_object

[in] Reference to any type of POD structure (containing only simple data types).

char_array[]

[in] uchar type array.

start_pos=0

[in] Position in the array, data copying starts from.

Return Value

Returns true if successful, otherwise false.

Example:

```
#define DATA_TOTAL 4

MqlRates ExtDataRates[DATA_TOTAL];
uchar    ExtCharArray[];

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- copy the data of the last four bars into the uchar array
   ResetLastError();
   for(int i=0; i<DATA_TOTAL; i++)
     {
      if(!CopyRatesToCharArray(i, ExtCharArray))
         return;
     }

//--- copy all available data into the MqlRates structure array in a loop by the amour
   for(int i=0; i<DATA_TOTAL; i++)
     {
      ResetLastError();
      if(!CharArrayToStruct(ExtDataRates[i], ExtCharArray, sizeof(MqlRates)*i))
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       Print("CharArrayToStruct() failed. Error code: ", GetLastError());
       return;
      }
    //--- upon successful copying of data from the uchar array to the MqlRates struc
    //--- print the data, copied into the structure, to the journal

StructToCharArray

Copy POD structure to uchar type array.

```
bool  StructToCharArray(
   const void&  struct_object,     // structure
   uchar&       char_array[],      // array
   uint         start_pos=0        // starting position in the array
   );
```

Parameters

struct_object

[in] Reference to any type of POD structure (containing only simple data types).

char_array[]

[in] uchar type array.

start_pos=0

[in] Position in the array, starting from which the copied data are added.

Return Value

Returns true if successful, otherwise false.

Note

When copying, the dynamic array automatically expands (ArrayResize) if there is not enough space. If the array cannot be expanded up to the required value, the function returns an error.

Example:

```
uchar    ExtCharArray[];
MqlRates ExtRates[1];

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- copy the data of one current bar into the MqlRates structure
   if(CopyRates(Symbol(), PERIOD_CURRENT, 0, 1, ExtRates)!=1)
     {
      Print("CopyRates() failed. Error code: ", GetLastError());
      return;
     }

//--- print the data received in the MqlRates structure in the journal
   Print("Data in the structure immediately after receiving it:");
   MqlRatesPrint(ExtRates[0]);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- copy the structure to the uchar type array
   ResetLastError();
   if(!StructToCharArray(ExtRates[0], ExtCharArray))
     {
      Print("StructToCharArray() failed. Error code: ", GetLastError());
      return;
     }

//--- clear the structure
   ZeroMemory(ExtRates[0]);
//--- print the data in the structure after clearing
   Print("\nData in the structure after ZeroMemory():");
   MqlRatesPrint(ExtRates[0]);

//--- now copy the data from the uchar array to the MqlRates structure
   if(!CharArrayToStruct(ExtRates[0], ExtCharArray))
     {
      Print("CharArrayToStruct() failed. Error code: ", GetLastError());
      return;
     }
//--- print the data in the MqlRates structure after copying it from the uchar array
   Print("\nData in the MqlRates structure after copying it from a uchar array:");
   MqlRatesPrint(ExtRates[0]);

   /*

ColorToARGB

The function converts color type into uint type to get ARGB representation of the color. ARGB color format is used to generate a graphical resource, text display, as well as for CCanvas standard library class.

```
uint  ColorToARGB(
   color  clr,          // converted color in color format
   uchar  alpha=255     // alpha channel managing color transparency
   );
```

Parameters

clr

[in] Color value in color type variable.

alpha

[in] The value of the alpha channel used to receive the color in ARGB format. The value may be set from 0 (a color of a foreground pixel does not change the display of an underlying one) up to 255 (a color of an underlying pixel is completely replaced by the foreground pixel's one). Color transparency in percentage terms is calculated as (1-alpha/255)*100%. In other words, the lesser value of the alpha channel leads to more transparent color.

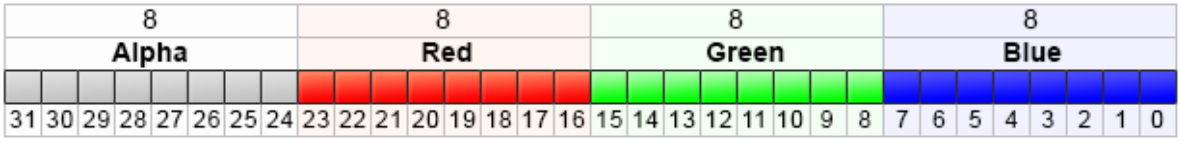
Return Value

Presenting the color in ARGB format where Alfa, Red, Green, Blue (alpha channel, red, green, blue) values are set in series in four uint type bytes.

Note

RGB is a basic and commonly used format for pixel color description on a screen in computer graphics. Names of basic colors are used to set red, green and blue color components. Each component is described by one byte specifying the color saturation in the range of 0 to 255 (0x00 to 0XFF in hexadecimal format). Since the white color contains all colors, it is described as 0xFFFFFF, that is, each one of three components is presented by the maximum value of 0xFF.

However, some tasks require to specify the color transparency to describe the look of an image in case it is covered by the color with some degree of transparency. The concept of alpha channel is introduced for such cases. It is implemented as an additional component of RGB format. ARGB format structure is shown below.



ARGB values are typically expressed using hexadecimal format with each pair of digits representing the values of Alpha, Red, Green and Blue channels, respectively. For example, 80FFFF00 color represents 50.2% opaque yellow. Initially, 0x80 sets 50.2% alpha value, as it is 50.2% of 0xFF value. Then, the first FF pair defines the highest value of the red component; the next FF pair is like the previous but for the green component; the final 00 pair represents the lowest value the blue component can have (absence of blue). Combination of green and red colors yields yellow one. If the

© 2000-2025, MetaQuotes Ltd.

alpha channel is not used, the entry can be reduced down to 6 RRGGBB digits, this is why the alpha channel values are stored in the top bits of uint integer type.

Depending on the context, hexadecimal digits can be written with '0x' or '#' prefix, for example, 80FFFF00, 0x80FFFF00 or #80FFFF00.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set transparency
   uchar alpha=0x55;  // 0x55 means 55/255=21.6 % of transparency
   //--- derive conversion to ARGB for clrBlue color
   PrintFormat("0x%.8X - clrBlue",clrBlue);
   PrintFormat("0x%.8X - clrBlue ARGB with alpha=0x55 (transparency 21.6%%)",ColorToAR
   //--- derive conversion to ARGB for clrGreen color
   PrintFormat("0x%.8X - clrGreen",clrGreen);
   PrintFormat("0x%.8X - clrGreen ARGB with alpha=0x55 (transparency 21.6%%)",ColorToA
   //--- derive conversion to ARGB for clrRed color
   PrintFormat("0x%.8X - clrRed",clrRed);
   PrintFormat("0x%.8X - clrRed ARGB with alpha=0x55 (transparency 21.6%%)",ColorToARG
  }
```

ColorToString

It converts color value into string of "R,G,B" form.

```
string  ColorToString(
   color  color_value,     // color value
   bool   color_name       // show color name or not
   );
```

Parameters

color_value

[in] Color value in color type variable.

color_name

[in] Return color name if it is identical to one of predefined color constants.

Return Value

String presentation of color as "R,G,B", where R, G and B are decimal constants from 0 to 255 converted into a string. If the color_name=true parameter is set, it will try to convert color value into color name.

Example:

```
   string clr=ColorToString(C'0,255,0'); // green color
   Print(clr);

   clr=ColorToString(C'0,255,0',true);   // get color constant
   Print(clr);
```

DoubleToString

Converting numeric value into text string.

```
string  DoubleToString(
   double  value,       // number
   int     digits=8     // number of digits after decimal point
   );
```

Parameters

value

[in] Value with a floating point.

digits

[in] Accuracy format. If the *digits* value is in the range between 0 and 16, a string presentation of a number with the specified number of digits after the point will be obtained. If the *digits* value is in the range between -1 and -16, a string representation of a number in the scientific format with the specified number of digits after the decimal point will be obtained. In all other cases the string value will contain 8 digits after the decimal point.

Return Value

String containing a symbol representation of a number with the specified accuracy.

Example:

```
   Print("DoubleToString(120.0 + M_PI) : ",DoubleToString(120.0+M_PI));
   Print("DoubleToString(120.0 + M_PI,16) : ",DoubleToString(120.0+M_PI,16));
   Print("DoubleToString(120.0 + M_PI,-16) : ",DoubleToString(120.0+M_PI,-16));
   Print("DoubleToString(120.0 + M_PI,-1) : ",DoubleToString(120.0+M_PI,-1));
   Print("DoubleToString(120.0 + M_PI,-20) : ",DoubleToString(120.0+M_PI,-20));
```

EnumToString

Converting an enumeration value of any type to a text form.

```
string  EnumToString(
   any_enum  value      // any type enumeration value
   );
```

Parameters

value

[in] Any type enumeration value.

Return Value

A string with a text representation of the enumeration. To get the error message call the GetLastError() function.

Note

The function can set the following error values in the _LastError variable:

- ERR_INTERNAL_ERROR - error of the execution environment
- ERR_NOT_ENOUGH_MEMORY - not enough memory to complete the operation
- ERR_INVALID_PARAMETER - can't allow the name of the enumeration value

Example:

```
enum interval  // enumeration of named constants
  {
   month=1,     // one-month interval
   two_months,  // two months
   quarter,     // three months - a quarter
   halfyear=6,  // half a year
   year=12,     // a year - 12 months
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set the time interval equal to one month
   interval period=month;
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- set the time interval equal to a quarter (three months)
   period=quarter;
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- set the time interval equal to one year (12 months)
   period=year;
```

© 2000-2025, MetaQuotes Ltd.

```
   Print(EnumToString(period)+"="+IntegerToString(period));

//--- check how the order type is shown
   ENUM_ORDER_TYPE type=ORDER_TYPE_BUY;
   Print(EnumToString(type)+"="+IntegerToString(type));

//--- check how incorrect values are shown
   type=WRONG_VALUE;
   Print(EnumToString(type)+"="+IntegerToString(type));

// Result:
// month=1
// quarter=3
// year=12
// ORDER_TYPE_BUY=0
// ENUM_ORDER_TYPE::-1=-1
  }
```

IntegerToString

This function converts value of integer type into a string of a specified length and returns the obtained string.

```
string  IntegerToString(
   long    number,              // number
   int     str_len=0,           // length of result string
   ushort  fill_symbol=' '      // filler
   );
```

Parameters

number

[in] Number for conversion.

str_len=0

[in] String length. If the resulting string length is larger than the specified one, the string is not cut off. If it is smaller, filler symbols will be added to the left.

fill_symbol=' '

[in] Filler symbol. By default it is a space.

Return Value

String.

Example:

```
#define DATA_TOTAL 1001

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- display rows with the index multiple of 100 in the loop by DATA_TOTAL
//--- the string displays the index value in the four-character format
//--- if the string length is less than 4 characters, then the value of the loop index
//--- in the string is preceded by leading zeros
   for(int i=0; i<DATA_TOTAL; i++)
     {
      if(i%100==0)
         Print("Converted index value: ",IntegerToString(i,4,'0'));
     }
   /*
   result:
   Converted index value: 0000
   Converted index value: 0100
   Converted index value: 0200
```

© 2000-2025, MetaQuotes Ltd.

```
   Converted index value: 0300
   Converted index value: 0400
   Converted index value: 0500
   Converted index value: 0600
   Converted index value: 0700
   Converted index value: 0800
   Converted index value: 0900
   Converted index value: 1000
   */
  }
```

See also

StringToInteger

© 2000-2025, MetaQuotes Ltd.

ShortToString

It converts the symbol code (unicode) into one-symbol string and returns resulting string.

```
string  ShortToString(
   ushort  symbol_code      // symbol
   );
```

Parameters

symbol_code

[in] Symbol code. Instead of a symbol code you can use literal string containing a symbol or a literal string with 2-byte hexadecimal code corresponding to the symbol from the Unicode table.

Return Value

String.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print 18 characters in a loop, starting with the character with the Unicode numb
   for(int i=0; i<18; i++)
     {
      ushort code=0x23E9+(ushort)i;
      PrintFormat("Unicode number U+%hX: %s",code,ShortToString(code));
     }
   /*
   result:
   Unicode number U+23E9: ⏩
   Unicode number U+23EA: ⏪

StringToCharArray, CharToString, StringGetCharacter

© 2000-2025, MetaQuotes Ltd.

ShortArrayToString

It copies part of array into a returned string.

```
string  ShortArrayToString(
   ushort  array[],      // array
   int     start=0,      // starting position in the array
   int     count=-1      // number of symbols
   );
```

Parameters

array[]

[in] Array of ushort type (analog of wchar_t type).

start=0

[in] Position, from which copying starts, Default - 0.

count=-1

[in] Number of array elements to copy. Defines the length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.

Return Value

String.

Example:

```
#define ROW_SIZE 16

ushort ExtShortArray[]={0x2190,0x2191,0x2192,0x2193,0x2194,0x2195,0x2196,0x2197,0x2198
                        0x21A0,0x21A1,0x21A2,0x21A3,0x21A4,0x21A5,0x21A6,0x21A7,0x21A8
                        0x21B0,0x21B1,0x21B2,0x21B3,0x21B4,0x21B5,0x21B6,0x21B7,0x21B8
                        0x21C0,0x21C1,0x21C2,0x21C3,0x21C4,0x21C5,0x21C6,0x21C7,0x21C8
                        0x21D0,0x21D1,0x21D2,0x21D3,0x21D4,0x21D5,0x21D6,0x21D7,0x21D8

TimeToString

Converting a value containing time in seconds elapsed since 01.01.1970 into a string of "yyyy.mm.dd hh:mi" format.

```
string  TimeToString(
   datetime  value,                          // number
   int       mode=TIME_DATE|TIME_MINUTES     // output format
   );
```

Parameters

value

[in] Time in seconds from 00:00 1970/01/01.

mode=TIME_DATE|TIME_MINUTES

[in] Additional data input mode. Can be one or combined flag:
TIME_DATE gets result as "yyyy.mm.dd",
TIME_MINUTES gets result as "hh:mi",
TIME_SECONDS gets results as "hh:mi:ss".

Return Value

String.

Example:

```
datetime ExtBarTimeOpen;

//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- set the timer to one second
   EventSetTimer(1);
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Custom indicator deinitialization function                       |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
   Comment("");
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
```

© 2000-2025, MetaQuotes Ltd.

```
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
                const int &spread[])
  {
//--- get the current bar opening time
   ExtBarTimeOpen=time[rates_total-1];
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
//| Timer function                                                   |

NormalizeDouble

Rounding floating point number to a specified accuracy.

```
double  NormalizeDouble(
   double   value,      // normalized number
   int      digits      // number of digits after decimal point
   );
```

Parameters

value

[in] Value with a floating point.

digits

[in] Accuracy format, number of digits after point (0-8).

Return Value

Value of double type with preset accuracy.

Note

Calculated values of StopLoss, TakeProfit, and values of open prices for pending orders must be normalized with the accuracy, the value of which can be obtained by Digits().

Please note that when output to Journal using the Print() function, a normalized number may contain a greater number of decimal places than you expect. For example, for:

```
   double a=76.671;              // A normalized number with three decimal places
   Print("Print(76.671)=",a);    // Output as is
   Print("DoubleToString(a,8)=",DoubleToString(a,8)); // Output with a preset accuracy
```

you will have the following in the terminal:

```
   DoubleToString(a,8)=76.67100000

   Print(76.671)=76.67100000000001
```

Example:

```
   double pi=M_PI;
   Print("pi = ",DoubleToString(pi,16));

   double pi_3=NormalizeDouble(M_PI,3);
   Print("NormalizeDouble(pi,3) = ",DoubleToString(pi_3,16))
   ;
   double pi_8=NormalizeDouble(M_PI,8);
   Print("NormalizeDouble(pi,8) = ",DoubleToString(pi_8,16));

   double pi_0=NormalizeDouble(M_PI,0);
   Print("NormalizeDouble(pi,0) = ",DoubleToString(pi_0,16));
```

© 2000-2025, MetaQuotes Ltd.

```
/*
   Result:
   pi= 3.1415926535897931
   NormalizeDouble(pi,3)= 3.1419999999999999
   NormalizeDouble(pi,8)= 3.1415926499999998
   NormalizeDouble(pi,0)= 3.0000000000000000
*/
```

StringToCharArray

Symbol-wise copies a string converted from Unicode to ANSI, to a selected place of array of uchar type. It returns the number of copied elements.

```
int  StringToCharArray(
   string  text_string,          // source string
   uchar&  array[],              // array
   int     start=0,              // starting position in the array
   int     count=-1              // number of symbols
   uint    codepage=CP_ACP       // code page
   );
```

Parameters

text_string

[in] String to copy.

array[]

[out] Array of uchar type.

start=0

[in] Position from which copying starts. Default - 0.

count=-1

[in] Number of array elements to copy. Defines length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0. Terminal 0 will also be copied to the recipient array, in this case the size of a dynamic array can be increased if necessary to the size of the string. If the size of the dynamic array exceeds the length of the string, the size of the array will not be reduced.

codepage=CP_ACP

[in] The value of the code page. For the most-used code pages provide appropriate constants.

Return Value

Number of copied elements.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- string to convert
   string text = "This is a test of the StringToCharArray() function";

//--- convert the input string into a uchar array in accordance with the set code page
   uchar char_array[];
```

© 2000-2025, MetaQuotes Ltd.

```
   int   copied=StringToCharArray(text, char_array);
   PrintFormat("String length: %u\nNumber of characters copied (with terminal 0): %d\r
               StringLen(text), copied, text);
//--- print the resulting array to the journal
   ArrayPrint(char_array, 0, " | ");
   /*
   result:
   String length: 50
   Number of characters copied (with terminal 0): 51
   Array of characters for the string 'This is a test of the StringToCharArray() funct
   [ 0]  84 | 104 | 105 | 115 |  32 | 105 | 115 |  32 |  97 |  32 | 116 | 101 | 115 |
   [17]  32 | 116 | 104 | 101 |  32 |  83 | 116 | 114 | 105 | 110 | 103 |  84 | 111 |
   [34]  65 | 114 | 114 |  97 | 121 |  40 |  41 |  32 | 102 | 117 | 110 |  99 | 116 |
   */
  }
```

StringToColor

Converting "R,G,B" string or string with color name into color type value.

```
color  StringToColor(
   string  color_string      // string representation of color
   );
```

Parameters

color_string

[in] String representation of a color of "R,G,B" type or name of one of predefined Web-colors.

Return Value

Color value.

Example:

```
   color str_color=StringToColor("0,127,0");
   Print(str_color);
   Print((string)str_color);
//--- change color a little
   str_color=StringToColor("0,128,0");
   Print(str_color);
   Print((string)str_color);
```

StringToDouble

The function converts string containing a symbol representation of number into number of double type.

```
double  StringToDouble(
   string  value      // string
   );
```

Parameters

value

[in] String containing a symbol representation of a number.

Return Value

Value of double type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- string to convert
   string str = "12345.54321";
//--- convert the input string as a real number into a double type variable
   double converted=StringToDouble(str);
//--- display the resulting number accurate to 8 decimal places in the journal
   PrintFormat("The string '%s' is converted to the real number %.8f", str, converted)
   /*
   result:
   The string '12345.54321' is converted to the real number 12345.54321000
   */
  }
```

StringToInteger

The function converts string containing a symbol representation of number into number of long (integer) type.

```
long  StringToInteger(
   string  value      // string
   );
```

Parameters

value

[in] String containing a number.

Return Value

Value of long type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- string to convert
   string str = "12345.54321";
//--- convert the input string as a number into a long type variable
   long converted=StringToInteger(str);
//--- display the obtained number in the journal with the fractional part cut off
   PrintFormat("The string '%s' is converted to the integer number %I64d", str, conver
   /*
   result:
   The string '12345.54321' is converted to the integer number 12345
   */
  }
```

StringToShortArray

The function symbol-wise copies a string into a specified place of an array of ushort type. It returns the number of copied elements.

```
int  StringToShortArray(
   string  text_string,      // source string
   ushort& array[],          // array
   int     start=0,          // starting position in the array
   int     count=-1          // number of symbols
   );
```

Parameters

text_string

[in] String to copy

array[]

[out] Array of ushort type (analog of wchar_t type).

start=0

[in] Position, from which copying starts. Default - 0.

count=-1

[in] Number of array elements to copy. Defines length of a resulting string. Default value is -1, which means copying up to the array end, or till terminal 0.Terminal 0 will also be copied to the recipient array, in this case the size of a dynamic array can be increased if necessary to the size of the string. If the size of the dynamic array exceeds the length of the string, the size of the array will not be reduced.

Return Value

Number of copied elements.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- string with chars to convert
   string text = "Chars: ♡♫☎✈☩☏❁✉☆☁♕♠®✧❄♣    ";
   ushort short_array[];
//--- find the position of the ":" character in the input string and extract the subst
   int    pos=StringFind(text, ":");
   string str=(pos<0 ? text : StringSubstr(text, pos+1));
//--- remove spaces, carriage movement and tabulation characters from the left and ric
   StringTrimLeft(str);
   StringTrimRight(str);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- copy the resulting string into the ushort array and print the resulting array to
   int copied=StringToShortArray(str, short_array);
   PrintFormat("String of characters length: %u\n"
               "Number of characters copied (with terminal 0): %d\n"
               "Array of chars for the string '%s':",
               StringLen(str), copied, str);
   ArrayPrint(short_array, 0, " | ");
   /*
   result:
   String of characters length: 16
   Number of characters copied (with terminal 0): 17
   Array of chars for the string '♡♫☎✠✣ ☎ ❁✉☆ ☁♕ ♠®✧ ❄ ♣':
   10084 |  9835 |  9742 |  9992 | 10019 |  9743 |  9728 |  9993 |  9734 |  9729 |  98
   */
  }
```

ShortArrayToString, StringToCharArray, Use of a Codepage

© 2000-2025, MetaQuotes Ltd.

StringToTime

Transforms the string containing time and/or date in the "yyyy.mm.dd [hh:mi]" format into the datetime type number.

```
datetime  StringToTime(
   const string  time_string      // date string
   );
```

Parameters

time_string

[in] String in one of the specified formats:

- "yyyy.mm.dd [hh:mi]"
- "yyyy.mm.dd [hh:mi:ss]"
- "yyyymmdd [hh:mi:ss]"
- "yyyymmdd [hhmiss]"
- "yyyy/mm/dd [hh:mi:ss]"
- "yyyy-mm-dd [hh:mi:ss]"

Return Value

datetime type value containing the number of seconds elapsed since 01.01.1970.

Note

Any sequence of space and tabulation characters between date and time is considered to be a single space to avoid additional processing of the *time_string* before calling StringToTime().

Example:

```
//--- input parameters
input group    "The date can be entered in any of the formats:"
input group    "yyyy.mm.dd [hh:mi], yyyy.mm.dd [hh:mi:ss]"
input group    "yyyymmdd [hh:mi:ss], yyyymmdd [hhmiss]"
input group    "yyyy/mm/dd [hh:mi:ss], yyyy-mm-dd [hh:mi:ss]"
input string   InpDateStr;    // Please enter the date here as a string

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- convert the time entered in the inputs as a string into a datetime value

StringFormat

The function formats obtained parameters and returns a string.

```
string  StringFormat(
   string  format,      // string with format description
   ...     ...          // parameters
   );
```

Parameters

format

[in] String containing method of formatting. Formatting rules are the same as for the PrintFormat function.

...

[in] Parameters, separated by a comma.

Return Value

String.

Example:

© 2000-2025, MetaQuotes Ltd.

```
void OnStart()
  {
//--- string variables
   string output_string;
   string temp_string;
   string format_string;
//--- prepare the specification header
   temp_string=StringFormat("Contract specification for %s:\n",_Symbol);
   StringAdd(output_string,temp_string);

Mathematical Functions

A set of mathematical and trigonometric functions.

Math functions were originally designed to perform relevant operations on scalar values. From this build on, most of the functions can be applied to matrices and vectors. These include MathAbs, MathArccos, MathArcsin, MathArctan, MathCeil, MathCos, MathExp, MathFloor, MathLog, MathLog10, MathMod, MathPow, MathRound, MathSin, MathSqrt, MathTan, MathExpm1, MathLog1p, MathArccosh, MathArcsinh, MathArctanh, MathCosh, MathSinh, and MathTanh. Such operations imply element-wise handling of matrices or vectors. Example:

```
//---
  matrix a= {{1, 4}, {9, 16}};
  Print("matrix a=\n",a);
  a=MathSqrt(a);
  Print("MatrSqrt(a)=\n",a);
  /*
   matrix a=
   [[1,4]
    [9,16]]
   MatrSqrt(a)=
   [[1,2]
    [3,4]]
  */
```

For MathMod and MathPow, the second element can be either a scalar or a matrix/vector of the appropriate size.

Function	Action
MathAbs	Returns absolute value (modulus) of the specified numeric value
MathArccos	Returns the arc cosine of x in radians
MathArcsin	Returns the arc sine of x in radians
MathArctan	Returns the arc tangent of x in radians
MathArctan2	Return the angle (in radians) whose tangent is the quotient of two specified numbers
MathClassify	Returns the type of a real number
MathCeil	Returns integer numeric value closest from above
MathCos	Returns the cosine of a number
MathExp	Returns exponent of a number
MathFloor	Returns integer numeric value closest from below
MathLog	Returns natural logarithm
MathLog10	Returns the logarithm of a number by base 10

© 2000-2025, MetaQuotes Ltd.

Function	Action
MathMax	Returns the maximal value of the two numeric values
MathMin	Returns the minimal value of the two numeric values
MathMod	Returns the real remainder after the division of two numbers
MathPow	Raises the base to the specified power
MathRand	Returns a pseudorandom value within the range of 0 to 32767
MathRound	Rounds of a value to the nearest integer
MathSin	Returns the sine of a number
MathSqrt	Returns a square root
MathSrand	Sets the starting point for generating a series of pseudorandom integers
MathTan	Returns the tangent of a number
MathIsValidNumber	Checks the correctness of a real number
MathExpm1	Returns the value of the expression MathExp(x)-1
MathLog1p	Returns the value of the expression MathLog(1+x)
MathArccosh	Returns the hyperbolic arccosine
MathArcsinh	Returns the hyperbolic arcsine
MathArctanh	Returns the hyperbolic arctangent
MathCosh	Returns the hyperbolic cosine
MathSinh	Returns the hyperbolic sine
MathTanh	Returns the hyperbolic tangent
MathSwap	Change the order of bytes in the ushort/uint/ushort types value

© 2000-2025, MetaQuotes Ltd.

MathAbs

The function returns the absolute value (modulus) of the specified numeric value.

```
double  MathAbs(
   double  value      // numeric value
   );
```

Parameters

value

[in] Numeric value.

Return Value

Value of double type more than or equal to zero.

Note

Instead the MathAbs() function you can use fabs().

Example:

```
//--- input parameters
input int      InpValue = -10;   // Enter any value here

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the absolute value of the number entered in the inputs
   uint abs_value=MathAbs(InpValue);
//--- print the values in the journal
   PrintFormat("The entered value %d received the value %u after using the MathAbs() f
  }
```

© 2000-2025, MetaQuotes Ltd.

MathArccos

The function returns the arccosine of x within the range 0 to π in radians.

```
double  MathArccos(
   double  val     // -1<val<1
   );
```

Parameters

val

[in] The val value between -1 and 1, the arc cosine of which is to be calculated.

Return Value

Arc cosine of a number in radians. If val is less than -1 or more than 1, the function returns NaN (indeterminate value).

Note

Instead of the MathArccos() function you can use acos().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/1000);
   delta[0]=-1;
//--- get 101 values from -1 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the arc cosine value for each value of the X vector
   vector Y=MathArccos(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+
void CurvePlot(double &x_array[], double &y_array[], const color colour)
  {
   ExtGraph.Create(ChartID(), "Graphic", 0, 0, 0, GRAPH_WIDTH, GRAPH_HEIGHT);
   ExtGraph.CurveAdd(x_array, y_array, ColorToARGB(colour), CURVE_LINES);
   ExtGraph.IndentUp(30);
   ExtGraph.CurvePlotAll();
   string text1="Press ESC to delete the graph and stop the script, or";
   string text2="Press PgDn to create a screen, delete the graph and stop the script";
   ExtGraph.TextAdd(54, 9, text1, ColorToARGB(clrBlack));
   ExtGraph.TextAdd(54,21, text2, ColorToARGB(clrBlack));
   ExtGraph.Update();
  }
//+------------------------------------------------------------------+
//| Take a screenshot and saves the image to a file                  |
//+------------------------------------------------------------------+
bool MakeAndSaveScreenshot(const string file_name)
  {
   string file_names[];
   ResetLastError();
```

© 2000-2025, MetaQuotes Ltd.

```
   int selected=FileSelectDialog("Save Picture", NULL, "All files (*.*)|*.*", FSD_WRIT
   if(selected<1)
     {
      if(selected<0)
         PrintFormat("%s: FileSelectDialog() function returned error %d", __FUNCTION__
      return false;
     }

   bool res=false;
   if(ChartSetInteger(0,CHART_SHOW,false))
      res=ChartScreenShot(0, file_names[0], GRAPH_WIDTH, GRAPH_HEIGHT);
   ChartSetInteger(0,CHART_SHOW,true);
   return(res);
  }
```

MathArcsin

The function returns the arc sine of x within the range of -π/2 to π/2 radians.

```
double  MathArcsin(
   double  val      // -1<value<1
   );
```

Parameters

val

[in] The val value between -1 and 1, the arc sine of which is to be calculated.

Return Value

Arc sine of the val number in radians within the range of -π/2 to π/2 radians. If val is less than -1 or more than 1, the function returns NaN (indeterminate value).

Note

Instead of the MathArcsin() function you can use asin().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/1000);
   delta[0]=-1;
//--- get 101 values from -1 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the sine value for each value of the X vector
   vector Y=MathArcsin(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;

MathArctan

The function returns the arc tangent of x. If x is equal to 0, the function returns 0.

```
double  MathArctan(
   double  value      // tangent
   );
```

Parameters

value

[in] A number representing a tangent.

Return Value

MathArctan returns a value within the range of -π/2 to π/2 radians.

Note

Instead of the MathArctan() function you can use atan().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the arc tangent value for each value of the X vector
   vector Y=MathArctan(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'

MathArctan2

Return the angle (in radians) whose tangent is the quotient of two specified numbers.

```
double MathArctan2(
 double y     // The y coordinate of a point
 double x     // The x coordinate of a point
  );
```

Parameters

y

[in] Y coordinate value.

x

[in] X coordinate value.

Return Value

MathArctan2 returns an angle, θ, within the range from -π to π radians, so that MathTan(θ)=y/x.

Please note as follows:

- For (x, y) in quadrant 1, 0< θ < π/2
- For (x, y) in quadrant 2, π/2< θ ≤ π
- For (x, y) in quadrant 3, -π < θ < -π/2
- For (x, y) in quadrant 4, -π/2 < θ < 0

For points on the boundaries of the quadrants, the return value is the following:

- If y is 0 and x is not negative, θ = 0.
- If y is 0 and x is negative, θ = π.
- If y is positive and x is 0, θ = π/2.
- If y is negative and x is 0, θ = -π/2.
- If y is 0 and x is 0, θ = 0.

Note

Instead of the MathArctan2() function, you can use the atan2() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
  {
   vector delta=vector::Full(10,10);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the arc tangent value for each value of the X vector
   vector Y=delta.CumSum();

   Print("vector delta = \n",delta);
   Print("vector X = \n",X);
   Print("vector Y = \n",Y);

//--- transfer the calculated values from vectors to arrays
   double x_array[];;
   double y_array[];;
   X.Swap(x_array);
   Y.Swap(y_array);

   double array[10];
   for(int i=0; i<10; i++)
     {
      array[i]=MathArctan2(y_array[i],x_array[i]);
     }

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())

MathClassify

Determines the type of a real number and returns a result as a value from the ENUM_FP_CLASS enumeration

```
ENUM_FP_CLASS  MathClassify(
   double  value      // real number
   );
```

Parameters

value

[in] The real number to be checked

Return Value

A value from the ENUM_FP_CLASS enumeration

ENUM_FP_CLASS

ID	Description
FP_SUBNORMAL	A subnormal number which is closer to zero than the smallest representable normal number DBL_MIN (2.2250738585072014e-308)
FP_NORMAL	A normal number in the range between 2.2250738585072014e-308 and 1.7976931348623158e+308
FP_ZERO	A positive or a negative zero
FP_INFINITE	A number which cannot be represented by the appropriate type, positive or negative infinity
FP_NAN	Not a number.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
//--- test NaN
  double nan=double("nan");
  PrintFormat("Test NaN: %G is %s, MathIsValidNumber(NaN)=%s",
              nan,
              EnumToString(MathClassify(nan)),
              (string)MathIsValidNumber(nan));
//--- test infinity
  double inf=double("inf");
  PrintFormat("Test Inf: %G is %s, MathIsValidNumber(inf)=%s",
```

© 2000-2025, MetaQuotes Ltd.

```
               inf,
               EnumToString(MathClassify(inf)),
               (string)MathIsValidNumber(inf));
//--- test normal value
  double normal=1.2345e6;
  PrintFormat("Test Normal: %G is %s, MathIsValidNumber(normal)=%s",
               normal,
               EnumToString(MathClassify(normal)),
               (string)MathIsValidNumber(normal));
//--- test subnormal value
  double sub_normal=DBL_MIN/2.0;
  PrintFormat("Test Subnormal: %G is %s, MathIsValidNumber(sub_normal)=%s",
               sub_normal,
               EnumToString(MathClassify(sub_normal)),
               (string)MathIsValidNumber(sub_normal));
//--- test zero value
  double zero=0.0/(-1);
  PrintFormat("Test Zero: %G is %s, MathIsValidNumber(zero)=%s",
               zero,
               EnumToString(MathClassify(zero)),
               (string)MathIsValidNumber(zero));
 }
 /*
 Result:
   Test NaN: NAN is FP_NAN, MathIsValidNumber(NaN)=false
   Test Inf: INF is FP_INFINITE, MathIsValidNumber(inf)=false
   Test Normal: 1.2345E+06 is FP_NORMAL, MathIsValidNumber(normal)=true
   Test Subnormal: 1.11254E-308 is FP_SUBNORMAL, MathIsValidNumber(sub_normal)=true
   Test Zero: -0 is FP_ZERO, MathIsValidNumber(zero)=true

MathCeil

The function returns integer numeric value closest from above.

```
double  MathCeil(
   double  val      // number
   );
```

Parameters

val

[in] Numeric value.

Return Value

Numeric value representing the smallest integer that exceeds or equals to val.

Note

Instead of the MathCeil() function you can use ceil().

Example:

```
#define VALUES_TOTAL 31

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare variables for conversion
   double value=0;                     // real number for MathCeil conversion
   int    ceil_value=0;                // get the result here
//--- in a loop by the number of decimal increments of a real number
   for(int i=0; i<VALUES_TOTAL; i++)
     {
      //--- increase the number value,
      //--- get the nearest integer value from above
      //--- and display control values in the journal
      value+=0.1;
      ceil_value=(int)MathCeil(NormalizeDouble(value,1));
      PrintFormat("value: %.1f, ceil value: %d",value,ceil_value);
      /*
      result:
      value: 0.1, ceil value: 1
      value: 0.2, ceil value: 1
      value: 0.3, ceil value: 1
      value: 0.4, ceil value: 1
      value: 0.5, ceil value: 1
      value: 0.6, ceil value: 1
```

© 2000-2025, MetaQuotes Ltd.

```
      value: 0.7, ceil value: 1
      value: 0.8, ceil value: 1
      value: 0.9, ceil value: 1
      value: 1.0, ceil value: 1
      value: 1.1, ceil value: 2
      value: 1.2, ceil value: 2
      value: 1.3, ceil value: 2
      value: 1.4, ceil value: 2
      value: 1.5, ceil value: 2
      value: 1.6, ceil value: 2
      value: 1.7, ceil value: 2
      value: 1.8, ceil value: 2

MathCos

The function returns the cosine of an angle.

```
double  MathCos(
   double  value      // number
   );
```

Parameters

value

[in] Angle in radians.

Return Value

Value of double type within the range of -1 to 1.

Note

Instead of MathCos() you can use cos().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the cosine value for each value of the X vector
   vector Y=MathCos(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+

MathExp

The function returns the value of e raised to the power of d.

```
double  MathExp(
   double  value      // power for the number e
   );
```

Parameters

value

[in] A number specifying the power.

Return Value

A number of double type. In case of overflow the function returns INF (infinity), in case of underflow MathExp returns 0.

Note

Instead of MathExp() you can use exp().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 9 values from 0 to 8 with step 1
   vector X(9,VectorArange);
   Print("vector X = \n",X);
//--- calculate the "e" (Euler number) to the power of each X vector value
   X=MathExp(X);
   Print("MathExp(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

MathFloor

The function returns integer numeric value closest from below.

```
double  MathFloor(
   double  val     // number
   );
```

Parameters

val

[in] Numeric value.

Return Value

A numeric value representing the largest integer that is less than or equal to val.

Note

Instead of MathFloor() you can use floor().

Example:

```
#define VALUES_TOTAL 31

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare variables for conversion
   double value=0;                     // real number for MathFloor conversion
   int    floor_value=0;               // get the result here
//--- in a loop by the number of decimal increments of a real number
   for(int i=0; i<VALUES_TOTAL; i++)
     {
      //--- increase the number value,
      //--- get the nearest integer value from below
      //--- and display control values in the journal
      value+=0.1;
      floor_value=(int)MathFloor(NormalizeDouble(value,1));
      PrintFormat("value: %.1f, floor value: %d",value,floor_value);
      /*
      result:
      value: 0.1, floor value: 0
      value: 0.2, floor value: 0
      value: 0.3, floor value: 0
      value: 0.4, floor value: 0
      value: 0.5, floor value: 0
      value: 0.6, floor value: 0
```

© 2000-2025, MetaQuotes Ltd.

```

MathLog

The function returns a natural logarithm.

```
double  MathLog(
   double  val      // value to take the logarithm
   );
```

Parameters

val

[in] Value logarithm of which is to be found.

Return Value

The natural logarithm of val in case of success. If val is negative, the function returns NaN (undetermined value). If val is equal to 0, the function returns INF (infinity).

Note

Instead of MathLog() you can use log().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 9 values from 0 to 8 with step 1
   vector X(9,VectorArange);
   Print("vector X = \n",X);
//--- calculate the logarithm for each value of the X vector
   X=MathLog(X);
   Print("MathLog(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
   /*

MathLog

Returns the logarithm of a number by base 10.

```
double  MathLog10(
   double  val      // number to take logarithm
   );
```

Parameters

val

[in] Numeric value the common logarithm of which is to be calculated.

Return Value

The common logarithm in case of success. If val is negative, the function returns NaN (undetermined value). If val is equal to 0, the function returns INF (infinity).

Note

Instead of MathLog10() you can use log10().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 9 values from 0 to 8 with step 1
   vector X(9,VectorArange);
   Print("vector X = \n",X);
//--- calculate the decimal logarithm for each value of the X vector
   X=MathLog10(X);
   Print("MathLog10(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot

MathMax

The function returns the maximal value of two values.

```
double  MathMax(
   double  value1,     // first value
   double  value2      // second value
   );
```

Parameters

value1

[in] First numeric value.

value2

[in] Second numeric value.

Return Value

The largest of the two values.

Note

Instead of MathMax() you can use fmax(). Functions fmax(), fmin(), MathMax(), MathMin() can work with integer types without typecasting them to the type of double.

If parameters of different types are passed into a function, the parameter of the smaller type is automatically cast to the larger type. The type of the return value corresponds to the larger type.

If data of the same type are passed, no casting is performed.

Example:

```
//--- input parameters
input int                  InpPeriod = 10;            // Moving average calculation pe
input ENUM_MA_METHOD       InpMethod = MODE_SMA;      // Moving average calculation me
input ENUM_APPLIED_PRICE   InpPrice  = PRICE_CLOSE;   // Moving average calculation pr

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- if the moving average period is set to a value less than 1, then the default va
   int period=(InpPeriod<1 ? 10 : InpPeriod);
//--- create the Moving Average indicator handle
   int handle=iMA(Symbol(),Period(),period,0,InpMethod,InpPrice);
   if(handle==INVALID_HANDLE)
     {
      Print("Failed to create the Moving Average indicator handle. Error ",GetLastErr
      return;
```

© 2000-2025, MetaQuotes Ltd.

```
      }
//--- get the current Bid price
   double bid=0;
   ResetLastError();
   if(!SymbolInfoDouble(Symbol(),SYMBOL_BID,bid))
     {
      Print("Failed to get Bid price. Error ",GetLastError());
      return;
     }
//--- get the moving average value on the current bar
   double array[1];
   int    copied=CopyBuffer(handle,0,0,1,array);
   if(copied!=1)
     {
      Print("Failed to get Moving Average data. Error ",GetLastError());
      return;
     }
//--- get the highest price of the two (Bid price and Moving Average value) and displa
   double max_price=MathMax(bid,array[0]);
   PrintFormat("Bid: %.*f, Moving Average: %.*f, highest price of the two: %.*f",_Digi
   PrintFormat("Bid price %s moving average",(bid>array[0] ? "higher" : bid<array[0] ?
  }
```

© 2000-2025, MetaQuotes Ltd.

MathMin

The function returns the minimal value of two values.

```
double  MathMin(
   double  value1,     // first value
   double  value2      // second value
   );
```

Parameters

value1

[in] First numeric value.

value2

[in] Second numeric value.

Return Value

The smallest of the two values.

Note

Instead of MathMin() you can use fmin(). Functions fmax(), fmin(), MathMax(), MathMin() can work with integer types without typecasting them to the type of double.

If parameters of different types are passed into a function, the parameter of the smaller type is automatically cast to the larger type. The type of the return value corresponds to the larger type.

If data of the same type are passed, no casting is performed.

Example:

```
//--- input parameters
input uint  InpBars  =  100000;  // Desired number of bars

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the number of available bars on the server
   uint bars_total = Bars(Symbol(),Period());
   if(bars_total==0)
     {
      PrintFormat("Data for timeseries %s %s not yet generated in the terminal. Please
      return;
     }
//--- get the minimum number of bars from two values - from those available on the ser
   int bars = (int)MathMin(bars_total,InpBars);
//--- if more bars are requested than are available on the server, report this in the
```

© 2000-2025, MetaQuotes Ltd.

```
   if(bars_total<InpBars)
      PrintFormat("Number of bars on the server (%u) is less than requested (%u)",bars
//--- display the number of bars available for work in the journal
   Print("Bars available for work: ",bars);
  }
```

© 2000-2025, MetaQuotes Ltd.

MathMod

The function returns the real remainder of division of two numbers.

```
double  MathMod(
   double  value,       // dividend value
   double  value2       // divisor value
   );
```

Parameters

value

[in] Dividend value.

value2

[in] Divisor value.

Return Value

The MathMod function calculates the real remainder f from expression val/y so that val = i * y + f , where i is an integer, f has the same sign as val, and the absolute value of f is less than the absolute value of y.

Note

Instead of MathMod() you can use fmod().

Example:

```
#property script_show_inputs

//--- input parameters
input double   InpDividentValue  =  10;   // Dividend value
input double   InpDivisorValue   =  3;    // Divisor value

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the real remainder of the division of the numbers entered in the inputs
   double res=MathMod(InpDividentValue,InpDivisorValue);
//--- print the result in the journal
   PrintFormat("Real remainder when dividing %.2f by %.2f = %.2f",InpDividentValue,Inp
  }
```

© 2000-2025, MetaQuotes Ltd.

MathPow

The function raises a base to a specified power.

```
double  MathPow(
   double  base,          // base
   double  exponent       // exponent value
   );
```

Parameters

base

[in] Base.

exponent

[in] Exponent value.

Return Value

Value of base raised to the specified power.

Note

Instead of MathPow() you can use pow().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#property script_show_inputs

#include <Graphics\Graphic.mqh>

//--- input parameters
input double   InpExponentValue  =  2;     // exponent value

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 11 values from 0 to 10 with step 1
   vector X(11,VectorArange);
   Print("vector X = \n",X);
//--- calculate each value of the X vector raised to the InpExponentValue power
   X=MathPow(X,InpExponentValue);
   Print("MathPow(X,",(string)InpExponentValue,") = \n",X);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
   /*
   result:
   vector X =
   [0,1,2,3,4,5,6,7,8,9,10]
   MathPow(X,2.0) =
   [0,1,4,9,16,25,36,49,64,81,100]
   */
  }
//+------------------------------------------------------------------+
//| Fill a vector with 'value' in 'step' increments                  |
//+------------------------------------------------------------------+
template<typename T>
void VectorArange(vector<T> &vec,T value=0.0,T step=1.0)
  {
   for(ulong i=0; i<vec.Size(); i++,value+=step)
      vec[i]=value;
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
```

© 2000-2025, MetaQuotes Ltd.

```
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+
void CurvePlot(double &x_array[], double &y_array[], const color colour)
  {
   ExtGraph.Create(ChartID(), "Graphic", 0, 0, 0, GRAPH_WIDTH, GRAPH_HEIGHT);
   ExtGraph.CurveAdd(x_array, y_array, ColorToARGB(colour), CURVE_LINES);
   ExtGraph.IndentUp(30);
   ExtGraph.CurvePlotAll();
   string text1="Press ESC to delete the graph and stop the script, or";
   string text2="Press PgDn to create a screen, delete the graph and stop the script";

MathRand

Returns a pseudorandom integer within the range of 0 to 32767.

```
int  MathRand();
```

Return Value

Integer value within the range of 0 to 32767.

Note

Before the first call of the function, it's necessary to call MathSrand to set the generator of pseudorandom numbers to the initial state.

Note

Instead of MathRand() you can use rand().

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set a new initial state to generate a series of pseudo-random integers at each l
   MathSrand(GetTickCount());
//--- in a loop, display 10 generated pseudo-random integers in the journal
   for(int i=0; i<10; i++)
     {
      int rand_value=MathRand();
      PrintFormat("Pseudorandom integer №%d: %u",i+1,rand_value);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

MathRound

The function returns a value rounded off to the nearest integer of the specified numeric value.

```
double  MathRound(
   double  value      // value to be rounded
   );
```

Parameters

value

[in] Numeric value before rounding.

Return Value

Value rounded till to the nearest integer.

Note

Instead of MathRound() you can use round().

Example:

```
#define VALUES_TOTAL 31

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare variables for conversion
   double value=0;                     // real number for MathRound conversion
   int    round_value=0;               // get the result here

MathSin

Returns the sine of a specified angle.

```
double  MathSin(
   double  value      // argument in radians
   );
```

Parameters

value

[in] Angle in radians.

Return Value

Sine of an angle measured in radians. Returns value within the range of -1 to 1.

Note

Instead of MathSin() you can use sin().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the sine value for each value of the X vector
   vector Y=MathSin(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+

MathSqrt

Returns the square root of a number.

```
double  MathSqrt(
   double  value      // positive number
   );
```

Parameters

value

[in] Positive numeric value.

Return Value

Square root of value. If value is negative, MathSqrt returns NaN (indeterminate value).

Note

Instead of MathSqrt() you can use sqrt().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 11 values from 0 to 10 with step 1
   vector X(11,VectorArange);
   Print("vector X = \n",X);
//--- calculate the square root of each value of the X vector
   X=MathSqrt(X);
   Print("MathSqrt(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       if(StopKeyPressed())
          break;
       Sleep(16);
      }

//--- clean up
   ExtGraph.Destroy();
   /*
   result:

MathSrand

Sets the starting point for generating a series of pseudorandom integers.

```
void  MathSrand(
   int  seed      // initializing number
   );
```

Parameters

seed

[in] Starting number for the sequence of random numbers.

Return Value

No return value.

Note

The MathRand() function is used for generating a sequence of pseudorandom numbers. Call of MathSrand() with a certain initializing number allows to always produces the same sequence of pseudorandom numbers.

To ensure receipt of non-recurring sequence, use the call of MathSrand(GetTickCount()), since the value of GetTickCount() increases from the moment of the start of the operating system and is not repeated within 49 days, until the built-in counter of milliseconds overflows. Use of MathSrand(TimeCurrent()) is not suitable, because the TimeCurrent() function returns the time of the last tick, which can be unchanged for a long time, for example at the weekend.

Initialization of the random number generator using MathSrand() for indicators and Expert Advisors is better performed in the OnInit() handler; it saves you from the following multiple restarts of the generator in OnTick() and OnCalculate().

Instead of the MathSrand() function you can use the srand() function.

Example:

```
#property description "The indicator shows the central limit theorem, which states:"
#property description "The sum of a sufficiently large number of weakly dependent ranc
#property description "having approximately equal magnitude (none of the summands dom
#property description "or makes a determining contribution to the sum), has a distribu

MathTan

The function returns a tangent of a number.

```
double  MathTan(
   double  rad      // argument in radians
   );
```

Parameters

rad

[in] Angle in radians.

Return Value

Tangent of rad. If rad is greater than or equal to 263, or less than or equal to -263, a loss of significance in the result occurs, in which case the function returns an indefinite number.

Note

Instead of MathTan() you can use tan().

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=-263;
//--- get 101 values from -263 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the tangent value for each value of the X vector
   vector Y=MathTan(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+
void CurvePlot(double &x_array[], double &y_array[], const color colour)
  {
   ExtGraph.Create(ChartID(), "Graphic", 0, 0, 0, GRAPH_WIDTH, GRAPH_HEIGHT);
   ExtGraph.CurveAdd(x_array, y_array, ColorToARGB(colour), CURVE_LINES);
   ExtGraph.IndentUp(30);
   ExtGraph.CurvePlotAll();
   string text1="Press ESC to delete the graph and stop the script, or";
   string text2="Press PgDn to create a screen, delete the graph and stop the script";
   ExtGraph.TextAdd(54, 9, text1, ColorToARGB(clrBlack));
   ExtGraph.TextAdd(54,21, text2, ColorToARGB(clrBlack));
   ExtGraph.Update();
  }
//+------------------------------------------------------------------+
//| Take a screenshot and save the image to a file                   |
//+------------------------------------------------------------------+
bool MakeAndSaveScreenshot(const string file_name)
  {
   string file_names[];
   ResetLastError();
```

© 2000-2025, MetaQuotes Ltd.

```
   int selected=FileSelectDialog("Save Picture", NULL, "All files (*.*)|*.*", FSD_WRIT
   if(selected<1)
     {
      if(selected<0)
         PrintFormat("%s: FileSelectDialog() function returned error %d", __FUNCTION__
      return false;
     }

   bool res=false;
   if(ChartSetInteger(0,CHART_SHOW,false))
      res=ChartScreenShot(0, file_names[0], GRAPH_WIDTH, GRAPH_HEIGHT);
   ChartSetInteger(0,CHART_SHOW,true);
   return(res);
  }
```

Result:

MathIsValidNumber

It checks the correctness of a real number.

```
bool  MathIsValidNumber(
   double  number      // number to check
   );
```

Parameters

number

[in] Checked numeric value.

Return Value

It returns true, if the checked value is an acceptable real number. If the checked value is a plus or minus infinity, or "not a number" (NaN), the function returns false.

Example:

```
   double abnormal=MathArcsin(2.0);
   if(!MathIsValidNumber(abnormal)) Print("Attention! MathArcsin(2.0) = ",abnormal);
```

See also

Real types (double, float)

© 2000-2025, MetaQuotes Ltd.

MathExpm1

Returns the value of the expression MathExp(x)-1.

```
double  MathExpm1(
   double  value      // power for the number e
   );
```

Parameters

value

[in] The number specifying the power.

Return Value

A value of the double type. In case of overflow the function returns INF (infinity), in case of underflow MathExpm1 returns 0.

Note

At values of *x* close to 0, the MathExpm1(x) function generates much more accurate values than the MathExp(x)-1 function.

Instead of the MathExpm1() function you can use the expm1() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 9 values from 0 to 8 with step 1
   vector X(9,VectorArange);
   Print("vector X = \n",X);
//--- calculate the ("e"(Euler number) to the power of each X vector value) - 1
   X=MathExpm1(X);
   Print("MathExpm1(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
```

© 2000-2025, MetaQuotes Ltd.

```
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+

MathLog1p

Returns the value of the expression MathLog(1+x).

```
double  MathLog1p(
   double  value      // value to take the logarithm
   );
```

Parameters

value

[in] The value, the logarithm of which is to be calculated.

Return Value

The natural logarithm of the value (value + 1) if successful. If value is < -1, the function returns NaN (undefined value). If value is equal to -1, the function returns INF (infinity).

Note

At values of x close to 0, the MathLog1p(x) function generates much more accurate values than the MathLog(1+x) function.

Instead of the MathLog1p() function you can use the log1p() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get 9 values from 0 to 8 with step 1
   vector X(9,VectorArange);
   Print("vector X = \n",X);
//--- for each vector value, calculate the logarithm for the expression (1 + X vector
   X=MathLog1p(X);
   Print("MathLog1p(X) = \n",X);

//--- transfer the calculated values from the vector to the array
   double y_array[];
   X.Swap(y_array);

//--- draw a graph of the calculated vector values
```

© 2000-2025, MetaQuotes Ltd.

```
   CurvePlot(y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
   /*
   result:
   vector X =
   [0,1,2,3,4,5,6,7,8]
   MathLog1p(X) =
   [0,0.6931471805599453,1.09861228866811,1.386294361119891,1.6094379124341,1.7917594
   */
  }
//+------------------------------------------------------------------+
//| Fill a vector with 'value' in 'step' increments                  |
//+------------------------------------------------------------------+

MathArccosh

Returns the hyperbolic arccosine.

```
double  MathArccosh(
   double  value     // 1 <= value < ∞
   );
```

Parameters

value

[in] The value, the hyperbolic arccosine of which is to be calculated.

Return Value

The hyperbolic arccosine of the number. If value is less than +1, the function returns NaN (undefined value).

Note

Instead of the MathArccosh() function you can use the acosh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/10);
   delta[0]=1;
//--- get 101 values from 1 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the hyperbolic arc cosine value for each value of the X vector
   vector Y=MathArccosh(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;

MathArcsinh

Returns the hyperbolic arcsine.

```
double  MathArcsinh(
   double  value      // -∞ < value < +∞
   );
```

Parameters

val

[in] The value, the hyperbolic arcsine of which is to be calculated.

Return Value

The hyperbolic arcsine of the number.

Note

Instead of the MathArcsinh() function you can use the asinh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/10);
   delta[0]=-31;
//--- get 101 values from -31 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the hyperbolic arc sine value for each value of the X vector
   vector Y=MathArcsinh(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())

MathArctanh

Returns the hyperbolic arctangent.

```
double  MathArctanh(
   double  value      // value in the range of -1 < value < 1
   );
```

Parameters

value

[in] Number within the range of -1 < value < 1, which represents the tangent.

Return Value

The hyperbolic arctangent of the number.

Note

Instead of the MathArctanh() function you can use the atanh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(34,2*M_PI/100);
   delta[0]=-1;
//--- get 34 values from -1 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the hyperbolic arc tangent value for each value of the X vector
   vector Y=MathArctanh(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values

MathCosh

Returns the hyperbolic cosine of the number.

```
double  MathCosh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic cosine of the number, value within the range of +1 to positive infinity.

Note

Instead of the MathCosh() function you can use the cosh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {

MathSinh

Returns the hyperbolic sine of the number.

```
double  MathSinh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic sine of the number.

Note

Instead of the MathSinh() function you can use the sinh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the hyperbolic sine value for each value of the X vector
   vector Y=MathSinh(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+
void CurvePlot(double &x_array[], double &y_array[], const color colour)
  {
   ExtGraph.Create(ChartID(), "Graphic", 0, 0, 0, GRAPH_WIDTH, GRAPH_HEIGHT);
   ExtGraph.CurveAdd(x_array, y_array, ColorToARGB(colour), CURVE_LINES);
   ExtGraph.IndentUp(30);
   ExtGraph.CurvePlotAll();
   string text1="Press ESC to delete the graph and stop the script, or";
   string text2="Press PgDn to create a screen, delete the graph and stop the script";
   ExtGraph.TextAdd(54, 9, text1, ColorToARGB(clrBlack));
   ExtGraph.TextAdd(54,21, text2, ColorToARGB(clrBlack));
   ExtGraph.Update();
  }
//+------------------------------------------------------------------+
//| Take a screenshot and save the image to a file                   |
//+------------------------------------------------------------------+
bool MakeAndSaveScreenshot(const string file_name)
  {
   string file_names[];
   ResetLastError();
   int selected=FileSelectDialog("Save Picture", NULL, "All files (*.*)|*.*", FSD_WRI
```

© 2000-2025, MetaQuotes Ltd.

```
   if(selected<1)
     {
      if(selected<0)
         PrintFormat("%s: FileSelectDialog() function returned error %d", __FUNCTION__
      return false;
     }

   bool res=false;
   if(ChartSetInteger(0,CHART_SHOW,false))
      res=ChartScreenShot(0, file_names[0], GRAPH_WIDTH, GRAPH_HEIGHT);
   ChartSetInteger(0,CHART_SHOW,true);
   return(res);
  }
```

MathTanh

Returns the hyperbolic tangent of the number.

```
double  MathTanh(
   double  value      // number
   );
```

Parameters

value

[in] Value.

Return Value

The hyperbolic tangent of the number, value within the range of -1 to +1.

Note

Instead of the MathTanh() function you can use the tanh() function.

Example:

```
#define GRAPH_WIDTH  750
#define GRAPH_HEIGHT 350

#include <Graphics\Graphic.mqh>

CGraphic ExtGraph;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   vector delta=vector::Full(101,2*M_PI/100);
   delta[0]=0;
//--- get 101 values from 0 to 2 pi with delta step
   vector X=delta.CumSum();
//--- calculate the hyperbolic tangent value for each value of the X vector
   vector Y=MathTanh(X);

//--- transfer the calculated values from vectors to arrays
   double x_array[],y_array[];
   X.Swap(x_array);
   Y.Swap(y_array);

//--- draw a graph of the calculated vector values
   CurvePlot(x_array,y_array,clrDodgerBlue);

//--- wait for pressing the Escape or PgDn keys to delete the graph (take a screenshot
```

© 2000-2025, MetaQuotes Ltd.

```
   while(!IsStopped())
     {
      if(StopKeyPressed())
         break;
      Sleep(16);
     }

//--- clean up
   ExtGraph.Destroy();
  }
//+------------------------------------------------------------------+
//| When pressing ESC, return 'true'                                 |
//| When pressing PgDn, take a graph screenshot and return 'true'    |
//| Otherwise, return 'false'                                        |
//+------------------------------------------------------------------+
bool StopKeyPressed()
  {
//--- if ESC is pressed, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_ESCAPE)!=0)
      return(true);
//--- if PgDn is pressed and a graph screenshot is successfully taken, return 'true'
   if(TerminalInfoInteger(TERMINAL_KEYSTATE_PAGEDOWN)!=0 && MakeAndSaveScreenshot(MQL
      return(true);
//--- return 'false'
   return(false);
  }
//+------------------------------------------------------------------+
//| Create a graph object and draw a curve                           |
//+------------------------------------------------------------------+
void CurvePlot(double &x_array[], double &y_array[], const color colour)
  {
   ExtGraph.Create(ChartID(), "Graphic", 0, 0, 0, GRAPH_WIDTH, GRAPH_HEIGHT);

MathSwap

Change the order of bytes in the ushort type value.

```
ushort  MathSwap(
   ushort  value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

ushort value with the reverse byte order.

MathSwap

Change the order of bytes in the uint type value.

```
uint  MathSwap(
   uint   value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

uint value with the reverse byte order.

MathSwap

Change the order of bytes in the ulong type value.

```
ulong  MathSwap(
   ulong  value      // value
   );
```

Parameters

value

[in] Value for changing the order of bytes.

Return Value

ulong value with the reverse byte order.

Example:

© 2000-2025, MetaQuotes Ltd.

```
#property script_show_inputs

input ulong  InpLongValue  =  1;     // Enter any ulong value here
input uint   InpIntValue   =  2;     // Enter any uint value here
input ushort InpShortValue =  3;     // Enter any ushort value here

String Functions

This is a group of functions intended for working with data of the string type.

Function	Action
StringAdd	Adds a string to the end of another string
StringBufferLen	Returns the size of buffer allocated for the string
StringCompare	Compares two strings and returns 1 if the first string is greater than the second; 0 - if the strings are equal; -1 (minus 1) - if the first string is less than the second one
StringConcatenate	Forms a string of parameters passed
StringFill	Fills out a specified string by selected symbols
StringFind	Search for a substring in a string
StringGetCharacter	Returns the value of a number located in the specified string position
StringInit	Initializes string by specified symbols and provides the specified string length
StringLen	Returns the number of symbols in a string
StringSetLength	Sets a specified length (in characters) for a string
StringReplace	Replaces all the found substrings of a string by a set sequence of symbols
StringReserve	Reserves the buffer of a specified size for a string in memory.
StringSetCharacter	Returns a copy of a string with a changed value of a symbol in a specified position
StringSplit	Gets substrings by a specified separator from the specified string, returns the number of substrings obtained
StringSubstr	Extracts a substring from a text string starting from a specified position
StringToLower	Transforms all symbols of a selected string to lowercase
StringToUpper	Transforms all symbols of a selected string into capitals
StringTrimLeft	Cuts line feed characters, spaces and tabs in the left part of the string
StringTrimRight	Cuts line feed characters, spaces and tabs in the right part of the string

© 2000-2025, MetaQuotes Ltd.

StringAdd

The function adds a substring to the end of a string.

```
bool  StringAdd(
   string&  string_var,         // string, to which we add
   string   add_substring       // string, which is added
   );
```

Parameters

string_var

[in][out] String, to which another one is added.

add_substring

[in] String that is added to the end of a source string.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Example:

```
void OnStart()
  {
   long length=1000000;
   string a="a",b="b",c;
//--- first method
   uint start=GetTickCount(),stop;
   long i;
   for(i=0;i<length;i++)
     {
      c=a+b;
     }
   stop=GetTickCount();
   Print("time for 'c = a + b' = ",(stop-start)," milliseconds, i = ",i);

//--- second method
   start=GetTickCount();
   for(i=0;i<length;i++)
     {
      StringAdd(a,b);
     }
   stop=GetTickCount();
   Print("time for 'StringAdd(a,b)' = ",(stop-start)," milliseconds, i = ",i);

//--- third method
   start=GetTickCount();
   a="a"; // re-initialize variable a
   for(i=0;i<length;i++)
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       StringConcatenate(c,a,b);
      }
   stop=GetTickCount();
   Print("time for 'StringConcatenate(c,a,b)' = ",(stop-start)," milliseconds, i = ",i
  }
```

StringConcatenate, StringSplit, StringSubstr

© 2000-2025, MetaQuotes Ltd.

StringBufferLen

The function returns the size of buffer allocated for the string.

```
int  StringBufferLen(
   string  string_var      // string
   )
```

Parameters

string_var

[in] String.

Return Value

The value 0 means that the string is constant and buffer size can't be changed. -1 means that the string belongs to the client terminal, and modification of the buffer contents can have indeterminate results.

Example:

```
void OnStart()
  {
   long length=1000;
   string a="a",b="b";
//---
   long i;
   Print("before: StringBufferLen(a) = ",StringBufferLen(a),
         "  StringLen(a) = ",StringLen(a));
   for(i=0;i<length;i++)
     {
      StringAdd(a,b);
     }
   Print("after: StringBufferLen(a) = ",StringBufferLen(a),
         "  StringLen(a) = ",StringLen(a));
  }
```

See also

StringAdd, StringInit, StringLen, StringFill

© 2000-2025, MetaQuotes Ltd.

StringCompare

The function compares two strings and returns the comparison result in form of an integer.

```
int  StringCompare(
   const string&  string1,                // the first string in the comparison
   const string&  string2,                // the second string in the comparison
   bool           case_sensitive=true     // case sensitivity mode selection for the
   );
```

Parameters

string1

[in] The first string.

string2

[in] The second string.

case_sensitive=true

[in] Case sensitivity mode selection. If it is true, then "A">"a". If it is false, then "A"="a". By default the value is equal to true.

Return Value

- -1 (minus one), if string1<string2
- 0 (zero), if string1=string2
- 1 (one), if string1>string2

Note

The strings are compared symbol by symbol, the symbols are compared in the alphabetic order in accordance with the current code page.

Example:

```
void OnStart()
  {
//--- what is larger - apple or home?
   string s1="Apple";
   string s2="home";

//--- compare case sensitive
   int result1=StringCompare(s1,s2);
   if(result1>0) PrintFormat("Case sensitive comparison: %s > %s",s1,s2);
   else
     {
      if(result1<0)PrintFormat("Case sensitive comparison: %s < %s",s1,s2);
      else PrintFormat("Case sensitive comparison: %s = %s",s1,s2);
     }

//--- compare case-insensitive
   int result2=StringCompare(s1,s2,false);
   if(result2>0) PrintFormat("Case insensitive comparison: %s > %s",s1,s2);
   else
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       if(result2<0)PrintFormat("Case insensitive comparison: %s < %s",s1,s2);
       else PrintFormat("Case insensitive comparison: %s = %s",s1,s2);
      }
/* Result
     Case-sensitive comparison: Apple < home
     Case insensitive comparison: Apple < home
*/
  }
```

© 2000-2025, MetaQuotes Ltd.

StringConcatenate

The function forms a string of passed parameters and returns the size of the formed string. Parameters can be of any type. Number of parameters can't be less than 2 or more than 64.

```
int  StringConcatenate(
   string&  string_var,    // string to form
   void argument1          // first parameter of any simple type
   void argument2          // second parameter of any simple type
   ...                     // next parameter of any simple type
   );
```

Parameters

string_var

[out] String that will be formed as a result of concatenation.

argumentN

[in] Any comma separated values. From 2 to 63 parameters of any simple type.

Return Value

Returns the string length, formed by concatenation of parameters transformed into string type. Parameters are transformed into strings according to the same rules as in Print() and Comment().

Example:

```
void OnStart()
  {
//--- declare and define variables participating in concatenation
   string text="";
   string text1="This script shows how the StringConcatenate() function works.\n";
   string text2="This is the second line, at the end of which there is a line break co
   string text3="This is line number ";
   int    num3=3;
   string text31=", the number of which is entered into the function as a separate pa
   string textN="\n";
   string text4="This is line number 4, preceded by a separate parameter with a line b
   int    length=StringConcatenate(text, text1, text2, text3, num3, text31, textN, te
   Print(text, "\nLength of the resulting string = ", length);

   /*
   Result
   This script shows how the StringConcatenate() function works.
   This is the second line, at the end of which there is a line break control code.
   This is line number 3, the number of which is entered into the function as a separa
   This is line number 4, preceded by a separate parameter with a line break code.
   Line 5 includes a real number: 0.12345
   Length of the resulting string = 358
   */
  }
```

StringAdd, StringSplit, StringSubstr

© 2000-2025, MetaQuotes Ltd.

StringFill

It fills out a selected string by specified symbols.

```
bool  StringFill(
   string&   string_var,       // string to fill
   ushort    character         // symbol that will fill the string
   );
```

Parameters

string_var

[in][out] String, that will be filled out by the selected symbol.

character

[in] Symbol, by which the string will be filled out.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Note

Filling out a string at place means that symbols are inserted directly to the string without transitional operations of new string creation or copying. This allows to save the operation time.

Example:

```
void OnStart()
  {
   string str;
   StringInit(str,20,'_');
   Print("str = ",str);
   StringFill(str,0);
   Print("str = ",str,": StringBufferLen(str) = ", StringBufferLen(str));
  }
// Result
//   str = ____________________
//   str =  : StringBufferLen(str) = 20
//
```

See also

StringBufferLen, StringLen, StringInit

© 2000-2025, MetaQuotes Ltd.

StringFind

Search for a substring in a string.

```
int  StringFind(
   string  string_value,        // string in which search is made
   string  match_substring,     // what is searched
   int     start_pos=0          // from what position search starts
   );
```

Parameters

string_value

[in] String, in which search is made.

match_substring

[in] Searched substring.

start_pos=0

[in] Position in the string from which search is started.

Return Value

Returns position number in a string, from which the searched substring starts, or -1, if the substring is not found.

Example:

```
#define   RESERVE    100

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the symbol base currency and the profit currency
   string symbol_currency_base  =SymbolInfoString(Symbol(), SYMBOL_CURRENCY_BASE);
   string symbol_currency_profit=SymbolInfoString(Symbol(), SYMBOL_CURRENCY_PROFIT);
   PrintFormat("Symbol Currency Base: %s\nSymbol Currency Profit: %s", symbol_currency

//--- in the loop through all symbols available on the server
   int total=SymbolsTotal(false), pos=-1;
   for(int i=0; i<total; i++)
     {
      //--- get the name of the next symbol
      string name=SymbolName(i, false);

      //--- look for a substring in the symbol name with the name of the base currency
      //--- if a substring is found, display the symbol name, its index in the curren
      pos = StringFind(name, symbol_currency_base);
      if(pos >= 0)
```

© 2000-2025, MetaQuotes Ltd.

```
         PrintFormat("The '%s' symbol at index %u in the list contains the '%s' currer

      //--- look for a substring in the symbol name with the name of the quoted currer
      //--- if a substring is found, display the symbol name, its index in the currenc
      pos = StringFind(name, symbol_currency_profit);
      if(pos >= 0)
         PrintFormat("The '%s' symbol at index %u in the list contains the '%s' currer
     }

  /*
  Result

StringGetCharacter

Returns value of a symbol, located in the specified position of a string.

```
ushort  StringGetCharacter(
   string  string_value,     // string
   int     pos               // symbol position in the string
   );
```

Parameters

string_value

[in] String.

pos

[in] Position of a symbol in the string. Can be from 0 to StringLen(text) -1.

Return Value

Symbol code or 0 in case of an error. To get the error code call GetLastError().

Example:

```
void OnStart()
  {
//--- delete all comments on the chart
   Comment("");
//--- declare a string, from which we will obtain the values of symbol codes and remem
   string message = "The script demonstrates the operation of the StringGetCharacter()
   int    length  = StringLen(message);
//--- declare a string variable, to which we will add the obtained symbols from the de
   string text    = "";
//--- in the loop by the demo string length
   for(int i=0; i<length; i++)
     {
      //--- wait 1/10 seconds
      Sleep(100);
      //--- get a symbol from a string located at the loop index in the demo string
      ushort char_code=StringGetCharacter(message, i);
      //--- add a symbol to the displayed string and display the resulting string as a
      text+=ShortToString(char_code);
      Comment(text);
     }
//--- wait two seconds and remove the comment from the chart
   Sleep(2000);
   Comment("");

   /*
   Result: the demo string appears on the screen character by character
   The script demonstrates the operation of the StringGetCharacter() function
   */
```

```
}
```

See also

StringSetCharacter, StringBufferLen, StringLen, StringFill, StringInit, StringToCharArray, StringToShortArray

© 2000-2025, MetaQuotes Ltd.

StringInit

Initializes a string by specified symbols and provides the specified string size.

```
bool  StringInit(
   string&    string_var,       // string to initialize
   int        new_len=0,        // required string length after initialization
   ushort     character=0       // symbol, by which the string will be filled
   );
```

Parameters

string_var

[in][out] String that should be initialized and deinitialized.

new_len=0

[in] String length after initialization. If length=0, it deinitializes the string, i.e. the string buffer is cleared and the buffer address is zeroed.

character=0

[in] Symbol to fill the string.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Note

If character=0 and the length new_len>0, the buffer of the string of indicated length will be distributed and filled by zeroes. The string length will be equal to zero, because the whole buffer is filled out by string terminators.

Example:

```
void OnStart()
  {
//---
   string str;
   StringInit(str,200,0);
   Print("str = ",str,": StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
  }
/*  Result
str = : StringBufferLen(str) = 200   StringLen(str) = 0
*/
```

See also

StringBufferLen, StringLen

© 2000-2025, MetaQuotes Ltd.

StringLen

Returns the number of symbols in a string.

```
int  StringLen(
   string  string_value      // string
   );
```

Parameters

string_value

[in] String to calculate length.

Return Value

Number of symbols in a string without the ending zero.

Example:

```
void OnStart()
  {
//--- define the test string
   string text="123456789012345";
//--- get the number of symbols in the string
   int str_len=StringLen(text);
//--- display the string and the number of symbols in it in the log
   PrintFormat("The StringLen() function returned the value of %d chars in string: '%s

   /*
   Result
   The StringLen() function returned the value of 15 chars in string: '12345678901234
   */
  }
```

See also

StringBufferLen, StringTrimLeft, StringTrimRight, StringToCharArray, StringToShortArray

© 2000-2025, MetaQuotes Ltd.

StringSetLength

Sets a specified length (in characters) for a string.

```
bool  StringSetLength(
   string&     string_var,       // string
   uint        new_length        // new string length
   );
```

Parameters

string_var

[in][out] String, for which a new length in characters should be set.

new_capacity

[in] Required string length in characters. If new_length is less than the current size, the excessive characters are discarded.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

TheStringSetLength() function does not change the size of the buffer allocated for a string.

Example:

```
void OnStart()
  {
//--- define the string
   string text="123456789012345";

//--- display a string and its length in the log
   PrintFormat("Before StringSetLength() the string '%s' has a size of %d characters",

//--- reduce the string size to 10 characters
   StringSetLength(text, 10);

//--- display a string, changed due to StringSetLength() operation, and its new length
   PrintFormat("After StringSetLength() the string is now '%s', and has a size of %d c

   /*
   Result
   Before StringSetLength() the string '123456789012345' has a size of 15 characters
   After StringSetLength() the string is now '1234567890', and has a size of 10 charac
   */
  }
```

See also

StringLen, StringBufferLen, StringReserve StringInit, StringSetCharacter

© 2000-2025, MetaQuotes Ltd.

StringReplace

It replaces all the found substrings of a string by a set sequence of symbols.

```
int  StringReplace(
   string&         str,              // the string in which substrings will be replace
   const string    find,             // the searched substring
   const string    replacement       // the substring that will be inserted to the fou
   );
```

Parameters

str

[in][out] The string in which you are going to replace substrings.

find

[in] The desired substring to replace.

replacement

[in] The string that will be inserted instead of the found one.

Return Value

The function returns the number of replacements in case of success, otherwise -1. To get an error code call the GetLastError() function.

Note

If the function has run successfully but no replacements have been made (the substring to replace was not found), it returns 0.

The error can result from incorrect *str* or *find* parameters (empty or non-initialized string, see StringInit()). Besides, the error occurs if there is not enough memory to complete the replacement.

Example:

```
  string text="The quick brown fox jumped over the lazy dog.";
  int replaced=StringReplace(text,"quick","slow");
  replaced+=StringReplace(text,"brown","black");
  replaced+=StringReplace(text,"fox","bear");
  Print("Replaced: ", replaced,". Result=",text);

//  Result
//  Replaced: 3. Result=The slow black bear jumped over the lazy dog.
//
```

See also

StringSetCharacter(), StringSubstr()

© 2000-2025, MetaQuotes Ltd.

StringReserve

Reserves the buffer of a specified size for a string in memory.

```
bool  StringReserve(
   string&     string_var,       // string
   uint        new_capacity      // buffer size for storing a string
   );
```

Parameters

string_var

[in][out] String the buffer size should change the size for.

new_capacity

[in] Buffer size required for a string. If the new_capacity size is less than the string length, the size of the current buffer does not change.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Generally, the string size is not equal to the size of the buffer meant for storing the string. When creating a string, the appropriate buffer is usually allocated with a margin. The StringReserve() function allows managing the buffer size and specify the optimal size for future operations.

Unlike StringInit(), the StringReserve() function does not change the string contents and does not fill it with characters.

Example:

```
void OnStart()
  {
   string s;
//--- check the operation speed without using StringReserve
   ulong t0=GetMicrosecondCount();
   for(int i=0; i< 1024; i++)
      s+=" "+(string)i;
   ulong msc_no_reserve=GetMicrosecondCount()-t0;
   s=NULL;
//--- now, let's do the same using StringReserve
   StringReserve(s,1024 * 3);
   t0=GetMicrosecondCount();
   for(int i=0; i< 1024; i++)
      s+=" "+(string)i;
   ulong msc_reserve=GetMicrosecondCount()-t0;
//--- check the time
   Print("Test with StringReserve passed for "+(string)msc_reserve+" msc");
   Print("Test without StringReserve passed for "+(string)msc_no_reserve+" msc");
/* Result
```

© 2000-2025, MetaQuotes Ltd.

```
      Test with StringReserve passed for 50 msc
      Test without StringReserve passed for 121 msc
*/
  }
```

See also

StringBufferLen, StringSetLength, StringInit, StringSetCharacter

© 2000-2025, MetaQuotes Ltd.

StringSetCharacter

Returns copy of a string with a changed character in a specified position.

```
bool  StringSetCharacter(
   string&   string_var,       // string
   int       pos,              // position
   ushort    character         // character
   );
```

Parameters

string_var

[in][out] String.

pos

[in] Position of a character in a string. Can be from 0 to StringLen(text).

character

[in] Symbol code Unicode.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Note

If pos is less than string length and the symbol code value = 0, the string is cut off (but the buffer size, distributed for the string remains unchanged). The string length becomes equal to pos.

If *pos* is equal to string length, the specified symbol is added at the string end, and the length is enlarged by one.

Example:

```
void OnStart()
  {
   string str="0123456789";
   Print("before: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
//--- add zero value in the middle
   StringSetCharacter(str,6,0);
   Print("after: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
//--- add symbol at the end
   int size=StringLen(str);
   StringSetCharacter(str,size,'+');
   Print("addition: str = ",str,",StringBufferLen(str) = ",
         StringBufferLen(str),"  StringLen(str) = ",StringLen(str));
  }
/* Result
   before: str = 0123456789 ,StringBufferLen(str) = 0    StringLen(str) = 10
```

© 2000-2025, MetaQuotes Ltd.

```
   after:  str = 012345 ,StringBufferLen(str) = 16   StringLen(str) = 6
   addition: str = 012345+ ,StringBufferLen(str) = 16   StringLen(str) = 7
*/
```

See also

StringBufferLen, StringLen, StringFill, StringInit, CharToString, ShortToString, CharArrayToString, ShortArrayToString

© 2000-2025, MetaQuotes Ltd.

StringSplit

Gets substrings by a specified separator from the specified string, returns the number of substrings obtained.

```
int  StringSplit(
   const string   string_value,        // A string to search in
   const ushort   separator,           // A separator using which substrings will be se
   string         & result[]           // An array passed by reference to get the found
   );
```

Parameters

string_value

[in] The string from which you need to get substrings. The string will not change.

pos

[in] The code of the separator character. To get the code, you can use the StringGetCharacter() function.

result[]

[out] An array of strings where the obtained substrings are located.

Return Value

The number of substrings in the result[] array. If the separator is not found in the passed string, only one source string will be placed in the array.

If string_value is empty or NULL, the function will return zero. In case of an error the function returns -1. To get the error code, call the GetLastError() function.

Example:

```
string to_split="_life_is_good_"; // A string to split into substrings
   string sep="_";                // A separator as a character
   ushort u_sep;                  // The code of the separator character
   string result[];               // An array to get strings
   //--- Get the separator code
   u_sep=StringGetCharacter(sep,0);
   //--- Split the string to substrings
   int k=StringSplit(to_split,u_sep,result);
   //--- Show a comment
   PrintFormat("Strings obtained: %d. Used separator '%s' with the code %d",k,sep,u_se
   //--- Now output all obtained strings
   if(k>0)
     {
      for(int i=0;i<k;i++)
        {
         PrintFormat("result[%d]=\"%s\"",i,result[i]);
        }
     }
```

© 2000-2025, MetaQuotes Ltd.

StringReplace(), StringSubstr(), StringConcatenate()

© 2000-2025, MetaQuotes Ltd.

StringSubstr

Extracts a substring from a text string starting from the specified position.

```
string  StringSubstr(
   string  string_value,      // string
   int     start_pos,         // position to start with
   int     length=-1          // length of extracted string
   );
```

Parameters

string_value

[in] String to extract a substring from.

start_pos

[in] Initial position of a substring. Can be from 0 to StringLen(text) -1.

length=-1

[in] Length of an extracted substring. If the parameter value is equal to -1 or parameter isn't set, the substring will be extracted from the indicated position till the string end.

Return Value

Copy of a extracted substring, if possible. Otherwise returns an empty string.

Example:

```
void OnStart()
  {
//--- get the name of the current symbol
   string name = Symbol();

//--- get the base and quoted symbol currencies
   string base   = StringSubstr(name, 0, 3);
   string quoted = StringSubstr(name, 3, 3);

//--- display the obtained symbol currencies in the log
   PrintFormat("Symbol: %s. Currency base: %s, currency quoted: %s", name, base, quote

   /*
   Result
   Symbol: EURUSD. Currency base: EUR, currency quoted: USD
   */
  }
```

StringToLower

Transforms all symbols of a selected string into lowercase.

```
bool  StringToLower(
   string&  string_var      // string to process
   );
```

Parameters

string_var

[in][out] String.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Example:

```
void OnStart()
  {
//--- define the source string in uppercase
   string text=" - THIS STRING, WRITTEN IN UPPERCASE, MUST BE WRITTEN IN LOWERCASE";
//--- Display the source string in the log
   Print("Source line:\n", text);
//--- convert all string characters to lowercase and display the result in the log
   if(StringToLower(text))
      Print("The original string after using the StringToLower() function:\n", text);

   /*
   Result
   Source line:
    - THIS STRING, WRITTEN IN UPPERCASE, MUST BE WRITTEN IN LOWERCASE
   The original string after using the StringToLower() function:
    - this string, written in uppercase, must be written in lowercase
   */
  }
```

StringToUpper

Transforms all symbols of a selected string into capitals.

```
bool  StringToUpper(
   string&  string_var      // string to process
   );
```

Parameters

string_var

[in][out] String.

Return Value

In case of success returns true, otherwise - false. To get the error code call GetLastError().

Example:

```
void OnStart()
  {
//--- define the source string in lowercase
   string text=" - this string, written in lowercase, must be written in uppercase";
//--- Display the source string in the log
   Print("Source line:\n", text);
//--- convert all string characters to uppercase and display the result in the log
   if(StringToUpper(text))
      Print("The original string after using the StringToUpper() function:\n", text);

   /*
   Result
   Source line:
    - this string, written in lowercase, must be written in uppercase
   The original string after using the StringToUpper() function:
    - THIS STRING, WRITTEN IN LOWERCASE, MUST BE WRITTEN IN UPPERCASE
   */
  }
```

StringToLower, StringTrimLeft, StringTrimRight

© 2000-2025, MetaQuotes Ltd.

StringTrimLeft

The function cuts line feed characters, spaces and tabs in the left part of the string till the first meaningful symbol. The string is modified at place.

```
int  StringTrimLeft(
   string&  string_var      // string to cut
   );
```

Parameters

string_var

[in][out] String that will be cut from the left.

Return Value

Returns the number of cut symbols.

Example:

```
void OnStart()
  {
//--- define the source string with six spaces on the left
   string text="      All spaces on the left will be removed from this string";
//--- Display the source string in the log
   PrintFormat("Source line:\n'%s'", text);
//--- remove all spaces on the left and display the number of removed characters and t
   int num=StringTrimLeft(text);
   PrintFormat("The StringTrimLeft() function removed %d chars from the left side. Nov

   /*
   Result
   Source line:
   '      All spaces on the left will be removed from this string'
   The StringTrimLeft() function removed 6 chars from the left side. Now the line lool
   'All spaces on the left will be removed from this string'
   */
  }
```

StringTrimRight, StringToLower, StringToUpper

© 2000-2025, MetaQuotes Ltd.

StringTrimRight

The function cuts line feed characters, spaces and tabs in the right part of the string after the last meaningful symbol. The string is modified at place.

```
int  StringTrimRight(
   string&  string_var      // string to cut
   );
```

Parameters

string_var

[in][out] String that will be cut from the right.

Return Value

Returns the number of cut symbols.

Example:

```
void OnStart()
  {
//--- define the source string with six spaces on the right
   string text="All spaces on the right will be removed from this string      ";
//--- Display the source string in the log
   PrintFormat("Source line:\n'%s'", text);
//--- remove all spaces on the right and display the number of removed characters and
   int num=StringTrimRight(text);
   PrintFormat("The StringTrimRight() function removed %d chars from the right side. N

   /*
   Result
   Source line:
   'All spaces on the right will be removed from this string      '
   The StringTrimRight() function removed 6 chars from the right side. Now the line lo
   'All spaces on the right will be removed from this string'
   */
  }
```

Date and Time

This is the group of functions for working with data of datetime type (an integer that represents the number of seconds elapsed from 0 hours of January 1, 1970).

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

Function	Action
TimeCurrent	Returns the last known server time (time of the last quote receipt) in the datetime format
TimeTradeServer	Returns the current calculation time of the trade server
TimeLocal	Returns the local computer time in datetime format
TimeGMT	Returns GMT in datetime format with the Daylight Saving Time by local time of the computer, where the client terminal is running
TimeDaylightSavings	Returns the sign of Daylight Saving Time switch
TimeGMTOffset	Returns the current difference between GMT time and the local computer time in seconds, taking into account DST switch
TimeToStruct	Converts a datetime value into a variable of MqlDateTime structure type
StructToTime	Converts a variable of MqlDateTime structure type into a datetime value

© 2000-2025, MetaQuotes Ltd.

TimeCurrent

Returns the last known server time, time of the last quote receipt for one of the symbols selected in the "Market Watch" window. In the OnTick() handler, this function returns the time of the received handled tick. In other cases (for example, call in handlers OnInit(), OnDeinit(), OnTimer() and so on) this is the time of the last quote receipt for any symbol available in the "Market Watch" window, the time shown in the title of this window. The time value is formed on a trade server and does not depend on the time settings on your computer. There are 2 variants of the function.

Call without parameters

```
datetime  TimeCurrent();
```

Call with MqlDateTime type parameter

```
datetime  TimeCurrent(
   MqlDateTime&  dt_struct      // structure type variable
   );
```

Parameters

dt_struct

[out] MqlDateTime structure type variable.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeCurrent() is simulated according to historical data.

Example:

```
void OnStart()
  {
//--- declare the MqlDateTime variable to be filled with date/time data and get the ti
   MqlDateTime tm={};
   datetime    time1=TimeCurrent();    // first form of call: time of the last quote i
   datetime    time2=TimeCurrent(tm);  // second form of call: time of the last quote

//--- display the result of receiving the date/time and filling the structure with the
   PrintFormat("Tick time: %s\n- Year: %u\n- Month: %02u\n- Day: %02u\n- Hour: %02u\n-
               (string)time1, tm.year, tm.mon, tm.day, tm.hour, tm.min, tm.sec, tm.day
   /*
   result:
   Tick time: 2024.04.18 15:40:06
   - Year: 2024
   - Month: 04
```

© 2000-2025, MetaQuotes Ltd.

```
   - Day: 18
   - Hour: 15
   - Min: 40
   - Sec: 06
   - Day of Year: 108
   - Day of Week: 4 (THURSDAY)
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeTradeServer

Returns the calculated current time of the trade server. Unlike TimeCurrent(), the calculation of the time value is performed in the client terminal and depends on the time settings on your computer. There are 2 variants of the function.

Call without parameters

```
datetime  TimeTradeServer();
```

Call with MqlDateTime type parameter

```
datetime  TimeTradeServer(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeTradeServer() is simulated according to historical data and always equal to TimeCurrent().

Example:

```
void OnStart()
  {
//--- declare the MqlDateTime variable to be filled with date/time data and get the ti
   MqlDateTime tm={};
   datetime    time_current=TimeCurrent();                  // first form of call: tir
   datetime    time_server =TimeTradeServer(tm);            // second form of call: es
   int         difference  =int(time_current-time_server);  // difference between Time

//--- display the time of the last quote and the estimated current time of the trade s
   PrintFormat("Time Current: %s\nTime Trade Server: %s\n- Year: %u\n- Month: %02u\n-
               "- Hour: %02u\n- Min: %02u\n- Sec: %02u\n- Day of Year: %03u\n- Day of
               (string)time_current, (string)time_server, tm.year, tm.mon, tm.day, tm.
               EnumToString((ENUM_DAY_OF_WEEK)tm.day_of_week), difference);
   /*
   result:
   Time Current: 2024.04.18 16:10:14
   Time Trade Server: 2024.04.18 16:10:15
```

© 2000-2025, MetaQuotes Ltd.

```
   - Year: 2024
   - Month: 04
   - Day: 18
   - Hour: 16
   - Min: 10
   - Sec: 15
   - Day of Year: 108
   - Day of Week: 4 (THURSDAY)
   Difference between Time Current and Time Trade Server: -1
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeLocal

Returns the local time of a computer, where the client terminal is running. There are 2 variants of the function.

Call without parameters

```
datetime  TimeLocal();
```

Call with MqlDateTime type parameter

```
datetime  TimeLocal(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeLocal() is always equal to TimeCurrent() simulated server time.

Example:

```
void OnStart()
  {
//--- declare the MqlDateTime variable to be filled with PC local time data
   MqlDateTime tm={};
   datetime    time1=TimeLocal();   // first form of call: PC local time
   datetime    time2=TimeLocal(tm); // second form of call: PC local time with filling

//--- display the result of receiving PC local time and filling the structure with the
   PrintFormat("Local time: %s\n- Year: %u\n- Month: %02u\n- Day: %02u\n- Hour: %02u\n
               (string)time1, tm.year, tm.mon, tm.day, tm.hour, tm.min, tm.sec, tm.day
   /*
   result:
   Local time: 2024.04.18 19:44:09
   - Year: 2024
   - Month: 04
   - Day: 18
   - Hour: 19
   - Min: 44
```

© 2000-2025, MetaQuotes Ltd.

```
   - Sec: 09
   - Day of Year: 108
   - Day of Week: 4 (THURSDAY)
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeGMT

Returns the GMT, which is calculated taking into account the DST switch by the local time on the computer where the client terminal is running. There are 2 variants of the function.

Call without parameters

```
datetime  TimeGMT();
```

Call with MqlDateTime type parameter

```
datetime  TimeGMT(
   MqlDateTime&  dt_struct      // Variable of structure type
   );
```

Parameters

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

Value of datetime type

Note

If the MqlDateTime structure type variable has been passed as a parameter, it is filled accordingly.

To arrange high-resolution counters and timers, use the GetTickCount() function, which produces values in milliseconds.

During testing in the strategy tester, TimeGMT() is always equal to TimeTradeServer() simulated server time.

Example:

```
void OnStart()
  {
//--- declare the MqlDateTime variable to be filled with date/time data and get the PC
   MqlDateTime tm={};
   datetime    time1=TimeLocal();            // first form of call: PC local time
   datetime    time2=TimeGMT(tm);            // second form of call: GMT calculated fi
   int         shift=int(time1-time2)/3600;  // local time offset relative to GMT

//--- display local time and GMT with the data of the filled MqlDateTime structure in
   PrintFormat("Time Local: %s\nTime GMT: %s\n- Year: %u\n- Month: %02u\n- Day: %02u\n
               "- Hour: %02u\n- Min: %02u\n- Sec: %02u\n- Day of Year: %03u\n- Day of
               (string)time1, (string)time2, tm.year, tm.mon, tm.day, tm.hour, tm.min,
               EnumToString((ENUM_DAY_OF_WEEK)tm.day_of_week), shift);
   /*
   result:
   Time Local: 2024.04.18 19:37:23
   Time GMT: 2024.04.18 12:37:23
   - Year: 2024
```

© 2000-2025, MetaQuotes Ltd.

```
   - Month: 04
   - Day: 18
   - Hour: 12
   - Min: 37
   - Sec: 23
   - Day of Year: 108
   - Day of Week: 4 (THURSDAY)
   Local time offset relative to GMT: +7
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeDaylightSavings

Returns correction for daylight saving time in seconds, if the switch to summer time has been made. It depends on the time settings of your computer.

```
int  TimeDaylightSavings();
```

Return Value

If switch to winter (standard) time has been made, it returns 0.

Example:

```
void OnStart()
  {
//--- get daylight saving time adjustment in seconds
   int sec_dl=TimeDaylightSavings();

//--- create the text describing the received value
   string text=(sec_dl==0 ? "Standard \"winter\" time is used" :
                StringFormat("Daylight saving time has been switched over. The correct

//--- display a description of the daylight saving time adjustment in seconds in the
   Print(text);
   /*
   result for "winter" time:
   Standard "winter" time is used

   result for "summer" time:
   Daylight saving time has been switched over. The correction is -3600 seconds
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeGMTOffset

Returns the current difference between GMT time and the local computer time in seconds, taking into account switch to winter or summer time. Depends on the time settings of your computer.

```
int  TimeGMTOffset();
```

Return Value

The value of int type, representing the current difference between GMT time and the local time of the computer TimeLocal in seconds.

```
TimeGMTOffset() =  TimeGMT() - TimeLocal()
```

Example:

```
void OnStart()
  {
//--- get local time, GMT and the difference between GMT and local computer time in se
   datetime time_local=TimeLocal();
   datetime time_gmt  =TimeGMT();
   int      offset    =TimeGMTOffset();

//--- show the obtained time and offset values in the log
   PrintFormat("Local Time: %s, GMT Time: %s, Seconds Offset: %+d", (string)time_local
   /*
   result:
   Local Time: 2024.04.18 19:35:52, GMT Time: 2024.04.18 12:35:52, Seconds Offset: -25
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TimeToStruct

Converts a value of datetime type (number of seconds since 01.01.1970) into a structure variable MqlDateTime.

```
bool  TimeToStruct(
   datetime      dt,            // date and time
   MqlDateTime&  dt_struct      // structure for the adoption of values
   );
```

Parameters

dt

[in] Date value to convert.

dt_struct

[out] Variable of structure type MqlDateTime.

Return Value

True if successful, otherwise false. To get information about the error, call the GetLastError() function.

Example:

```
void OnStart()
  {
//--- get the last known time of the server, declare the date/time structure and fill
   datetime    time=TimeCurrent();
   MqlDateTime tm  ={};
   if(!TimeToStruct(time,tm))
      Print("TimeToStruct() failed. Error ", GetLastError());

//--- display the obtained server time and the result of filling the MqlDateTime struc
   PrintFormat("Server time: %s\n- Year: %u\n- Month: %02u\n- Day: %02u\n- Hour: %02u\
               (string)time, tm.year, tm.mon, tm.day, tm.hour, tm.min, tm.sec, tm.day_
   /*
   result:
   Server time: 2024.04.18 15:47:27
   - Year: 2024
   - Month: 04
   - Day: 18
   - Hour: 15
   - Min: 47
   - Sec: 27
   - Day of Year: 108
   - Day of Week: 4 (THURSDAY)
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

StructToTime

Converts a structure variable MqlDateTime into a value of datetime type and returns the resulting value.

```
datetime  StructToTime(
   MqlDateTime&  dt_struct      // structure of the date and time
   );
```

Parameters

dt_struct

[in] Variable of structure type MqlDateTime.

Return Value

The value of datetime type containing the number of seconds since 01.01.1970.

Example:

```
#property script_show_inputs

input int   InpYear  =  0;    // Year
input int   InpMonth =  0;    // Month
input int   InpDay   =  0;    // Day
input int   InpHour  =  0;    // Hour
input int   InpMin   =  0;    // Minutes
input int   InpSec   =  0;    // Seconds

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- adjust the entered values and write them to variables
   int year =  (InpYear<1970 ? 1970 : InpYear); // If the year entered is less than 19
   int month=  (InpMonth<1 ?  1  :  InpMonth > 12  ?  12 :  InpMonth);
   int day  =  (InpDay  <1 ?  1  :  InpDay   > 31  ?  31 :  InpDay);
   int hour =  (InpHour <0 ?  0  :  InpHour  > 23  ?  23 :  InpHour);
   int min  =  (InpMin  <0 ?  0  :  InpMin   > 59  ?  59 :  InpMin);
   int sec  =  (InpSec  <0 ?  0  :  InpSec   > 59  ?  59 :  InpSec);

//--- display the entered values in the log
   PrintFormat("Entered date and time: %04u.%02u.%02u %02u:%02u:%02u", InpYear, InpMor

//--- display the adjusted entered values in the log
   PrintFormat("Corrected date and time: %04u.%02u.%02u %02u:%02u:%02u", year, month,

//--- write the input values to the corresponding structure fields
   MqlDateTime time_struct={};
   time_struct.year= year;
```

© 2000-2025, MetaQuotes Ltd.

```
   time_struct.mon = month;
   time_struct.day = day;
   time_struct.hour= hour;
   time_struct.min = min;
   time_struct.sec = sec;

//--- convert the date and time from the structure into a variable of datetime type ar
   datetime time = StructToTime(time_struct);

//--- display the result of conversion from an MqlDateTime structure type variable to
   Print("Converted date and time: ",TimeToString(time,TIME_DATE|TIME_MINUTES|TIME_SEC
   /*
   results if zero default values are entered:
   Entered date and time: 0000.00.00 00:00:00
   Corrected date and time: 1970.01.01 00:00:00
   Converted date and time: 1970.01.01 00:00:00

   results if the wrong day of the current year's February is entered:
   Entered date and time: 2024.02.31 00:00:00
   Corrected date and time: 2024.02.31 00:00:00
   Converted date and time: 2024.03.02 00:00:00
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

Account Information

Functions that return parameters of the current account.

Function	Action
AccountInfoDouble	Returns a value of double type of the corresponding account property
AccountInfoInteger	Returns a value of integer type (bool, int or long) of the corresponding account property
AccountInfoString	Returns a value string type corresponding account property

© 2000-2025, MetaQuotes Ltd.

AccountInfoDouble

Returns the value of the appropriate account property.

```
double  AccountInfoDouble(
   ENUM_ACCOUNT_INFO_DOUBLE  property_id      // Property identifier
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_DOUBLE.

Return Value

Value of double type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoDouble()
   printf("ACCOUNT_BALANCE =  %G",AccountInfoDouble(ACCOUNT_BALANCE));
   printf("ACCOUNT_CREDIT =  %G",AccountInfoDouble(ACCOUNT_CREDIT));
   printf("ACCOUNT_PROFIT =  %G",AccountInfoDouble(ACCOUNT_PROFIT));
   printf("ACCOUNT_EQUITY =  %G",AccountInfoDouble(ACCOUNT_EQUITY));
   printf("ACCOUNT_MARGIN =  %G",AccountInfoDouble(ACCOUNT_MARGIN));
   printf("ACCOUNT_MARGIN_FREE =  %G",AccountInfoDouble(ACCOUNT_MARGIN_FREE));
   printf("ACCOUNT_MARGIN_LEVEL =  %G",AccountInfoDouble(ACCOUNT_MARGIN_LEVEL));
   printf("ACCOUNT_MARGIN_SO_CALL = %G",AccountInfoDouble(ACCOUNT_MARGIN_SO_CALL));
   printf("ACCOUNT_MARGIN_SO_SO = %G",AccountInfoDouble(ACCOUNT_MARGIN_SO_SO));
  }
```

AccountInfoInteger

Returns the value of the appropriate account property.

```
long  AccountInfoInteger(
   ENUM_ACCOUNT_INFO_INTEGER  property_id      // Identifier of the property
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_INTEGER.

Return Value

Value of long type.

Note

The property must be of bool, int or long type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoInteger()
   printf("ACCOUNT_LOGIN =  %d",AccountInfoInteger(ACCOUNT_LOGIN));
   printf("ACCOUNT_LEVERAGE =  %d",AccountInfoInteger(ACCOUNT_LEVERAGE));
   bool thisAccountTradeAllowed=AccountInfoInteger(ACCOUNT_TRADE_ALLOWED);
   bool EATradeAllowed=AccountInfoInteger(ACCOUNT_TRADE_EXPERT);
   ENUM_ACCOUNT_TRADE_MODE tradeMode=(ENUM_ACCOUNT_TRADE_MODE)AccountInfoInteger(ACCOU
   ENUM_ACCOUNT_STOPOUT_MODE stopOutMode=(ENUM_ACCOUNT_STOPOUT_MODE)AccountInfoIntege

//--- Inform about the possibility to perform a trade operation
   if(thisAccountTradeAllowed)
      Print("Trade for this account is permitted");
   else
      Print("Trade for this account is prohibited!");

//--- Find out if it is possible to trade on this account by Expert Advisors
   if(EATradeAllowed)
      Print("Trade by Expert Advisors is permitted for this account");
   else
      Print("Trade by Expert Advisors is prohibited for this account!");

//--- Find out the account type
   switch(tradeMode)
     {
      case(ACCOUNT_TRADE_MODE_DEMO):
         Print("This is a demo account");
         break;
      case(ACCOUNT_TRADE_MODE_CONTEST):
```

© 2000-2025, MetaQuotes Ltd.

```
         Print("This is a competition account");
         break;
      default:Print("This is a real account!");
     }

//--- Find out the StopOut level setting mode
   switch(stopOutMode)
     {
      case(ACCOUNT_STOPOUT_MODE_PERCENT):
         Print("The StopOut level is specified percentage");
         break;
      default:Print("The StopOut level is specified in monetary terms");
     }
  }
```

AccountInfoString

Returns the value of the appropriate account property.

```
string  AccountInfoString(
   ENUM_ACCOUNT_INFO_STRING  property_id      // Property identifier
   );
```

Parameters

property_id

[in] Property identifier. The value can be one of the values of ENUM_ACCOUNT_INFO_STRING.

Return Value

Value of string type.

Example:

```
void OnStart()
  {
//--- Show all the information available from the function AccountInfoString()
   Print("The name of the broker = ",AccountInfoString(ACCOUNT_COMPANY));
   Print("Deposit currency = ",AccountInfoString(ACCOUNT_CURRENCY));
   Print("Client name = ",AccountInfoString(ACCOUNT_NAME));
   Print("The name of the trade server = ",AccountInfoString(ACCOUNT_SERVER));
  }
```

State Checking

Functions that return parameters of the current state of the client terminal

Function	Action
GetLastError	Returns the last error
IsStopped	Returns true, if an mql5 program has been commanded to stop its operation
UninitializeReason	Returns the code of the reason for deinitialization
TerminalInfoInteger	Returns an integer value of a corresponding property of the mql5 program environment
TerminalInfoDouble	Returns a double value of a corresponding property of the mql5 program environment
TerminalInfoString	Returns a string value of a corresponding property of the mql5 program environment
MQLInfoInteger	Returns an integer value of a corresponding property of a running mql5 program
MQLInfoString	Returns a string value of a corresponding property of a running mql5 program
Symbol	Returns the name of a symbol of the current chart
Period	Returns the current chart timeframe
Digits	Returns the number of decimal digits determining the accuracy of the price value of the current chart symbol
Point	Returns the point size of the current symbol in the quote currency

© 2000-2025, MetaQuotes Ltd.

GetLastError

Returns the contents of the system variable _LastError.

```
int  GetLastError();
```

Return Value

Returns the value of the last error that occurred during the execution of an mql5 program.

Note

After the function call, the contents of _LastError are not reset. To reset this variable, you need to call ResetLastError().

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   MqlRates rates[1]={};   // display the current bar data here

//--- intentionally call a function with inappropriate parameters
   int res=CopyRates(NULL, PERIOD_CURRENT, 0, 2, rates);
   if(res!=2)
      PrintFormat("CopyRates() returned %d. LastError %d", res, GetLastError());

//--- reset the last error code before copying the current bar data to the MqlRates st
   ResetLastError();
//--- if the function does not work correctly, the error code will differ from 0
   CopyRates(NULL, PERIOD_CURRENT, 0, 1, rates);
   Print("CopyRates() error ", GetLastError());

//--- print the array of obtained values
   ArrayPrint(rates);
  }
```

See also

Trade Server Return Codes

© 2000-2025, MetaQuotes Ltd.

IsStopped

Checks the forced shutdown of an mql5 program.

```
bool  IsStopped();
```

Return Value

Returns true, if the _StopFlag system variable contains a value other than 0. A nonzero value is written into _StopFlag, if a mql5 program has been commanded to complete its operation. In this case, you must immediately terminate the program, otherwise the program will be completed forcibly from the outside after 3 seconds.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- in an endless loop with a stop check
   while(!IsStopped())
     {
      //--- display the local PC time on the chart
      Comment("Time Local: ", TimeToString(TimeLocal(), TIME_DATE|TIME_MINUTES|TIME_SE
      Sleep(16);
     }
   Print("The StopFlag is set. The program will be stopped.");

//--- clean up
   Comment("");
  }
```

© 2000-2025, MetaQuotes Ltd.

UninitializeReason

Returns the code of a reason for deinitialization.

```
int  UninitializeReason();
```

Return Value

Returns the value of _UninitReason which is formed before OnDeinit() is called. Value depends on the reasons that led to deinitialization.

Example:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- get the deinitialization reason code into the 'reason' variable
   int reason=UninitializeReason();
//--- create a message string with a deinitialization reason and send the message to t
   string message=StringFormat("%s: Uninitialize reason code: %d (%s)",__FUNCTION__, r
   Print(message);
//--- successful
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- create a message string with a deinitialization reason code from the 'reason' fo
   string message=StringFormat("%s: Uninitialize reason code: %d (%s)",__FUNCTION__, r
   Print(message);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
  }
//+------------------------------------------------------------------+
//| Return a description of the deinitialization reason code         |
//+------------------------------------------------------------------+
string UninitializeReasonDescription(const int reason)
  {
   switch(reason)
     {
      //--- the EA has stopped working calling the ExpertRemove() function
      case REASON_PROGRAM :
```

© 2000-2025, MetaQuotes Ltd.

```
        return("Expert Advisor terminated its operation by calling the ExpertRemove()
      //--- program removed from a chart
      case REASON_REMOVE :
        return("Program has been deleted from the chart");
      //--- program recompiled
      case REASON_RECOMPILE :
        return("Program has been recompiled");
      //--- symbol or chart period changed
      case REASON_CHARTCHANGE :
        return("Symbol or chart period has been changed");
      //--- chart closed
      case REASON_CHARTCLOSE :
        return("Chart has been closed");
      //--- inputs changed by user
      case REASON_PARAMETERS :
        return("Input parameters have been changed by a user");
      //--- another account has been activated or reconnection to the trade server has
      case REASON_ACCOUNT :
        return("Another account has been activated or reconnection to the trade serve
      //--- another chart template applied
      case REASON_TEMPLATE :
        return("A new template has been applied");
      //--- OnInit() handler returned a non-zero value
      case REASON_INITFAILED :
        return("This value means that OnInit() handler has returned a nonzero value");
      //--- terminal closed
      case REASON_CLOSE :
        return("Terminal has been closed");
     }

//--- deinitialization reason unknown
   return("Unknown reason");
  }
```

TerminalInfoInteger

Returns the value of a corresponding property of the mql5 program environment.

```
int  TerminalInfoInteger(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_INTEGER enumeration.

Return Value

Value of int type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the build number of the running terminal and its "64-bit terminal" property
   int  build = TerminalInfoInteger(TERMINAL_BUILD);
   bool x64   = TerminalInfoInteger(TERMINAL_X64);

//--- print the obtained terminal data in the journal
   PrintFormat("MetaTrader 5 %s build %d", (x64 ? "x64" : "x32"), build);
   /*
   result:
   MetaTrader 5 x64 build 4330
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TerminalInfoDouble

Returns the value of a corresponding property of the mql5 program environment.

```
double  TerminalInfoDouble(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_DOUBLE enumeration.

Return Value

Value of double type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the build number of the running terminal and its "64-bit terminal" property
   int  build = TerminalInfoInteger(TERMINAL_BUILD);
   bool x64   = TerminalInfoInteger(TERMINAL_X64);

//--- print the obtained terminal data in the journal
   PrintFormat("MetaTrader 5 %s build %d", (x64 ? "x64" : "x32"), build);
   /*
   result:
   MetaTrader 5 x64 build 4330
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

TerminalInfoString

Returns the value of a corresponding property of the mql5 program environment. The property must be of string type.

```
string  TerminalInfoString(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the values of the ENUM_TERMINAL_INFO_STRING enumeration.

Return Value

Value of string type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get OS and terminal data
   string os_ver  = TerminalInfoString(TERMINAL_OS_VERSION);      // user's OS
   string name    = TerminalInfoString(TERMINAL_NAME);            // terminal name
   string path    = TerminalInfoString(TERMINAL_PATH);            // folder the termi
   string data    = TerminalInfoString(TERMINAL_DATA_PATH);       // folder for stori
   string common  = TerminalInfoString(TERMINAL_COMMONDATA_PATH); // common folder fo

//--- send the obtained data to the journal
   PrintFormat("OS: %s\nTerminal: %s\n- Path: %s\n- Data path: %s\n- Common Data path:
   /*
   OS: Windows 10 build 19045
   Terminal: MetaTrader 5
   - Path: E:\MetaQuotes\MetaTrader 5
   - Data path: E:\MetaQuotes\MetaTrader 5
   - Common Data path: C:\Users\admin\AppData\Roaming\MetaQuotes\Terminal\Common
   */
  }
```

MQLInfoInteger

Returns the value of a corresponding property of a running mql5 program.

```
int  MQLInfoInteger(
   int  property_id      // identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of values of the ENUM_MQL_INFO_INTEGER enumeration.

Return Value

Value of int type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the values of available and consumed memory for the MQL program
   int limit = MQLInfoInteger(MQL_MEMORY_LIMIT);    // maximum possible amount of dynar
   int used  = MQLInfoInteger(MQL_MEMORY_USED);     // memory size used by MQL5 prograr

//--- send the received values to the journal
   PrintFormat("Maximum possible amount of dynamic memory for MQL5 program: %d Mb\n"+
               "Memory used by MQL5 program: %d Mb", limit, used);
   /*
   result
   Maximum possible amount of dynamic memory for MQL5 program: 8388608 Mb
   Memory used by MQL5 program: 2 Mb
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

MQLInfoString

Returns the value of a corresponding property of a running mql5 program.

```
string  MQLInfoString(
   int  property_id      // Identifier of a property
   );
```

Parameters

property_id

[in] Identifier of a property. Can be one of the ENUM_MQL_INFO_STRING enumeration.

Return Value

Value of string type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the launched program data
   string name = MQLInfoString(MQL_PROGRAM_NAME);  // name of the launched MQL5 progra
   string path = MQLInfoString(MQL_PROGRAM_PATH);  // running program path

//--- send the obtained data to the journal
   PrintFormat("Name of the running MQL program: '%s'\nPath of the running MQL prograr
   /*
   result:
   Name of the running MQL program: 'MQLInfoString'
   Path of the running MQL program: E:\MetaQuotes\MetaTrader 5\MQL5\Scripts\MQLInfoSt
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

Symbol

Returns the name of a symbol of the current chart.

```
string  Symbol();
```

Return Value

Value of the _Symbol system variable, which stores the name of the current chart symbol.

Note

Unlike Expert Advisors, indicators and scripts, services are not bound to a specific chart. Therefore, Symbol() returns an empty string ("") for a service.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart symbol name
   string name = Symbol();

//--- send the obtained data to the journal
   PrintFormat("Current chart symbol name: '%s'", name);
   /*
   result
   Current chart symbol name: 'EURUSD'
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

Period

Returns the current chart timeframe.

```
ENUM_TIMEFRAMES  Period();
```

Return Value

The contents of the _Period variable that contains the value of the current chart timeframe. The value can be one of the values of the ENUM_TIMEFRAMES enumeration.

Note

Unlike Expert Advisors, indicators and scripts, services are not bound to a specific chart. Therefore, Period() returns 0 for a service.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the timeframe value of the current chart and its description
   ENUM_TIMEFRAMES period    = Period();
   string          timeframe = StringSubstr(EnumToString(period), 7);

//--- send the obtained data to the journal
   PrintFormat("Current chart timeframe: %s\nTimeframe value: %s (%d)",
               timeframe, EnumToString(period), period);
   /*
   result:
   Current chart timeframe: H4
   Timeframe value: PERIOD_H4 (16388)
   */
  }
```

Digits

Returns the number of decimal digits determining the accuracy of price of the current chart symbol.

```
int  Digits();
```

Return Value

The value of the _Digits variable which stores the number of decimal digits determining the accuracy of price of the current chart symbol.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the number of decimal places for the current chart symbol
   int digits = Digits();

//--- send the obtained data to the journal
   Print("Number of decimal digits for the current chart symbol: ", digits);
   /*
   result:
   Number of decimal digits for the current chart symbol: 5
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

Point

Returns the point size of the current symbol in the quote currency.

```
double  Point();
```

Return Value

The value of the _Point variable which stores the point size of the current symbol in the quote currency.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current symbol point size in the quote currency
   double point = Point();

//--- send the obtained data to the journal
   Print("Point size of the current symbol in the quote currency: ", DoubleToString(po
   /*
   result:
   Point size of the current symbol in the quote currency: 0.00001
   */
  }
```

Event Handling

The MQL5 language provides handling of certain predefined events. The functions for handling these events should be defined in an MQL5 program: function name, return type, a set of parameters (if any) and their types should strictly correspond to the description of an event handling function.

The client terminal event handler uses the return and parameter types to identify functions processing an event. If a certain function has some parameters or a return type not corresponding to the descriptions below, such a function cannot be used for handling an event.

Function	Description
OnStart	The function is called when the Start event occurs to perform actions set in the script
OnInit	The function is called in indicators and EAs when the Init event occurs to initialize a launched MQL5 program
OnDeinit	The function is called in indicators and EAs when the Deinit event occurs to de-initialize a launched MQL5 program
OnTick	The function is called in EAs when the NewTick event occurs to handle a new quote
OnCalculate	The function is called in indicators when the Calculate event occurs to handle price data changes
OnTimer	The function is called in indicators and EAs during the Timer periodic event generated by the terminal at fixed time intervals
OnTrade	The function is called in EAs during the Trade event generated at the end of a trading operation on a trade server
OnTradeTransaction	The function is called in EAs when the TradeTransaction event occurs to process a trade request execution results
OnBookEvent	The function is called in EAs when the BookEvent event occurs to process changes in the market depth
OnChartEvent	The function is called in indicators and EAs when the ChartEvent event occurs to process chart changes made by a user or an MQL5 program
OnTester	The function is called in EAs when the Tester event occurs to perform necessary actions after testing an EA on history data
OnTesterInit	The function is called in EAs when the TesterInit event occurs to perform necessary actions before optimization in the strategy tester
OnTesterDeinit	The function is called in EAs when the TesterDeinit event occurs after EA optimization in the strategy tester
OnTesterPass	The function is called in EAs when the TesterPass even occurs to handle an arrival of a new data frame during EA optimization in the strategy tester

© 2000-2025, MetaQuotes Ltd.

The client terminal sends incoming events to corresponding open charts. Also, events may be generated by charts (chart events) or mql5 programs (custom events). Generating graphical object creation/deletion events can be enabled/disabled by setting the CHART_EVENT_OBJECT_CREATE and CHART_EVENT_OBJECT_DELETE chart properties. Each mql5 application and chart have their own queue of events where all newly arrived events are placed.

A program gets events only from the chart it is running on. All events are handled one after another in the order of their receipt. If the queue already contains the NewTick event or this event is in the processing stage, then the new NewTick event is not added to mql5 application queue. Similarly, if the ChartEvent is already in an mql5 program queue or such an event is being handled, then a new event of this type is not placed into a queue. Timer event handling is processed in the same way – if the Timer event is already in the queue or is being handled, no new timer event is set into a queue.

Event queues have a limited but sufficient size, so the queue overflow is unlikely for a correctly developed program. When the queue overflows, new events are discarded without being set into a queue.

It is strongly recommended not to use infinite loops to handle events. Possible exceptions are scripts handling a single Start event.

Libraries do not handle any events.

© 2000-2025, MetaQuotes Ltd.

OnStart

The function is called in scripts and services when the Start event occurs. The function is intended for one-time execution of actions implemented in a program. There are two function types.

The version that returns the result

```
int  OnStart(void);
```

Return Value

The value of int type displayed in the Journal tab.

The entry "script script_name removed (result code N)" is created in the terminal journal after a script execution is complete. Here N is a value returned by the OnStart() function.

The entry "service service_name stopped (result code N)" is created in the terminal journal after a service execution is complete. Here N is a value returned by the OnStart() function.

The OnStart() call that returns the execution result is recommended for use since it not only allows for a script or service execution, but also returns an error code or other useful data to analyze the program execution result.

The version without a result return is left only for compatibility with old codes. It is not recommended for use

```
void  OnStart(void);
```

Note

OnStart() is the only function for handling events in scripts and services. No other events are sent to these programs. In turn, the Start event is not passed to EAs and custom indicators.

Sample script:

```
//--- macros for working with colors
#define XRGB(r,g,b)     (0xFF000000|(uchar(r)<<16)|(uchar(g)<<8)|uchar(b))
#define GETRGB(clr)     ((clr)&0xFFFFFF)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set a downward candle color
   Comment("Set a downward candle color");
   ChartSetInteger(0,CHART_COLOR_CANDLE_BEAR,GetRandomColor());
   ChartRedraw(); // update the chart immediately without waiting for a new tick
   Sleep(1000);   // pause for 1 second to see all the changes
//--- set an upward candle color
   Comment("Set an upward candle color");
   ChartSetInteger(0,CHART_COLOR_CANDLE_BULL,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set the background color
```

© 2000-2025, MetaQuotes Ltd.

```
   Comment("Set the background color");
   ChartSetInteger(0,CHART_COLOR_BACKGROUND,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of Ask line
   Comment("Set color of Ask line");
   ChartSetInteger(0,CHART_COLOR_ASK,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of Bid line
   Comment("Set color of Bid line");
   ChartSetInteger(0,CHART_COLOR_BID,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of a downward bar and a downward candle frame
   Comment("Set color of a downward bar and a downward candle frame");
   ChartSetInteger(0,CHART_COLOR_CHART_DOWN,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of a chart line and Doji candlesticks
   Comment("Set color of a chart line and Doji candlesticks");
   ChartSetInteger(0,CHART_COLOR_CHART_LINE,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of an upward bar and an upward candle frame
   Comment("Set color of an upward bar and an upward candle frame");
   ChartSetInteger(0,CHART_COLOR_CHART_UP,GetRandomColor());
   ChartRedraw();
   Sleep(1000);
//--- set color of axes, scale and OHLC line
   Comment("Set color of axes, scale and OHLC line");
   ChartSetInteger(0,CHART_COLOR_FOREGROUND,GetRandomColor());
   ChartRedraw();

Event handling functions, Program running, Client terminal events

© 2000-2025, MetaQuotes Ltd.

OnInit

The function is called in indicators and EAs when the Init event occurs. It is used to initialize a running MQL5 program. There are two function types.

The **version that returns the result**

```
int  OnInit(void);
```

Return Value

int type value, zero means successful initialization.

When returning INIT_FAILED, the EA is forcibly unloaded from the chart.

When returning INIT_FAILED, the indicator is not unloaded from the chart. The indicator remaining on the chart is non-operational — event handlers are not called in the indicator.

The OnInit() call that returns the execution result is recommended for use since it not only allows for program initialization, but also returns an error code in case of an early program termination.

The version without a result return is left only for compatibility with old codes. It is not recommended for use

```
void  OnInit(void);
```

Note

The Init event is generated immediately after loading an EA or an indicator. The event is not generated for scripts. The OnInit() function is used to initialize an MQL5 program. If OnInit() has a return value of int type, the non-zero return code means failed initialization and generates the Deinit event with the REASON_INITFAILED deinitialization reason code.

OnInit() function of void type always means successful initialization and is not recommended for use.

For optimizing the EA inputs, it is recommended to use values from the ENUM_INIT_RETCODE enumeration as a return code. These values are intended for establishing the optimization process management, including selection of the most suitable test agents. It is possible to request data on agent configuration and resources (number of cores, free memory amount, etc.) using the TerminalInfoInteger() function during the EA initialization before launching the test. Based on the obtained data, you can either allow using the test agent or ban it from optimizing the EA.

ID	Description
INIT_SUCCEEDED	Initialization successful, EA test can be continued. This code means the same as the zero value - the EA initialization in the tester is successful.
INIT_FAILED	Initialization failed. There is no point in continuing the test due to unavoidable errors. For example, it is impossible to create an indicator necessary for the EA operation. The return of this value means the same as returning the value different from zero - EA initialization in the tester failed.

© 2000-2025, MetaQuotes Ltd.

ID	Description
INIT_PARAMETERS_INCORRECT	Designed to denote an incorrect set of input parameters by a programmer. In the general optimization table, the result string with this return code is highlighted in red. A test for such a set of EA inputs is not performed. The agent is ready to receive a new task. When this value is received, the strategy tester does not pass this task to other agents for repeated execution.
INIT_AGENT_NOT_SUITABLE	No program execution errors during initialization. However, for some reasons, the agent is not suitable for conducting a test. For example, there is not enough RAM, no OpenCL support, etc. After returning this code, the agent no longer receives tasks until the very end of this optimization.

Using OnInit() returning INIT_FAILED/INIT_PARAMETERS_INCORRECT in the tester have some peculiarities that should be considered when optimizing EAs:

- the set of parameters the OnInit() returned INIT_PARAMETERS_INCORRECT for is considered unsuitable for testing and is not used to obtain the next population during genetic optimization. Too many "discarded" parameter sets may lead to incorrect results when searching for optimal EA parameters. The search algorithm assumes that the optimization criterion function is smooth and has no gaps on the entire multitude of input parameters.
- if OnInit() returns INIT_FAILED, this means that a test cannot be launched, and the EA is unloaded from the agent's memory. The EA is loaded again to perform the next pass with a new set of parameters. Launching the next optimization pass takes much more time as compared to calling TesterStop().

Sample OnInit() function for an EA

```
//--- input parameters
input int      ma_period=20; // moving average period

//--- handle of the indicator used in the EA
int indicator_handle;
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- check ma_period validity
   if(ma_period<=0)
     {
      PrintFormat("Invalid ma_period input value: %d",ma_period);
      return (INIT_PARAMETERS_INCORRECT);
     }
//--- during optimization
   if(MQLInfoInteger(MQL_OPTIMIZATION))
     {
```

© 2000-2025, MetaQuotes Ltd.

```
      //--- check available RAM for the agent
      int available_memory_mb=TerminalInfoInteger(TERMINAL_MEMORY_TOTAL);
      if(available_memory_mb<2000)
        {
         PrintFormat("Insufficient memory for the test agent: %d MB",
                     available_memory_mb);
         return (INIT_AGENT_NOT_SUITABLE);
        }
     }
//--- check for the indicator
   indicator_handle=iCustom(_Symbol,_Period,"My_Indicator",ma_period);
   if(indicator_handle==INVALID_HANDLE)
     {
      PrintFormat("Failed to generate My_Indicator handle. Error code %d",
                  GetLastError());
      return (INIT_FAILED);
     }
//--- EA initialization successful
   return(INIT_SUCCEEDED);
  }
```

© 2000-2025, MetaQuotes Ltd.

OnDeinit

The function is called in indicators and EAs when the Deinit event occurs. It is used to deinitialize a running MQL5 program.

```
void  OnDeinit(
   const int  reason         // deinitialization reason code
   );
```

Parameters

reason

[in] Deinitialization reason code.

Return Value

No return value

Note

Deinit event is generated for EAs and indicators in the following cases:

- before a re-initialization due to the change of a symbol or a chart period the mql5 program is attached to;
- before a re-initialization due to the change of the inputs;
- before unloading an mql5 program.

The *reason* parameter may have the following values:

Constant	Value	Description
REASON_PROGRAM	0	The EA has stopped working calling the ExpertRemove() function
REASON_REMOVE	1	Program removed from a chart
REASON_RECOMPILE	2	Program recompiled
REASON_CHARTCHANGE	3	A symbol or a chart period is changed
REASON_CHARTCLOSE	4	Chart closed
REASON_PARAMETERS	5	Inputs changed by a user
REASON_ACCOUNT	6	Another account has been activated or reconnection to the trade server has occurred due to changes in the account settings
REASON_TEMPLATE	7	Another chart template applied
REASON_INITFAILED	8	The OnInit() handler returned a non-zero value
REASON_CLOSE	9	Terminal closed

EA deinitialization reason codes can be received by the UninitializeReason() function or from the predefined _UninitReason variable.

Sample OnInit() and OnDeinit() functions for the EA

© 2000-2025, MetaQuotes Ltd.

```
input int fake_parameter=3;      // useless parameter
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- Get the number of a build where the program is compiled
   Print(__FUNCTION__," Build #",__MQLBUILD__);
//--- Reset reason code can also be obtained in OnInit()
   Print(__FUNCTION__," Deinitialization reason code can be received during the EA res
//--- The first way to get a deinitialization reason code
   Print(__FUNCTION__," _UninitReason = ",getUninitReasonText(_UninitReason));
//--- The second way to get a deinitialization reason code
   Print(__FUNCTION__," UninitializeReason() = ",getUninitReasonText(UninitializeReasc
//---
   return(INIT_SUCCEEDED);
  }

OnTick

The function is called in EAs when the NewTick event occurs to handle a new quote.

```
void  OnTick(void);
```

Return Value

No return value

Note

The NewTick event is generated only for EAs upon receiving a new tick for a symbol of the chart the EA is attached to. There is no point in defining the OnTick() function in a custom indicator or a script since a NewTick event is not generated for them.

The Tick event is generated only for EAs, but this does not mean that EAs have to feature the OnTick() function, since Timer, BookEvent and ChartEvent events are also generated for EAs in addition to NewTick.

All events are handled one after another in the order of their receipt. If the queue already contains the NewTick event or this event is in the processing stage, then the new NewTick event is not added to mql5 application queue.

The NewTick event is generated regardless of whether auto trading is enabled (AutoTrading button). Disabled auto trading means only a ban on sending trade requests from an EA. The EA operation is not stopped.

Disabling auto trading by pressing the AutoTrading button does not interrupt the current execution of the OnTick() function.

Example of the EA featuring its entire trading logic in the OnTick() function

```

OnCalculate

The function is called in the indicators when the Calculate event occurs for processing price data changes. There are two function types. Only one of them can be used within a single indicator.

Calculation based on data array

```
int  OnCalculate(
   const int        rates_total,       // price[] array size
   const int        prev_calculated,   // number of handled bars at the previous call
   const int        begin,             // index number in the price[] array meaningful
   const double&    price[]            // array of values for calculation
   );
```

Calculations based on the current timeframe timeseries

```
int  OnCalculate(
   const int        rates_total,       // size of input time series
   const int        prev_calculated,   // number of handled bars at the previous call
   const datetime&  time[],            // Time array
   const double&    open[],            // Open array
   const double&    high[],            // High array
   const double&    low[],             // Low array
   const double&    close[],           // Close array
   const long&      tick_volume[],     // Tick Volume array
   const long&      volume[],          // Real Volume array
   const int&       spread[]           // Spread array
   );
```

Parameters

rates_total

[in] Size of the price[] array or input series available to the indicator for calculation. In the second function type, the parameter value corresponds to the number of bars on the chart it is launched at.

prev_calculated

[in] Contains the value returned by the OnCalculate() function during the previous call. It is designed to skip the bars that have not changed since the previous launch of this function.

begin

[in] Index value in the price[] array meaningful data starts from. It allows you to skip missing or initial data, for which there are no correct values.

price[]

[in] Array of values for calculations. One of the price timeseries or a calculated indicator buffer can be passed as the price[] array. Type of data passed for calculation can be defined using the _AppliedTo predefined variable.

time{}

[in] Array with bar open time values.

© 2000-2025, MetaQuotes Ltd.

open[]

[in] Array with Open price values.

high[]

[in] Array with High price values.

low[]

[in] Array with Low price values.

close[]

[in] Array with Close price values.

tick_volume[]

[in] Array with tick volume values.

volume[]

[in] Array with trade volume values.

spread[]

[in] Array with spread values for bars.

Return Value

int type value to be passed as the *prev_calculated* parameter during the next function call.

Note

If the OnCalculate() function is equal to zero, no indicator values are shown in the DataWindow of the client terminal.

If the price data have been changed since the last call of the OnCalculate() function (a deeper history has been loaded or gaps in the history have been filled), the value of the *prev_calculated* input parameter is set to zero by the terminal itself.

To define the indexing direction in the *time[]*, *open[]*, *high[]*, *low[]*, *close[]*, *tick_volume[]*, *volume[]* and *spread[]* arrays, call the ArrayGetAsSeries() function. In order not to depend on defaults, call the ArraySetAsSeries() function for the arrays to work with.

When using the first function type, a necessary timeseries or indicator is selected by a user as the price[] array in the Parameters tab when launching the indicator. To do this, specify the necessary element in the drop-down list of the "Apply to" field.

To get custom indicator values from other mql5 programs, the iCustom() function is used. It returns the indicator handle for subsequent operations. It is also possible to specify the required *price []* array or the handle of another indicator. This parameter should be passed the last in the list of input variables of a custom indicator.

It is necessary to use the connection between the value returned by the OnCalculate() function and the *prev_calculated* second input parameter. When calling the function, the *prev_calculated* parameter contains the value returned by the OnCalculate() function during the previous call. This makes it possible to implement resource-saving algorithms for calculating a custom indicator in order to avoid repetitive calculations for the bars that have not changed since the previous launch of this function.

OnTimer

The function is called in EAs during the Timer event generated by the terminal at fixed time intervals.

```
void  OnTimer(void);
```

Return Value

No return value

Note

The Timer event is periodically generated by the client terminal for an EA, which activated the timer using the EventSetTimer() function. Usually, this function is called in the OnInit() function. When the EA stops working, the timer should be eliminated using EventKillTimer(), which is usually called in the OnDeinit() function.

Each Expert Advisor and each indicator work with its own timer receiving events solely from this timer. During mql5 application shutdown, the timer is forcibly destroyed in case it has been created but has not been disabled by EventKillTimer() function.

If you need to receive timer events more frequently than once per second, use EventSetMillisecondTimer() for creating a high-resolution timer.

In general, when the timer period is reduced, the testing time is increased, as the handler of timer events is called more often. When working in real-time mode, timer events are generated no more than 1 time in 10-16 milliseconds due to hardware limitations.

Only one timer can be launched for each program. Each mql5 application and chart have their own queue of events where all newly arrived events are placed. If the queue already contains Timer event or this event is in the processing stage, then the new Timer event is not added to mql5 application queue.

Sample EA with the OnTimer() handler

```
//+------------------------------------------------------------------+

OnTrade

The function is called in EAs when the Trade event occurs. The function is meant for processing changes in order, position and trade lists.

```
void  OnTrade(void);
```

Return Value

No return value

Note

OnTrade() is called only for Expert Advisors. It is not used in indicators and scripts even if you add there a function with the same name and type.

For any trade action (placing a pending order, opening/closing a position, placing stops, activating pending orders, etc.), the history of orders and trades and/or the list of positions and current orders is changed appropriately.

When handling an order, a trade server sends the terminal a message about the incoming Trade event. To retrieve relevant data on orders and trades from history, it is necessary to perform a trading history request using HistorySelect() first.

The trade events are generated by the server in case of:

- changing active orders,
- changing positions,
- changing deals,
- changing trade history.

Each Trade event may appear as a result of one or several trade requests. Trade requests are sent to the server using OrderSend() or OrderSendAsync(). Each request can lead to several trade events. You cannot rely on the statement "One request - one Trade event", since the processing of events may be performed in several stages, and each operation may change the state of orders, positions and the trade history.

OnTrade() handler is called after the appropriate OnTradeTransaction() calls. In general, there is no exact correlation in the number of OnTrade () and OnTradeTransaction () calls. One OnTrade() call corresponds to one or several OnTradeTransaction calls.

Sample EA with OnTrade() handler

```
//+------------------------------------------------------------------+

OnTradeTransaction

The function is called in EAs when the TradeTransaction event occurs. The function is meant for handling trade request execution results.

```
void  OnTradeTransaction()
   const MqlTradeTransaction&    trans,     // trade transaction structure
   const MqlTradeRequest&        request,   // request structure
   const MqlTradeResult&         result     // response structure
   );
```

Parameters

trans

[in] MqlTradeTransaction type variable describing a transaction made on a trading account.

request

[in] MqlTradeRequest type variable describing a trade request that led to a transaction. It contains the values for TRADE_TRANSACTION_REQUEST type transaction only.

result

[in] MqlTradeResult type variable containing an execution result of a trade request that led to a transaction. It contains the values for TRADE_TRANSACTION_REQUEST type transaction only.

Return Value

No return value

Note

OnTradeTransaction() is called to handle the TradeTransaction event sent by the trade server to the terminal in the following cases:

- sending a trade request from an MQL5 program using the OrderSend()/OrderSendAsync() functions and its subsequent execution;
- sending a trade request manually via the GUI and its subsequent execution;
- activations of pending and stop orders on the server;
- performing operations on the trade server side.

Data on transaction type is contained in the *type* field of the *trans* variable. Types of trade transactions are described in the ENUM_TRADE_TRANSACTION_TYPE enumeration:

- TRADE_TRANSACTION_ORDER_ADD - adding a new active order
- TRADE_TRANSACTION_ORDER_UPDATE - changing an existing order
- TRADE_TRANSACTION_ORDER_DELETE - deleting an order from the list of active ones
- TRADE_TRANSACTION_DEAL_ADD - adding a deal to history
- TRADE_TRANSACTION_DEAL_UPDATE - changing a deal in history
- TRADE_TRANSACTION_DEAL_DELETE - deleting a deal from history
- TRADE_TRANSACTION_HISTORY_ADD - adding an order to history as a result of execution or cancelation
- TRADE_TRANSACTION_HISTORY_UPDATE - changing an order in the order history
- TRADE_TRANSACTION_HISTORY_DELETE - deleting an order from the order history
- TRADE_TRANSACTION_POSITION - position change not related to a trade execution

© 2000-2025, MetaQuotes Ltd.

- TRADE_TRANSACTION_REQUEST - notification that a trade request has been processed by the server and the result of its processing has been received.

When handling transactions of TRADE_TRANSACTION_REQUEST type, it is necessary to analyze the second and third parameters of the OnTradeTransaction() function - *request* and *result* - to receive additional information.

Sending a buy trade request leads to a chain of trade transactions on a trading account: 1) request is accepted for processing, 2) an appropriate purchase order is created for the account, 3) the order is then executed, 4) the executed order is removed from the list of active ones, 5) adding to the history of orders, 6) the subsequent transaction is added to history and 7) a new position is created. All these stages are trade transactions. The arrival of each such transaction to the terminal is the TradeTransaction event. Priority of these transactions' arrival at the terminal is not guaranteed. Thus, you should not expect that one group of transactions will arrive after another one when developing your trading algorithm.

When transactions are processed by the EA's OnTradeTransaction() handler, the terminal goes on handling the incoming trade transactions. Thus, the trading account status may change at the course of OnTradeTransaction() operation. For example, while an MQL5 program handles adding a new order, it can be executed, deleted from the list of open orders and moved to history. The program is notified of all these events.

Transactions queue length comprises 1024 elements. If OnTradeTransaction() handles yet another transaction for too long, the previous ones can be superseded by new transactions in the queue.

OnTrade() handler is called after the appropriate OnTradeTransaction() calls. In general, there is no exact correlation in the number of OnTrade () and OnTradeTransaction () calls. One OnTrade() call corresponds to one or several OnTradeTransaction calls.

Each Trade event may appear as a result of one or several trade requests. Trade requests are sent to the server using OrderSend() or OrderSendAsync(). Each request can lead to several trade events. You cannot rely on the statement "One request - one Trade event", since the processing of events may be performed in several stages and each operation may change the state of orders, positions and the trade history.

OnBookEvent

The function is called in indicators and EAs when the BookEvent event occurs. It is meant for handling Depth of Market changes.

```
void  OnBookEvent(
   const string&  symbol          // symbol
   );
```

Parameters

symbol

[in] Name of a symbol the BookEvent has arrived for

Return Value

No return value

Note

To get the BookEvent events for any symbol, simply subscribe to receive them for this symbol using the MarketBookAdd() function. To cancel subscription for receiving the BookEvent for a certain symbol, call the MarketBookRelease() function.

The BookEvent broadcasts within the entire chart. This means that if one application on a chart subscribes to the BookEvent using the MarketBookAdd function, all other indicators and EAs launched on the same chart and having the OnBookEvent() handler receive this event as well. Therefore, it is necessary to analyze a symbol name passed to the OnBookEvent() handler as the *symbol* parameter.

Separate BookEvent counters sorted by symbols are provided for all applications running on the same chart. This means that each chart may have multiple subscriptions to different symbols, and a counter is provided for each symbol. Subscribing and unsubscribing from BookEvent changes the subscription counter for specified symbols only within one chart. In other words, there may be two adjacent charts to the BookEvent for the same symbol but different subscription counter values.

The initial subscription counter value is zero. At each MarketBookAdd() call, the subscription counter for a specified symbol on the chart is increased by one (chart symbol and symbol in MarketBookAdd() do not have to match). When calling MarketBookRelease(), the counter of subscriptions for a specified symbol within the chart is decreased by one. The BookEvent events for any symbol are broadcast within the chart till the counter is equal to zero. Therefore, it is important that each MQL5 program that contains MarketBookAdd () calls correctly unsubscribes from getting events for each symbol using MarketBookRelease () at the end of its work. To achieve this, the number of MarketBookAdd() and MarketBookRelease() calls should be even for each call during the entire MQL5 program lifetime. Using flags or custom subscription counters within the program allows you to safely work with BookEvent events and prevents disabling subscriptions for getting this event in third-party programs within the same chart.

BookEvent events are never skipped and are always placed into a queue even if handling the previous BookEvent handling is not over yet.

OnChartEvent

The function is called in indicators and EAs when the ChartEvent event occurs. The function is meant for handling chart changes made by a user or an MQL5 program.

```
void  OnChartEvent()
   const int       id,       // event ID
   const long&     lparam,   // long type event parameter
   const double&   dparam,   // double type event parameter
   const string&   sparam    // string type event parameter
   );
```

Parameters

id

[in] Event ID from the ENUM_CHART_EVENT enumeration.

lparam

[in] long type event parameter

dparam

[in] double type event parameter

sparam

[in] string type event parameter

Return Value

No return value

Note

There are 11 types of events that can be handled using the predefined OnChartEvent() function. 65535 IDs from CHARTEVENT_CUSTOM to CHARTEVENT_CUSTOM_LAST inclusive are provided for custom events. To generate a custom event, use the EventChartCustom() function.

Short event description from the ENUM_CHART_EVENT enumeration:

- CHARTEVENT_KEYDOWN — pressing a key on the keyboard when a chart window is in focus;
- CHARTEVENT_MOUSE_MOVE — moving the mouse and mouse button clicks (if CHART_EVENT_MOUSE_MOVE=true for a chart);
- CHARTEVENT_OBJECT_CREATE — create a graphical object (if CHART_EVENT_OBJECT_CREATE=true for a chart);
- CHARTEVENT_OBJECT_CHANGE — change object properties via the properties dialog;
- CHARTEVENT_OBJECT_DELETE — delete a graphical object (if CHART_EVENT_OBJECT_DELETE=true for a chart);
- CHARTEVENT_CLICK — clicking on a chart;
- CHARTEVENT_OBJECT_CLICK — mouse click on a graphical object belonging to a chart;
- CHARTEVENT_OBJECT_DRAG — dragging a graphical object with a mouse;
- CHARTEVENT_OBJECT_ENDEDIT — finish editing text in the Edit input box of a graphical object (OBJ_EDIT);
- CHARTEVENT_CHART_CHANGE — change a chart;

© 2000-2025, MetaQuotes Ltd.

- CHARTEVENT_CUSTOM+n — custom event ID, where n is within the range from 0 to 65535. CHARTEVENT_CUSTOM_LAST contains the last acceptable custom event ID (CHARTEVENT_CUSTOM+65535).

All MQL5 programs work in threads other than the main thread of the application. The main application thread is responsible for handling all Windows system messages and, in its turn, generates Windows messages for its own application as a result of this handling. For example, moving the mouse on a chart (WM_MOUSE_MOVE event) generates several system messages for subsequent rendering of the application window, and also sends internal messages to experts and indicators launched on the chart. A situation may occur, where the main application thread has not yet processed the WM_PAINT system message (and therefore has not yet rendered the modified chart), while an EA or an indicator has already received the mouse movement event. In this case, the chart property CHART_FIRST_VISIBLE_BAR will be changed only after the chart is rendered.

For each event type, the inputs of the OnChartEvent() function have certain values necessary for handling that event. The table lists events and values passed via the parameters.

Event	'id' parameter value	'lparam' parameter value	'dparam' parameter value	'sparam' parameter value
Keystroke event	CHARTEVENT_KEYDOWN	pressed button code	The number of keypresses generated while the key was held in the pressed state	String value of the bit mask, which describes the status of the keyboard keys
Mouse events (if CHART_EVENT_MOUSE_MOVE=true for a chart)	CHARTEVENT_MOUSE_MOVE	X coordinate	Y coordinate	String value of the bit mask, which describes the status of the mouse keys
Mouse wheel event (if CHART_EVENT_MOUSE_WHEEL=true for the chart)	CHARTEVENT_MOUSE_WHEEL	Flags of states of keys and mouse buttons, X and Y coordinates of the cursor. See the description in the example	The Delta value of the mouse wheel scroll	—
Creating a graphical object (if CHART_EVENT_OBJECT_CREATE=true for a chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of a created graphical object
Changing object properties via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of a changed graphical object

© 2000-2025, MetaQuotes Ltd.

Event	'id' parameter value	'lparam' parameter value	'dparam' parameter value	'sparam' parameter value
Removing a graphical object (if CHART_EVENT_OBJECT_DELETE =true for a chart)	CHARTEVENT_OBJECT_DELETE	—	—	Name of a removed graphical object
Mouse click on a chart	CHARTEVENT_CLICK	X coordinate	Y coordinate	—
Mouse click on a graphical object	CHARTEVENT_OBJECT_CLICK	X coordinate	Y coordinate	Name of a graphical object the event has occurred on
Moving a graphical object with mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of a moved graphical object
Finishing a text editing in the "Input field" graphical object input box	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the "Input field" graphical object, in which text editing completed
Resizing the chart or modifying the chart properties via the properties dialog window	CHARTEVENT_CHART_CHANGE	—	—	—
Custom event with N number	CHARTEVENT_CUSTOM+N	Value defined by the EventChartCustom() function	Value defined by the EventChartCustom() function	Value defined by the EventChartCustom() function

Sample chart event listener:

OnTester

The function is called in Expert Advisors when the Tester event occurs to perform necessary actions after testing.

```
double  OnTester(void);
```

Return Value

Value of the custom criterion optimization for assessing test results.

Note

The OnTester() function can be used only when testing EAs and is intended primarily for the calculation of a value that is used as a 'Custom max' criterion when optimizing input parameters.

During the genetic optimization, sorting results within one generation is performed in descending order. This means that the results with the highest value are deemed the best from the optimization criterion point of view. The worst values for such sorting are placed at the end and are subsequently discarded. Therefore, they do not take part in forming the next generation.

Thus, the OnTester() function allows you not only to create and save your own test results reports, but also control the optimization process to find the best parameters of the trading strategy.

Below is an **example** of calculating the custom criterion optimization. The idea is to calculate the linear regression of the balance graph. It is described in the article Optimizing a strategy using balance graph and comparing results with "Balance + max Sharpe Ratio" criterion.

```
//+------------------------------------------------------------------+
//|                                              OnTester_Sample.mq5 |

OnTesterInit

The function is called in EAs when the TesterInit event occurs to perform necessary actions before optimization in the strategy tester. There are two function types.

The **version that returns the result**

```
int  OnTesterInit(void);
```

Return Value

int type value, zero means successful initialization of an EA launched on a chart before optimization starts.

The OnTesterInit() call that returns the execution result is recommended for use since it not only allows for program initialization, but also returns an error code in case of an early optimization stop. Return of any value other than INIT_SUCCEEDED (0) means an error, no optimization is launched.

The version without a result return is left only for compatibility with old codes. Not recommended for use

```
void  OnTesterInit(void);
```

Note

The TesterInit event is generated before EA optimization in the strategy tester starts. At this event, an EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart. It has the symbol and the period that have been specified in the tester.

Such an event receives the TesterInit, TesterDeinit and TesterPass events, but not Init, Deinit and NewTick ones. Accordingly, all necessary logic for processing the results of each pass during optimization should be implemented in the OnTesterInit (), OnTesterDeinit () and OnTesterPass () handlers.

The result of each single pass during a strategy optimization can be passed via a frame from the OnTester () handler using the FrameAdd () function.

The OnTesterInit() function is used to initiate an Expert Advisor before start of optimization for further processing of optimization results. It is always used together with the OnTesterDeinit() handler.

The time for OnTesterInit() execution is limited. If it is exceeded, the EA is forcibly stopped, while the optimization itself is canceled. A message is displayed in the tester journal:

```
TesterOnTesterInit works too long. Tester cannot be initialized.
```

The example is taken from OnTick. The OnTesterInit() handler is added for setting optimization parameters:

```

OnTesterDeinit

The function is called in EAs when the TesterDeinit event occurs after EA optimization.

```
void  OnTesterDeinit(void);
```

Return Value

No return value

Note

The TesterDeinit event is generated after the end of EA optimization in the strategy tester.

An EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart during the optimization start. It has the symbol and the period that have been specified in the tester. The function is designed for the final processing of all optimization results.

Keep in mind that optimization frames sent by test agents using the FrameAdd() function may come in bundles and take time to deliver. Therefore, not all frames, as well as TesterPass events, may arrive and be processed in OnTesterPass() before the end of optimization. If you want to receive all belated frames in OnTesterDeinit(), place the code block using the FrameNext() function.

OnTesterPass

The function is called in EAs when the TesterPass event occurs for handling a new data frame during EA optimization.

```
void  OnTesterPass(void);
```

Return Value

No return value

Note

The TesterPass event is generated automatically when receiving a frame during an Expert Advisor optimization in the strategy tester.

An EA having OnTesterDeInit() or OnTesterPass() event handler is automatically downloaded on a separate terminal chart during the optimization start. It has the symbol and the period that have been specified in the tester. The function is meant for handling frames received from test agents during optimization. The frame containing test results should be sent from the OnTester() handler using the FrameAdd() function.

Keep in mind that optimization frames sent by test agents using the FrameAdd() function may come in bundles and take time to deliver. Therefore, not all frames, as well as TesterPass events, may arrive and be processed in OnTesterPass() before the end of optimization. If you want to receive all belated frames in OnTesterDeinit(), place the code block using the FrameNext() function.

After completing OnTesterDeinit() optimization, it is possible to sort all received frames again using the FrameFirst()/FrameFilter and FrameNext() functions.

Getting Market Information

These are functions intended for receiving information about the market state.

Function	Action
SymbolsTotal	Returns the number of available (selected in Market Watch or all) symbols
SymbolExist	Checks if a symbol with a specified name exists
SymbolName	Returns the name of a specified symbol
SymbolSelect	Selects a symbol in the Market Watch window or removes a symbol from the window
SymbolIsSynchronized	Checks whether data of a selected symbol in the terminal are synchronized with data on the trade server
SymbolInfoDouble	Returns the double value of the symbol for the corresponding property
SymbolInfoInteger	Returns a value of an integer type (long, datetime, int or bool) of a specified symbol for the corresponding property
SymbolInfoString	Returns a value of the string type of a specified symbol for the corresponding property
SymbolInfoMarginRate	Returns the margin rates depending on the order type and direction
SymbolInfoTick	Returns the current prices for the specified symbol in a variable of the MqlTick type
SymbolInfoSessionQuote	Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.
SymbolInfoSessionTrade	Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.
MarketBookAdd	Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes
MarketBookRelease	Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes
MarketBookGet	Returns a structure array MqlBookInfo containing records of the Depth of Market of a specified symbol

© 2000-2025, MetaQuotes Ltd.

SymbolsTotal

Returns the number of available (selected in Market Watch or all) symbols.

```
int  SymbolsTotal(
   bool  selected      // True - only symbols in MarketWatch
   );
```

Parameters

selected

[in] Request mode. Can be true or false.

Return Value

If the 'selected' parameter is true, the function returns the number of symbols selected in MarketWatch. If the value is false, it returns the total number of all symbols.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the number of available symbols
   int total    = SymbolsTotal(false);       // all symbols on the server
   int selected = SymbolsTotal(true);        // all symbols added to the Market Watch

//--- send the obtained data to the journal
   PrintFormat("Number of available symbols on the server: %d\n"+
               "Number of available symbols selected in MarketWatch: %d", total, selec
   /*
   result:
   Number of available symbols on the server: 140
   Number of available symbols selected in MarketWatch: 11
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

SymbolExist

Checks if a symbol with a specified name exists.

```
bool  SymbolExist(
   const string  name,     // symbol name
   bool&   is_custom       // custom symbol property
   );
```

Parameters

name

[in] Symbol name.

is_custom

[out] Custom symbol property set upon successful execution. If true, the detected symbol is a custom one.

Return Value

If false, the symbol is not found among standard and custom ones.

Example:

```
#define SYMBOL_NAME "GBPUSDn"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the custom symbol flag and check the presence of a symbol having its nar
   bool custom = false;
   bool result = SymbolExist(SYMBOL_NAME, custom);

//--- declare the default 'symbol not found' message text
   string text = StringFormat("The symbol '%s' was not found among either the standard

//--- if a symbol is found, create a message text depending on which list the symbol
   if(result)
     {
      //--- if this is a standard symbol
      if(!custom)
         text = StringFormat("The '%s' symbol is available on the server.", SYMBOL_NAM
      //--- if this is a custom symbol
      else
         text = StringFormat("The symbol '%s' was found in the list of custom symbols.
     }

//--- send the message about the check result to the journal
   Print(text);
   /*
```

© 2000-2025, MetaQuotes Ltd.

```
   result for standard 'GBPUSD' symbol:
   The 'GBPUSD' symbol is available on the server.

   result for custom 'GBPUSDx' symbol:
   The symbol 'GBPUSDx' was found in the list of custom symbols.

   result for missing 'GBPUSDn' symbol:
   The symbol 'GBPUSDn' was not found among either the standard or custom symbols.
   */
  }
```

SymbolName

Returns the name of a symbol.

```
string  SymbolName(
   int   pos,          // number in the list
   bool  selected      // true - only symbols in MarketWatch
   );
```

Parameters

pos

[in] Order number of a symbol.

selected

[in] Request mode. If the value is true, the symbol is taken from the list of symbols selected in MarketWatch. If the value is false, the symbol is taken from the general list.

Return Value

Value of string type with the symbol name.

Example:

```
#define SYMBOL_NAME "GBPHKD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set the flag of the server symbol search result
   bool found = false;

//--- find the 'SYMBOL_NAME' symbol in the list of all server symbols
   int total = SymbolsTotal(false);
   for(int i=0; i<total; i++)
     {
      //--- get a symbol name in the list by loop index
      string name = SymbolName(i, false);

      //--- if this is the desired symbol, send its name and position in the list to t
      if(name == SYMBOL_NAME)
        {
         PrintFormat("The '%s' symbol was found in the list of server symbols at index
         found = true;
         break;
        }
     }

//--- if a symbol is not found on the server, report this before shutting down
```

© 2000-2025, MetaQuotes Ltd.

```
   if(!found)
      PrintFormat("The '%s' symbol was not found on the server.", SYMBOL_NAME);
}
```

© 2000-2025, MetaQuotes Ltd.

SymbolSelect

Selects a symbol in the Market Watch window or removes a symbol from the window.

```
bool  SymbolSelect(
   string  name,        // symbol name
   bool    select       // add or remove
   );
```

Parameters

name

[in] Symbol name.

select

[in] Switch. If the value is false, a symbol should be removed from MarketWatch, otherwise a symbol should be selected in this window. A symbol can't be removed if the symbol chart is open, or there are open positions for this symbol.

Return Value

In case of failure returns false.

Example:

```
#define SYMBOL_NAME "GBPHKD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- check for the presence of a symbol in the lists, if not found, report it and cor
   bool custom = false;
   if(!SymbolExist(SYMBOL_NAME, custom))
     {
      PrintFormat("'%s' symbol not found in the lists", SYMBOL_NAME);
      return;
     }

//--- add a symbol to the Market Watch window
   ResetLastError();
   if(!SymbolSelect(SYMBOL_NAME, true))
     {
      Print("SymbolSelect() failed. Error ", GetLastError());
      return;
     }
//--- if a symbol is successfully added to the list, get its index in the Market Watch
   int index = SymbolIndex(SYMBOL_NAME);
   PrintFormat("The '%s' symbol has been added to the MarketWatch list. Symbol index
```

© 2000-2025, MetaQuotes Ltd.

```
//--- now remove the symbol from the Market Watch window
   ResetLastError();
   if(!SymbolSelect(SYMBOL_NAME, false))
     {
      Print("SymbolSelect() failed. Error ", GetLastError());
      return;
     }
//--- if a symbol is successfully removed from the list, its index in the Market Watch
   index = SymbolIndex(SYMBOL_NAME);
   PrintFormat("The '%s' symbol has been removed from the MarketWatch list. Symbol ind

   /*
   result:
   The 'GBPHKD' symbol has been added to the MarketWatch list. Symbol index in the lis
   The 'GBPHKD' symbol has been removed from the MarketWatch list. Symbol index in the
   */
  }
//+------------------------------------------------------------------+
//| Return the symbol index in the Market Watch symbol list          |
//+------------------------------------------------------------------+
int SymbolIndex(const string symbol)
  {
   int total = SymbolsTotal(true);
   for(int i=0; i<total; i++)
     {
      string name = SymbolName(i, true);
      if(name == symbol)
         return i;
     }
   return(WRONG_VALUE);
  }
```

© 2000-2025, MetaQuotes Ltd.

SymbolIsSynchronized

The function checks whether data of a selected symbol in the terminal are synchronized with data on the trade server.

```
bool  SymbolIsSynchronized(
   string  name,        // symbol name
   );
```

Parameters

name

[in] Symbol name.

Return value

If data are synchronized, returns 'true'; otherwise returns 'false'.

Example:

```
#define SYMBOL_NAME "EURUSD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the flag for synchronizing data in the terminal using the 'SYMBOL_NAME' symb
   bool    sync = SymbolIsSynchronized(SYMBOL_NAME);

//--- create a message depending on the synchronization flag
   string text = StringFormat("The data on the '%s' symbol in the terminal is synchron
   if(!sync)
      text = StringFormat("The data for the '%s' symbol in the terminal is not synchr

//--- send the obtained result to the journal
   Print(text);

   /*
   result for synchronized data:
   The data on the 'EURUSD' symbol in the terminal is synchronized with the data on th

   result for data not yet synchronized:
   The data for the 'GBPHKD' symbol in the terminal is not synchronized with the data
   */
  }
```

SymbolInfoInteger, Organizing Data Access

© 2000-2025, MetaQuotes Ltd.

SymbolInfoDouble

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  SymbolInfoDouble(
   string                    name,        // symbol
   ENUM_SYMBOL_INFO_DOUBLE   prop_id      // identifier of the property
   );
```

2. Returns true or false depending on whether a function is successfully performed. In case of success, the value of the property is placed into a recipient variable, passed by reference by the last parameter.

```
bool  SymbolInfoDouble(
   string                    name,        // symbol
   ENUM_SYMBOL_INFO_DOUBLE   prop_id,     // identifier of the property
   double&                   double_var   // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_DOUBLE enumeration.

double_var

[out] Variable of double type receiving the value of the requested property.

Return Value

The value of double type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

The SymbolInfoMarginRate() function provides data on the amount of charged margin depending on the order type and direction.

© 2000-2025, MetaQuotes Ltd.

Example:

```
void OnTick()
  {
//--- obtain spread from the symbol properties
   bool spreadfloat=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD_FLOAT);
   string comm=StringFormat("Spread %s = %I64d points\r\n",
                            spreadfloat?"floating":"fixed",
                            SymbolInfoInteger(Symbol(),SYMBOL_SPREAD));
//--- now let's calculate the spread by ourselves
   double ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   double bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   double spread=ask-bid;
   int spread_points=(int)MathRound(spread/SymbolInfoDouble(Symbol(),SYMBOL_POINT));
   comm=comm+"Calculated spread = "+(string)spread_points+" points";
   Comment(comm);
  }
```

© 2000-2025, MetaQuotes Ltd.

SymbolInfoInteger

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  SymbolInfoInteger(
   string                     name,      // symbol
   ENUM_SYMBOL_INFO_INTEGER   prop_id    // identifier of a property

   );
```

2. Returns true or false depending on whether a function is successfully performed. In case of success, the value of the property is placed into a recipient variable, passed by reference by the last parameter.

```
bool  SymbolInfoInteger(
   string                     name,      // symbol
   ENUM_SYMBOL_INFO_INTEGER   prop_id,   // identifier of a property
   long&                      long_var   // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_INTEGER enumeration.

long_var

[out] Variable of the long type receiving the value of the requested property.

Return Value

The value of long type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

Example:

© 2000-2025, MetaQuotes Ltd.

```
void OnTick()
  {
//--- obtain spread from the symbol properties
   bool spreadfloat=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD_FLOAT);
   string comm=StringFormat("Spread %s = %I64d points\r\n",
                            spreadfloat?"floating":"fixed",
                            SymbolInfoInteger(Symbol(),SYMBOL_SPREAD));
//--- now let's calculate the spread by ourselves
   double ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   double bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   double spread=ask-bid;
   int spread_points=(int)MathRound(spread/SymbolInfoDouble(Symbol(),SYMBOL_POINT));
   comm=comm+"Calculated spread = "+(string)spread_points+" points";
   Comment(comm);
  }
```

© 2000-2025, MetaQuotes Ltd.

SymbolInfoString

Returns the corresponding property of a specified symbol. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  SymbolInfoString(
   string                    name,         // Symbol
   ENUM_SYMBOL_INFO_STRING   prop_id       // Property identifier
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a placeholder variable passed by reference in the last parameter.

```
bool  SymbolInfoString(
   string                    name,         // Symbol
   ENUM_SYMBOL_INFO_STRING   prop_id,      // Property identifier
   string&                   string_var    // here we accept the property value
   );
```

Parameters

name

[in] Symbol name.

prop_id

[in] Identifier of a symbol property. The value can be one of the values of the ENUM_SYMBOL_INFO_STRING enumeration.

string_var

[out] Variable of the string type receiving the value of the requested property.

Return Value

The value of string type. In case of execution failure, information about the error can be obtained using GetLastError() function:

- 5040 - invalid string parameter for specifying a symbol name,
- 4301 - unknown symbol (financial instrument),
- 4302 - symbol is not selected in "Market Watch" (not found in the list of available ones),
- 4303 - invalid identifier of a symbol property.

Note

It is recommended to use SymbolInfoTick() if the function is used for getting information about the last tick. It may well be that not a single quote has appeared yet since the terminal is connected to a trading account. In such a case, the requested value will be indefinite.

In most cases, it is enough to use SymbolInfoTick() function allowing a user to receive the values of Ask, Bid, Last, Volume and the time of the last tick's arrival during a single call.

Example:

```
#define SYMBOL_NAME "USDJPY"

```

© 2000-2025, MetaQuotes Ltd.

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get string data for SYMBOL_NAME symbol
   string currency_base   = SymbolInfoString(SYMBOL_NAME, SYMBOL_CURRENCY_BASE);     //
   string currency_profit = SymbolInfoString(SYMBOL_NAME, SYMBOL_CURRENCY_PROFIT);   //
   string currency_margin = SymbolInfoString(SYMBOL_NAME, SYMBOL_CURRENCY_MARGIN);   //
   string symbol_descript = SymbolInfoString(SYMBOL_NAME, SYMBOL_DESCRIPTION);       //

//--- create a message text with the obtained data
   string text=StringFormat("Symbol %s:\n"+
                            "- Currency Base: %s\n"+
                            "- Currensy Profit: %s\n"+
                            "- Currency Margin: %s\n"+
                            "- Symbol Description: %s",
                            SYMBOL_NAME, currency_base,
                            currency_profit, currency_margin,
                            symbol_descript);

//--- send the obtained data to the journal
   Print(text);
   /*

SymbolInfoMarginRate

Returns the margin rates depending on the order type and direction.

```
bool  SymbolInfoMarginRate(
   string             name,                    // symbol name
   ENUM_ORDER_TYPE    order_type,              // order type
   double&            initial_margin_rate,     // initial margin rate
   double&            maintenance_margin_rate  // maintenance margin rate
   );
```

Parameters

name

[in] Symbol name.

order_type

[in] Order type.

initial_margin_rate

[in] A double type variable for receiving an initial margin rate. Initial margin is a security deposit for 1 lot deal in the appropriate direction. Multiplying the rate by the initial margin, we receive the amount of funds to be reserved on the account when placing an order of the specified type.

maintenance_margin_rate

[out] A double type variable for receiving a maintenance margin rate. Maintenance margin is a minimum amount for maintaining an open position of 1 lot in the appropriate direction. Multiplying the rate by the maintenance margin, we receive the amount of funds to be reserved on the account after an order of the specified type is activated.

Return Value

Returns true if request for properties is successful, otherwise false.

Example:

```
#define SYMBOL_NAME Symbol()

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare the variables the ratios are set into
   double initial_margin_rate = 0;      // initial margin rate
   double maintenance_margin_rate = 0; // maintenance margin rate

//--- get and send the SYMBOL_NAME symbol ratios for the Buy market order to the jour
   SymbolInfoMarginRatePrint(SYMBOL_NAME, ORDER_TYPE_BUY, initial_margin_rate, mainte

//--- get and send the SYMBOL_NAME symbol ratios for the Sell market order to the jou
   SymbolInfoMarginRatePrint(SYMBOL_NAME, ORDER_TYPE_SELL, initial_margin_rate, maint
```

© 2000-2025, MetaQuotes Ltd.

```
   /*
   result:
   Initial margin rate for symbol AFKS for the Buy market order: 0.225600
   Maintenance margin rate for symbol AFKS for the Buy market order: 0.112800
   Initial margin rate for symbol AFKS for the Sell market order: 0.254400
   Maintenance margin rate for symbol AFKS for the Sell market order: 0.127200
   */
  }
//+------------------------------------------------------------------+
//| Send the margin ratios to the journal                            |
//+------------------------------------------------------------------+
void SymbolInfoMarginRatePrint(const string symbol, const ENUM_ORDER_TYPE order_type,
  {
//--- get the 'symbol' ratios for the order_type market order
   ResetLastError();
   if(!SymbolInfoMarginRate(symbol, order_type, initial_margin_rate, maintenance_margi
     {
      Print("SymbolInfoMarginRate() failed. Error ", GetLastError());
      return;
     }
//--- print the obtained ratio values
   string type=(order_type==ORDER_TYPE_BUY ? "Buy" : order_type==ORDER_TYPE_SELL ? "Se
   PrintFormat("Initial margin rate for symbol %s for the %s market order: %f\n"+
               "Maintenance margin rate for symbol %s for the %s market order: %f",
               SYMBOL_NAME, type, initial_margin_rate,
               SYMBOL_NAME, type, maintenance_margin_rate);
  }
```

SymbolInfoTick

The function returns current prices of a specified symbol in a variable of the MqlTick type.

```
bool  SymbolInfoTick(
   string    symbol,      // symbol name
   MqlTick&  tick         // reference to a structure
   );
```

Parameters

symbol

[in] Symbol name.

tick

[out] Link to the structure of the MqlTick type, to which the current prices and time of the last price update will be placed.

Return Value

The function returns true if successful, otherwise returns false.

Example:

```
#define SYMBOL_NAME "EURUSD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare an array with the MqlTick structure type of dimension 1
   MqlTick tick[1]={};

//--- get the latest prices for the SYMBOL_NAME symbol into the MqlTick structure
   if(!SymbolInfoTick(SYMBOL_NAME, tick[0]))
     {
      Print("SymbolInfoTick() failed. Error ", GetLastError());
      return;
     }

//--- send the obtained data to the journal
   PrintFormat("Latest price data for the '%s' symbol:", SYMBOL_NAME);
   ArrayPrint(tick);
   /*
   result:
   Latest price data for the 'EURUSD' symbol:
                    [time]    [bid]    [ask] [last] [volume]     [time_msc] [flags] [volu
   [0] 2024.05.17 23:58:54 1.08685 1.08695 0.0000         0 1715990334319       6
   */
  }
```

SymbolInfoSessionQuote

Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.

```
bool  SymbolInfoSessionQuote(
   string            name,                // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,         // day of the week
   uint              session_index,       // session index
   datetime&         from,                // time of the session beginning
   datetime&         to                   // time of the session end
   );
```

Parameters

name

[in] Symbol name.

ENUM_DAY_OF_WEEK

[in] Day of the week, value of enumeration ENUM_DAY_OF_WEEK.

uint

[in] Ordinal number of a session, whose beginning and end time we want to receive. Indexing of sessions starts with 0.

from

[out] Session beginning time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

to

[out] Session end time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

Return Value

If data for the specified session, symbol and day of the week are received, returns true, otherwise returns false.

Example:

```
#define SYMBOL_NAME    Symbol()
#define SESSION_INDEX 0

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the header with a symbol and SESSION_INDEX and
//--- in a loop by day of the week from Mon to Fri, print the start and end times of t
   PrintFormat("Symbol %s, Quote session %d:", SYMBOL_NAME, SESSION_INDEX);
   for(int i=MONDAY; i<SATURDAY; i++)
```

© 2000-2025, MetaQuotes Ltd.

```
      SymbolInfoSessionQuotePrint(SYMBOL_NAME, (ENUM_DAY_OF_WEEK)i, SESSION_INDEX);
   /*
   result:
   Symbol RU000A103661, Quote session 0:
   - Monday     06:45 - 00:00
   - Tuesday    06:45 - 00:00
   - Wednesday  06:45 - 00:00
   - Thursday   06:45 - 00:00
   - Friday     06:45 - 00:00
   */
  }
//+------------------------------------------------------------------+
//| Send the start and end times of the specified quote session      |
//| for the specified symbol and day of the week to the journal      |
//+------------------------------------------------------------------+
void SymbolInfoSessionQuotePrint(const string symbol, const ENUM_DAY_OF_WEEK day_of_we
  {
//--- declare variables to record the beginning and end of the quote session
   datetime date_from;  // session start time
   datetime date_to;    // session end time

//--- get data from the quotation session by symbol and day of the week
   if(!SymbolInfoSessionQuote(symbol, day_of_week, session_index, date_from, date_to))
     {
      Print("SymbolInfoSessionQuote() failed. Error ", GetLastError());
      return;
     }

//--- create the week day name from the enumeration constant
   string week_day=EnumToString(day_of_week);
   if(week_day.Lower())
      week_day.SetChar(0, ushort(week_day.GetChar(0)-32));

//--- send data for the specified quote session to the journal
   PrintFormat("- %-10s %s - %s", week_day, TimeToString(date_from, TIME_MINUTES), Tir
  }
```

SymbolInfoSessionTrade

Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.

```
bool  SymbolInfoSessionTrade(
   string            name,                // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,         // day of the week
   uint              session_index,       // session index
   datetime&         from,                // session beginning time
   datetime&         to                   // session end time
   );
```

Parameters

name

[in] Symbol name.

ENUM_DAY_OF_WEEK

[in] Day of the week, value of enumeration ENUM_DAY_OF_WEEK.

uint

[in] Ordinal number of a session, whose beginning and end time we want to receive. Indexing of sessions starts with 0.

from

[out] Session beginning time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

to

[out] Session end time in seconds from 00 hours 00 minutes, in the returned value date should be ignored.

Return value

If data for the specified session, symbol and day of the week are received, returns true, otherwise returns false.

Example:

```
#define SYMBOL_NAME    Symbol()
#define SESSION_INDEX 0

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the header with a symbol and SESSION_INDEX and
//--- in a loop by day of the week from Mon to Fri, print the start and end times of t
   PrintFormat("Symbol %s, Trade session %d:", SYMBOL_NAME, SESSION_INDEX);
   for(int i=MONDAY; i<SATURDAY; i++)
```

© 2000-2025, MetaQuotes Ltd.

```
      SymbolInfoSessionTradePrint(SYMBOL_NAME, (ENUM_DAY_OF_WEEK)i, SESSION_INDEX);
   /*
   result:

MarketBookAdd

Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes.

```
bool  MarketBookAdd(
   string  symbol      // symbol
   );
```

Parameters

symbol

[in] The name of a symbol, whose Depth of Market is to be used in the Expert Advisor or script.

Return Value

The true value if opened successfully, otherwise false.

Note

Normally, this function must be called from the OnInit() function or in the class constructor. To handle incoming alerts, in the Expert Advisor program must contain the function void OnBookEvent(string& symbol).

Example:

```
#define   SYMBOL_NAME   "GBPUSD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- open the market depth for SYMBOL_NAME symbol
   if(!MarketBookAdd(SYMBOL_NAME))
     {
      PrintFormat("MarketBookAdd(%s) failed. Error ", SYMBOL_NAME, GetLastError());
      return;
     }

//--- send the message about successfully opening the market depth to the journal
   PrintFormat("The MarketBook for the '%s' symbol was successfully opened and a subsc

//--- wait 2 seconds
   Sleep(2000);

//--- upon completion, unsubscribe from the open market depth
   ResetLastError();
   if(MarketBookRelease(SYMBOL_NAME))
      PrintFormat("MarketBook for the '%s' symbol was successfully closed", SYMBOL_NAM
   else
      PrintFormat("Error %d occurred when closing MarketBook using the '%s' symbol", G
```

© 2000-2025, MetaQuotes Ltd.

```
   /*
   result:
   The MarketBook for the 'GBPUSD' symbol was successfully opened and a subscription t
   MarketBook for the 'GBPUSD' symbol was successfully closed
   */
  }
```

Structure of Depth of Market, Structures and Classes

© 2000-2025, MetaQuotes Ltd.

MarketBookRelease

Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes.

```
bool  MarketBookRelease(
   string  symbol      // symbol
   );
```

Parameters

symbol

[in] Symbol name.

Return Value

The true value if closed successfully, otherwise false.

Note

Normally, this function must be called from the OnDeinit() function, if the corresponding MarketBookAdd() function has been called in the OnInit() function. Or it must be called from the class destructor, if the corresponding MarketBookAdd() function has been called from the class constructor.

Example:

```
#define SYMBOL_NAME "GBPUSD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- open the market depth for SYMBOL_NAME symbol
   if(!MarketBookAdd(SYMBOL_NAME))
     {
      PrintFormat("MarketBookAdd(%s) failed. Error ", SYMBOL_NAME, GetLastError());
      return;
     }

//--- send the message about successfully opening the market depth to the journal
   PrintFormat("The MarketBook for the '%s' symbol was successfully opened and a subsc

//--- wait 2 seconds
   Sleep(2000);

//--- upon completion, unsubscribe from the open market depth
//--- send the message about successfully unsubscribing from the market depth or about
   ResetLastError();
   if(MarketBookRelease(SYMBOL_NAME))
      PrintFormat("MarketBook for the '%s' symbol was successfully closed", SYMBOL_NAM
```

© 2000-2025, MetaQuotes Ltd.

```
   else
      PrintFormat("Error %d occurred when closing MarketBook using the '%s' symbol", G

   /*
   result:
   The MarketBook for the 'GBPUSD' symbol was successfully opened and a subscription t
   MarketBook for the 'GBPUSD' symbol was successfully closed
   */
  }
```

See also

Structure of Depth of Market, Structures and Classes

© 2000-2025, MetaQuotes Ltd.

MarketBookGet

Returns a structure array MqlBookInfo containing records of the Depth of Market of a specified symbol.

```
bool  MarketBookGet(
   string        symbol,      // symbol
   MqlBookInfo&  book[]       // reference to an array
   );
```

Parameters

symbol

[in] Symbol name.

book[]

[in] Reference to an array of Depth of Market records. The array can be pre-allocated for a sufficient number of records. If a dynamic array hasn't been pre-allocated in the operating memory, the client terminal will distribute the array itself.

Return Value

Returns true in case of success, otherwise false.

Note

The Depth of Market must be pre-opened by the MarketBookAdd() function.

Example:

```
   MqlBookInfo priceArray[];
   bool getBook=MarketBookGet(NULL,priceArray);
   if(getBook)
     {
      int size=ArraySize(priceArray);
      Print("MarketBookInfo for ",Symbol());
      for(int i=0;i<size;i++)
        {
         Print(i+":",priceArray[i].price
               +"    Volume = "+priceArray[i].volume,
               " type = ",priceArray[i].type);
        }
     }
   else
     {
      Print("Could not get contents of the symbol DOM ",Symbol());
     }
```

Economic calendar functions

This section describes the functions for working with the economic calendar available directly in the MetaTrader platform. The economic calendar is a ready-made encyclopedia featuring descriptions of macroeconomic indicators, their release dates and degrees of importance. Relevant values of macroeconomic indicators are sent to the MetaTrader platform right at the moment of publication and are displayed on a chart as tags allowing you to visually track the required indicators by countries, currencies and importance.

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

Economic calendar functions allow conducting the auto analysis of incoming events according to custom importance criteria from a perspective of necessary countries/currencies.

Function	Action
CalendarCountryById	Get a country description by its ID
CalendarEventById	Get an event description by its ID
CalendarValueById	Get an event value description by its ID
CalendarCountries	Get the array of country names available in the calendar
CalendarEventByCountry	Get the array of descriptions of all events available in the calendar by a specified country code
CalendarEventByCurrency	Get the array of descriptions of all events available in the calendar by a specified currency
CalendarValueHistoryByEvent	Get the array of values for all events in a specified time range by an event ID
CalendarValueHistory	Get the array of values for all events in a specified time range with the ability to sort by country and/or currency
CalendarValueLastByEvent	Get the array of event values by its ID since the calendar database status with a specified change_id
CalendarValueLast	Get the array of values for all events with the ability to sort by country and/or currency since the calendar database status with a specified change_id

© 2000-2025, MetaQuotes Ltd.

CalendarCountryById

Get a country description by its ID.

```
bool  CalendarCountryById(
   const long           country_id,     // country ID
   MqlCalendarCountry&  country         // variable for receiving a country descripti
   );
```

Parameters

country_id

[in] Country ID (ISO 3166-1).

country

[out] MqlCalendarCountry type variable for receiving a country description.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the list of countries from the economic calendar
   MqlCalendarCountry countries[];
   int count=CalendarCountries(countries);
//--- check the result
   if(count==0)
      PrintFormat("CalendarCountries() returned 0! Error %d",GetLastError());
//--- if there are two or more countries
   if(count>=2)
     {
      MqlCalendarCountry country;
      //--- now get a country description by its ID
      if(CalendarCountryById(countries[1].id, country))
        {
         //--- prepare a country description
         string descr="id = "+IntegerToString(country.id)+"\n";
         descr+=("name = " + country.name+"\n");
         descr+=("code = " + country.code+"\n");
         descr+=("currency = " + country.currency+"\n");
         descr+=("currency_symbol = " + country.currency_symbol+"\n");
```

© 2000-2025, MetaQuotes Ltd.

```
         descr+=("url_name = " + country.url_name);
         //--- display a country description
         Print(descr);
        }
      else
         Print("CalendarCountryById() failed. Error ",GetLastError());
     }
//---
  }
/*
  Result:
   id = 999
   name = European Union
   code = EU
   currency = EUR
   currency_symbol = €
   url_name = european-union
*/
```

CalendarCountries, CalendarEventByCountry

© 2000-2025, MetaQuotes Ltd.

CalendarEventById

Get an event description by its ID.

```
bool  CalendarEventById(
   ulong                event_id,      // event ID
   MqlCalendarEvent&    event          // variable for receiving an event description
   );
```

Parameters

event_id

[in] Event ID.

event

[out] MqlCalendarEvent type variable for receiving an event description.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for Germany (ISO 3166-1 Alpha-2)
   string germany_code="DE";
//--- get Germany events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(germany_code,events);
//--- display Germany events in the Journal
   if(events_count>0)
     {
      PrintFormat("Germany events: %d",events_count);
      ArrayPrint(events);
     }
   else
     {
      PrintFormat("Failed to receive events for the country code %s, error %d",
                  germany_code,GetLastError());
      //--- script early completion
      return;
     }
//--- get description of the last event from the events[] array
```

© 2000-2025, MetaQuotes Ltd.

```
   MqlCalendarEvent event;
   ulong event_id=events[events_count-1].id;
   if(CalendarEventById(event_id,event))
     {
      MqlCalendarCountry country;
      CalendarCountryById(event.country_id,country);
      PrintFormat("Event description with event_id=%d received",event_id);

CalendarEventByCountry, CalendarEventByCurrency, CalendarValueById

© 2000-2025, MetaQuotes Ltd.

CalendarValueById

Get an event value description by its ID.

```
bool  CalendarValueById(
   ulong                value_id,      // event value ID
   MqlCalendarValue&    value          // variable for receiving an event value
   );
```

Parameters

value_id

[in] Event value ID.

value

[out] MqlCalendarValue type variable for receiving an event description. See the example of handling calendar events.

Return Value

Returns true if successful, otherwise - false. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5402 - ERR_CALENDAR_NO_DATA (country is not found),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded).

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for Japan (ISO 3166-1 Alpha-2)
```

© 2000-2025, MetaQuotes Ltd.

```
   string japan_code="JP";
//--- set the boundaries of the interval we take the events from
   datetime date_from=D'01.01.2018';  // take all events from 2018
   datetime date_to=0;                // 0 means all known events, including the ones
//--- get the array of the Japan event values
   MqlCalendarValue values[];
   int values_count=CalendarValueHistory(values,date_from,date_to,japan_code);
//--- move along the detected event values
   if(values_count>0)
     {
      PrintFormat("Number of values for Japan events: %d",values_count);
      //--- delete all "empty" values (actual_value==-9223372036854775808)
      for(int i=values_count-1;i>=0;i--)
        {
         if(values[i].actual_value==-9223372036854775808)
            ArrayRemove(values,i,1);
        }
      PrintFormat("Number of values after deleting empty ones: %d",ArraySize(values));
     }
   else
     {
      PrintFormat("Failed to receive events for the country code %s, error %d",
                  japan_code,GetLastError());
      //--- script early completion
      return;
     }
//--- leave no more than 10 values in the values[] array
   if(ArraySize(values)>10)
     {
      PrintFormat("Reduce the list of values to 10 and display them");
      ArrayRemove(values,0,ArraySize(values)-10);
     }
   ArrayPrint(values);

//--- now let's display how to get an event value description based on the known value
   for(int i=0;i<ArraySize(values);i++)
     {
      MqlCalendarValue value;
      CalendarValueById(values[i].id,value);
      PrintFormat("%d: value_id=%d value=%d impact=%s",
                  i,values[i].id,value.actual_value,EnumToString(ENUM_CALENDAR_EVENT_I
     }
//---
  }
/*
  Result:
  Number of values for Japan events: 1734
  Number of values after deleting empty ones: 1017
  Reduce the list of values to 10 and display them
```

CalendarCountries

Get the array of country names available in the Calendar.

```
int  CalendarCountries(
   MqlCalendarCountry&  countries[]         // array for receiving a list of Calendar
   );
```

Parameters

countries[]

[out] An array of MqlCalendarCountry type for receiving all Calendar countries' descriptions.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all countries, only the ones that managed to fit in were received).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the list of countries from the economic calendar
   MqlCalendarCountry countries[];
   int count=CalendarCountries(countries);
//--- display the array in the Journal
   if(count>0)
      ArrayPrint(countries);
   else
      PrintFormat("CalendarCountries() returned 0! Error %d",GetLastError());

CalendarEventByCountry

Get the array of descriptions of all events available in the Calendar by a specified country code.

```
int  CalendarEventByCountry(
   string               country_code,     // country code name (ISO 3166-1 alpha-2)
   MqlCalendarEvent&    events[]          // variable for receiving the description ar
   );
```

Parameters

country_code

[in] Country code name (ISO 3166-1 alpha-2)

events[]

[out] MqlCalendarEvent type array for receiving descriptions of all events for a specified country.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- errors of failed execution of ArrayResize()

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get EU events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(EU_code,events);
//--- display EU events in the Journal
   if(events_count>0)
     {
      PrintFormat("EU events: %d",events_count);
      ArrayPrint(events);
     }
//---
  }
/*
  Result:

CalendarEventByCurrency

Get the array of descriptions of all events available in the Calendar by a specified currency.

```
int  CalendarEventByCurrency(
   const string         currency,     // country currency code name
   MqlCalendarEvent&    events[]      // variable for receiving the description array
   );
```

Parameters

currency

[in] Country currency code name.

events[]

[out] MqlCalendarEvent type array for receiving descriptions of all events for a specified currency.

Return Value

Number of received descriptions. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),

CalendarValueHistoryByEvent

Get the array of values for all events in a specified time range by an event ID.

```
int  CalendarValueHistoryByEvent(
   ulong              event_id,          // event ID
   MqlCalendarValue&  values[],          // array for value descriptions
   datetime           datetime_from,     // left border of a time range
   datetime           datetime_to=0      // right border of a time range
   );
```

Parameters

event_id

[in] Event ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

datetime_from

[in] Initial date of a time range events are selected from by a specified ID, while *datetime_from* < *datetime_to*.

datetime_to=0

[in] End date of a time range events are selected from by a specified ID. If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

Return Value

If successful, return the number of available values in the 'values' array, otherwise -1. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Note

© 2000-2025, MetaQuotes Ltd.

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get EU events
   MqlCalendarEvent events[];
   int events_count=CalendarEventByCountry(EU_code,events);
//--- display EU events in the Journal
   if(events_count>0)
     {
      PrintFormat("EU events: %d",events_count);
      //--- reduce the event list, 10 events are sufficient for analysis
      ArrayResize(events,10);
      ArrayPrint(events);
     }
//--- see that the "ECB Interest Rate Decision" event has event_id=999010007
   ulong event_id=events[6].id;        // the event's ID may change in the Calendar, s
   string event_name=events[6].name;   // name of a Calendar event
   PrintFormat("Get values for event_name=%s event_id=%d",event_name,event_id);
//--- get all values of the "ECB Interest Rate Decision" event
   MqlCalendarValue values[];
//--- set the boundaries of the interval we take the events from
   datetime date_from=0;           // take all events from the beginning of the availa
   datetime date_to=D'01.01.2016'; // take events not older than 2016
   if(CalendarValueHistoryByEvent(event_id,values,date_from,date_to))
     {
      PrintFormat("Received values for %s: %d",
                  event_name,ArraySize(values));
      //--- reduce the value list, 10 events are sufficient for analysis
      ArrayResize(values,10);
      ArrayPrint(values);
     }
   else
     {
      PrintFormat("Error! Failed to get values for event_id=%d",event_id);
      PrintFormat("Error code: %d",GetLastError());
     }
  }
//---
```

CalendarValueHistory

Get the array of values for all events in a specified time range with the ability to sort by country and/or currency.

```
int  CalendarValueHistory(
   MqlCalendarValue&  values[],              // array for value descriptions
   datetime           datetime_from,         // left border of a time range
   datetime           datetime_to=0          // right border of a time range
   const string       country_code=NULL,     // country code name (ISO 3166-1 alpha-2)
   const string       currency=NULL          // country currency code name
   );
```

Parameters

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

datetime_from

[in] Initial date of a time range events are selected from by a specified ID, while *datetime_from* < *datetime_to*.

datetime_to=0

[in] End date of a time range events are selected from by a specified ID. If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

country_code=NULL

[in] Country code name (ISO 3166-1 alpha-2)

currency=NULL

[in] Country currency code name.

Return Value

If successful, return the number of available values in the 'values' array, otherwise -1. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

© 2000-2025, MetaQuotes Ltd.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If the *datetime_to* is not set (or is 0), all event values beginning from the specified *datetime_from* date in the Calendar database are returned (including the values of future events).

For the *country_code* and *currency* filters, NULL and "" values are equivalent and mean the absence of the filter.

For *country_code*, the *code* field of the MqlCalendarCountry structure, for example "US", "RU" or "EU", should be used.

For *currency*, the *currency* field of the MqlCalendarCountry structure, for example "USD", "RUB" or "EUR", should be used.

The filters are applied by conjunction, i.e. logical 'AND' is used to select only the values of events both conditions (country and currency) are simultaneously met for.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- country code for EU (ISO 3166-1 Alpha-2)
   string EU_code="EU";
//--- get all EU event values
   MqlCalendarValue values[];
//--- set the boundaries of the interval we take the events from
   datetime date_from=D'01.01.2018';  // take all events from 2018
   datetime date_to=0;                // 0 means all known events, including the ones
//--- request EU event history since 2018 year
   if(CalendarValueHistory(values,date_from,date_to,EU_code))
     {
      PrintFormat("Received event values for country_code=%s: %d",
                  EU_code,ArraySize(values));
      //--- decrease the size of the array for outputting to the Journal
      ArrayResize(values,10);
//--- display event values in the Journal
      ArrayPrint(values);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
    else
      {
       PrintFormat("Error! Failed to receive events for country_code=%s",EU_code);
       PrintFormat("Error code: %d",GetLastError());
      }
//---
  }
/*
  Result:

CalendarValueLastByEvent

Get the array of event values by its ID since the Calendar database status with a specified change_id.

```
int  CalendarValueLastByEvent(
   ulong                event_id,      // event ID
   ulong&               change_id,     // Calendar change ID
   MqlCalendarValue&    values[]       // array for value descriptions
   );
```

Parameters

event_id

[in] Event ID.

change_id

[in][out] Change ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

Return Value

Number of received event values. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If *change_id* = 0 is passed to the function, the function always returns zero but the current calendar database is returned to *change_id*.

The function returns the array for a specified news and a new *change_id* that can be used for subsequent calls of the function to receive the new values of the news. Thus, it is possible to update values for a specified news by calling this function with the last known *change_id*.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

© 2000-2025, MetaQuotes Ltd.

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

© 2000-2025, MetaQuotes Ltd.

CalendarValueLast

Get the array of values for all events with the ability to sort by country and/or currency since the calendar database status with a specified change_id.

```
int  CalendarValueLast(
   ulong&               change_id,              // change ID
   MqlCalendarValue&    values[],               // array for value descriptions
   const string         country_code=NULL,      // country code name (ISO 3166-1 alpha-
   const string         currency=NULL           // country currency code name
   );
```

Parameters

change_id

[in][out] Change ID.

values[]

[out] MqlCalendarValue type array for receiving event values. See the example of handling calendar events.

country_code=NULL

[in] Country code name (ISO 3166-1 alpha-2)

currency=NULL

[in] Country currency code name.

Return Value

Number of received event values. To get information about an error, call the GetLastError() function. Possible errors:

- 4001 - ERR_INTERNAL_ERROR (general runtime error),
- 4004 - ERR_NOT_ENOUGH_MEMORY (not enough memory for executing a request),
- 5401 - ERR_CALENDAR_TIMEOUT (request time limit exceeded),
- 5400 - ERR_CALENDAR_MORE_DATA (array size is insufficient for receiving descriptions of all values, only the ones that managed to fit in were received),
- errors of failed execution of ArrayResize()

Note

All functions for working with the economic calendar use the trade server time (TimeTradeServer). This means that the time in the MqlCalendarValue structure and the time inputs in the CalendarValueHistoryByEvent/CalendarValueHistory functions are set in a trade server timezone, rather than a user's local time.

If the *events[]* array of fixed length was passed to the function and there was not enough space to save the entire result, the ERR_CALENDAR_MORE_DATA (5400) error is activated.

If *change_id* = 0 is passed to the function, you will get the current *change_id* of the calendar database to that parameter; and the function returns 0

For the *country_code* and *currency* filters, NULL and "" values are equivalent and mean the absence of the filter.

© 2000-2025, MetaQuotes Ltd.

For *country_code*, the *code* field of the MqlCalendarCountry structure, for example "US", "RU" or "EU", should be used.

For *currency*, the *currency* field of the MqlCalendarCountry structure, for example "USD", "RUB" or "EUR", should be used.

The filters are applied by conjunction, i.e. logical 'AND' is used to select only the values of events both conditions (country and currency) are simultaneously met for

The function returns the array for a specified news and a new *change_id* that can be used for subsequent calls of the function to receive the new values of the news. Thus, it is possible to update values for a specified news by calling this function with the last known *change_id*.

The MqlCalendarValue structure provides methods for checking and setting values from the actual_value, forecast_value, prev_value and revised_prev_value fields. If no value is specified, the field stores LONG_MIN (-9223372036854775808).

Please note that the values stored in these field are multiplied by one million. It means that when you receive values in MqlCalendarValue using functions CalendarValueById, CalendarValueHistoryByEvent, CalendarValueHistory, CalendarValueLastByEvent and CalendarValueLast, you should check if the field values are equal to LONG_MIN; if a value is specified in a field, then you should divide the value by 1,000,000 in order to get the value. Another method to get the values is to check and to get values using the functions of the MqlCalendarValue structure.

Access to Timeseries and Indicator Data

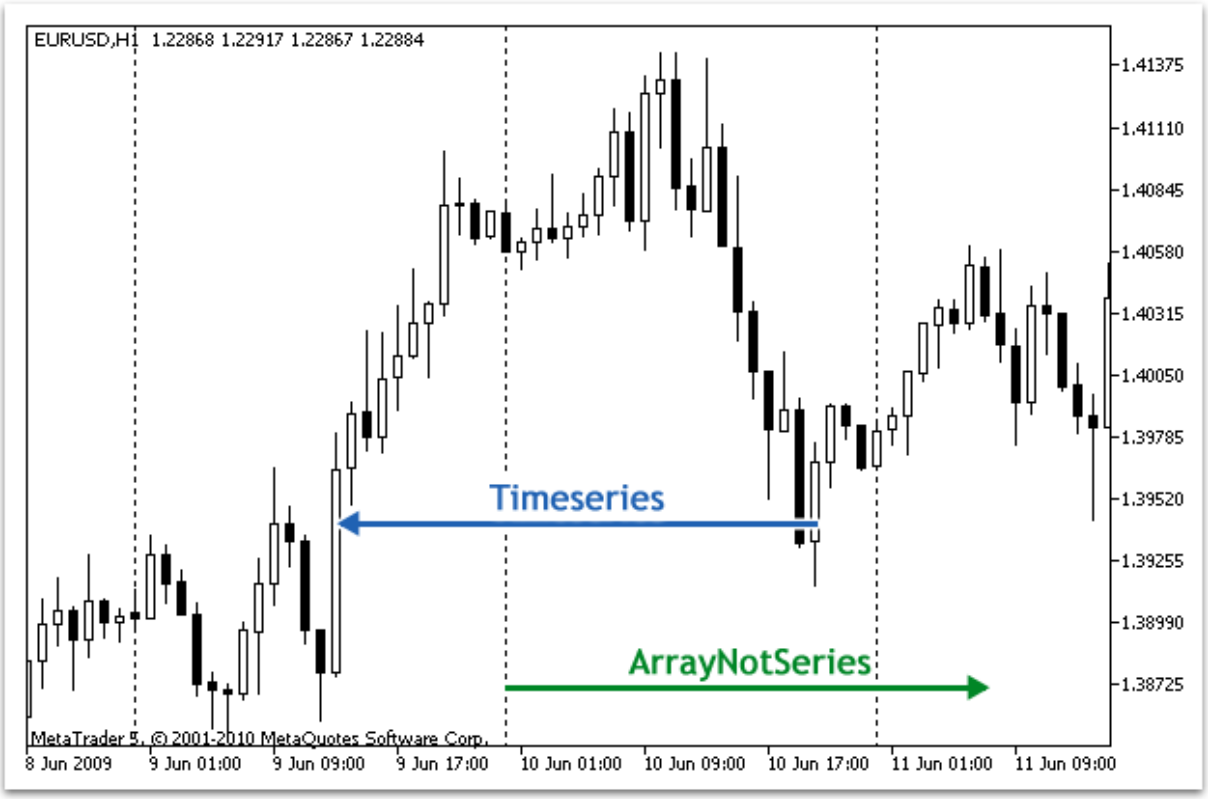
These are functions for working with timeseries and indicators. A timeseries differs from the usual data array by its reverse ordering - elements of timeseries are indexed from the end of an array to its begin (from the most recent data to the oldest ones). To copy the time-series values and indicator data, it's recommended to use dynamic arrays only, because copying functions are designed to allocate the necessary size of arrays that receive values.

There is an **important exception** to this rule: if timeseries and indicator values need to be copied often, for example at each call of OnTick() in Expert Advisors or at each call of OnCalculate() in indicators, in this case one should better use statically distributed arrays, because **operations of memory allocation** for dynamic arrays **require additional time**, and this will have effect during testing and optimization.

When using functions accessing timeseries and indicator values, indexing direction should be taken into account. This is described in the Indexing Direction in Arrays, Buffers and Timeseries section.

Access to indicator and timeseries data is implemented irrespective of the fact whether the requested data are ready (the so called asynchronous access). This is critically important for the calculation of custom indicator, so if there are no data, functions of *Copy...()* type immediately return an error. However, when accessing form Expert Advisors and scripts, several attempts to receive data are made in a small pause, which is aimed at providing some time necessary to download required timeseries or to calculate indicator values.

The Organizing Data Access section describes details of receiving, storing and requesting price data in the MetaTrader 5 client terminal.



It is historically accepted that an access to the price data in an array is performed from the end of the data. Physically, the new data are always written at the array end, but the index of the array is always

© 2000-2025, MetaQuotes Ltd.

equal to zero. The 0 index in the timeseries array denotes data of the current bar, i.e. the bar that corresponds to the unfinished time interval in this timeframe.

A timeframe is the time period, during which a single price bar is formed. There are 21 predefined standard timeframes.

Function	Action
SeriesInfoInteger	Returns information about the state of historical data
Bars	Returns the number of bars count in the history for a specified symbol and period
BarsCalculated	Returns the number of calculated data in an indicator buffer or -1 in the case of error (data hasn't been calculated yet)
IndicatorCreate	Returns the handle to the specified technical indicator created by an array of MqlParam type parameters
IndicatorParameters	Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters
IndicatorRelease	Removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else
CopyBuffer	Gets data of a specified buffer from a specified indicator into an array
CopyRates	Gets history data of the Rates structure for a specified symbol and period into an array
CopySeries	Gets the synchronized timeseries from the Rates structure for the specified symbol-period and the specified amount
CopyTime	Gets history data on bar opening time for a specified symbol and period into an array
CopyOpen	Gets history data on bar opening price for a specified symbol and period into an array
CopyHigh	Gets history data on maximal bar price for a specified symbol and period into an array
CopyLow	Gets history data on minimal bar price for a specified symbol and period into an array
CopyClose	Gets history data on bar closing price for a specified symbol and period into an array
CopyTickVolume	Gets history data on tick volumes for a specified symbol and period into an array
CopyRealVolume	Gets history data on trade volumes for a specified symbol and period into an array
CopySpread	Gets history data on spreads for a specified symbol and period into an array

© 2000-2025, MetaQuotes Ltd.

Function	Action
CopyTicks	Gets ticks in the MqlTick format into ticks_array
CopyTicksRange	Gets ticks in the MqlTick format within the specified date range to ticks_array
iBars	Returns the number of bars of a corresponding symbol and period, available in history
iBarShift	Returns the index of the bar corresponding to the specified time
iClose	Returns the Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iHigh	Returns the High price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iHighest	Returns the index of the highest value found on the corresponding chart (shift relative to the current bar)
iLow	Returns the Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iLowest	Returns the index of the smallest value found on the corresponding chart (shift relative to the current bar)
iOpen	Returns the Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart
iTime	Returns the opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart
iTickVolume	Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iRealVolume	Returns the real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iVolume	Returns the tick volume of the bar (indicated by the 'shift' parameter) on the corresponding chart
iSpread	Returns the spread value of the bar (indicated by the 'shift' parameter) on the corresponding chart

Despite the fact that by using the ArraySetAsSeries() function it is possible to set up in arrays access to elements like that in timeseries, it should be remembered that the array elements are physically stored in one and the same order - only indexing direction changes. To demonstrate this fact let's perform an example:

```
   datetime TimeAsSeries[];
//--- set access to the array like to a timeseries
   ArraySetAsSeries(TimeAsSeries,true);
   ResetLastError();
   int copied=CopyTime(NULL,0,0,10,TimeAsSeries);
   if(copied<=0)
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       Print("The copy operation of the open time values for last 10 bars has failed");
       return;
      }
   Print("TimeCurrent =",TimeCurrent());
   Print("ArraySize(Time) =",ArraySize(TimeAsSeries));
   int size=ArraySize(TimeAsSeries);
   for(int i=0;i<size;i++)
      {
       Print("TimeAsSeries["+i+"] =",TimeAsSeries[i]);
      }

   datetime ArrayNotSeries[];
   ArraySetAsSeries(ArrayNotSeries,false);
   ResetLastError();
   copied=CopyTime(NULL,0,0,10,ArrayNotSeries);
   if(copied<=0)
      {
       Print("The copy operation of the open time values for last 10 bars has failed");
       return;
      }
   size=ArraySize(ArrayNotSeries);
   for(int i=size-1;i>=0;i--)
      {
       Print("ArrayNotSeries["+i+"] =",ArrayNotSeries[i]);
      }
```

As a result we will get the output like this:

```
TimeCurrent = 2009.06.11 14:16:23
ArraySize(Time) = 10
TimeAsSeries[0] = 2009.06.11 14:00:00
TimeAsSeries[1] = 2009.06.11 13:00:00
TimeAsSeries[2] = 2009.06.11 12:00:00
TimeAsSeries[3] = 2009.06.11 11:00:00
TimeAsSeries[4] = 2009.06.11 10:00:00
TimeAsSeries[5] = 2009.06.11 09:00:00
TimeAsSeries[6] = 2009.06.11 08:00:00
TimeAsSeries[7] = 2009.06.11 07:00:00
TimeAsSeries[8] = 2009.06.11 06:00:00
TimeAsSeries[9] = 2009.06.11 05:00:00

ArrayNotSeries[9] = 2009.06.11 14:00:00
ArrayNotSeries[8] = 2009.06.11 13:00:00
ArrayNotSeries[7] = 2009.06.11 12:00:00
ArrayNotSeries[6] = 2009.06.11 11:00:00
ArrayNotSeries[5] = 2009.06.11 10:00:00
ArrayNotSeries[4] = 2009.06.11 09:00:00
ArrayNotSeries[3] = 2009.06.11 08:00:00
```

© 2000-2025, MetaQuotes Ltd.

```
ArrayNotSeries[2] = 2009.06.11 07:00:00
ArrayNotSeries[1] = 2009.06.11 06:00:00
ArrayNotSeries[0] = 2009.06.11 05:00:00
```

As we see from the output, as the index of TimeAsSeries array increases, the time value of the index decreases, i.e. we move from the present to the past. For the common array ArrayNotSeries the result is different - as index grows, we move from past to present.

Indexing Direction in Arrays, Buffers and Timeseries

The default indexing of all arrays and indicator buffers is left to right. The index of the first element is always equal to zero. Thus, the very first element of an array or indicator buffer with index 0 is by default on the extreme left position, while the last element is on the extreme right position.

An indicator buffer is a dynamic array of type double, whose size is managed by the client terminals, so that it always corresponds to the number of bars the indicator is calculated on. A usual dynamic array of type double is assigned as an indicator buffer using the SetIndexBuffer() function. Indicator buffers do not require setting of their size using function ArrayResize() - this will be done by the executing system of the terminal.

Timeseries are arrays with reverse indexing, i.e. the first element of a timeseries is in the extreme right position, and the last element is in the extreme left position. Timeseries being used for storing history price data and contain the time information, we can say that the newest data are placed in the extreme right position of the timeseries, while the oldest data are in the extreme left position.

So the timeseries element with index 0 contains the information about the latest quote of a symbol. If a timeseries contains data on a daily timeframe, data of the current yet uncompleted day are located on the zero position, and the position with index 1 contains yesterday data.

Changing the Indexing Direction

Function ArraySetAsSeries() allows changing the method of accessing elements of a dynamic array; the physical order of data storing in the computer memory is not changed at that. This function simply changes the method of addressing array elements, so when copying one array to another using function ArrayCopy(), the contents of the recipient array will not depend on the indexing direction in the source array.

Direction of indexing cannot be changed for statically distributed arrays. Even if an array was passed as a parameter to a function, attempts to change the indexing direction inside this function will bring no effect.

For indicator buffers, like for usual arrays, indexing direction can also be set as backward (like in timeseries), i.e. reference to the zero position in the indicator buffer will mean reference to the last value on the corresponding indicator buffer and this will correspond to the value of the indicator on the latest bar. Still, the physical location of indicator bars will be unchanged.

Receiving Price Data in Indicators

Each custom indicator must necessarily contain the OnCalculate() function, to which price data required for calculating values in indicator buffers are passed. Indexing direction in these passed arrays can be found out using function ArrayGetAsSeries().

Arrays passed to the function reflect price data, i.e. these arrays have the sign of a timeseries and function ArrayIsSeries() will return true when checking these arrays. However, in any case indexing direction should be checked only by function ArrayGetAsSeries().

In order not to be dependent on default values, ArraySetAsSeries() should be unconditionally called for the arrays you are going to work with, and set the required direction.

Receiving Price Data and Indicator Values

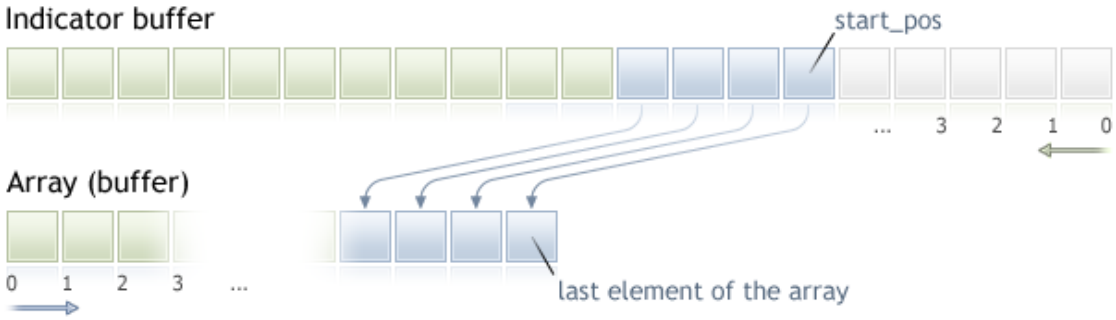
© 2000-2025, MetaQuotes Ltd.

Default indexing direction of all arrays in Expert Advisors, indicators and scripts is left-to-right. If necessary, in any mql5 program you can request timeseries values on any symbol and timeframe, as well as values of indicators calculated on any symbol and timeframe.

Use functions Copy...() for these purposes:

- CopyBuffer - copy values of an indicator buffer to an array of double type;
- CopyRates - copy price history to an array of structures MqlRates;
- CopyTime - copy Time values to an array of datetime type;
- CopyOpen - copy Open values to an array of double type;
- CopyHigh - copy High values to an array of double type;
- CopyLow - copy Low values to an array of double type;
- CopyClose - copy Close values to an array of double type;
- CopyTickVolume - copy tick volumes to an array of long type;
- CopyRealVolume - copy equity volumes to a long type array;
- CopySpread - copy the spread history to an array of int type;

All these functions work in a similar way. Let's consider the data obtaining mechanism on the example of CopyBuffer(). It is implied that the indexing direction of requested data is that of timeseries, and the position with index 0 (zero) stores data of the current yet uncompleted bar. In order to get access to these data we need to copy the necessary volume of data into the recipient array, e.g. into array *buffer*.



When copying we need to specify the starting position in the source array, starting from which data will be copied to the recipient array. In case of success, the specified number of elements will be copied to the recipient array from the source array (from the indicator buffer in this case). Irrespective of the indexing value set in the recipient array, copying is always performed as is shown in the above figure.

If it is expected that price data will be handled in a loop with a large number of iterations, it is advisable that you check the fact of forced program termination using the IsStopped() function:

```
int copied=CopyBuffer(ma_handle,// Indicator handle
                      0,        // The index of the indicator buffer
                      0,        // Start position for copying
                      number,   // Number of values to copy
                      Buffer    // The array that receives the values
```

© 2000-2025, MetaQuotes Ltd.

```
                        );
if(copied<0) return;
int k=0;
while(k<copied && !IsStopped())
  {
   //--- Get the value for the k index
   double value=Buffer[k];
   // ...
   // work with value
   k++;
  }
```

Example:

```
input int per=10; // period of the exponent
int ma_handle;    // indicator handle
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//---
   ma_handle=iMA(_Symbol,0,per,0,MODE_EMA,PRICE_CLOSE);
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
//---
   double ema[10];
   int copied=CopyBuffer(ma_handle,// indicator handle
                         0,        // index of the indicator buffer
                         0,        // starting position to copy from
                         10,       // number of values for copying
                         ema       // value receiving array
                         );
   if(copied<0) return;
// .... further code
  }
```

Organizing Data Access

© 2000-2025, MetaQuotes Ltd.

Organizing Data Access

In this section questions connected with obtaining, storing and requesting price data (timeseries) are considered.

Receiving Data from a Trade Server

Before price data become available in the MetaTrader 5 terminal, they must be received and processed. To receive data, connection to the MetaTrader 5 trade server must be established. Data are received in the form of packed blocks of minute bars from the server upon the request of a terminal.

The mechanism of server reference for data doesn't depend on how the request has been initiated - by a user when navigating in a chart or in a program way in the MQL5 language.

Storing Intermediate Data

Data received from a server are automatically unpacked and saved in the HCC intermediate format. Data on each symbol are written into a separate folder: *terminal_directory*\bases*server_name*\history*symbol_name*. For example, data on EURUSD received from the MetaQuotes-Demo server will be stored in *terminal_directory*\bases\MetaQuotes-Demo\history\EURUSD\.

Data are written into files with .hcc extension. Each file stores data of minute bars for one year. For example, the file named 2009.hcc in the EURUSD folder contains minute bars of EURUSD for year 2009. These files are used for preparing price data for all timeframes and are not intended for direct access.

Obtaining Data on a Necessary Timeframe out of Intermediate Data

Intermediate HCC files are used as the data source for building price data for requested timeframes in the HC format. Data of HC format are timeseries that are maximally prepared for a quick access. They are created upon a request of a chart or a MQL5 program. The volume of data should not exceed the value of the "Max bars in charts" parameter. Data are stored for further using in files with hc extension.

To save resources, data on a timeframe are stored and saved in RAM only if necessary. If not called for a long time, they are released from RAM and saved into a file. For each timeframe, data are prepared regardless of whether there are ready data for other timeframes or not. Rules of forming and accessing data are the same for all timeframes. I.e., despite the fact that the unit data stored in HCC is one minute (M1), the availability of HCC data doesn't mean the availability of data on M1 timeframe as HC in the same volume.

Receipt of new data from a server calls automatic update of used price data in HC format of all timeframes. It also leads to the recalculation of all indicators that implicitly use them as input data for calculations.

Parameter "Max bars in chart"

The "Max bars in charts" parameter restricts number of bars in HC format available to charts, indicators and mql5 programs. This is valid for all available timeframes and serves, first of all, to save computer resources.

© 2000-2025, MetaQuotes Ltd.

When setting a large value of this parameter, it should be remembered, that if deep history price data for small timeframes are available, memory used for storing timeseries and indicator buffers can become hundreds of megabytes and reach the RAM restriction for the client terminal program (2Gb for 32-bit applications of MS Windows).

Change of the "Max bars in charts" comes into effect after the client terminal is restarted. Change of this parameter causes neither automatic referring to a server for additional data, nor forming of additional bars of timeseries. Additional price data are requested from the server, and timeseries are updated taking into account the new limitation, in case of either chart scroll to the area with no data, or when data are requested by a mql5 program.

Volume of data requested from the server corresponds to the required number of bars of this timeframe with the "Max bars in charts" parameter taken into account. The restriction set by this parameter is not strict, and in some cases the number of available bars for a timeframe can be a little more than the current parameter value.

Data Availability

Presence of data on HCC format or even in the prepared for using HC format does not always denote the absolute availability of these data to be shown in a chart or to be used in MQL5 programs.

When accessing to price data or indicator values from a mql5 program it should be remembered that their availability in a certain moment of time or starting from a certain moment of time is not guaranteed. It is connected with the fact that with the purpose of saving resources, the full copy of data necessary for a mql5 program isn't stored in MetaTrader 5; only direct access to the terminal database is given.

The price history for all timeframes is built from common data of HCC format, and any update of data from a server leads to the update of data for all timeframes and to the recalculation of indicators. Due to this access to data can be closed, even if these data were available a moment ago.

Synchronization of the Terminal Data and Server Data

Since a mql5 program can call data from any symbol and timeframe, there is a possibility that data of a necessary timeseries are not formed yet in the terminal or the necessary price data aren't synchronized with the trade server. In this case it's hard to predict the latency time.

Algorithms using "do-nothing" loops are not the best solution. The only exception in this case are scripts, because they do not have any alternative algorithm choice due to not having event handling. For custom indicators such algorithms, as well as any other "do-nothing" loops are strongly not recommended, because they lead to termination of calculation of all indicators and any other handling of price data of the symbol.

For Expert Advisors and indicators, it is better to use the event model of handling. If during handling of OnTick() or OnCalculate() event, data receipt for the required timeseries failed, you should exit the event handler, relying on the access availability during the next call of the handler.

Example of a Script for Adding History

Let's consider the example of a script that executes a request to receive history for the selected symbol from a trade server. The script is intended for running in a chart of a selected symbol;

© 2000-2025, MetaQuotes Ltd.

timeframe doesn't matter, because, as it was mentioned above, price data are received from a trade server as packed one minute data, from which any predefined timeseries is constructed then.

Write all actions concerning data receipt as a separate function CheckLoadHistory(symbol, timeframe, start_date):

```
int CheckLoadHistory(string symbol,ENUM_TIMEFRAMES period,datetime start_date)
  {
  }
```

The CheckLoadHistory() function is designed as a universal function that can be called from any program (Expert Advisor, script or indicator); and therefore it requires three input parameters: symbol name, period and start date to indicate the beginning of price history you need.

Insert necessary checks into the function code before requesting the missing history. First of all, we should make sure that the symbol name and period value are correct:

```
   if(symbol==NULL || symbol=="") symbol=Symbol();
   if(period==PERIOD_CURRENT)     period=Period();
```

Then let's make sure that the symbol is available in the MarketWatch window, i.e., the history for the symbol will be available when sending a request to a trade server. If there is no such a symbol in MarketWatch, add it using the SymbolSelect() function.

```
   if(!SymbolInfoInteger(symbol,SYMBOL_SELECT))
     {f
      if(GetLastError()==ERR_MARKET_UNKNOWN_SYMBOL) return(-1);
      SymbolSelect(symbol,true);
     }
```

Now we should receive the start date of the available history for the indicated symbol/period pair. Perhaps, the value of the input parameter startdate, passed to CheckLoadHistory(), is within the available history; then request to a trade server is not needed. In order to obtain the very first date for the symbol-period as of the moment, the SeriesInfoInteger() function with the SERIES_FIRSTDATE modifier is used.

```
   SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date);
   if(first_date>0 && first_date<=start_date) return(1);
```

The next important check is checking the type of the program, from which the function is called. Note that it is not desirable to send a request to update the timeseries from indicator with the same period. The undesirability of requesting data on the same symbol-period as that of the indicator is conditioned by the fact that update of history data is performed in the same thread where the indicator operates. So the possibility of deadlock occurrence is high. To check this use the MQL5InfoInteger() function with the MQL5_PROGRAM_TYPE modifier.

```
   if(MQL5InfoInteger(MQL5_PROGRAM_TYPE)==PROGRAM_INDICATOR && Period()==period && Sy
      return(-4);
```

If all the checks have been passed successfully, make the last attempt to do without referring to the trade server. First let's find out the start date, for which minute data in HCC format are available. Request this value using the SeriesInfoInteger() function with the SERIES_TERMINAL_FIRSTDATE modifier and again compare it to the value of the start_date parameter.

© 2000-2025, MetaQuotes Ltd.

```
   if(SeriesInfoInteger(symbol,PERIOD_M1,SERIES_TERMINAL_FIRSTDATE,first_date))
     {
      //--- there is loaded data to build timeseries
      if(first_date>0)
        {
         //--- force timeseries build
         CopyTime(symbol,period,first_date+PeriodSeconds(period),1,times);
         //--- check date
         if(SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date))
            if(first_date>0 && first_date<=start_date) return(2);
        }
     }
```

If after all the checks the execution thread is still in the body of the CheckLoadHistory() function, it means there is a necessity to request the missing price data from a trade server. First, return the value of "Max bars in chart" using the TerminalInfoInteger() function:

```
   int max_bars=TerminalInfoInteger(TERMINAL_MAXBARS);
```

We'll need it to prevent requesting extra data. Then find the very first date in the symbol history on the trade server (regardless of the period) using already known function SeriesInfoInteger() with the SERIES_SERVER_FIRSTDATE modifier.

```
   datetime first_server_date=0;
   while(!SeriesInfoInteger(symbol,PERIOD_M1,SERIES_SERVER_FIRSTDATE,first_server_date
      Sleep(5);
```

Since the request is an asynchronous operation, the function is called in the loop with a small delay of 5 milliseconds until the first_server_date variable receives a value, or the loop execution is terminated by a user (IsStopped() will return *true* in this case). Let's indicate a correct value of the start date, starting from which we request price data from a trade server.

```
   if(first_server_date>start_date) start_date=first_server_date;
   if(first_date>0 && first_date<first_server_date)
      Print("Warning: first server date ",first_server_date," for ",
symbol," does not match to first series date ",first_date);
```

If the start date *first_server_date* of the server is lower than the start date *first_date* of the symbol in HCC format, the corresponding entry will be output in the journal.

Now we are ready to make a request to a trade server asking for missing price data. Make the request in the form of a loop and start filling out its body:

```
   while(!IsStopped())
     {
      //1. wait for synchronization between the re-built timeseries and intermediate h
      //2. receive the current number of bars in this timeseries
      //    if bars is larger than Max_bars_in_chart, we can exit, work is over
      //3. obtain the start date first_date in the re-built timeseries and compare it
      //    if first_date is lower than start_date, we can exit, work is over
      //4. request from a server a new part of history - 100 bars starting from last a
     }
```

© 2000-2025, MetaQuotes Ltd.

The first three points are implemented by already known means.

```
   while(!IsStopped())
     {
      //--- 1.wait till timeseries re-build process is over
      while(!SeriesInfoInteger(symbol,period,SERIES_SYNCHRONIZED) && !IsStopped())
         Sleep(5);
      //--- 2.request how many bars we have
      int bars=Bars(symbol,period);
      if(bars>0)
        {
         //--- bars more than ones that can be drawn in the chart, exit
         if(bars>=max_bars) return(-2);
         //--- 3. return the current start date in the timeseries
         if(SeriesInfoInteger(symbol,period,SERIES_FIRSTDATE,first_date))
            // start date was earlier than that requested, task completed
            if(first_date>0 && first_date<=start_date) return(0);
        }
      //4. Request from a server a new part of history - 100 bars starting from last a
     }
```

The last fourth point is left - requesting history. We can't refer to a server directly, but any Copy-function automatically initiates request sending to a server, if the history in HCC format is not enough. Since the time of the very first start date in the *first_date* variable is the simple and natural criterion to evaluate the request execution degree, then the easiest way is to use the CopyTime() function.

When calling functions that copy any data from timeseries, it should be noted that the *start* parameter (number of the bar, starting from which price data should be copied) must always be within the available terminal history. If you have only 100 bars, it meaningless to try copying 300 bars starting from the bar with the index 500. Such a request will be understood as an erroneous and won't be handled, i.e. no additional history will be loaded from a trade server.

That's why we'll copy bars in groups of 100 starting from the bar with the *bars* index. This will provide the smooth loading of missing history from a trade server. Actually a little more than the requested 100 bars will be loaded, while server sends oversized history.

```
   int copied=CopyTime(symbol,period,bars,100,times);
```

After the copying operation, we should analyze the number of copied elements. If the attempt fails, then value of the *copied* will be equal to null and the value of the fail_cnt counter will be increased by 1. After 100 failing attempts, the operation of the function will be stopped.

```
int fail_cnt=0;
...
   int copied=CopyTime(symbol,period,bars,100,times);
   if(copied>0)
     {
      //--- check data
      if(times[0]<=start_date)  return(0);  // the copied value is smaller, ready
      if(bars+copied>=max_bars) return(-2); // bars are more than can be drawn in the
```

© 2000-2025, MetaQuotes Ltd.

```
      fail_cnt=0;
     }
   else
     {
      //--- no more than 100 failing attempts in succession
      fail_cnt++;
      if(fail_cnt>=100) return(-5);
      Sleep(10);
     }
```

So, not only correct handling of the current situation at each moment of execution is implemented in the function, but also the termination code is returned, that can be handled after calling the CheckLoadHistory() function for getting additional information. For example, this way:

```
   int res=CheckLoadHistory(InpLoadedSymbol,InpLoadedPeriod,InpStartDate);
   switch(res)
     {
      case -1 : Print("Unknown symbol ",InpLoadedSymbol);                      break;
      case -2 : Print("More requested bars than can be drawn in the chart"); break;
      case -3 : Print("Execution stopped by user");                          break;
      case -4 : Print("Indicator mustn't load its own data");               break;
      case -5 : Print("Loading failed");                                    break;
      case  0 : Print("All data loaded");                                   break;
      case  1 : Print("Already available data in timeseries are enough");   break;
      case  2 : Print("Timeseries is built from available terminal data");  break;
      default : Print("Execution result undefined");
     }
```

The full code of the function can be found in the example of a script that shows the correct organization of access to any data with the handling of request's results.

Code:

SeriesInfoInteger

Returns information about the state of historical data. There are 2 variants of function calls.

Directly returns the property value.

```
long  SeriesInfoInteger(
   string                      symbol_name,      // symbol name
   ENUM_TIMEFRAMES             timeframe,        // period
   ENUM_SERIES_INFO_INTEGER    prop_id,          // property identifier
   );
```

Returns true or false depending on the success of the function run.

```
bool  SeriesInfoInteger(
   string                      symbol_name,      // symbol name
   ENUM_TIMEFRAMES             timeframe,        // period
   ENUM_SERIES_INFO_INTEGER    prop_id,          // property ID
   long&                       long_var          // variable for getting info
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

prop_id

[in] Identifier of the requested property, value of the ENUM_SERIES_INFO_INTEGER enumeration.

long_var

[out] Variable to which the value of the requested property is placed.

Return Value

In the first case, it returns value of the long type.

For the second case, it returns true, if the specified property is available and its value has been placed into long_var variable, otherwise it returns false. For more details about an error, call GetLastError().

Example:

```
void OnStart()
  {
//---
   Print("Total number of bars for the symbol-period at this moment = ",
         SeriesInfoInteger(Symbol(),Period(),SERIES_BARS_COUNT));

   Print("The first date for the symbol-period at this moment = ",
         (datetime)SeriesInfoInteger(Symbol(),Period(),SERIES_FIRSTDATE));
```

© 2000-2025, MetaQuotes Ltd.

```
   Print("The first date in the history for the symbol-period on the server = ",
         (datetime)SeriesInfoInteger(Symbol(),Period(),SERIES_SERVER_FIRSTDATE));

   Print("Symbol data are synchronized = ",
         (bool)SeriesInfoInteger(Symbol(),Period(),SERIES_SYNCHRONIZED));
  }
```

© 2000-2025, MetaQuotes Ltd.

Bars

Returns the number of bars count in the history for a specified symbol and period. There are 2 variants of functions calls.

Request all of the history bars

```
int  Bars(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe         // period
   );
```

Request the history bars for the selected time interval

```
int  Bars(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time         // end date and time
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_time

[in] Bar time corresponding to the first element.

stop_time

[in] Bar time corresponding to the last element.

Return Value

If the start_time and stop_time parameters are defined, the function returns the number of bars in the specified time interval, otherwise it returns the total number of bars.

Note

If data for the timeseries with specified parameters are not formed in the terminal by the time of the Bars() function call, or data of the timeseries are not synchronized with a trade server by the moment of the function call, the function returns a zero value.

When requesting the number of bars in a specified time interval, only bars with an open time falling within the interval are considered. For example, if the current day of the week is Saturday and the request is made for the number of W1 bars with start_time=last_tuesday and stop_time=last_friday, the function will return 0 since the open time of a W1 timeframe is always Sunday and not a single W1 bar falls within the specified interval.

Sample request for the number of all history bars:

© 2000-2025, MetaQuotes Ltd.

```
int bars=Bars(_Symbol,_Period);
if(bars>0)
  {
   Print("Number of bars in the terminal history for the symbol-period at the momer
  }
else  //no available bars
  {
   //--- data on the symbol might be not synchronized with data on the server
   bool synchronized=false;
   //--- loop counter
   int attempts=0;
   // make 5 attempts to wait for synchronization
   while(attempts<5)
     {
      if(SeriesInfoInteger(Symbol(),0,SERIES_SYNCHRONIZED))
        {
         //--- synchronization done, exit
         synchronized=true;
         break;
        }
      //--- increase the counter
      attempts++;
      //--- wait 10 milliseconds till the next iteration
      Sleep(10);
     }
   //--- exit the loop after synchronization
   if(synchronized)
     {
      Print("Number of bars in the terminal history for the symbol-period at the mo
      Print("The first date in the terminal history for the symbol-period at the mo
            (datetime)SeriesInfoInteger(Symbol(),0,SERIES_FIRSTDATE));
      Print("The first date in the history for the symbol on the server = ",
            (datetime)SeriesInfoInteger(Symbol(),0,SERIES_SERVER_FIRSTDATE));
     }
   //--- synchronization of data didn't happen
   else
     {
      Print("Failed to get number of bars for ",_Symbol);
     }
  }
```

Sample request for the number of bars in the specified interval:

```
int n;
datetime date1 = D'2016.09.02 23:55'; // Friday
datetime date2 = D'2016.09.05 00:00'; // Monday
datetime date3 = D'2016.09.08 00:00'; // Thursday
//---
n=Bars(_Symbol,PERIOD_H1,D'2016.09.02 02:05',D'2016.09.02 10:55');
```

© 2000-2025, MetaQuotes Ltd.

```
   Print("Number of bars: ",n); // Output: "Number of bars: 8", H2 bar is considered
   n=Bars(_Symbol,PERIOD_D1,date1,date2);
   Print("Number of bars: ",n); // Output: "Number of bars: 1", since an open time of
   n=Bars(_Symbol,PERIOD_W1,date2,date3);
   Print("Number of bars: ",n); // Output: "Number of bars: 0", since not a single W1
```

BarsCalculated

Returns the number of calculated data for the specified indicator.

```
int  BarsCalculated(
   int       indicator_handle,     // indicator handle
   );
```

Parameters

indicator_handle

[in] The indicator handle, returned by the corresponding indicator function.

Return Value

Returns the amount of calculated data in the indicator buffer or -1 in the case of error (data not calculated yet)

Note

The function is useful when it's necessary to get the indicator data immediately after its creation (indicator handle is available).

Example:

```
void OnStart()
  {
   double Ups[];
//--- set timeseries ordering for the arrays
   ArraySetAsSeries(Ups,true);
//--- create handle for the Fractal Indicator
   int FractalsHandle=iFractals(NULL,0);
//--- reset the error code
   ResetLastError();
//--- try to copy the indicator values
   int i,copied=CopyBuffer(FractalsHandle,0,0,1000,Ups);
   if(copied<=0)
     {
      Sleep(50);
      for(i=0;i<100;i++)
        {
         if(BarsCalculated(FractalsHandle)>0)
            break;
         Sleep(50);
        }
      copied=CopyBuffer(FractalsHandle,0,0,1000,Ups);
      if(copied<=0)
        {
         Print("Failed to copy upper fractals. Error = ",GetLastError(),
         "i = ",i,"    copied = ",copied);
         return;
        }
```

© 2000-2025, MetaQuotes Ltd.

```
      else
        Print("Upper fractals copied",
        "i = ",i,"    copied = ",copied);
    }
  else Print("Upper fractals copied. ArraySize = ",ArraySize(Ups));
}
```

© 2000-2025, MetaQuotes Ltd.

IndicatorCreate

The function returns the handle of a specified technical indicator created based on the array of parameters of MqlParam type.

```
int  IndicatorCreate(
   string           symbol,                    // symbol name
   ENUM_TIMEFRAMES  period,                    // timeframe
   ENUM_INDICATOR   indicator_type,            // indicator type from the enur
   int              parameters_cnt=0,          // number of parameters
   const MqlParam&  parameters_array[]=NULL,   // array of parameters
   );
```

Parameters

symbol

[in] Name of a symbol, on data of which the indicator is calculated. NULL means the current symbol.

period

[in] The value of the timeframe can be one of values of the ENUM_TIMEFRAMES enumeration, 0 means the current timeframe.

indicator_type

[in] Indicator type, can be one of values of the ENUM_INDICATOR enumeration.

parameters_cnt

[in] The number of parameters passed in the parameters_array[] array. The array elements have a special structure type MqlParam. By default, zero - parameters are not passed. If you specify a non-zero number of parameters, the parameter *parameters_array* is obligatory. You can pass no more than 64 parameters.

parameters_array[]=NULL

[in] An array of MqlParam type, whose elements contain the type and value of each input parameter of a technical indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE.

Note

If the indicator handle of IND_CUSTOM type is created, the *type* field of the first element of the array of input parameters *parameters_array* must have the TYPE_STRING value of the ENUM_DATATYPE enumeration, and the *string_value* field of the first element must contain the name of the custom indicator. The custom indicator must be compiled (file with EX5 extension) and located in the directory MQL5/Indicators of the client terminal or in a subdirectory.

Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter that sets the indicator name) the property #property tester_indicator is required:

```
#property tester_indicator "indicator_name.ex5"
```

© 2000-2025, MetaQuotes Ltd.

If the first form of the call is used in a custom indicator, you can additionally indicate as the last parameter on what data it will be calculated when passing input parameters. If the "Apply to" parameter is not specified explicitly, the default calculation is based on the PRICE_CLOSE values.

Example:

```
void OnStart()
  {
   MqlParam params[];
   int      h_MA,h_MACD;
//--- create iMA("EURUSD",PERIOD_M15,8,0,MODE_EMA,PRICE_CLOSE);
   ArrayResize(params,4);
//--- set ma_period
   params[0].type         =TYPE_INT;
   params[0].integer_value=8;
//--- set ma_shift
   params[1].type         =TYPE_INT;
   params[1].integer_value=0;
//--- set ma_method
   params[2].type         =TYPE_INT;
   params[2].integer_value=MODE_EMA;
//--- set applied_price
   params[3].type         =TYPE_INT;
   params[3].integer_value=PRICE_CLOSE;
//--- create MA
   h_MA=IndicatorCreate("EURUSD",PERIOD_M15,IND_MA,4,params);
//--- create iMACD("EURUSD",PERIOD_M15,12,26,9,h_MA);
   ArrayResize(params,4);
//--- set fast ma_period
   params[0].type         =TYPE_INT;
   params[0].integer_value=12;
//--- set slow ma_period
   params[1].type         =TYPE_INT;
   params[1].integer_value=26;
//--- set smooth period for difference
   params[2].type         =TYPE_INT;
   params[2].integer_value=9;
//--- set indicator handle as applied_price
   params[3].type         =TYPE_INT;
   params[3].integer_value=h_MA;
//--- create MACD based on moving average
   h_MACD=IndicatorCreate("EURUSD",PERIOD_M15,IND_MACD,4,params);
//--- use indicators
//--- . . .
//--- release indicators (first h_MACD)
   IndicatorRelease(h_MACD);
   IndicatorRelease(h_MA);
  }
```

© 2000-2025, MetaQuotes Ltd.

IndicatorParameters

Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters.

```
int  IndicatorParameters(
   int               indicator_handle,     // indicator handle
   ENUM_INDICATOR&   indicator_type,       // a variable for receiving the indicator t
   MqlParam&         parameters[]          // an array for receiving parameters
   );
```

Parameters

indicator_handle

[in] The handle of the indicator, for which you need to know the number of parameters its is calculated on.

indicator_type

[out] A variable if the ENUM_INDICATOR type, into which the indicator type will be written.

parameters[]

[out] A dynamic array for receiving values of the MqlParam type, into which the list of indicator parameters will be written. The array size is returned by the IndicatorParameters() function.

Return Value

The number of input parameters of the indicator with the specified handle. In case of an error returns -1. For more details about the error call the GetLastError() function.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {

//--- The number of windows on the chart (at least one main window is always present)
   int windows=(int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);
//--- Go through the chart windows
   for(int w=0;w<windows;w++)
     {
      //--- The number of indicators in this window/subwindow
      int total=ChartIndicatorsTotal(0,w);
      //--- Take all indicators in the window
      for(int i=0;i<total;i++)
        {
         //--- Get the short name of the indicator
         string name=ChartIndicatorName(0,w,i);
         //--- Get the indicator handle
         int handle=ChartIndicatorGet(0,w,name);
         //--- Add to log
```

© 2000-2025, MetaQuotes Ltd.

```
         PrintFormat("Window=%d,  indicator #%d,  handle=%d",w,i,handle);
         //---
         MqlParam parameters[];
         ENUM_INDICATOR indicator_type;
         int params=IndicatorParameters(handle,indicator_type,parameters);
         //--- The header of the message
         string par_info="Short name "+name+", type "
                         +EnumToString(ENUM_INDICATOR(indicator_type))+"\r\n";
         //---
         for(int p=0;p<params;p++)
           {
            par_info+=StringFormat("parameter %d: type=%s, long_value=%d, double_value
                                   p,
                                   EnumToString((ENUM_DATATYPE)parameters[p].type),
                                   parameters[p].integer_value,
                                   parameters[p].double_value,
                                   parameters[p].string_value
                                   );
           }
         Print(par_info);
        }
      //--- Done for all indicators in the window
     }
//---
  }
```

ChartIndicatorGet()

© 2000-2025, MetaQuotes Ltd.

IndicatorRelease

The function removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else.

```
bool  IndicatorRelease(
   int       indicator_handle     // indicator handle
   );
```

Return Value

Returns true in case of success, otherwise returns false.

Note

The function allows removing an indicator handle, if it's no longer needed, thus saving memory. The handle is removed immediately, the calculation block is deleted in some time (if it's not called anymore).

When working in the strategy tester, the IndicatorRelease() function is not executed.

Example:

```
//+------------------------------------------------------------------+
//|                                        Test_IndicatorRelease.mq5 |

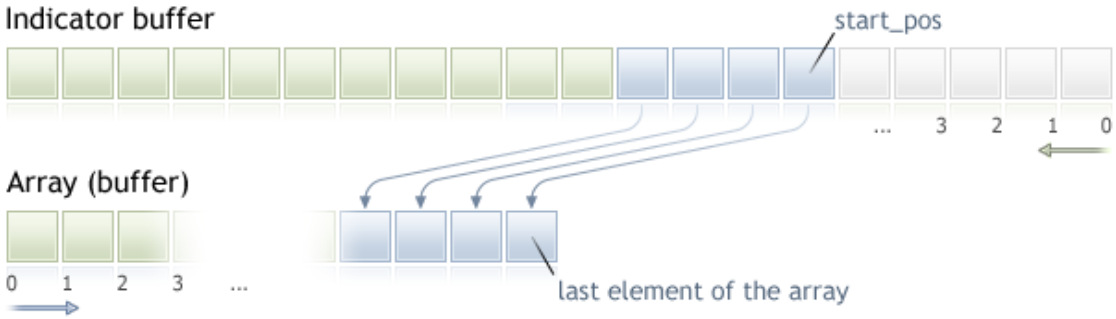
CopyBuffer

Gets data of a specified buffer of a certain indicator in the necessary quantity.



Counting of elements of copied data (indicator buffer with the index buffer_num) from the starting position is performed from the present to the past, i.e., starting position of 0 means the current bar (indicator value for the current bar).

When copying the yet unknown amount of data, it is recommended to use a dynamic array as a buffer[] recipient buffer, because the CopyBuffer() function tries to allocate the size of the receiving array to the size of the copied data. If an indicator buffer (array that is pre-allocated for storing indicator values by the SetIndexBufer() function) is used as the buffer[] recipient array, partial copying is allowed. An example can be found in the Awesome_Oscillator.mql5 custom indicator in the standard terminal package.

If you need to make a partial copy of the indicator values into another array (non-indicator buffer), you should use an intermediate array, to which the desired number is copied. After that conduct the element-wise copying of the required number of values into the required places of a receiving array from this intermediate one.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyBuffer(
   int       indicator_handle,     // indicator handle
   int       buffer_num,           // indicator buffer number
   int       start_pos,            // start position
   int       count,                // amount to copy
   double    buffer[]              // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyBuffer(
   int       indicator_handle,     // indicator handle
```

© 2000-2025, MetaQuotes Ltd.

```
   int       buffer_num,          // indicator buffer number
   datetime  start_time,          // start date and time
   int       count,               // amount to copy
   double    buffer[]             // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyBuffer(
   int       indicator_handle,    // indicator handle
   int       buffer_num,          // indicator buffer number
   datetime  start_time,          // start date and time
   datetime  stop_time,           // end date and time
   double    buffer[]             // target array to copy
   );
```

Parameters

indicator_handle

[in] The indicator handle, returned by the corresponding indicator function.

buffer_num

[in] The indicator buffer number.

start_pos

[in] The position of the first element to copy.

count

[in] Data count to copy.

start_time

[in] Bar time, corresponding to the first element.

stop_time

[in] Bar time, corresponding to the last element.

buffer[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration.

//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

The above example illustrates how an indicator buffer is filled out with the values of another indicator buffer from the indicator on the same symbol/period.

See a detailed example of history requesting data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

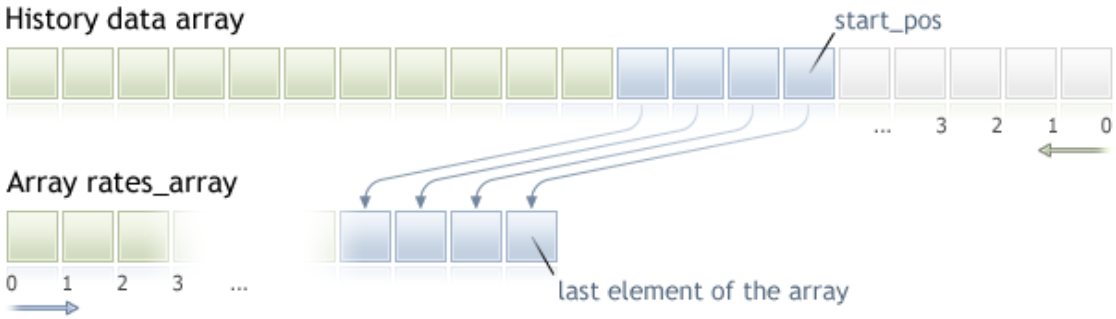
CopyRates

Gets history data of MqlRates structure of a specified symbol-period in specified quantity into the rates_array array. The elements ordering of the copied data is from present to the past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyRates(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   int               start_pos,         // start position
   int               count,             // data count to copy
   MqlRates          rates_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyRates(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   datetime          start_time,        // start date and time
   int               count,             // data count to copy
   MqlRates          rates_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyRates(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   datetime         start_time,        // start date and time
   datetime         stop_time,         // end date and time
   MqlRates         rates_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_time

[in] Bar time for the first element to copy.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

rates_array[]

[out] Array of MqlRates type.

Return Value

Returns the number of copied elements or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

© 2000-2025, MetaQuotes Ltd.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
void OnStart()
  {
//---
   MqlRates rates[];
   ArraySetAsSeries(rates,true);
   int copied=CopyRates(Symbol(),0,0,100,rates);
   if(copied>0)
     {
      Print("Bars copied: "+copied);
      string format="open = %G, high = %G, low = %G, close = %G, volume = %d";
      string out;
      int size=fmin(copied,10);
      for(int i=0;i<size;i++)
        {
         out=i+":"+TimeToString(rates[i].time);
         out=out+" "+StringFormat(format,
                                  rates[i].open,
                                  rates[i].high,
                                  rates[i].low,
                                  rates[i].close,
                                  rates[i].tick_volume);
         Print(out);
        }
     }
   else Print("Failed to get history data for the symbol ",Symbol());
  }
```

See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,

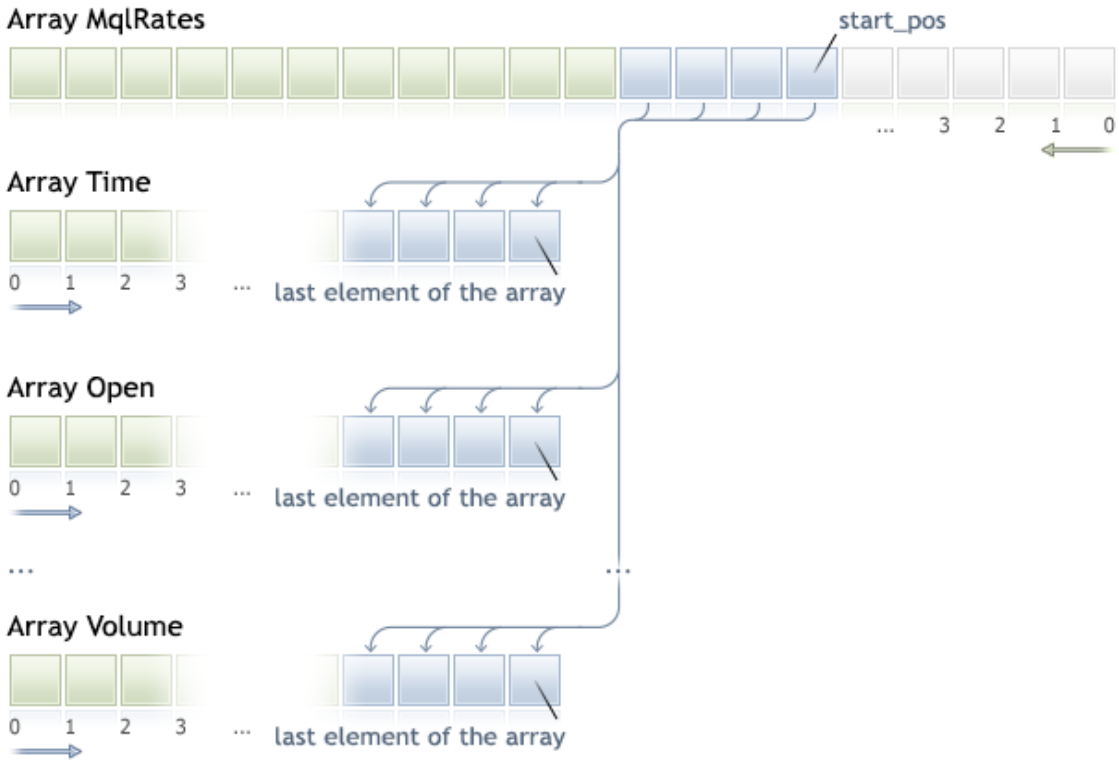
CopySeries

Gets the synchronized timeseries from the MqlRates structure for the specified symbol-period and the specified amount. The data is received into the specified set of arrays. Elements are counted down from the present to the past, which means that the starting position equal to 0 means the current bar.



If the data amount to be copied is unknown, it is recommended to use the dynamic array for the receiving arrays, since if the data amount exceeds what an array can contain, this can cause the attempt to redistribute the array to fit all of the requested data.

If you need to copy a predetermined amount of data, it is recommended to use a statistically allocated buffer to avoid unnecessary memory reallocation.

The property of the receiving array — as_series=true or as_series=false — will be ignored: during copying, the oldest timeseries element will be copied to the beginning of the physical memory allocated for the array.

```
int  CopySeries(
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   int              start_pos,         // start position
   int              count,             // amount to copy
   ulong            rates_mask,        // combination of flags to specify the requeste
   void&            array1[],          // array to receive the data of the first copie
   void&            array2[]           // array to receive the data of the second copi
   ...
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

symbol_name

[in] Symbol.

timeframe

[in] Period.

start_pos

[in] First copied element index.

count

[in] Number of copied elements.

rates_mask

[in] A combination of flags from the ENUM_COPY_RATES enumeration.

array1, array2,...

[out] Array of the appropriate type to receive the timeseries from the MqlRates structure. The order of the arrays passed to the function must match the order of the fields in the MqlRates structure.

Return Value

The number of copied elements or -1 if error occurs.

Note

If the entire interval of the requested data is beyond the data available on the server, the function returns -1. If the requested data is beyond TERMINAL_MAXBARS (the maximum number of bars on the chart), the function also returns -1.

When requesting data from an indicator, the function immediately returns -1 if requested timeseries are not constructed yet or they should be downloaded from the server. However, this will initiate data download/constructing itself.

When requesting data from an Expert Advisor or a script, download from the server is initiated if the terminal does not have the appropriate data locally, or construction of the necessary timeseries starts if the data can be constructed from the local history but they are not ready yet. The function returns the amount of data that is ready by the time the timeout expires, however the history download continues, and the function returns more data during the next similar request.

Difference between CopySeries and CopyRates

The CopySeries function allows obtaining only the necessary timeseries into different specified arrays during one call, while all of timeseries data will be synchronized. This means that all values in the resulting arrays at a certain index N will belong to the same bar on the specified Symbol/Timeframe pair. Therefore, there is no need for the programmer to ensure the synchronization of all received timeseries by the bar opening time.

Unlike CopyRates, which returns the full set of timeseries as an MqlRates array, the CopySeries function allows the programmer to get only the required timeseries as separate arrays. This can be

© 2000-2025, MetaQuotes Ltd.

done by specifying a combination of flags to select the type of timeseries. The order of the arrays passed to the function must match the order of the fields in the MqlRates structure:

```
struct MqlRates
  {
   datetime time;         // period start time
   double   open;         // open price
   double   high;         // high price for the period
   double   low;          // low price for the period
   double   close;        // close price
   long     tick_volume;  // tick volume
   int      spread;       // spread
   long     real_volume;  // exchange volume
  }
```

Thus, if you need to get the values of the *time*, *close* and *real_volume* timeseries for the last 100 bars of the current Symbol/Timeframe, you should use the following call:

```
datetime time[];
double   close[];
long     volume[];
CopySeries(NULL,0,0,100,COPY_RATES_TIME|COPY_RATES_CLOSE|COPY_RATES_VOLUME_REAL,time,c
```

Mind the order of the arrays "*time*, *close*, *volume*" — it must match the order of the fields in the MqlRates structure. The order of values in the *rates_mask* does not matter. The mask could be as follows:

```
COPY_RATES_VOLUME_REAL|COPY_RATES_TIME|COPY_RATES_CLOSE
```

Example:

```
//--- input parameters
input datetime InpDateFrom=D'2022.01.01 00:00:00';
input datetime InpDateTo  =D'2023.01.01 00:00:00';
input uint     InpCount   =20;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
//--- arrays to get timeseries from the MqlRates price structure
   double   open[];
   double   close[];
   float    closef[];
   datetime time1[], time2[];
//--- request close prices to a double array
   ResetLastError();
   int res1=CopySeries(NULL, PERIOD_CURRENT, 0, InpCount,
                       COPY_RATES_TIME|COPY_RATES_CLOSE, time1, close);
   PrintFormat("1. CopySeries  returns %d values. Error code=%d", res1, GetLastError()
```

© 2000-2025, MetaQuotes Ltd.

```
   ArrayPrint(close);

//--- now also request open prices; use float array for close prices
   ResetLastError();
   int res2=CopySeries(NULL, PERIOD_CURRENT, 0, InpCount,
                       COPY_RATES_TIME|COPY_RATES_CLOSE|COPY_RATES_OPEN, time2, open,
   PrintFormat("2. CopySeries  returns %d values. Error code=%d", res2, GetLastError()
   ArrayPrint(closef);
//--- Compare the received data
   if((res1==res2) && (time1[0]==time2[0]))
     {
      Print("  | Time             |    Open      | Close double | Close float |");
      for(int i=0; i<10; i++)
        {
         PrintFormat("%d | %s |   %.5f    |   %.5f    |   %.5f   |",
                     i, TimeToString(time1[i]), open[i], close[i], closef[i]);
        }

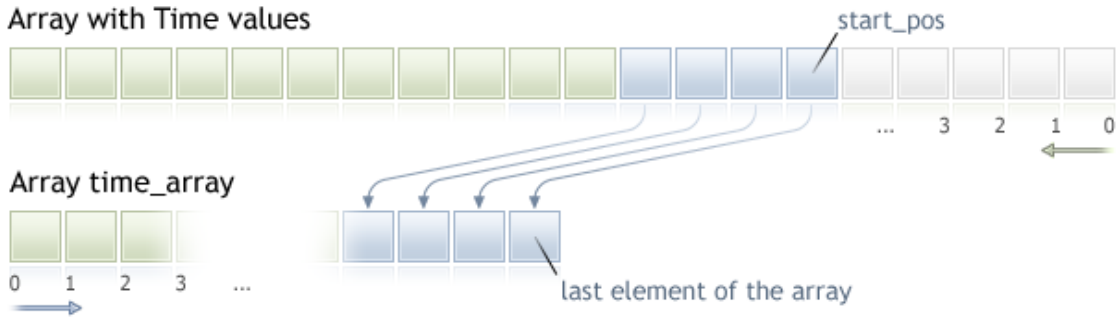
CopyTime

The function gets to time_array history data of bar opening time for the specified symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyTime(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   datetime          time_array[]      // target array to copy open times
   );
```

Call by the start date and the number of required elements

```
int  CopyTime(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   datetime          time_array[]      // target array to copy  open times
   );
```

Call by the start and end dates of a required time interval

```
int  CopyTime(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   datetime         time_array[]      // target array to copy open times
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time corresponding to the last element to copy.

time_array[]

[out] Array of datetime type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

© 2000-2025, MetaQuotes Ltd.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

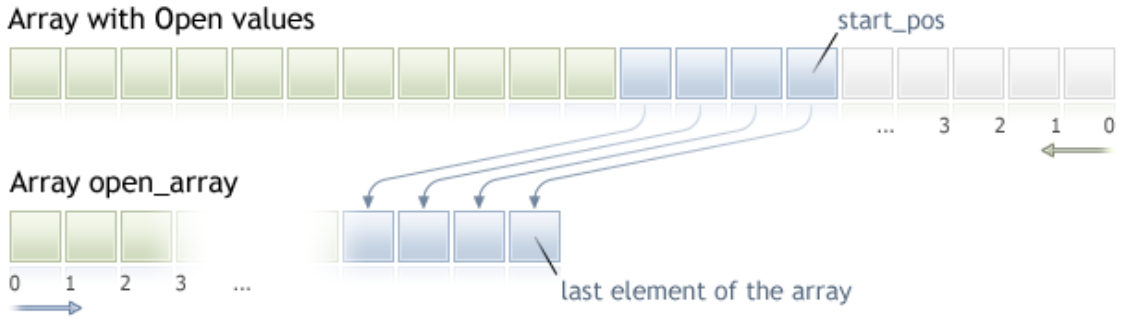
See a detailed example of requesting history data in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

© 2000-2025, MetaQuotes Ltd.

CopyOpen

The function gets into open_array the history data of bar open prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyOpen(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            open_array[]      // target array to copy open prices
   );
```

Call by the start date and the number of required elements

```
int  CopyOpen(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            open_array[]      // target array for bar open prices
   );
```

Call by the start and end dates of a required time interval

```
int  CopyOpen(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           open_array[]      // target array for bar open values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] The start time for the last element to copy.

open_array[]

[out] Array of double type.

Return Value

Returns the number of element in the array or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

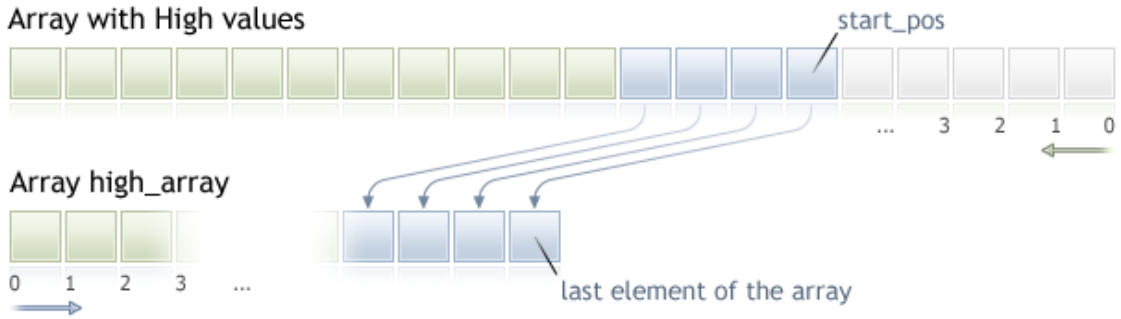
CopyHigh

The function gets into high_array the history data of highest bar prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyHigh(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            high_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyHigh(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            high_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyHigh(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           high_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

high_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

© 2000-2025, MetaQuotes Ltd.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

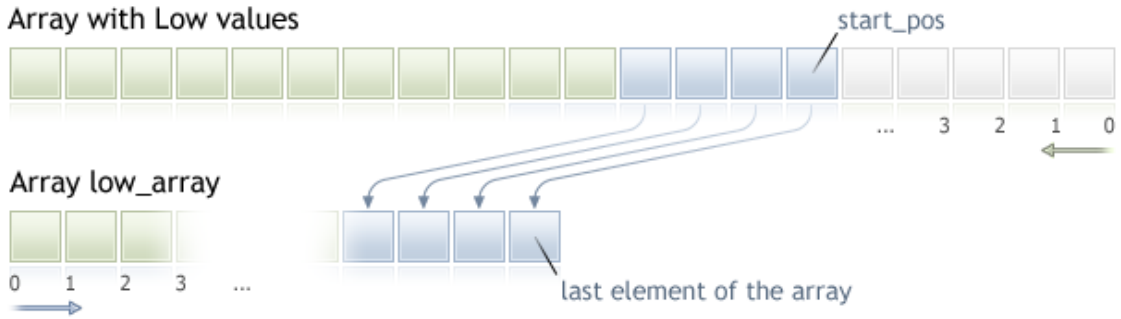
CopyLow

The function gets into low_array the history data of minimal bar prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyLow(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   double            low_array[]       // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyLow(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   double            low_array[]       // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyLow(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   double           low_array[]       // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] Bar time, corresponding to the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

low_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

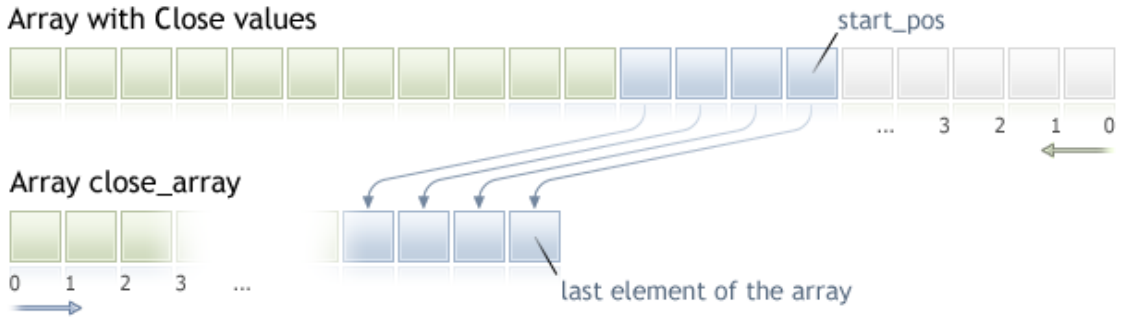
CopyClose

The function gets into close_array the history data of bar close prices for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyClose(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   int               start_pos,         // start position
   int               count,             // data count to copy
   double            close_array[]      // target array to copy
   );
```

Call by the start date and the number of required elements

```
int  CopyClose(
   string            symbol_name,       // symbol name
   ENUM_TIMEFRAMES   timeframe,         // period
   datetime          start_time,        // start date and time
   int               count,             // data count to copy
   double            close_array[]      // target array to copy
   );
```

Call by the start and end dates of a required time interval

```
int  CopyClose(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,       // symbol name
   ENUM_TIMEFRAMES  timeframe,         // period
   datetime         start_time,        // start date and time
   datetime         stop_time,         // stop date and time
   double           close_array[]      // target array to copy
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

close_array[]

[out] Array of double type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

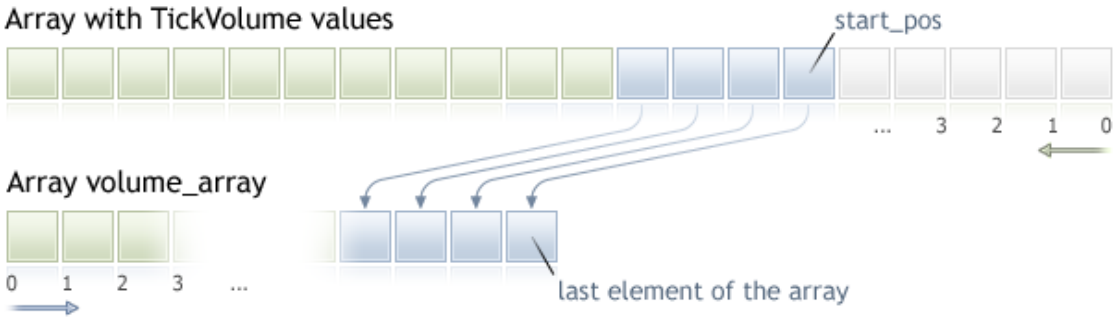
CopyTickVolume

The function gets into volume_array the history data of tick volumes for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyTickVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   int              start_pos,        // start position
   int              count,            // data count to copy
   long             volume_array[]    // target array for tick volumes
   );
```

Call by the start date and the number of required elements

```
int  CopyTickVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   int              count,            // data count to copy
   long             volume_array[]    // target array for tick volumes
   );
```

Call by the start and end dates of a required time interval

```
int  CopyTickVolume(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   long             volume_array[]    // target array for tick volumes
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

volume_array[]

[out] Array of long type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

© 2000-2025, MetaQuotes Ltd.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot TickVolume
#property indicator_label1  "TickVolume"
#property indicator_type1   DRAW_HISTOGRAM
#property indicator_color1  C'143,188,139'
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- input parameters
input int      bars=3000;
//--- indicator buffers
double         TickVolumeBuffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,TickVolumeBuffer,INDICATOR_DATA);
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
```

© 2000-2025, MetaQuotes Ltd.

```
                  const int &spread[])
  {
//---
   if(prev_calculated==0)
     {
      long timeseries[];
      ArraySetAsSeries(timeseries,true);
      int prices=CopyTickVolume(Symbol(),0,0,bars,timeseries);
      for(int i=0;i<rates_total-prices;i++) TickVolumeBuffer[i]=0.0;
      for(int i=0;i<prices;i++) TickVolumeBuffer[rates_total-1-i]=timeseries[prices-1-
      Print("We have received the following number of TickVolume values: "+prices);
     }
   else
     {
      long timeseries[];
      int prices=CopyTickVolume(Symbol(),0,0,1,timeseries);
      TickVolumeBuffer[rates_total-1]=timeseries[0];
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

See a detailed example of history data requesting in section Methods of Object Binding. The script available in that section shows how to get the values of indicator iFractals on the last 1000 bars and how to display the last 10 up and 10 down fractals on the chart. A similar technique can be used for all indicators that have missing data and that are usually drawn using the following styles:

- DRAW_SECTION,
- DRAW_ARROW,
- DRAW_ZIGZAG,
- DRAW_COLOR_SECTION,
- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

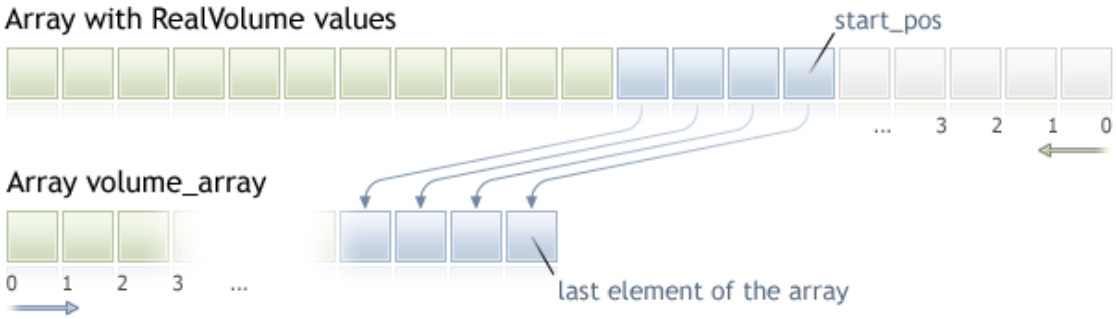
CopyRealVolume

The function gets into volume_array the history data of trade volumes for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopyRealVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   int              start_pos,        // start position
   int              count,            // data count to copy
   long             volume_array[]    // target array for volumes values
   );
```

Call by the start date and the number of required elements

```
int  CopyRealVolume(
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   int              count,            // data count to copy
   long             volume_array[]    // target array for volumes values
   );
```

Call by the start and end dates of a required time interval

```
int  CopyRealVolume(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   long             volume_array[]    // target array for volumes values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

volume_array[]

[out] Array of long type.

Return Value

Returns the copied data count or -1 in the case of error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

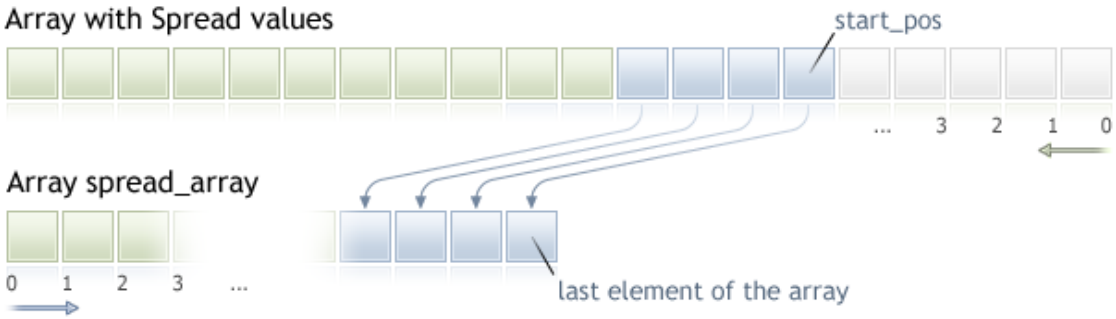
CopySpread

The function gets into spread_array the history data of spread values for the selected symbol-period pair in the specified quantity. It should be noted that elements ordering is from present to past, i.e., starting position of 0 means the current bar.



When copying the yet unknown amount of data, it is recommended to use dynamic array as a target array, because if the requested data count is less (or more) than the length of the target array, function tries to reallocate the memory so that the requested data fit entirely.

If you know the amount of data you need to copy, it should better be done to a statically allocated buffer, in order to prevent the allocation of excessive memory.

No matter what is the property of the target array - as_series=true or as_series=false. Data will be copied so that the oldest element will be located at the start of the physical memory allocated for the array. There are 3 variants of function calls.

Call by the first position and the number of required elements

```
int  CopySpread(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   int               start_pos,        // start position
   int               count,            // data count to copy
   int               spread_array[]    // target array for spread values
   );
```

Call by the start date and the number of required elements

```
int  CopySpread(
   string            symbol_name,      // symbol name
   ENUM_TIMEFRAMES   timeframe,        // period
   datetime          start_time,       // start date and time
   int               count,            // data count to copy
   int               spread_array[]    // target array for spread values
   );
```

Call by the start and end dates of a required time interval

```
int  CopySpread(
```

© 2000-2025, MetaQuotes Ltd.

```
   string           symbol_name,      // symbol name
   ENUM_TIMEFRAMES  timeframe,        // period
   datetime         start_time,       // start date and time
   datetime         stop_time,        // stop date and time
   int              spread_array[]    // target array for spread values
   );
```

Parameters

symbol_name

[in] Symbol name.

timeframe

[in] Period.

start_pos

[in] The start position for the first element to copy.

count

[in] Data count to copy.

start_time

[in] The start time for the first element to copy.

stop_time

[in] Bar time, corresponding to the last element to copy.

spread_array[]

[out] Array of int type.

Return Value

Returns the copied data count or -1 in case of an error.

Note

If the whole interval of requested data is out of the available data on the server, the function returns -1. If data outside TERMINAL_MAXBARS (maximal number of bars on the chart) is requested, the function will also return -1.

When requesting data from the indicator, if requested timeseries are not yet built or they need to be downloaded from the server, the function will immediately return -1, but the process of downloading/building will be initiated.

When requesting data from an Expert Advisor or script, downloading from the server will be initiated, if the terminal does not have these data locally, or building of a required timeseries will start, if data can be built from the local history but they are not ready yet. The function will return the amount of data that will be ready by the moment of timeout expiration, but history downloading will continue, and at the next similar request the function will return more data.

When requesting data by the start date and the number of required elements, only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always less or equal to the specified one.

© 2000-2025, MetaQuotes Ltd.

When requesting data in a specified range of dates, only data from this interval will be returned. The interval is set and counted up to seconds. It means, the open time of any bar, for which value is returned (volume, spread, value on the indicator buffer, prices Open, High, Low, Close or open time Time) is always within the requested interval.

Thus, if the current day is Saturday, at the attempt to copy data on a week timeframe specifying *start_time=Last_Tuesday* and *stop_time=Last_Friday* the function will return 0, because the open time on a week timeframe is always Sunday, but one week bar does not fall into the specified interval.

If you need to return value corresponding to the current uncompleted bar, you can use the first form of call specifying *start_pos*=0 and *count*=1.

Example:

```
#property indicator_separate_window
#property indicator_buffers 1
#property indicator_plots   1

  {
//--- indicator buffers mapping
   SetIndexBuffer(0,SpreadBuffer,INDICATOR_DATA);
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const datetime &time[],
                const double &open[],
                const double &high[],
                const double &low[],
                const double &close[],
                const long &tick_volume[],
                const long &volume[],
```

© 2000-2025, MetaQuotes Ltd.

```
                  const int &spread[])
  {
//---
   if(prev_calculated==0)
     {
      int spread_int[];
      ArraySetAsSeries(spread_int,true);
      int spreads=CopySpread(Symbol(),0,0,bars,spread_int);
      Print("We have received the following number of Spread values: ",spreads);
      for (int i=0;i<spreads;i++)
      {
      SpreadBuffer[rates_total-1-i]=spread_int[i];
      if(i<=30) Print("spread["+i+"] = ",spread_int[i]);
      }
     }
   else
     {
      double Ask,Bid;
      Ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
      Bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
      Comment("Ask = ",Ask,"  Bid = ",Bid);
      SpreadBuffer[rates_total-1]=(Ask-Bid)/Point();
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

- DRAW_COLOR_ARROW,
- DRAW_COLOR_ZIGZAG.

© 2000-2025, MetaQuotes Ltd.

CopyTicks

The function receives ticks in the MqlTick format into ticks_array. In this case, ticks are indexed from the past to the present, i.e. the 0 indexed tick is the oldest one in the array. For tick analysis, check the *flags* field, which shows what exactly has changed in the tick.

```
int  CopyTicks(
   string           symbol_name,           // Symbol name
   MqlTick&         ticks_array[],         // Tick receiving array
   uint             flags=COPY_TICKS_ALL,  // The flag that determines the type of req
   ulong            from=0,                // The date from which you want to request
   uint             count=0                // The number of ticks that you want to req
   );
```

Parameters

symbol_name

[in] Symbol.

ticks_array

[out] An array of the MqlTick type for receiving ticks.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from

[in] The date from which you want to request ticks. In milliseconds since 1970.01.01. If *from*=0, the last *count* ticks will be returned.

count

[in] The number of requested ticks. If the 'from' and 'count' parameters are not specified, all available recent ticks (but not more than 2000) will be written to ticks_array[].

Returned value

The number of copied tick or -1 in case of an error.

Note

The CopyTicks() function allows requesting and analyzing all received ticks. The first call of CopyTicks() initiates synchronization of the symbol's tick database stored on the hard disk. If the local database does not provide all the requested ticks, then missing ticks will be automatically downloaded from the trade server. Ticks beginning with the ***from*** date specified in CopyTicks() till the current moment will be synchronized. After that, all ticks arriving for this symbol will be added to the tick database thus keeping it in the synchronized state.

If the *from* and *count* parameters are not specified, all available recent ticks (but not more than 2000) will be written to *ticks_array[]*. The *flags* parameter allows specifying the type of required ticks.

© 2000-2025, MetaQuotes Ltd.

COPY_TICKS_INFO - ticks with Bid and/or Ask price changes are returned. Data of other fields will also be added. For example, if only the Bid has changed, the *ask* and *volume* fields will be filled with last known values. To find out exactly what has changed, analyze the *flags* field, which will have the value of TICK_FLAG_BID and/or TICK_FLAG_ASK. If a tick has zero values of the Bid and Ask prices, and the flags show that these data have changed (*flags*=TICK_FLAG_BID|TICK_FLAG_ASK), this means that the order book (Market Depth) is empty. In other words, there are no buy and sell orders.

COPY_TICKS_TRADE - ticks with the Last price and volume changes are returned. Data of other fields will also be added, i.e. last known values of Bid and Ask will be specified in the appropriate fields. To find out exactly what has changed, analyze the *flags* field, which will have the TICK_FLAG_LAST and TICK_FLAG_VOLUME value.

COPY_TICKS_ALL - all ticks with any change are returned. Unchanged fields will be filled with last known values.

Call of CopyTicks() with the COPY_TICKS_ALL flag immediately returns all ticks from the request interval, while calls in other modes require some time to process and select ticks, therefore they do not provide significant speed advantage.

When requesting ticks (either COPY_TICKS_INFO or COPY_TICKS_TRADE), every tick contains full price information as of the time of the tick (*bid, ask, last* and *volume*). This feature is provided for an easier analysis of the trade state at the time of each tick, so there is no need to request a deep tick history and search for the values of other fields.

In indicators, the CopyTicks() function returns the result: when called from an indicator, CopyTick() immediately returns all available ticks of a symbol, and will launch synchronization of the tick database, if available data is not enough. All indicators in one symbol operate in one common thread, so the indicator cannot wait for the completion of synchronization. After synchronization, CopyTicks() will return all requested ticks during the next call. In indicators, the OnCalculate() function is called after the arrival of each tick.

CopyTicks() can wait for the result for 45 seconds in Expert Advisors and scripts: as distinct from indicators, every Expert Advisor and script operate in a separate thread, and therefore can wait 45 seconds till the completion of synchronization. If the required amount of ticks fails to be synchronized during this time, CopyTicks() will return available ticks by timeout and will continue synchronization. OnTick() in Expert Advisor is not a handler of every tick, it only notifies an Expert Advisor about changes in the market. It can be a batch of changes: the terminal can simultaneously make a few ticks, but OnTick() will be called only once to notify the EA of the latest market state.

The rate of data return: the terminal stores in the fast access cache 4,096 last ticks for each instrument (65,536 ticks for symbols with a running Market Depth). If requested ticks for the current trading session are beyond the cache, CopyTicks() calls the ticks stored in the terminal memory. These requests require more time for execution. The slowest requests are those requesting ticks for other days, since the data is read from the disk in this case.

CopyTicksRange

The function receives ticks in the MqlTick format within the specified date range to ticks_array. Indexing goes from the past to the present meaning that a tick with the index 0 is the oldest one in the array. For tick analysis, check the *flags* field, which shows what exactly has changed.

```
int  CopyTicksRange(
   const string      symbol_name,           // symbol name
   MqlTick&          ticks_array[],         // tick receiving array
   uint              flags=COPY_TICKS_ALL,  // flag that defines the type of the ticks
   ulong             from_msc=0,            // date, starting from which ticks are requ
   ulong             to_msc=0               // date, up to which ticks are requested
   );
```

Parameters

symbol_name

[in] Symbol.

ticks_array

[out] MqlTick static or dynamic array for receiving ticks. If the static array cannot hold all the ticks from the requested time interval, the maximum possible amount of ticks is received. In this case, the function generates the error ERR_HISTORY_SMALL_BUFFER (4407) .

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. For any type of request, the values of the previous tick are added to the remaining fields of the MqlTick structure.

from_msc

[in] The date, from which you want to request ticks. In milliseconds since 1970.01.01. If the *from_msc* parameter is not specified, ticks from the beginning of the history are sent. Ticks with the time >= from_msc are sent.

to_msc

[in] The date, up to which you want to request ticks. In milliseconds since 01.01.1970. Ticks with the time <= to_msc are sent. If the *to_msc* parameter is not specified, all ticks up to the end of the history are sent.

Return Value

The number of copied tick or -1 in case of an error. GetLastError() is able to return the following errors:

- ERR_HISTORY_TIMEOUT - ticks synchronization waiting time is up, the function has sent all it had.
- ERR_HISTORY_SMALL_BUFFER - static buffer is too small. Only the amount the array can store has been sent.
- ERR_NOT_ENOUGH_MEMORY - insufficient memory for receiving a history from the specified range to the dynamic tick array. Failed to allocate enough memory for the tick array.

Note

© 2000-2025, MetaQuotes Ltd.

The CopyTicksRange() function is used for requesting ticks strictly from a specified range, for example, from a certain day in history. At the same time, CopyTicks() allows specifying only a start date, for example – receive all ticks from the beginning of the month till the current moment.

iBars

Returns the number of bars of a corresponding symbol and period, available in history.

```
int  iBars(
   const string           symbol,          // Symbol
   ENUM_TIMEFRAMES        timeframe        // Period
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

Return Value

The number of bars of a corresponding symbol and period, available in history, but no more than allowed by the "Max bars in chart" parameter in platform settings.

Example:

```
  Print("Bar count on the 'EURUSD,H1' is ",iBars("EURUSD",PERIOD_H1));
```

See also

Bars

© 2000-2025, MetaQuotes Ltd.

iBarShift

Search bar by time. The function returns the index of the bar corresponding to the specified time.

```
int  iBarShift(
   const string        symbol,          // Symbol
   ENUM_TIMEFRAMES     timeframe,       // Period
   datetime            time,            // Time
   bool                exact=false      // Mode
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. PERIOD_CURRENT means the current chart period.

time

[in] Time value to search for.

exact=false

[in] A return value, in case the bar with the specified time is not found. If *exact=false*, *iBarShift* returns the index of the nearest bar, the Open time of which is less than the specified time (*time_open<time*). If such a bar is not found (history before the specified time is not available), then the function returns -1. If *exact=true*, iBarShift does not search for a nearest bar but immediately returns -1.

Return Value

The index of the bar corresponding to the specified time. If the bar corresponding to the specified time is not found (there is a gap in the history), the function returns -1 or the index of the nearest bar (depending on the *'exact'* parameter).

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- The date is on Sunday
   datetime time=D'2002.04.25 12:00';
   string symbol="GBPUSD";
   ENUM_TIMEFRAMES tf=PERIOD_H1;
   bool exact=false;
//--- If there is no bar at the specified time, iBarShift will return the index of the
   int bar_index=iBarShift(symbol,tf,time,exact);
//--- Check the error code after the call of iBarShift()
   int error=GetLastError();
```

© 2000-2025, MetaQuotes Ltd.

```
   if(error!=0)
     {
      PrintFormat("iBarShift(): GetLastError=%d - The requested date %s "+
                  "for %s %s is not found in the available history",
                  error,TimeToString(time),symbol,EnumToString(tf));
      return;
     }
//--- The iBarShift() function was executed successfully, return a result for exact=fa
   PrintFormat("1. %s %s %s(%s): bar index is %d (exact=%s)",
               symbol,EnumToString(tf),TimeToString(time),
               DayOfWeek(time),bar_index,string(exact));
   datetime bar_time=iTime(symbol,tf,bar_index);
   PrintFormat("Time of bar #%d is %s (%s)",
               bar_index,TimeToString(bar_time),DayOfWeek(bar_time));
//--- Request the index of the bar with the specified time; if there is no bar -1 wil
   exact=true;
   bar_index=iBarShift(symbol,tf,time,exact);
//--- The iBarShift() function was executed successfully, return a result for exact=t
   PrintFormat("2. %s %s %s (%s):bar index is %d (exact=%s)",
               symbol,EnumToString(tf),TimeToString(time)
               ,DayOfWeek(time),bar_index,string(exact));
  }
//+------------------------------------------------------------------+
//| Returns the name of the day of the week                          |
//+------------------------------------------------------------------+
string DayOfWeek(const datetime time)
  {
   MqlDateTime dt;

iClose

Returns the Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iClose(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Close price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

© 2000-2025, MetaQuotes Ltd.

```
            "Time: "   ,TimeToString(time,TIME_DATE|TIME_SECONDS),"\n",
            "Open: "   ,DoubleToString(open,Digits()),"\n",
            "High: "   ,DoubleToString(high,Digits()),"\n",
            "Low: "    ,DoubleToString(low,Digits()),"\n",
            "Close: "  ,DoubleToString(close,Digits()),"\n",
            "Volume: ",IntegerToString(volume),"\n",
            "Bars: "   ,IntegerToString(bars),"\n"
            );
  }
```

iHigh

Returns the High price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iHigh(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The High price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",
```

iHighest

Returns the index of the highest value found on the corresponding chart (shift relative to the current bar).

```
int  iHighest(
   const string        symbol,              // Symbol
   ENUM_TIMEFRAMES     timeframe,           // Period
   ENUM_SERIESMODE     type,                // Timeseries identifier
   int                 count=WHOLE_ARRAY,   // Number of elements
   int                 start=0              // Index
  );
```

Parameters

symbol

[in] The symbol, on which the search will be performed. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

type

[in] The identifier of the timeseries, in which the search will be performed. Can be equal to any value from ENUM_SERIESMODE.

count=WHOLE_ARRAY

[in] The number of elements in the timeseries (from the current bar towards index increasing direction), among which the search should be performed.

start=0

[in] The index (shift relative to the current bar) of the initial bar, from which search for the highest value begins. Negative values are ignored and replaced with a zero value.

Return Value

The index of the highest value found on the corresponding chart (shift relative to the current bar) or -1 in case of an error. For error details, call the GetLastError() function.

Example:

```
   double val;
//--- Calculation of the highest Close value among 20 consecutive bars
//--- From index 4 to index 23 inclusive, on the current timeframe
   int val_index=iHighest(NULL,0,MODE_CLOSE,20,4);
   if(val_index!=-1)
      val=High[val_index];
   else
      PrintFormat("iHighest() call error. Error code=%d",GetLastError());
```

© 2000-2025, MetaQuotes Ltd.

iLow

Returns the Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iLow(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Low price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

   Comment(Symbol(),",",EnumToString(Period()),"\n",

iLowest

Returns the index of the smallest value found on the corresponding chart (shift relative to the current bar).

```
int  iLowest(
   const string        symbol,              // Symbol
   ENUM_TIMEFRAMES     timeframe,           // Period
   ENUM_SERIESMODE     type,                // Timeseries identifier
   int                 count=WHOLE_ARRAY,   // Number of elements
   int                 start=0              // Index
  );
```

Parameters

symbol

[in] The symbol, on which the search will be performed. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

type

[in] The identifier of the timeseries, in which the search will be performed. Can be equal to any value from ENUM_SERIESMODE.

count=WHOLE_ARRAY

[in] The number of elements in the timeseries (from the current bar towards index increasing direction), among which the search should be performed.

start=0

[in] The index (shift relative to the current bar) of the initial bar, from which search for the lowest value begins. Negative values are ignored and replaced with a zero value.

Return Value

The index of the lowest value found on the corresponding chart (shift relative to the current bar) or -1 in case of an error. For error details, call the GetLastError() function.

Example:

```
   double val;
//--- Search for a bar with the lowest value of the real volume among 15 consecutive b
//--- From index 10 to index 24 inclusive, on the current timeframe
   int val_index=iLowest(NULL,0,MODE_REAL_VOLUME,15,10);
   if(val_index!=-1)
      val=Low[val_index];
   else
      PrintFormat("iLowest() call error. Error code=%d",GetLastError());
```

iOpen

Returns the Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
double  iOpen(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The Open price of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```
input int shift=0;
//+------------------------------------------------------------------+
//| Function-event handler "tick"                                    |
//+------------------------------------------------------------------+
void OnTick()
  {
   datetime time  = iTime(Symbol(),Period(),shift);
   double   open  = iOpen(Symbol(),Period(),shift);
   double   high  = iHigh(Symbol(),Period(),shift);
   double   low   = iLow(Symbol(),Period(),shift);
   double   close = iClose(NULL,PERIOD_CURRENT,shift);
   long     volume= iVolume(Symbol(),0,shift);
   int      bars  = iBars(NULL,0);

iTime

Returns the opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
datetime  iTime(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The opening time of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

iRealVolume

Returns the real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart.

```
long  iRealVolume(
   const string         symbol,          // Symbol
   ENUM_TIMEFRAMES      timeframe,       // Period
   int                  shift            // Shift
   );
```

Parameters

symbol

[in] The symbol name of the financial instrument. NULL means the current symbol.

timeframe

[in] Period. It can be one of the values of the ENUM_TIMEFRAMES enumeration. 0 means the current chart period.

shift

[in] The index of the received value from the timeseries (backward shift by specified number of bars relative to the current bar).

Return Value

The real volume of the bar (indicated by the 'shift' parameter) on the corresponding chart or 0 in case of an error. For error details, call the GetLastError() function.

Note

The function always returns actual data. For this purpose it performs a request to the timeseries for the specified symbol/period during each call. This means that if there is no ready data during the first function call, some time may be taken to prepare the result.

The function does not store previous calls results, and there is no local cache for quick value return.

Example:

```

Custom symbols

Functions for creating and editing the custom symbol properties.

When connecting the terminal to a certain trade server, a user is able to work with time series of the financial symbols provided by a broker. Available financial symbols are displayed as a list in the Market Watch window. A separate group of functions allows receiving data on the symbol properties, trading sessions and market depth updates.

The group of functions described in this section allows creating custom symbols. To do this, users are able to apply the trade server's existing symbols, text files or external data sources.

Function	Action
CustomSymbolCreate	Create a custom symbol with the specified name in the specified group
CustomSymbolDelete	Delete a custom symbol with the specified name
CustomSymbolSetInteger	Set the integer type property value for a custom symbol
CustomSymbolSetDouble	Set the real type property value for a custom symbol
CustomSymbolSetString	Set the string type property value for a custom symbol
CustomSymbolSetMarginRate	Set the margin rates depending on the order type and direction for a custom symbol
CustomSymbolSetSessionQuote	Set the start and end time of the specified quotation session for the specified symbol and week day
CustomSymbolSetSessionTrade	Set the start and end time of the specified trading session for the specified symbol and week day
CustomRatesDelete	Delete all bars from the price history of the custom symbol in the specified time interval
CustomRatesReplace	Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlRates type array
CustomRatesUpdate	Add missing bars to the custom symbol history and replace existing data with the ones from the MqlRates type array
CustomTicksAdd	Adds data from an array of the MqlTick type to the price history of a custom symbol. The custom symbol must be selected in the Market Watch window
CustomTicksDelete	Delete all ticks from the price history of the custom symbol in the specified time interval
CustomTicksReplace	Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlTick type array
CustomBookAdd	Passes the status of the Depth of Market for a custom symbol

© 2000-2025, MetaQuotes Ltd.

CustomSymbolCreate

Creates a custom symbol with the specified name in the specified group.

```
bool  CustomSymbolCreate(
   const string      symbol_name,          // custom symbol name
   const string      symbol_path="",       // name of a group a symbol is to be created
   const string      symbol_origin=NULL    // name of a symbol used as a basis to create
   );
```

Parameters

symbol_name

[in] Custom symbol name. It should not contain groups or subgroups the symbol is located in.

symbol_path=""

[in] The group name a symbol is located in.

symbol_origin=NULL

[in] Name of a symbol the properties of a created custom symbol are to be copied from. After creating a custom symbol, any property value can be changed to a necessary one using the appropriate functions.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

All custom symbols are created in the special Custom section. If a group name is not specified (the *symbol_path* parameter in the CustomSymbolCreate function contains an empty string or NULL), a custom symbol is generated in the Custom section root. Here we can draw an analogy with the file system, where groups and subgroups can be viewed as folders and subfolders

The symbol and group names may only contain Latin letters without punctuation, spaces or special characters (may only contain ".", "_", "&" and "#"). It is not recommended to use characters <, >, :, ", /, |, ?, *.

The custom symbol name should be unique regardless of a group name it is created in. If a symbol with the same name already exists, the CustomSymbolCreate() function returns 'false', while the subsequent GetLastError() call returns the error 5300 (ERR_NOT_CUSTOM_SYMBOL) or 5304 (ERR_CUSTOM_SYMBOL_EXIST).

The length of the symbol name should not exceed 31 characters. Otherwise, CustomSymbolCreate() returns 'false' and the error 5302 - ERR_CUSTOM_SYMBOL_NAME_LONG is activated.

The *symbol_path* parameter can be set in two ways:

- only a group name without a name of the custom symbol, for example - "CFD\\Metals". It is best to use this option to avoid errors.
- or <group> name + groups separator "\\"+<custom symbol name>, for example - "CFD\\Metals\\Platinum". In this case, the group name should end with the exact name of the custom symbol. In case of a mismatch, the custom symbol is still created, but not in the intended group. For example, if *symbol_path*="CFD\\Metals\\Platinum" and *symbol_name*="platinum" (register error),

© 2000-2025, MetaQuotes Ltd.

then a custom symbol named "platinum" is created in the "Custom\CFD\Metals\Platinum" group. The SymbolInfoGetString("platinum",SYMBOL_PATH) function returns the "Custom\CFD\Metals\Platinum\platinum" value.

Note that the SYMBOL_PATH property returns the path with the symbol name at the end. Therefore, it cannot be copied without changes if you want to create a custom symbol in the exact same group. In this case, it is necessary to cut the symbol name in order not to get the result described above.

If a non-existent symbol is set as the *symbol_origin* parameter, then the custom symbol is created empty as if the *symbol_origin* parameter is not set. The error 4301 - ERR_MARKET_UNKNOWN_SYMBOL is activated in that case.

The *symbol_path* parameter length should not exceed 127 characters considering "Custom\\", "\\" groups separators and the symbol name if it is specified at the end.

Example:

```

CustomSymbolDelete

Deletes a custom symbol with the specified name.

```
bool  CustomSymbolDelete(
   const string      symbol_name          // custom symbol name
   );
```

Parameters

symbol

[in] Custom symbol name. It should not match the name of an already existing symbol.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The custom symbol displayed in the Market Watch or the one a chart is opened for cannot be deleted.

Example:

```
//+------------------------------------------------------------------+
//|                                          CustomSymbolDelete.mq5 |

CustomSymbolSetInteger

Sets the integer type property value for a custom symbol.

```
bool  CustomSymbolSetInteger(
   const string               symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_INTEGER   property_id,      // property ID
   long                       property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_INTEGER enumeration.

property_value

[in] A long type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if any of these properties is changed in the symbol specification:

- SYMBOL_CHART_MODE - price type for constructing bars (Bid or Last)
- SYMBOL_DIGITS - number of digits after the decimal point to display the price

After deleting the custom symbol history, the terminal attempts to create a new history using the updated properties. The same happens when the custom symbol properties are changed manually.

Example:

CustomSymbolSetDouble

Sets the real type property value for a custom symbol.

```
bool  CustomSymbolSetDouble(
   const string              symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_DOUBLE   property_id,      // property ID
   double                    property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_DOUBLE enumeration.

property_value

[in] A double type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if any of these properties is changed in the symbol specification:

- SYMBOL_POINT - one point value
- SYMBOL_TRADE_TICK_SIZE - value of a tick that specifies the minimum allowable price change
- SYMBOL_TRADE_TICK_VALUE - one-tick price change value for a profitable position

After deleting the custom symbol history, the terminal attempts to create a new history using the updated properties. The same happens when the custom symbol properties are changed manually.

Example:

```

CustomSymbolSetString

Sets the string type property value for a custom symbol.

```
bool  CustomSymbolSetString(
   const string               symbol_name,      // symbol name
   ENUM_SYMBOL_INFO_STRING    property_id,      // property ID
   string                     property_value    // property value
   );
```

Parameters

symbol_name

[in] Custom symbol name.

property_id

[in] Symbol property ID. The value can be one of the values of the ENUM_SYMBOL_INFO_STRING enumeration.

property_value

[in] A string type variable containing the property value.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The minute and tick history of the custom symbol is completely removed if the SYMBOL_FORMULA property (setting the equation for the custom symbol price construction) is changed in the symbol specification. After deleting the custom symbol history, the terminal attempts to create a new history using the new equation. The same happens when the custom symbol equation is changed manually.

Example:

```

CustomSymbolSetMarginRate

Sets the margin rates depending on the order type and direction for a custom symbol.

```
bool  CustomSymbolSetMarginRate(
   const string       symbol_name,              // symbol name
   ENUM_ORDER_TYPE    order_type,               // order type
   double             initial_margin_rate,      // initial margin rate
   double             maintenance_margin_rate   // maintenance margin rate
   );
```

Parameters

symbol_name

[in] Custom symbol name.

order_type

[in] Order type.

initial_margin_rate

[in] A double type variable with an initial margin rate. Initial margin is a security deposit for 1 lot deal in the appropriate direction. Multiplying the rate by the initial margin, we receive the amount of funds to be reserved on the account when placing an order of the specified type.

maintenance_margin_rate

[in] A double type variable with a maintenance margin rate. Maintenance margin is a minimum amount for maintaining an open position of 1 lot in the appropriate direction. Multiplying the rate by the maintenance margin, we receive the amount of funds to be reserved on the account after an order of the specified type is activated.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

CustomSymbolSetSessionQuote

Sets the start and end time of the specified quotation session for the specified symbol and week day.

```
bool  CustomSymbolSetSessionQuote(
   const string      symbol_name,          // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,          // week day
   uint              session_index,        // session index
   datetime          from,                 // session start time
   datetime          to                    // session end time
   );
```

Parameters

symbol_name

[in] Custom symbol name.

ENUM_DAY_OF_WEEK

[in] Week day, value from the ENUM_DAY_OF_WEEK enumeration.

uint

[in] Index of the session, for which start and end times are to be set. Session indexing starts from 0.

from

[in] Session start time in seconds from 00:00, data value in the variable is ignored.

to

[in] Session end time in seconds from 00:00, data value in the variable is ignored.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

If the session with the specified *session_index* already exists, the function simply edits the beginning and end of the session.

If zero start and end parameters have been passed for the session (*from=0* and *to=0*), the appropriate session with the *session_index* is deleted, while the session indexing is shifted downwards.

Sessions can be added only sequentially. In other words, you can add *session_index=1* only if the session with the index 0 already exists. If this rule is broken, a new session is not created, while the function itself returns 'false'.

Example:

```
//+------------------------------------------------------------------+
//|                                  CustomSymbolSetSessionQuote.mq5 |

CustomSymbolSetSessionTrade

Sets the start and end time of the specified trading session for the specified symbol and week day.

```
bool  CustomSymbolSetSessionTrade(
   const string      symbol_name,          // symbol name
   ENUM_DAY_OF_WEEK  day_of_week,          // week day
   uint              session_index,        // session index
   datetime          from,                 // session start time
   datetime          to                    // session end time
   );
```

Parameters

symbol_name

[in] Custom symbol name.

ENUM_DAY_OF_WEEK

[in] Week day, value from the ENUM_DAY_OF_WEEK enumeration.

uint

[in] Index of the session, for which start and end times are to be set. Session indexing starts from 0.

from

[in] Session start time in seconds from 00:00, data value in the variable is ignored.

to

[in] Session end time in seconds from 00:00, data value in the variable is ignored.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

If the session with the specified *session_index* already exists, the function simply edits the beginning and end of the session.

If zero start and end parameters have been passed for the session (*from=0* and *to=0*), the appropriate session with the *session_index* is deleted, while the session indexing is shifted downwards.

Sessions can be added only sequentially. In other words, you can add *session_index=1* only if the session with the index 0 already exists. If this rule is broken, a new session is not created, while the function itself returns 'false'.

Example:

```
//+------------------------------------------------------------------+
//|                                  CustomSymbolSetSessionTrade.mq5 |

CustomRatesDelete

Deletes all bars from the price history of the custom symbol in the specified time interval.

```
int  CustomRatesDelete(
   const string      symbol,        // symbol name
   datetime          from,          // start date
   datetime          to             // end date
   );
```

Parameters

symbol

[in] Custom symbol name.

from

[in] Time of the first bar in the price history within the specified range to be removed.

to

[in] Time of the last bar in the price history within the specified range to be removed.

Return Value

Number of deleted bars or -1 in case of an error.

Example:

```

CustomRatesReplace

Fully replaces the price history of the custom symbol within the specified time interval with the data from the MqlRates type array.

```
int  CustomRatesReplace(
   const string     symbol,              // symbol name
   datetime         from,                // start date
   datetime         to,                  // end date
   const MqlRates&  rates[],             // array for the data to be applied to a custo
   uint             count=WHOLE_ARRAY    // number of the rates[] array elements to be
   );
```

Parameters

symbol

[in] Custom symbol name.

from

[in] Time of the first bar in the price history within the specified range to be updated.

to

[in] Time of the last bar in the price history within the specified range to be updated.

rates[]

[in] Array of the MqlRates type history data for M1.

count=WHOLE_ARRAY

[in] Number of the *rates[]* array elements to be used for replacement. WHOLE_ARRAY means that all *rates[]* array elements should be used for replacement.

Return Value

Number of updated bars or -1 in case of an error.

Note

If the bar from the *rates[]* array goes beyond the specified range, it is ignored. If such a bar is already present in the price history and enters the given range, it is replaced. All other bars in the current price history outside the specified range remain unchanged. The *rates[]* array data should be correct regarding OHLC prices, while the bars opening time should correspond to the M1 timeframe.

Example:

```
//+------------------------------------------------------------------+

CustomRatesUpdate

Adds missing bars to the custom symbol history and replaces existing data with the ones from the MqlRates type array.

```
int  CustomRatesUpdate(
   const string     symbol,             // custom symbol name
   const MqlRates&  rates[],            // array for the data to be applied to a custo
   uint             count=WHOLE_ARRAY   // number of the rates[] array elements to be
   );
```

Parameters

symbol

[in] Custom symbol name.

rates[]

[in] Array of the MqlRates type history data for M1.

count=WHOLE_ARRAY

[in] Number of the *rates[]* array elements to be used for update. WHOLE_ARRAY means that all *rates[]* array elements should be used.

Return Value

Number of updated bars or -1 in case of an error.

Note

If there is no bar from the *rates[]* array in the current custom symbol history, it is added. If such a bar already exists, it is replaced. All other bars in the current price history remain unchanged. The *rates[]* array data should be correct regarding OHLC prices, while the bars opening time should correspond to the M1 timeframe.

CustomRatesReplace, CustomRatesDelete, CopyRates

© 2000-2025, MetaQuotes Ltd.

CustomTicksAdd

Adds data from an array of the MqlTick type to the price history of a custom symbol. The custom symbol must be selected in the Market Watch window.

```
int  CustomTicksAdd(
   const string     symbol,              // Symbol name
   const MqlTick&   ticks[],             // The array with tick data that should be app
   uint             count=WHOLE_ARRAY    // number of the ticks[] array elements to be
   );
```

Parameters

symbol

[in] The name of the custom symbol.

ticks[]

[in] An array of tick data of the MqlTick type arranged in order of time from earlier data to more recent ones, i.e. ticks[k].time_msc <= ticks[n].time_msc, if k<n.

count=WHOLE_ARRAY

[in] Number of the *ticks[]* array elements to be used for adding. WHOLE_ARRAY means that all *ticks[]* array elements should be used.

Return Value

The number of added ticks or -1 in case of an error.

Further Note

The CustomTicksAdd function only works for custom symbols opened in the Market Watch window. If the symbol is not selected in Market Watch, then you should add ticks using CustomTicksReplace.

The CustomTicksAdd function allows transmitting ticks as if they are delivered from the broker's server. Data are sent to the Market Watch window instead of being written directly to the tick database. The terminal then saves ticks from the Market Watch to a database. If the amount of data transmitted during one function call is large, the behavior of the function changes in order to reduce resource usage. If more than 256 ticks are passed, data is divided into two parts. The first, i.e. the larger part is written directly to the tick database (as it is done in CustomTicksReplace). The second part containing 128 ticks is passed to the Market Watch window, from which the terminal saves the ticks to a database.

The MqlTick structure has two fields with the time value: time (the tick time in seconds) and time_msc (the tick time in milliseconds), which are counted from January 1, 1970. These fields in the added ticks are processed in the following order:

1. If ticks[k].time_msc!=0, we use it to fill the ticks[k].time field, i.e. ticks[k].time=ticks[k].time_msc/1000 (integer division) is set for the tick
2. If ticks[k].time_msc==0 and ticks[k].time!=0, time in milliseconds is obtained by multiplying by 1000, i.e. ticks[k].time_msc=ticks[k].time*1000
3. If ticks[k].time_msc==0 and ticks[k].time==0, the current trade server time up to a millisecond as of the moment of CustomTicksAdd call is written to these fields.

© 2000-2025, MetaQuotes Ltd.

If the value of ticks[k].bid, ticks[k].ask, ticks[k].last or ticks[k].volume is greater than zero, a combination of appropriate flags is written to the ticks[k].flags field:

- TICK_FLAG_BID - the tick has changed the bid price
- TICK_FLAG_ASK - the tick has changed the ask price
- TICK_FLAG_LAST - the tick has changed the last deal price
- TICK_FLAG_VOLUME - the tick has changed the volume

If the value of a field is less than or equal to zero, the corresponding flag is not written to the ticks[k].flags field.

Flags TICK_FLAG_BUY and TICK_FLAG_SELL are not added to the history of a custom symbol.

Example:

CustomRatesDelete, CustomRatesUpdate, CustomTicksReplace, CopyTicks, CopyTicksRange

© 2000-2025, MetaQuotes Ltd.

CustomTicksDelete

Deletes all ticks from the price history of the custom symbol in the specified time interval.

```
int  CustomTicksDelete(
   const string     symbol,           // symbol name
   long             from_msc,         // start date
   long             to_msc            // end date
   );
```

Parameters

symbol

[in] Custom symbol name.

from_msc

[in] Time of the first tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

to_msc

[in] Time of the last tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

Return Value

Number of deleted ticks or -1 in case of an error.

Example:

```

CustomTicksReplace

Fully replaces the price history of the custom symbol within the specified time interval with the data from the MqlTick type array.

```
int  CustomTicksReplace(
   const string     symbol,            // symbol name
   long             from_msc,          // start date
   long             to_msc,            // end date
   const MqlTick&   ticks[],           // array for the data to be applied to a custor
   uint             count=WHOLE_ARRAY  // number of the ticks[] array elements to be u
   );
```

Parameters

symbol

[in] Custom symbol name.

from_msc

[in] Time of the first tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

to_msc

[in] Time of the last tick in the price history within the specified range to be removed. Time in milliseconds since 01.01.1970.

ticks[]

[in] Array of the MqlTick type tick data ordered in time in ascending order.

count=WHOLE_ARRAY

[in] Number of the *ticks[]* array elements to be used for replacement in the specified time interval. WHOLE_ARRAY means that all *ticks[]* array elements should be used.

Return Value

Number of updated ticks or -1 in case of an error.

Note

Since several ticks may often have the same time up to a millisecond in a stream of quotes (accurate tick time is stored in the *time_msc* field of the MqlTick structure), the CustomTicksReplace function does not automatically sort out the *ticks[]* array elements by time. Therefore, the array of ticks must be pre-arranged in time ascending order.

The ticks are replaced consecutively, day after day, until the time specified in *to_msc* or until an error occurs. The first day from the specified range is processed followed by the next one, etc. As soon as the mismatch between the tick time and the ascending (non-descending) order is detected, the tick replacement stops on the current day. All ticks from the previous days are successfully replaced, while the current day (at the moment of a wrong tick) and all the remaining days in the specified interval remain unchanged.

If the *ticks[]* array contains no tick data for any day (generally, any time interval), a "hole" corresponding to the missing data appears in the custom symbol history after the tick data from *ticks[]* are applied. In other words, the call of CustomTicksReplace with missing ticks is

© 2000-2025, MetaQuotes Ltd.

equivalent to deleting part of the tick history, as if CustomTicksDelete with the "hole" interval is called.

If the tick database has no data for the specified time interval, CustomTicksReplace will add to the database ticks form the ticks[] array.

The CustomTicksReplace function works directly with the tick database.

Example:

CustomBookAdd

Passes the status of the Depth of Market for a custom symbol. The function allows broadcasting the Depth of Market as if the prices arrive from a broker's server.

```
bool  CustomBookAdd(
   const string        symbol,            // symbol name
   const MqlBookInfo&  books[]            // array with descriptions of the Depth of M
   uint                count=WHOLE_ARRAY  // number of elements to be used
   );
```

Parameters

symbol

[in] Custom symbol name.

books[]

[in] The array of MqlBookInfo type data fully describing the Depth of Market status — all buy and sell requests. The passed Depth of Market status completely replaces the previous one.

count=WHOLE_ARRAY

[in] The number of 'books' array elements to be passed to the function. The entire array is used by default.

Return Value

true - success, otherwise - false. To get information about the error, call the GetLastError() function.

Note

The CustomBookAdd function works only for custom symbols the Depth of Market is opened for — via the platform interface or the MarketBookAdd function.

When throwing the Depth of Market in, the symbol's Bid and Ask prices are not updated. You should control the change of the best prices and throw in the ticks using CustomTicksAdd.

The function verifies the accuracy of transmitted data: the type, price and volume must be indicated for each element. Furthermore, MqlBookInfo.volume and MqlBookInfo.volume_real must not be zero or negative; if both volumes are negative, this will be considered an error. You can specify any of the volumes or both of them: the one that is indicated or is positive will be used:

```
volume=-1 && volume_real=2 — volume_real=2 will be used,
a volume=3 && volume_real=0 — volume=3 will be used.
```

The MqlBookInfo.volume_real extended accuracy volume has a higher priority over the regular MqlBookInfo.volume. If both values are specified for the Depth of Market element, the volume_real one is used.

The order of the MqlBookInfo elements in the 'books' array does not matter. When saving the data, the terminal sorts them by price on its own.

© 2000-2025, MetaQuotes Ltd.

When saving data, the "Book depth" (SYMBOL_TICKS_BOOKDEPTH) parameter of the recipient custom symbol is checked. If the number of sell requests exceeds this value in the passed Depth of Market, the excess levels are discarded. The same is true for buy requests.

Sample filling of the 'books' array:

Depth of Market status	Filling books[]

	books[0].type=BOOK_TYPE_SELL;
	books[0].price=1.14337;
	books[0].volume=100;
	books[1].type=BOOK_TYPE_SELL;
	books[1].price=1.14330;
	books[1].volume=50;
	books[2].type=BOOK_TYPE_SELL;
	books[2].price=1.14335;
	books[2].volume=40;
	books[3].type=BOOK_TYPE_SELL;
	books[3].price=1.14333;
	books[3].volume=10;
	books[4].type=BOOK_TYPE_BUY;
	books[4].price=1.14322;
	books[4].volume=10;
	books[5].type=BOOK_TYPE_BUY;
	books[5].price=1.14320;
	books[5].volume=90;
	books[6].type=BOOK_TYPE_BUY;
	books[6].price=1.14319;
	books[6].volume=100;
	books[7].type=BOOK_TYPE_BUY;
	books[7].price=1.14318;
	books[7].volume=10;

Example:

Chart Operations

Functions for setting chart properties (ChartSetInteger, ChartSetDouble, ChartSetString) are asynchronous and are used for sending update commands to a chart. If these functions are executed successfully, the command is included in the common queue of the chart events. Chart property changes are implemented along with handling of the events queue of this chart.

Thus, do not expect an immediate update of the chart after calling asynchronous functions. Use the ChartRedraw() function to forcedly update the chart appearance and properties.

Function	Action
ChartApplyTemplate	Applies a specific template from a specified file to the chart
ChartSaveTemplate	Saves current chart settings in a template with a specified name
ChartWindowFind	Returns the number of a subwindow where an indicator is drawn
ChartTimePriceToXY	Converts the coordinates of a chart from the time/price representation to the X and Y coordinates
ChartXYToTimePrice	Converts the X and Y coordinates on a chart to the time and price values
ChartOpen	Opens a new chart with the specified symbol and period
ChartClose	Closes the specified chart
ChartFirst	Returns the ID of the first chart of the client terminal
ChartNext	Returns the chart ID of the chart next to the specified one
ChartSymbol	Returns the symbol name of the specified chart
ChartPeriod	Returns the period value of the specified chart
ChartRedraw	Calls a forced redrawing of a specified chart
ChartSetDouble	Sets the double value for a corresponding property of the specified chart
ChartSetInteger	Sets the integer value (datetime, int, color, bool or char) for a corresponding property of the specified chart
ChartSetString	Sets the string value for a corresponding property of the specified chart
ChartGetDouble	Returns the double value property of the specified chart
ChartGetInteger	Returns the integer value property of the specified chart
ChartGetString	Returns the string value property of the specified chart
ChartNavigate	Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart
ChartID	Returns the ID of the current chart

© 2000-2025, MetaQuotes Ltd.

Function	Action
ChartIndicatorAdd	Adds an indicator with the specified handle into a specified chart window
ChartIndicatorDelete	Removes an indicator with a specified name from the specified chart window
ChartIndicatorGet	Returns the handle of the indicator with the specified short name in the specified chart window
ChartIndicatorName	Returns the short name of the indicator by the number in the indicators list on the specified chart window
ChartIndicatorsTotal	Returns the number of all indicators applied to the specified chart window.
ChartWindowOnDropped	Returns the number (index) of the chart subwindow the Expert Advisor or script has been dropped to
ChartPriceOnDropped	Returns the price coordinate of the chart point the Expert Advisor or script has been dropped to
ChartTimeOnDropped	Returns the time coordinate of the chart point the Expert Advisor or script has been dropped to
ChartXOnDropped	Returns the X coordinate of the chart point the Expert Advisor or script has been dropped to
ChartYOnDropped	Returns the Y coordinate of the chart point the Expert Advisor or script has been dropped to
ChartSetSymbolPeriod	Changes the symbol value and a period of the specified chart
ChartScreenShot	Provides a screenshot of the chart of its current state in a GIF, PNG or BMP format depending on specified extension

© 2000-2025, MetaQuotes Ltd.

ChartApplyTemplate

Applies a specific template from a specified file to the chart. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartApplyTemplate(
   long          chart_id,      // Chart ID
   const string  filename       // Template file name
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] The name of the file containing the template.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The Expert Advisor will be unloaded and will not be able to continue operating in case of successful loading of a new template to the chart it is attached to.

When applying the template to the chart, trade permissions may be limited due to security reasons:

> **Live trading permission cannot be extended for the Expert Advisors launched by applying the template using ChartApplyTemplate() function.**

If the mql5-program calling ChartApplyTemplate() function has no permission to trade, the Expert Advisor launched via the template will also not be able to trade regardless of the template settings.

If the mql5-program calling ChartApplyTemplate() function has permission to trade, while there is no such permission in the template settings, the Expert Advisor launched via the template will not be able to trade.

Using Templates

The resources of the MQL5 language allow setting multiple chart properties, including colors using the ChartSetInteger() function:

- Chart background color;
- Color of the axes, scale and the OHLC line;
- Grid color;
- Color of volumes and position open levels;
- Color of the up bar, shadow and edge of a bullish candlestick;
- Color of the down bar, shadow and edge of a bearish candlestick;
- Color of the chart line and Doji candlesticks;

© 2000-2025, MetaQuotes Ltd.

- Color of the bullish candlestick body;
- Color of the bearish candlestick body;
- Color of the Bid price line;
- Color of the Ask price line;
- Color of the line of the last deal price (Last);
- Color of the stop order levels (Stop Loss and Take Profit).

Besides, there can be multiple graphical objects and indicators on a chart. You may set up a chart with all the necessary indicators once and then save it as a template. Such a template can be applied to any chart.

The ChartApplyTemplate() function is intended for using a previously saved template, and it can be used in any mql5 program. The path to the file that stores the template is passed as the second parameter to ChartApplyTemplate(). The template file is searched according to the following rules:

- if the backslash "\" separator (written as "\\") is placed at the beginning of the path, the template is searched for relative to the path _terminal_data_directory\MQL5,
- if there is no backslash, the template is searched for relative to the executable EX5 file, in which ChartApplyTemplate() is called;
- if a template is not found in the first two variants, the search is performed in the folder terminal_directory\Profiles\Templates\.

Here terminal_directory is the folder from which the MetaTrader 5 Client Terminal is running, and terminal_data_directory is the folder, in which editable files are stored, its location depends on the operating system, user name and computer's security settings. Normally they are different folders, but in some cases they may coincide.

The location of folders terminal_data_directory and terminal_directory can be obtained using the TerminalInfoString() function.

```
//--- directory from which the terminal is started
   string terminal_path=TerminalInfoString(TERMINAL_PATH);
   Print("Terminal directory:",terminal_path);
//--- terminal data directory, in which the MQL5 folder with EAs and indicators is loc
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
   Print("Terminal data directory:",terminal_data_path);
```

For example:

```
//--- search for a template in terminal_data_directory\MQL5\
ChartApplyTemplate(0,"\\first_template.tpl"))
//--- search for a template in directory_of_EX5_file\, then in folder terminal_data_di
ChartApplyTemplate(0,"second_template.tpl"))
//--- search for a template in directory_of_EX5_file\My_templates\, then in folder ter
ChartApplyTemplate(0,"My_templates\\third_template.tpl"))
```

Templates are not resources, they cannot be included into an executable EX5 file.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
```

© 2000-2025, MetaQuotes Ltd.

```
void OnStart()
  {
//--- example of applying template, located in \MQL5\Files
   if(FileIsExist("my_template.tpl"))
     {
      Print("The file my_template.tpl found in \Files'");
      //--- apply template
      if(ChartApplyTemplate(0,"\\Files\\my_template.tpl"))
        {
         Print("The template 'my_template.tpl' applied successfully");
         //--- redraw chart
         ChartRedraw();
        }
      else
         Print("Failed to apply 'my_template.tpl', error code ",GetLastError());
     }
   else
     {
      Print("File 'my_template.tpl' not found in "
            +TerminalInfoString(TERMINAL_PATH)+"\\MQL5\\Files");
     }
  }
```

ChartSaveTemplate

Saves current chart settings in a template with a specified name.

```
bool  ChartSaveTemplate(
   long          chart_id,     // Chart ID
   const string  filename      // Filename to save the template
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] The filename to save the template. The ".tpl" extension will be added to the filename automatically; there is no need to specify it. The template is saved in **data_folder**\Profiles\Templates\ and can be used for manual application in the terminal. If a template with the same filename already exists, the contents of this file will be overwritten.

Return Value

If successful, the function returns true, otherwise it returns false. To get information about the error, call the GetLastError() function.

Note

Using templates, you can save chart settings with all applied indicators and graphical objects, to then apply it to another chart.

Example:

```
//+------------------------------------------------------------------+
//|                                      Test_ChartSaveTemplate.mq5 |

ChartWindowFind

The function returns the number of a subwindow where an indicator is drawn. There are 2 variants of the function.

1. The function searches in the indicated chart for the subwindow with the specified "short name" of the indicator (the short name is displayed in the left top part of the subwindow), and it returns the subwindow number in case of success.

```
int  ChartWindowFind(
   long     chart_id,                  // chart identifier
   string   indicator_shortname        // short indicator name, see INDICATOR_SHORTNAM
```

2. The function must be called from a custom indicator. It returns the number of the subwindow where the indicator is working.

```
int  ChartWindowFind();
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

indicator_shortname

[in] Short name of the indicator.

Return Value

Subwindow number in case of success. In case of failure the function returns -1.

Note

If the second variant of the function (without parameters) is called from a script or Expert Advisor, the function returns -1.

Don't mix up the short name of an indicator and a file name, which is specified when an indicator is created using iCustom() and IndicatorCreate() functions. If the indicator's short name is not set explicitly, then the name of the file containing the source code of the indicator, is specified in it during compilation.

It is important to correctly form the short name of an indicator, which is recorded in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name contains values of the indicator's input parameters, because the indicator deleted from a chart in the ChartIndicatorDelete() function is identified by its short name.

Example:

```
#property script_show_inputs
//--- input parameters
input string   shortname="MACD(12,26,9)";
//+------------------------------------------------------------------+
//| Returns number of the chart window with this indicator           |
//+------------------------------------------------------------------+
int GetIndicatorSubWindowNumber(long chartID=0,string short_name="")
```

© 2000-2025, MetaQuotes Ltd.

```
  {
   int window=-1;
//---
   if((ENUM_PROGRAM_TYPE)MQL5InfoInteger(MQL5_PROGRAM_TYPE)==PROGRAM_INDICATOR)
     {
      //--- the function is called from the indicator, name is not required
      window=ChartWindowFind();
     }
   else
     {
      //--- the function is called from an Expert Advisor or script
      window=ChartWindowFind(0,short_name);
      if(window==-1) Print(__FUNCTION__+"(): Error = ",GetLastError());
     }
//---
   return(window);
  }
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//---
   int window=GetIndicatorSubWindowNumber(0,shortname);
   if(window!=-1)
      Print("Indicator "+shortname+" is in the window #"+(string)window);
   else
      Print("Indicator "+shortname+" is not found. window = "+(string)window);
  }
```

ChartTimePriceToXY

Converts the coordinates of a chart from the time/price representation to the X and Y coordinates.

```
bool  ChartTimePriceToXY(
   long           chart_id,      // Chart ID
   int            sub_window,    // The number of the subwindow
   datetime       time,          // Time on the chart
   double         price,         // Price on the chart
   int&           x,             // The X coordinate for the time on the chart
   int&           y              // The Y coordinates for the price on the chart
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart subwindow. 0 means the main chart window.

time

[in] The time value on the chart, for which the value in pixels along the X axis will be received. The origin is in the upper left corner of the main chart window.

price

[in] The price value on the chart, for which the value in pixels along the Y axis will be received. The origin is in the upper left corner of the main chart window.

x

[out] The variable, into which the conversion of time to X will be received.

y

[out] The variable, into which the conversion of price to Y will be received.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Example:

```
#define   BAR_NUMBER    0  // number of the bar we get the price and time from

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- copy data of a single bar by the BAR_NUMBER index
   MqlRates rates[]={};
   if(CopyRates(_Symbol, _Period, BAR_NUMBER, 1, rates)!=1)
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       PrintFormat("CopyRates() failed for bar %d. Error %d", BAR_NUMBER, GetLastError
       return;
      }

//--- convert the obtained price and time into chart pixel coordinates
   int x=0, y=0;
   ResetLastError();
   if(!ChartTimePriceToXY(ChartID(), 0, rates[0].time, rates[0].close, x, y))
     {
      Print("ChartTimePriceToXY() failed. Error ", GetLastError());
      return;
     }

//--- print the obtained result in the journal
   PrintFormat("For bar[%d] with opening time %s and price %.*f, the chart coordinates

   /*
   result:
   For bar[0] with opening time 2024.08.09 15:06 and price 1.27378, the chart coordina
   */
  }
```

ChartXYToTimePrice()

© 2000-2025, MetaQuotes Ltd.

ChartXYToTimePrice

Converts the X and Y coordinates on a chart to the time and price values.

```
bool  ChartXYToTimePrice(
   long            chart_id,      // Chart ID
   int             x,             // The X coordinate on the chart
   int             y,             // The Y coordinate on the chart
   int&            sub_window,    // The number of the subwindow
   datetime&       time,          // Time on the chart
   double&         price          // Price on the chart
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

x

[in] The X coordinate.

y

[in] The Y coordinate.

sub_window

[out] The variable, into which the chart subwindow number will be written. 0 means the main chart window.

time

[out] The time value on the chart, for which the value in pixels along the X axis will be received. The origin is in the upper left corner of the main chart window.

price

[out] The price value on the chart, for which the value in pixels along the Y axis will be received. The origin is in the upper left corner of the main chart window.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Example:

```
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,
                  const long &lparam,

ChartOpen

Opens a new chart with the specified symbol and period.

```
long  ChartOpen(
   string           symbol,     // Symbol name
   ENUM_TIMEFRAMES  period      // Period
   );
```

Parameters

symbol

[in] Chart symbol. NULL means the symbol of the current chart (the Expert Advisor is attached to).

period

[in] Chart period (timeframe). Can be one of the ENUM_TIMEFRAMES values. 0 means the current chart period.

Return Value

If successful, it returns the opened chart ID. Otherwise returns 0.

Note

The maximum possible number of simultaneously open charts in the terminal can't exceed the CHARTS_MAX value.

Example:

```
#define CHART_SYMBOL  NULL
#define CHART_PERIOD  PERIOD_CURRENT

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- set a new chart symbol and timeframe
   string symbol=CHART_SYMBOL;
   if(symbol==NULL)
      symbol=Symbol();
   ENUM_TIMEFRAMES timeframe = (CHART_PERIOD==PERIOD_CURRENT ? Period() : CHART_PERIOI

//--- open a new chart with the specified symbol and period
   long chart_id=ChartOpen(symbol, timeframe);
   if(chart_id==0)
     {
      Print("ChartOpen() failed. Error ", GetLastError());
      return;
     }
```

© 2000-2025, MetaQuotes Ltd.

```
//--- print open chart parameters in the journal
   PrintFormat("A new chart of the %s symbol has been opened with a period of %s and C
               symbol, StringSubstr(EnumToString(timeframe), 7), chart_id);
   /*
   result:
   A new chart of the GBPUSD symbol has been opened with a period of M1 and ChartID 13
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartFirst

Returns the ID of the first chart of the client terminal.

```
long  ChartFirst();
```

Return Value

Chart ID.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the ID of the very first chart opened in the client terminal
   long            chart_id= ChartFirst();

//--- additionally get the chart symbol and period using the obtained ID
   string          symbol  = ChartSymbol(chart_id);
   ENUM_TIMEFRAMES period  = ChartPeriod(chart_id);

//--- display the description of the client terminal first chart in the journal
   PrintFormat("ID of the first chart of the client terminal: %I64d, chart symbol: %s,
   /*
   result:
   ID of the first chart of the client terminal: 133246248352168440, chart symbol: EUR
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartNext

Returns the chart ID of the chart next to the specified one.

```
long  ChartNext(
   long  chart_id      // Chart ID
   );
```

Parameters

chart_id

[in] Chart ID. 0 does not mean the current chart. 0 means "return the first chart ID".

Return Value

Chart ID. If this is the end of the chart list, it returns -1.

Example:

```
//--- variables for chart ID
   long currChart,prevChart=ChartFirst();
   int i=0,limit=100;
   Print("ChartFirst =",ChartSymbol(prevChart)," ID =",prevChart);
   while(i<limit)// We have certainly not more than 100 open charts
     {
      currChart=ChartNext(prevChart); // Get the new chart ID by using the previous ch
      if(currChart<0) break;          // Have reached the end of the chart list
      Print(i,ChartSymbol(currChart)," ID =",currChart);
      prevChart=currChart;// let's save the current chart ID for the ChartNext()
      i++;// Do not forget to increase the counter
     }
```

© 2000-2025, MetaQuotes Ltd.

ChartClose

Closes the specified chart.

```
bool  ChartClose(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

If successful, returns true, otherwise false.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- open a new chart with the same symbol and period as the current one
   long chart_id=ChartOpen(_Symbol, _Period);
   if(chart_id==0)
     {
      Print("ChartOpen() failed. Error ", GetLastError());
      return;
     }

//--- print open chart parameters in the journal
   PrintFormat("A new chart of the %s symbol has been opened with a period of %s and C
               _Symbol, StringSubstr(EnumToString(_Period), 7), chart_id);

//--- wait two seconds and close the newly opened chart
   PrintFormat("Waiting 3 seconds before closing a newly opened chart with ID %I64d ..
   Sleep(3000);
   ResetLastError();
   if(!ChartClose(chart_id))
     {
      Print("ChartClose() failed. Error ", GetLastError());
      return;
     }

//--- print successful chart closure message in the journal
   PrintFormat("The chart with ID %I64d was successfully closed", chart_id);
   /*
   result:
   A new chart of the GBPUSD symbol has been opened with a period of M1 and ChartID 1
```

© 2000-2025, MetaQuotes Ltd.

```
   Waiting 3 seconds before closing a newly opened chart with ID 133346697706632016 ..
   The chart with ID 133346697706632016 was successfully closed
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartSymbol

Returns the symbol name for the specified chart.

```
string  ChartSymbol(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

If chart does not exist, the result will be an empty string.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart symbol and display the obtained value in the journal
   string chart_symbol = ChartSymbol();
   Print("Current chart symbol: ", chart_symbol);

//--- take the existing (in this case, the current) chart ID
   long chart_id=ChartID();
   chart_symbol=ChartSymbol(chart_id);
   PrintFormat("Chart symbol with ID %I64d: %s", chart_id, chart_symbol);

//--- set a random chart ID when receiving a symbol
   chart_symbol = ChartSymbol(1234567890);
   if(chart_symbol=="")
      Print("The chart with ID 1234567890 does not exist");
   else
      Print("Chart symbol with ID 1234567890: ", chart_symbol);
   /*
   result:
   Current chart symbol: GBPUSD
   Chart symbol with ID 132966427583395104: GBPUSD
   The chart with ID 1234567890 does not exist
   */
  }
```

ChartSetSymbolPeriod

© 2000-2025, MetaQuotes Ltd.

ChartPeriod

Returns the timeframe period of specified chart.

```
ENUM_TIMEFRAMES  ChartPeriod(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Return Value

The function returns one of the ENUM_TIMEFRAMES values. If chart does not exist, it returns 0.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart period and display the obtained value in the journal
   ENUM_TIMEFRAMES period=ChartPeriod();
   Print("Current chart period: ", EnumToString(period));

//--- take the existing (in this case, the current) chart ID
   long chart_id=ChartID();
   period=ChartPeriod(chart_id);
   PrintFormat("Chart period with ID %I64d: %s", chart_id, EnumToString(period));

//--- set a random chart ID
   period=ChartPeriod(1234567890);
   if(period==0)
      Print("The chart with ID 1234567890 does not exist");
   else
      Print("Chart period with ID 1234567890: ", EnumToString(period));
   /*
   result:
   Current chart period: PERIOD_M15
   Chart period with ID 133510090240498505: PERIOD_M15
   The chart with ID 1234567890 does not exist
   */
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartRedraw

This function calls a forced redrawing of a specified chart.

```
void  ChartRedraw(
   long  chart_id=0      // Chart ID
   );
```

Parameters

chart_id=0

[in] Chart ID. 0 means the current chart.

Note

Usually it is used after changing the object properties.

Example:

```
#define   WIDTH      50    // rectangle width in bars

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart ID and set the graphical object name
   long   chart_id = ChartID();
   string obj_name = MQLInfoString(MQL_PROGRAM_NAME)+"_RectLabel";

//--- get two rectangle time coordinates
   datetime time1  = iTime(_Symbol, _Period, WIDTH);
   datetime time2  = iTime(_Symbol, _Period, 0);
   if(time1==0 || time2==0)
     {
      Print("Error getting time ", GetLastError());
      return;
     }

//--- get the maximum and minimum prices in the range of the rectangle width
   double price1 = HighestHigh(_Symbol, _Period, 0, WIDTH);
   double price2 = LowestLow(_Symbol, _Period, 0, WIDTH);
   if(price1==EMPTY_VALUE || price2==EMPTY_VALUE)
      return;

//--- create a rectangle object
   Print("Create a wheat-colored rectangle");
   if(!ObjectCreate(chart_id, obj_name, OBJ_RECTANGLE, 0, time1, price1, time2, price2

Objects functions

© 2000-2025, MetaQuotes Ltd.

ChartSetDouble

Sets a value for a corresponding property of the specified chart. Chart property should be of a double type. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetDouble(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE     prop_id,       // Property ID
   double                         value          // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. Can be one of the ENUM_CHART_PROPERTY_DOUBLE values (except the read-only properties).

value

[in] Property value.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart ID
   long chart_id = ChartID();
```

© 2000-2025, MetaQuotes Ltd.

```
//--- save the initial offset of the zero bar from the right edge in percentage and th
   double shift = ChartGetDouble(chart_id, CHART_SHIFT_SIZE);
   bool   scroll= ChartGetInteger(chart_id,CHART_AUTOSCROLL);

//--- reset the auto scroll chart flag
   ChartSetInteger(chart_id, CHART_AUTOSCROLL, true);
   PrintFormat("Initial chart shift size: %.2f", shift);

//--- in the loop from 2.0% to 50.0% with the step of 0.5%
   for(int i=20; i<=500; i+=5)
     {
      //--- set the shift size as i / 10 and print the specified value in the journal
      ChartSetDouble(chart_id, CHART_SHIFT_SIZE, i/10.0);
      PrintFormat("Set chart shift size to %.1f%%", i/10.0);

      //--- keep the chart zero bar at the specified shift distance
      ChartNavigate(chart_id, CHART_END, 0);

      //--- wait a bit
      Sleep(16);
     }

//--- set the initial chart shift and auto scroll
   Print("Set the chart shift size to the initial value of ", shift);
   ChartSetDouble(ChartID(), CHART_SHIFT_SIZE, shift);
   ChartSetInteger(chart_id, CHART_AUTOSCROLL, scroll);
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartSetInteger

Sets a value for a corresponding property of the specified chart. Chart property must be datetime, int, color, bool or char. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetInteger(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_INTEGER    prop_id,       // Property ID
   long                           value          // Value
   );
```

Sets a value for a corresponding property of the specified subwindow.

```
bool  ChartSetInteger(
   long                           chart_id,      // Chart ID
   ENUM_CHART_PROPERTY_INTEGER    prop_id,       // Property ID
   int                            sub_window,    // Subwindow number
   long                           value          // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. It can be one of the ENUM_CHART_PROPERTY_INTEGER value (except the read-only properties).

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

value

[in] Property value.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

© 2000-2025, MetaQuotes Ltd.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

Example:

```
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- Enabling events of mouse movements on the chart window
   ChartSetInteger(0,CHART_EVENT_MOUSE_MOVE,1);
//--- Forced updating of chart properties ensures readiness for event processing
   ChartRedraw();
  }
//+------------------------------------------------------------------+
//| MouseState                                                       |
//+------------------------------------------------------------------+
string MouseState(uint state)
  {
   string res;
   res+="\nML: "   +(((state& 1)== 1)?"DN":"UP");   // mouse left
   res+="\nMR: "   +(((state& 2)== 2)?"DN":"UP");   // mouse right
   res+="\nMM: "   +(((state&16)==16)?"DN":"UP");   // mouse middle
   res+="\nMX: "   +(((state&32)==32)?"DN":"UP");   // mouse first X key
   res+="\nMY: "   +(((state&64)==64)?"DN":"UP");   // mouse second X key
   res+="\nSHIFT: "+(((state& 4)== 4)?"DN":"UP");   // shift key
   res+="\nCTRL: " +(((state& 8)== 8)?"DN":"UP");   // control key
   return(res);
  }
//+------------------------------------------------------------------+
//| ChartEvent function                                              |
//+------------------------------------------------------------------+
void OnChartEvent(const int id,const long &lparam,const double &dparam,const string &s
  {
   if(id==CHARTEVENT_MOUSE_MOVE)
      Comment("POINT: ",(int)lparam,",",(int)dparam,"\n",MouseState((uint)sparam));
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartSetString

Sets a value for a corresponding property of the specified chart. Chart property must be of the string type. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetString(
   long                          chart_id,     // Chart ID
   ENUM_CHART_PROPERTY_STRING    prop_id,      // Property ID
   string                        str_value     // Value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. Its value can be one of the ENUM_CHART_PROPERTY_STRING values (except the read-only properties).

str_value

[in] Property value string. String length cannot exceed 2045 characters (extra characters will be truncated).

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

ChartSetString can be used for a comment output on the chart instead of the Comment function.

The function is asynchronous, which means that the function does not wait for the execution of the command, which has been successfully added to the queue of specified the chart. Instead, it immediately returns control. The property will only change after the handling of the appropriate command from the chart queue. To immediately execute commands from the chart queue, call the ChartRedraw function.

If you want to immediately change several chart properties at once, then the corresponding functions (ChartSetString, ChartSetDouble, ChartSetString) should be executed in one code block, after which you should call ChartRedraw once.

To check the command execution result, you can use a function, which requests the specified chart property (ChartGetInteger, ChartGetDouble, ChartSetString). However, note that these functions are synchronous and wait for execution results.

Example:

```
void OnTick()
  {
//---
   double Ask,Bid;
```

© 2000-2025, MetaQuotes Ltd.

```
   int Spread;
   Ask=SymbolInfoDouble(Symbol(),SYMBOL_ASK);
   Bid=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   Spread=SymbolInfoInteger(Symbol(),SYMBOL_SPREAD);
   string comment=StringFormat("Display prices:\nAsk = %G\nBid = %G\nSpread = %d",
                               Ask,Bid,Spread);
   ChartSetString(0,CHART_COMMENT,comment);
  }
```

ChartGetDouble

Returns the value of a corresponding property of the specified chart. Chart property must be of double type. There are 2 variants of the function calls.

1. Returns the property value directly.

```
double  ChartGetDouble(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE    prop_id,           // Property ID
   int                           sub_window=0       // subwindow number, if necessary
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable double_var passed by reference.

```
bool  ChartGetDouble(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_DOUBLE    prop_id,           // Property ID
   int                           sub_window,      // Subwindow number
   double&                       double_var       // Target variable for the chart prop
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_DOUBLE values.

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

double_var

[out] Target variable of double type for the requested property.

Return Value

The value of double type.

For the second call case it returns true if the specified property is available and its value has been placed into double_var variable, otherwise returns false. To get an additional information about the error, it is necessary to call the function GetLastError().

Note

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
{
 double priceMin=ChartGetDouble(0,CHART_PRICE_MIN,0);
 double priceMax=ChartGetDouble(0,CHART_PRICE_MAX,0);
 Print("CHART_PRICE_MIN =",priceMin);
 Print("CHART_PRICE_MAX =",priceMax);
}
```

© 2000-2025, MetaQuotes Ltd.

ChartGetInteger

Returns the value of a corresponding property of the specified chart. Chart property must be of datetime, int or bool type. There are 2 variants of the function calls.

1. Returns the property value directly.

```
long  ChartGetInteger(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_INTEGER   prop_id,           // Property ID
   int                           sub_window=0       // subwindow number, if necessary
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable long_var passed by reference.

```
bool  ChartGetInteger(
   long                          chart_id,          // Chart ID
   ENUM_CHART_PROPERTY_INTEGER   prop_id,           // Property ID
   int                           sub_window=0       // subwindow number
   long&                         long_var           // Target variable for the propert
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_INTEGER values.

sub_window

[in] Number of the chart subwindow. For the first case, the default value is 0 (main chart window). The most of the properties do not require a subwindow number.

long_var

[out] Target variable of long type for the requested property.

Return Value

The value of long type.

For the second call case it returns true if specified property is available and its value has been stored into long_var variable, otherwise returns false. To get additional information about the error, it is necessary to call the function GetLastError().

Note

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
{
 int height=ChartGetInteger(0,CHART_HEIGHT_IN_PIXELS,0);
 int width=ChartGetInteger(0,CHART_WIDTH_IN_PIXELS,0);
 Print("CHART_HEIGHT_IN_PIXELS =",height,"pixels");
 Print("CHART_WIDTH_IN_PIXELS =",width,"pixels");
}
```

© 2000-2025, MetaQuotes Ltd.

ChartGetString

Returns the value of a corresponding property of the specified chart. Chart property must be of string type. There are 2 variants of the function call.

1. Returns the property value directly.

```
string  ChartGetString(
   long                        chart_id,         // Chart ID
   ENUM_CHART_PROPERTY_STRING  prop_id           // Property ID
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable string_var passed by reference.

```
bool  ChartGetString(
   long                        chart_id,         // Chart ID
   ENUM_CHART_PROPERTY_STRING  prop_id,          // Property ID
   string&                     string_var        // Target variable for the property
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

prop_id

[in] Chart property ID. This value can be one of the ENUM_CHART_PROPERTY_STRING values.

string_var

[out] Target variable of string type for the requested property.

Return Value

The value of string type.

For the second call case it returns true if the specified property is available and its value has been stored into string_var variable, otherwise returns false. To get additional information about the error, it is necessary to call the function GetLastError().

Note

ChartGetString can be used for reading comments plotted on the chart using the Comment or ChartSetString functions.

The function is synchronous, which means that it waits for the execution of all the commands that have been added to the chart queue prior to its call.

Example:

```
void OnStart()
  {
   ChartSetString(0,CHART_COMMENT,"Test comment.\nSecond line.\nThird!");
   ChartRedraw();
```

© 2000-2025, MetaQuotes Ltd.

```
   Sleep(1000);
   string comm=ChartGetString(0,CHART_COMMENT);
   Print(comm);
  }
```

See also

Comment, ChartSetString

© 2000-2025, MetaQuotes Ltd.

ChartNavigate

Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart.

```
bool  ChartNavigate(
   long                  chart_id,      // Chart ID
   ENUM_CHART_POSITION   position,      // Position
   int                   shift=0        // Shift value
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

position

[in] Chart position to perform a shift. Can be one of the ENUM_CHART_POSITION values.

shift=0

[in] Number of bars to shift the chart. Positive value means the right shift (to the end of chart), negative value means the left shift (to the beginning of chart). The zero shift can be used to navigate to the beginning or end of chart.

Return Value

Returns true if successful, otherwise returns false.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get handle of the current chart
   long handle=ChartID();
   string comm="";
   if(handle>0) // if successful, additionally set up the chart
     {
      //--- disable auto scroll
      ChartSetInteger(handle,CHART_AUTOSCROLL,false);
      //--- set a shift from the right chart border
      ChartSetInteger(handle,CHART_SHIFT,true);
      //--- draw candlesticks
      ChartSetInteger(handle,CHART_MODE,CHART_CANDLES);
      //--- set the display mode for tick volumes
      ChartSetInteger(handle,CHART_SHOW_VOLUMES,CHART_VOLUME_TICK);

      //--- prepare a text to output in Comment()
      comm="Scroll 10 bars to the right of the history start";
      //--- show comment
```

© 2000-2025, MetaQuotes Ltd.

```
   Comment(comm);
   //--- scroll 10 bars to the right of the history start
   ChartNavigate(handle,CHART_BEGIN,10);
   //--- get the number of the first bar visible on the chart (numeration like in t
   long first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   //--- add line feed character
   comm=comm+"\r\n";
   //--- add to comment
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   //--- show comment
   Comment(comm);
   //--- wait 5 seconds to see how the chart moves
   Sleep(5000);

   //--- add to the comment text
   comm=comm+"\r\n"+"Scroll 10 bars to the left of the right chart border";
   Comment(comm);
   //--- scroll 10 bars to the left of the right chart border
   ChartNavigate(handle,CHART_END,-10);
   //--- get the number of the first bar visible on the chart (numeration like in t
   first_bar=ChartGetInteger(0,CHART_FIRST_VISIBLE_BAR,0);
   comm=comm+"\r\n";
   comm=comm+"The first bar on the chart is number "+IntegerToString(first_bar)+"\r
   Comment(comm);

```

© 2000-2025, MetaQuotes Ltd.

ChartID

Returns the ID of the current chart.

```
long  ChartID();
```

Return Value

Value of long type.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- variables for chart identifiers
   long curr_chart=ChartFirst();
   int i=0;
   //--- print the first chart data in the journal
   PrintFormat("Chart[%d] ID: %I64d,  symbol: %s", i, curr_chart, ChartSymbol(curr_cha

//--- until the open chart limit is reached (CHARTS_MAX)
   while(!IsStopped() && i < CHARTS_MAX)
     {
      //--- increase the chart counter
      i++;
      //--- get the next chart ID based on the previous one
      curr_chart=ChartNext(curr_chart);

      //--- terminate the loop if the end of the chart list is reached
      if(curr_chart<0)
         break;

      //--- print the next chart data in the journal
      PrintFormat("Chart[%d] ID: %I64d,  symbol: %s", i, curr_chart, ChartSymbol(curr_
     }
   /*
   result:

```
}
```

© 2000-2025, MetaQuotes Ltd.

ChartIndicatorAdd

Adds an indicator with the specified handle into a specified chart window. Indicator and chart should be generated on the same symbol and time frame.

```
bool  ChartIndicatorAdd(
   long  chart_id,                  // chart ID
   int   sub_window                 // number of the sub-window
   int   indicator_handle           // handle of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart sub-window. 0 means the main chart window. To add an indicator in a new window, the parameter must be one greater than the index of the last existing window, i.e. equal to CHART_WINDOWS_TOTAL. If the value of the parameter is greater than CHART_WINDOWS_TOTAL, a new window will not be created, and the indicator will not be added.

indicator_handle

[in] The handle of the indicator.

Return Value

The function returns true in case of success, otherwise it returns false. In order to obtain information about the error, call the GetLastError() function. Error 4114 means that a chart and an added indicator differ by their symbol or time frame.

Note

If an indicator that should be drawn in a separate subwindow (for example, built-in iMACD or a custom indicator with specified #property indicator_separate_window property) is applied to the main chart window, it may not be visible though it will still be present in the list of indicators. This means that the scale of the indicator is different from the scale of the price chart, and applied indicator's values do not fit in the displayed range of the price chart. In this case, GetLastError() returns zero code indicating the absence of an error. The values of such "invisible" indicator can be seen in Data Window and received from other MQL5 applications.

Example:

```
#property description "Expert Advisor demonstrating the work with ChartIndicatorAdd()
#property description "After launching on the chart (and receiving the error in Journa
#property description "the Expert Advisor's properties and specify correct <symbol> ar
#property description "MACD indicator will be added on the chart."

//--- input parameters
input string          symbol="AUDUSD";     // symbol name

ChartIndicatorDelete

Removes an indicator with a specified name from the specified chart window.

```
bool  ChartIndicatorDelete(
   long           chart_id,              // chart id
   int            sub_window             // number of the subwindow
   const string   indicator_shortname    // short name of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

const indicator_shortname

[in] The short name of the indicator which is set in the INDICATOR_SHORTNAME property with the IndicatorSetString() function. To get the short name of an indicator use the ChartIndicatorName() function.

Return Value

Returns true in case of successful deletion of the indicator. Otherwise it returns false. To get error details use the GetLastError() function.

Note

If two indicators with identical short names exist in the chart subwindow, the first one in a row will be deleted.

If other indicators on this chart are based on the values of the indicator that is being deleted, such indicators will also be deleted.

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions iCustom() and IndicatorCreate(). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

Deletion of an indicator from a chart doesn't mean that its calculation part will be deleted from the terminal memory. To release the indicator handle use the IndicatorRelease() function.

The indicator's short name should be formed correctly. It will be written to the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the ChartIndicatorDelete() function is identified by the short name.

Example of deleting an indicator after initialization has failed:

```
//+------------------------------------------------------------------+

ChartIndicatorGet

Returns the handle of the indicator with the specified short name in the specified chart window.

```
int  ChartIndicatorGet(
   long           chart_id,              // Chart ID
   int            sub_window             // The number of the subwindow
   const string   indicator_shortname    // Short name of the indicator
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

sub_window

[in] The number of the chart subwindow. 0 means the main chart window.

const indicator_shortname

[in] The short name if the indicator, which is set in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. To get the short name of an indicator, use the ChartIndicatorName() function.

Return Value

Returns an indicator handle if successful, otherwise returns INVALID_HANDLE. To get information about the error, call the GetLastError() function.

Note

The indicator handle obtained using the ChartIndicatorGet() function increases the internal indicator usage counter. The terminal runtime system keeps all indicators, whose counter is greater than zero, loaded. Therefore, the indicator handle that is no longer needed should be immediately and explicitly released using IndicatorRelease() in the same program that received it, as shown in the example below. Otherwise, it will be impossible to find the “abandoned” handle and release it from another program correctly.

When creating an indicator, be careful forming its short name, which is written in the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that a short name should contain the values of input parameters of the indicator, since the indicator is identified in the ChartIndicatorGet() function based on its short name.

Another way to identify the indicator is to get a list of its parameters for a given handle using the IndicatorParameters() function and then to analyze the obtained values.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   //--- The number of windows on the chart (at least one main window is always preser
   int windows=(int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- Check all windows
   for(int w=0;w<windows;w++)
     {
      //--- the number of indicators in this window/subwindow
      int total=ChartIndicatorsTotal(0,w);
      //--- Go through all indicators in the window
      for(int i=0;i<total;i++)
        {
         //--- get the short name of an indicator
         string name=ChartIndicatorName(0,w,i);
         //--- get the handle of an indicator
         int handle=ChartIndicatorGet(0,w,name);
         //--- Add to log
         PrintFormat("Window=%d,  index=%d,  name=%s,  handle=%d",w,i,name,handle);
         //--- You should obligatorily release the indicator handle when it is no long
         IndicatorRelease(handle);
        }
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

ChartIndicatorName

Returns the short name of the indicator by the number in the indicators list on the specified chart window.

```
string  ChartIndicatorName(
   long  chart_id,       // chart id
   int   sub_window      // number of the subwindow
   int   index           // index of the indicator in the list of indicators added to t
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

index

[in] the index of the indicator in the list of indicators. The numeration of indicators start with zero, i.e. the first indicator in the list has the 0 index. To obtain the number of indicators in the list use the ChartIndicatorsTotal() function.

Return Value

The short name of the indicator which is set in the INDICATOR_SHORTNAME property with the IndicatorSetString() function. To get error details use the GetLastError() function.

Note

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions iCustom() and IndicatorCreate(). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

The indicator's short name should be formed correctly. It will be written to the INDICATOR_SHORTNAME property using the IndicatorSetString() function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the ChartIndicatorDelete() function is identified by the short name.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart ID and the number of its subwindows, including the main w
   long chart_id = ChartID();
   int  wnd_total= (int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- iterate over all current chart windows in a loop
   for(int w=0; w<wnd_total; w++)
     {
      //--- get the number of indicators attached to the chart window specified by the
      int ind_total=ChartIndicatorsTotal(chart_id, w);

      //--- print the header for the selected chart window
      PrintFormat("Chart window %d indicators: ", w);

      //--- get in the loop and write to the variable all the names of indicators atta
      string ind_names="";
      for(int i=0; i<ind_total; i++)
        {
         ind_names+="  "+ChartIndicatorName(chart_id, w, i)+(i<ind_total-1 ? "\n": "")
        }
      //--- print the obtained list of names of all indicators, attached to the speci
      Print(ind_names);
     }
   /*
   result:
   Chart window 0 indicators:
     AMA(9,2,30)
     SAR(0.02,0.20)
     Fractals
   Chart window 1 indicators:
     RSI(14)
     AMA(9,2,30)
   Chart window 2 indicators:
     MFI(14)
   */
  }
```

ChartIndicatorsTotal

Returns the number of all indicators applied to the specified chart window.

```
int  ChartIndicatorsTotal(
   long  chart_id,       // chart id
   int   sub_window      // number of the subwindow
   );
```

Parameters

chart_id

[in] Chart ID. 0 denotes the current chart.

sub_window

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

Return Value

The number of indicators in the specified chart window. To get error details use the GetLastError() function.

Note

The function allows going searching through all the indicators attached to the chart. The number of all the windows of the chart can be obtained from the CHART_WINDOWS_TOTAL property using the ChartGetInteger() function.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart ID and the number of its subwindows, including the main wi
   long chart_id = ChartID();
   int  wnd_total= (int)ChartGetInteger(0,CHART_WINDOWS_TOTAL);

//--- iterate over all current chart windows in a loop
   for(int w=0; w<wnd_total; w++)
     {
      //--- get the number of indicators attached to the chart window specified by the
      int ind_total=ChartIndicatorsTotal(chart_id, w);

      //--- get the number of indicators attached to the specified chart window
      PrintFormat("Chart ID %I64d, subwindow %d. Attached indicators: %d", chart_id, w
     }
   /*
   result:
   Chart ID 133246248352168439, subwindow 0. Attached indicators: 3
   Chart ID 133246248352168439, subwindow 1. Attached indicators: 2
```

© 2000-2025, MetaQuotes Ltd.

```
   Chart ID 133246248352168439, subwindow 2. Attached indicators: 1
   */
  }
```

ChartWindowOnDropped

Returns the number (index) of the chart subwindow the Expert Advisor or script has been dropped to. 0 means the main chart window.

```
int  ChartWindowOnDropped();
```

Return Value

Value of int type.

Example:

```
   int myWindow=ChartWindowOnDropped();
   int windowsTotal=ChartGetInteger(0,CHART_WINDOWS_TOTAL);
   Print("Script is running on the window #"+myWindow+
         ". Total windows on the chart "+ChartSymbol()+":",windowsTotal);
```

ChartPriceOnDropped, ChartTimeOnDropped, ChartXOnDropped, ChartYOnDropped

© 2000-2025, MetaQuotes Ltd.

ChartPriceOnDropped

Returns the price coordinate corresponding to the chart point the Expert Advisor or script has been dropped to.

```
double  ChartPriceOnDropped();
```

Return Value

Value of double type.

Example:

```
   double p=ChartPriceOnDropped();
   Print("ChartPriceOnDropped() = ",p);
```

See also

ChartXOnDropped, ChartYOnDropped

© 2000-2025, MetaQuotes Ltd.

ChartTimeOnDropped

Returns the time coordinate corresponding to the chart point the Expert Advisor or script has been dropped to.

```
datetime  ChartTimeOnDropped();
```

Return Value

Value of datetime type.

Example:

```
   datetime t=ChartTimeOnDropped();
   Print("Script was dropped on the "+t);
```

See also

ChartXOnDropped, ChartYOnDropped

© 2000-2025, MetaQuotes Ltd.

ChartXOnDropped

Returns the X coordinate of the chart point the Expert Advisor or script has been dropped to.

```
int  ChartXOnDropped();
```

Return Value

The X coordinate value.

Note

X axis direction from left to right.

Example:

```
   int X=ChartXOnDropped();
   int Y=ChartYOnDropped();
   Print("(X,Y) = ("+X+","+Y+")");
```

See also

ChartWindowOnDropped, ChartPriceOnDropped, ChartTimeOnDropped

© 2000-2025, MetaQuotes Ltd.

ChartYOnDropped

Returns the Y coordinateof the chart point the Expert Advisor or script has been dropped to.

```
int  ChartYOnDropped();
```

Return Value

The Y coordinate value.

Note

Y axis direction from top to bottom.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get and print the X and Y coordinates of the chart point the script was dropped
   int x=ChartXOnDropped();
   int y=ChartYOnDropped();
   PrintFormat("Script dropped to coordinates X = %d, Y = %d", x, y);
   /*
   result:
   Script dropped to coordinates X = 429, Y = 114
   */
  }
```

ChartSetSymbolPeriod

Changes the symbol and period of the specified chart. The function is asynchronous, i.e. it sends the command and does not wait for its execution completion. The command is added to chart messages queue and will be executed after processing of all previous commands.

```
bool  ChartSetSymbolPeriod(
   long             chart_id,      // Chart ID
   string           symbol,        // Symbol name
   ENUM_TIMEFRAMES  period         // Period
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

symbol

[in] Chart symbol. NULL value means the current chart symbol (Expert Advisor is attached to)

period

[in] Chart period (timeframe). Can be one of the ENUM_TIMEFRAMES values. 0 means the current chart period.

Return Value

Returns true if the command has been added to chart queue, otherwise false. To get an information about the error, call the GetLastError() function.

Note

The symbol/period change leads to the re-initialization of the Expert Advisor attached to a chart.

The call of ChartSetSymbolPeriod with the same symbol and timeframe can be used to update the chart (similar to the terminal's Refresh command). In its turn, the chart update triggers re-calculation of the indicators attached to it. Thus, you are able to calculate an indicator on the chart even if there are no ticks (e.g., on weekends).

Example:

```
#define   SYMBOL    "GBPUSD"
#define   PERIOD    PERIOD_H1

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the current chart ID, symbol and period
   long            chart_id= ChartID();
   string          symbol  = Symbol();
   ENUM_TIMEFRAMES period  = Period();
```

© 2000-2025, MetaQuotes Ltd.

```
//--- report in the journal on replacing the current chart symbol and period with the
   PrintFormat("Change the %s symbol and the %s period of the chart %I64u to %s %s",
               symbol, TimeframeDescrioption(period), chart_id, SYMBOL, TimeframeDesc

//--- change the chart symbol and period
   ChartSetSymbolPeriod(chart_id, SYMBOL, PERIOD);
   /*
   result:
   Change the EURUSD symbol and the M1 period of the chart 133246248352168440 to GBPUS
   */
  }
//+------------------------------------------------------------------+
//| Return the chart period description                              |
//+------------------------------------------------------------------+

ChartScreenShot

The function provides a screenshot of the chart in its current state in the GIF, PNG or BMP format depending on specified extension.

```
bool  ChartScreenShot(
   long             chart_id,                  // Chart ID
   string           filename,                  // Symbol name
   int              width,                     // Width
   int              height,                    // Height
   ENUM_ALIGN_MODE  align_mode=ALIGN_RIGHT     // Alignment type
   );
```

Parameters

chart_id

[in] Chart ID. 0 means the current chart.

filename

[in] Screenshot file name. Cannot exceed 63 characters. Screenshot files are placed in the \Files directory.

width

[in] Screenshot width in pixels.

height

[in] Screenshot height in pixels.

align_mode=ALIGN_RIGHT

[in] Output mode of a narrow screenshot. A value of the ENUM_ALIGN_MODE enumeration. ALIGN_RIGHT means align to the right margin (the output from the end). ALIGN_LEFT means Left justify.

Return Value

Returns true if successful, otherwise false.

Note

If you need to take a screenshot from a chart from a certain position, first it's necessary to position the graph using the ChartNavigate() function. If the horizontal size of the screenshot is smaller than the chart window, either the right part of the chart window, or its left part is output, depending on the align_mode settings.

Example:

```
#property description "The Expert Advisor demonstrates how to create a series of scree
#property description "chart using the ChartScreenShot() function. For convenience, th

Trade Functions

This is the group of functions intended for managing trading activities.

Before you proceed to study the trade functions of the platform, you must have a clear understanding of the basic terms: order, deal and position:

- An order is an instruction given to a broker to buy or sell a financial instrument. There are two main types of orders: Market and Pending. In addition, there are special Take Profit and Stop Loss levels.
- A deal is the commercial exchange (buying or selling) of a financial security. Buying is executed at the demand price (Ask), and Sell is performed at the supply price (Bid). A deal can be opened as a result of market order execution or pending order triggering. Note that in some cases, execution of an order can result in several deals.
- A position is a trade obligation, i.e. the number of bought or sold contracts of a financial instrument. A long position is financial security bought expecting the security price go higher. A short position is an obligation to supply a security expecting the price will fall in future.

General information about trading operations is available in the client terminal help.

Trading functions can be used in Expert Advisors and scripts. Trading functions can be called only if in the properties of the Expert Advisor or script the "Allow live trading" checkbox is enabled.

Trading can be allowed or prohibited depending on various factors described in the Trade Permission section.

Function	Action
OrderCalcMargin	Calculates the margin required for the specified order type, in the deposit currency
OrderCalcProfit	Calculates the profit based on the parameters passed, in the deposit currency
OrderCheck	Checks if there are enough funds to execute the required trade operation.
OrderSend	Sends trade requests to a server
OrderSendAsync	Asynchronously sends trade requests without waiting for the trade response of the trade server
PositionsTotal	Returns the number of open positions
PositionGetSymbol	Returns the symbol corresponding to the open position
PositionSelect	Chooses an open position for further working with it
PositionSelectByTicket	Selects a position to work with by the ticket number specified in it
PositionGetDouble	Returns the requested property of an open position (double)
PositionGetInteger	Returns the requested property of an open position (datetime or int)
PositionGetString	Returns the requested property of an open position (string)

© 2000-2025, MetaQuotes Ltd.

Function	Action
PositionGetTicket	Returns the ticket of the position with the specified index in the list of open positions
OrdersTotal	Returns the number of orders
OrderGetTicket	Return the ticket of a corresponding order
OrderSelect	Selects a order for further working with it
OrderGetDouble	Returns the requested property of the order (double)
OrderGetInteger	Returns the requested property of the order (datetime or int)
OrderGetString	Returns the requested property of the order (string)
HistorySelect	Retrieves the history of transactions and orders for the specified period of the server time
HistorySelectByPosition	Requests the history of deals with a specified position identifier.
HistoryOrderSelect	Selects an order in the history for further working with it
HistoryOrdersTotal	Returns the number of orders in the history
HistoryOrderGetTicket	Return order ticket of a corresponding order in the history
HistoryOrderGetDouble	Returns the requested property of an order in the history (double)
HistoryOrderGetInteger	Returns the requested property of an order in the history (datetime or int)
HistoryOrderGetString	Returns the requested property of an order in the history (string)
HistoryDealSelect	Selects a deal in the history for further calling it through appropriate functions
HistoryDealsTotal	Returns the number of deals in the history
HistoryDealGetTicket	Returns a ticket of a corresponding deal in the history
HistoryDealGetDouble	Returns the requested property of a deal in the history (double)
HistoryDealGetInteger	Returns the requested property of a deal in the history (datetime or int)
HistoryDealGetString	Returns the requested property of a deal in the history (string)

OrderCalcMargin

The function calculates the margin required for the specified order type, on the current account, in the current market environment not taking into account current pending orders and open positions. It allows the evaluation of margin for the trade operation planned. The value is returned in the account currency.

```
bool  OrderCalcMargin(
   ENUM_ORDER_TYPE       action,           // type of order
   string                symbol,           // symbol name
   double                volume,           // volume
   double                price,            // open price
   double&               margin            // variable for obtaining the margin value
   );
```

Parameters

action

[in] The order type, can be one of the values of the ENUM_ORDER_TYPE enumeration.

symbol

[in] Symbol name.

volume

[in] Volume of the trade operation.

price

[in] Open price.

margin

[out] The variable, to which the value of the required margin will be written in case the function is successfully executed. The calculation is performed as if there were no pending orders and open positions on the current account. The margin value depends on many factors, and can differ in different market environments.

Return Value

The function returns true in case of success; otherwise it returns false. In order to obtain information about the error, call the GetLastError() function.

Example:

```
#define   VOLUME     1.0   // order volume
#define   DEVIATION  100   // distance for setting a pending order
#define   STOP_LIMIT 50    // order StopLimit distance

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string currency=AccountInfoString(ACCOUNT_CURRENCY);
```

OrderCalcProfit

The function calculates the profit for the current account, in the current market conditions, based on the parameters passed. The function is used for pre-evaluation of the result of a trade operation. The value is returned in the account currency.

```
bool  OrderCalcProfit(
   ENUM_ORDER_TYPE       action,          // type of the order (ORDER_TYPE_BUY or ORI
   string                symbol,          // symbol name
   double                volume,          // volume
   double                price_open,      // open price
   double                price_close,     // close price
   double&               profit           // variable for obtaining the profit value
   );
```

Parameters

action

[in] Type of the order, can be one of the two values of the ENUM_ORDER_TYPE enumeration: ORDER_TYPE_BUY or ORDER_TYPE_SELL.

symbol

[in] Symbol name.

volume

[in] Volume of the trade operation.

price_open

[in] Open price.

price_close

[in] Close price.

profit

[out] The variable, to which the calculated value of the profit will be written in case the function is successfully executed. The estimated profit value depends on many factors, and can differ in different market environments.

Return Value

The function returns true in case of success; otherwise it returns false. If an invalid order type is specified, the function will return false. In order to obtain information about the error, call GetLastError().

Example:

```
#define   VOLUME     1.0   // order volume
#define   DEVIATION  100   // number of points before the close price

//+------------------------------------------------------------------+
//| Script program start function                                    |

OrderCheck

The OrderCheck() function checks if there are enough money to execute a required trade operation. The check results are placed to the fields of the MqlTradeCheckResult structure.

```
bool  OrderCheck(
   MqlTradeRequest&        request,      // request structure
   MqlTradeCheckResult&    result        // result structure
   );
```

Parameters

request

[in] Pointer to the structure of the MqlTradeRequest type, which describes the required trade action.

result

[in,out] Pointer to the structure of the MqlTradeCheckResult type, to which the check result will be placed.

Return Value

If funds are not enough for the operation, or parameters are filled out incorrectly, the function returns false. In case of a successful basic check of structures (check of pointers), it returns true. **However, this is not an indication that the requested trade operation is sure to be successfully executed**. For a more detailed description of the function execution result, analyze the fields of the *result* structure.

In order to obtain information about the error, call the GetLastError() function.

Example:

```
#define   DEVIATION     5              // allowed deviation from the price
#define   VOLUME        1.0            // order volume
#define   EXPERT_MAGIC  123            // MagicNumber
#define   DIRECTION     ORDER_TYPE_BUY // opened position direction (ORDER_TYPE_BUY o

//+------------------------------------------------------------------+

OrderSend

The OrderSend() function is used for executing trade operations by sending requests to a trade server.

```
bool  OrderSend(
   MqlTradeRequest&  request,      // query structure
   MqlTradeResult&   result        // structure of the answer
   );
```

Parameters

request

[in] Pointer to a structure of MqlTradeRequest type describing the trade activity of the client.

result

[in,out] Pointer to a structure of MqlTradeResult type describing the result of trade operation in case of a successful completion (if true is returned).

Return Value

In case of a successful basic check of structures (index checking) returns true. **However, this is not a sign of successful execution of a trade operation**. For a more detailed description of the function execution result, analyze the fields of *result* structure.

Note

The trade requests go through several stages of checking on a trade server. First of all, it checks if all the required fields of the *request* parameter are filled out correctly. If there are no errors, the server accepts the order for further processing. If the order is successfully accepted by the trade server, the OrderSend() function returns true.

It is recommended to check the request before sending it to a trade server. To check requests, use the OrderCheck() function. It checks if there are enough funds to execute the trade operation, and returns many useful parameters in the results of trade request checking:

- return code containing information about errors in the checked request;
- balance value that will appear after the trade operation is executed;
- equity value that will appear after the trade operation is executed;
- floating point value that will appear after the trade operation is executed;
- margin required for the trade operation;
- amount of free equity that will remain after the execution of the trade operation;
- the margin level that will be set after the trade operation is executed;
- comment to the reply code, error description.

When sending a market order (MqlTradeRequest.action=TRADE_ACTION_DEAL), the successful result of the OrderSend() function does not mean that the order has been executed (appropriate trades have been performed). In this case, 'true' means only that the order has been successfully placed in the trading system for further execution. The trade server can fill in the *deal or order* field values *in the returned* result structure, if it is aware of these data when forming a response to an OrderSend() call. Generally, event(s) of executing trades corresponding to an order may happen after sending a response to the OrderSend() call. Therefore, for any type of a trade request, when receiving the OrderSend() execution result, we should first check the *retcode* trade server response code and the

© 2000-2025, MetaQuotes Ltd.

retcode_external external system response code (if necessary) available in the obtained result structure.

Each accepted order is stored on the trade server awaiting processing until one of the conditions for its execution occurs:

- expiration,
- appearance of an opposite request,
- order execution when the execution price appears,
- a request to cancel the order is received.

At the moment of the order processing, the trade server sends to the terminal a message about the occurrence of the Trade event, which can be processed by the OnTrade() function.

The result of executing the trade request on a server sent by OrderSend() function can be tracked by OnTradeTransaction handler. It should be noted that OnTradeTransaction handler will be called several times when executing one trade request.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. OnTradeTransaction function will be called for each of these events.

Example:

```
//--- value for ORDER_MAGIC
input long order_magic=55555;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- make sure that the account is demo
   if(AccountInfoInteger(ACCOUNT_TRADE_MODE)==ACCOUNT_TRADE_MODE_REAL)
     {
      Alert("Script operation is not allowed on a live account!");
      return;
     }
//--- place or delete order
   if(GetOrdersTotalByMagic(order_magic)==0)
     {
      //--- no current orders - place an order
      uint res=SendRandomPendingOrder(order_magic);
      Print("Return code of the trade server ",res);
     }
   else // there are orders - delete orders
     {
      DeleteAllOrdersByMagic(order_magic);
     }
//---
  }
//+------------------------------------------------------------------+
```

OrderSendAsync

The OrderSendAsync() function is used for conducting asynchronous trade operations without waiting for the trade server's response to a sent request. The function is designed for high-frequency trading, when under the terms of the trading algorithm it is unacceptable to waste time waiting for a response from the server.

```
bool  OrderSendAsync(
   MqlTradeRequest&  request,      // Request structure
   MqlTradeResult&   result        // Response structure
   );
```

Parameters

request

[in] A pointer to a structure of the MqlTradeRequest type that describes the trade action of the client.

result

[in,out] A pointer to a structure of the MqlTradeResult type that describes the result of a trade operation in case of successful execution of the function (if true is returned).

Return Value

Returns true if the request is sent to a trade server. In case the request is not sent, it returns false. In case the request is sent, in the *result* variable the response code contains TRADE_RETCODE_PLACED value (code 10008) - "order placed". Successful execution means only the fact of sending, but does not give any guarantee that the request has reached the trade server and has been accepted for processing. When processing the received request, a trade server sends a reply to a client terminal notifying of change in the current state of positions, orders and deals, which leads to the generation of the Trade event.

The result of executing the trade request on a server sent by OrderSendAsync() function can be tracked by OnTradeTransaction handler. It should be noted that OnTradeTransaction handler will be called several times when executing one trade request.

For example, when sending a market buy order, it is handled, an appropriate buy order is created for the account, the order is then executed and removed from the list of the open ones, then it is added to the orders history, an appropriate deal is added to the history and a new position is created. OnTradeTransaction function will be called for each of these events. To get such a data, the function parameters should be analyzed:

- **trans** - this parameter gets MqlTradeTransaction structure describing a trade transaction applied to a trade account;
- **request** - this parameter gets MqlTradeRequest structure describing the trade request resulted in a trade transaction;
- **result** - this parameter gets MqlTradeResult structure describing a trade request execution result.

Note

In terms of purposes and parameters, the function is similar to OrderSend(), but unlike it, it is asynchronous, i.e. does not hold the program operation while waiting for the function execution result. You can compare the rate of trade operations of these two functions using the sample Expert Advisor.

PositionsTotal

Returns the number of open positions.

```
int  PositionsTotal();
```

Return Value

Value of int type.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get and print the number of open positions on the account in the journal
   int total=PositionsTotal();
   Print("Number of open positions on account: ", total);
   /*
   result:
   Number of open positions on account: 2
   */
  }
```

See also

PositionGetSymbol(), PositionSelect(), Position Properties

© 2000-2025, MetaQuotes Ltd.

PositionGetSymbol

Returns the symbol corresponding to the open position and automatically selects the position for further working with it using functions PositionGetDouble, PositionGetInteger, PositionGetString.

```
string  PositionGetSymbol(
   int  index      // Number in the list of positions
   );
```

Parameters

index

[in] Number of the position in the list of open positions.

Return Value

Value of the string type. If the position was not found, an empty string will be returned. To get an error code, call the GetLastError() function.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the number of open positions on the account
   int total=PositionsTotal();
   for(int i=0; i<total; i++)
     {
      //--- get position symbol by i loop index
      ResetLastError();
      string symbol=PositionGetSymbol(i);

      //--- if the position symbol is successfully received, then the position at the
      //--- and we can obtain its properties using PositionGetDouble, PositionGetInteg
      if(symbol!="")
        {
         ENUM_POSITION_TYPE type=(ENUM_POSITION_TYPE)PositionGetInteger(POSITION_TYPE)
         PrintFormat("Position symbol at index %d: %s, position type: %s", i, symbol,
        }
      else
```

PositionSelect

Chooses an open position for further working with it. Returns true if the function is successfully completed. Returns false in case of failure. To obtain information about the error, call GetLastError().

```
bool  PositionSelect(
   string  symbol      // Symbol name
   );
```

Parameters

symbol

[in] Name of the financial security.

Return Value

Value of the bool type.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol. In this case, PositionSelect will select a position with the lowest ticket.

Function PositionSelect() copies data about a position into the program environment, and further calls of PositionGetDouble(), PositionGetInteger() and PositionGetString() return the earlier copied data. This means that the position itself may no longer exist (or its volume, direction, etc. has changed), but data of this position still can be obtained. To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

Example:

```
#define   SYMBOL_NAME   "EURUSD"

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- select a position on a specified symbol
   if(!PositionSelect(SYMBOL_NAME))
     {
      PrintFormat("PositionSelect(%s) failed. Error %d",SYMBOL_NAME, GetLastError());
      return;
     }

//--- if a position is selected, we can obtain its data using PositionGetDouble(), Pos
//--- get the selected position ticket
   ResetLastError();
```

© 2000-2025, MetaQuotes Ltd.

```
   long ticket=PositionGetInteger(POSITION_TICKET);
   if(ticket==0)
     {
      PrintFormat("Failed to get %s position ticket. Error %d", SYMBOL_NAME, GetLastEr
      return;
     }

//--- if a ticket is successfully received, print the selected position symbol and tic
   PrintFormat("The position that is selected on the %s symbol has ticket %I64d", SYMB
   /*
   result:
   The position that is selected on the EURUSD symbol has ticket 2810846623
   */
  }
```

PositionSelectByTicket

Selects an open position to work with based on the ticket number specified in the position. If successful, returns true. Returns false if the function failed. Call GetLastError() for error details.

```
bool  PositionSelectByTicket(
   ulong   ticket     // Position ticket
   );
```

Parameters

ticket

[in] Position ticket.

Return Value

A value of the bool type.

Note

The PositionSelectByTicket() function copies position data to the program environment. Further calls of PositionGetDouble(), PositionGetInteger() and PositionGetString() return the previously copied data. Even if a position does not exist already (or its size, direction etc. has changed), the data may still be received sometimes. To make sure that you receive valid position data, it is recommended to call PositionSelectByTicket() before you access the data.

Example:

```
#define   EXPERT_MAGIC  123456   // MagicNumber

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- declare and initialize the request and result structures
   MqlTradeRequest request={};
   MqlTradeResult  result ={};

//--- fill in trade request parameters to open a long position
   request.action    = TRADE_ACTION_DEAL;                       // trading operation ty
   request.symbol    = Symbol();                                // symbol
   request.volume    = 0.1;                                     // volume of 0.1 lot
   request.type      = ORDER_TYPE_BUY;                          // order type
   request.price     = SymbolInfoDouble(Symbol(), SYMBOL_ASK); // open price
   request.deviation = 5;                                       // allowed deviation fi
   request.magic     = EXPERT_MAGIC;                            // order MagicNumber

//--- send a request. If failed to send a request, display the error code and complete
   if(!OrderSend(request, result))
     {
      PrintFormat("OrderSend error ", GetLastError());
```

PositionGetDouble

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  PositionGetDouble(
   ENUM_POSITION_PROPERTY_DOUBLE  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variable passed by reference by the last parameter.

```
bool  PositionGetDouble(
   ENUM_POSITION_PROPERTY_DOUBLE  property_id,     // Property identifier
   double&                        double_var       // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type, accepting the value of the requested property.

Return Value

Value of the double type. If the function fails, 0 is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- in a loop by all account positions
```

© 2000-2025, MetaQuotes Ltd.

```
   int total=PositionsTotal();
   for(int i=0; i<total; i++)
     {
      //--- get the ticket of the next position by automatically selecting a position
      ulong ticket=PositionGetTicket(i);
      if(ticket==0)
         continue;

      //--- get the position type and display the header for the list of position real
      string type=(PositionGetInteger(POSITION_TYPE)==POSITION_TYPE ? "Buy" : "Sell");
      PrintFormat("Double properties of an open position %s #%I64u:", type, ticket);

      //--- print all the real properties of the selected position under the header
      PositionPropertiesDoublePrint(15);
     }

PositionGetInteger

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property should be of datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  PositionGetInteger(
   ENUM_POSITION_PROPERTY_INTEGER  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variables passed by reference by the last parameter.

```
bool  PositionGetInteger(
   ENUM_POSITION_PROPERTY_INTEGER  property_id,     // Property identifier
   long&                           long_var         // Here we accept the property val
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type accepting the value of the requested property.

Return Value

Value of the long type. If the function fails, 0 is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Trade function                                                   |
//+------------------------------------------------------------------+
void OnTrade()
  {
//--- check if a position is present and display the time of its changing
```

© 2000-2025, MetaQuotes Ltd.

```
   if(PositionSelect(_Symbol))
     {
//--- receive position ID for further work
      ulong position_ID=PositionGetInteger(POSITION_IDENTIFIER);
      Print(_Symbol," position #",position_ID);
//--- receive the time of position forming in milliseconds since 01.01.1970
      long create_time_msc=PositionGetInteger(POSITION_TIME_MSC);
      PrintFormat("Position #%d  POSITION_TIME_MSC = %i64 milliseconds => %s",positior
                  create_time_msc,TimeToString(create_time_msc/1000));
//--- receive the time of the position's last change in seconds since 01.01.1970
      long update_time_sec=PositionGetInteger(POSITION_TIME_UPDATE);
      PrintFormat("Position #%d  POSITION_TIME_UPDATE = %i64 seconds => %s",
                  position_ID,update_time_sec,TimeToString(update_time_sec));
//--- receive the time of the position's last change in milliseconds since 01.01.1970

PositionGetString

The function returns the requested property of an open position, pre-selected using PositionGetSymbol or PositionSelect. The position property should be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  PositionGetString(
   ENUM_POSITION_PROPERTY_STRING  property_id      // Property identifier
   );
```

2. Returns true or false, depending on the success of the function execution. If successful, the value of the property is placed in a receiving variables passed by reference by the last parameter.

```
bool  PositionGetString(
   ENUM_POSITION_PROPERTY_STRING  property_id,     // Property identifier
   string&                        string_var       // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of a position property. The value can be one of the values of the ENUM_POSITION_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type accepting the value of the requested property.

Return Value

Value of the string type. If the function fails, an empty string is returned.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- in a loop by all account positions
```

© 2000-2025, MetaQuotes Ltd.

PositionGetTicket

The function returns the ticket of a position with the specified index in the list of open positions and automatically selects the position to work with using functions PositionGetDouble, PositionGetInteger, PositionGetString.

```
ulong  PositionGetTicket(
   int  index      // The number of a position in the list
   );
```

Parameters

index

[in] The index of a position in the list of open positions, numeration starts with 0.

Return Value

The ticket of the position. Returns 0 if the function fails.

Note

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about a position, it is recommended to call PositionSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- in a loop by all account positions
   int total=PositionsTotal();
   for(int i=0; i<total; i++)
     {
      //--- get the ticket of the next position by automatically selecting a position
      ulong ticket=PositionGetTicket(i);
      if(ticket==0)
         continue;

      //--- get the position type and display the description of the selected positio
      string type=(PositionGetInteger(POSITION_TYPE)==POSITION_TYPE ? "Buy" : "Sell");
      PrintFormat("[%d] Selected position %s #%I64u", i, type, ticket);
     }
   /*
```

© 2000-2025, MetaQuotes Ltd.

```
   result:
   [0] Selected position Sell #2810802718
   [1] Selected position Buy #2810802919
   */
  }
```

OrdersTotal

Returns the number of current orders.

```
int  OrdersTotal();
```

Return Value

Value of the int type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal. An order is a request to conduct a transaction, while a position is a result of one or more deals.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get and print in the journal the number of active pending orders on the account
   int total=OrdersTotal();
   Print("Number of active pending orders on the account: ", total);
   /*
   result:
   Number of active pending orders on the account: 2
   */
  }
```

OrderGetTicket

Returns ticket of a corresponding order and automatically selects the order for further working with it using functions.

```
ulong  OrderGetTicket(
   int  index      // Number in the list of orders
   );
```

Parameters

index

[in] Number of an order in the list of current orders.

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal. An order is a request to conduct a transaction, while a position is a result of one or more deals.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Function OrderGetTicket() copies data about an order into the program environment, and further calls of OrderGetDouble(), OrderGetInteger(), OrderGetString() return the earlier copied data. This means that the order itself may no longer exist (or its open price, Stop Loss/Take Profit levels or expiration has changed), but data of this order still can be obtained. To ensure receipt of fresh data about an order, it is recommended to call OrderGetTicket() right before referring to them.

Example:

```
void OnStart()
  {
//--- variables for returning values from order properties
   ulong    ticket;
   double   open_price;
   double   initial_volume;
   datetime time_setup;
   string   symbol;
   string   type;
   long     order_magic;
   long     positionID;
//--- number of current pending orders
   uint     total=OrdersTotal();
```

© 2000-2025, MetaQuotes Ltd.

```
//--- go through orders in a loop
   for(uint i=0;i<total;i++)
     {
      //--- return order ticket by its position in the list
      if((ticket=OrderGetTicket(i))>0)
        {
         //--- return order properties
         open_price    =OrderGetDouble(ORDER_PRICE_OPEN);
         time_setup    =(datetime)OrderGetInteger(ORDER_TIME_SETUP);
         symbol        =OrderGetString(ORDER_SYMBOL);
         order_magic   =OrderGetInteger(ORDER_MAGIC);
         positionID    =OrderGetInteger(ORDER_POSITION_ID);
         initial_volume=OrderGetDouble(ORDER_VOLUME_INITIAL);
         type          =EnumToString(ENUM_ORDER_TYPE(OrderGetInteger(ORDER_TYPE)));
         //--- prepare and show information about the order
         printf("#ticket %d %s %G %s at %G was set up at %s",
                ticket,                 // order ticket
                type,                   // type
                initial_volume,         // placed volume
                symbol,                 // symbol
                open_price,             // specified open price
                TimeToString(time_setup)// time of order placing
                );
        }
     }
//---
  }
```

OrdersTotal(), OrderSelect(), OrderGetInteger()

© 2000-2025, MetaQuotes Ltd.

OrderSelect

Selects an order to work with. Returns true if the function has been successfully completed. Returns false if the function completion has failed. For more information about an error call GetLastError().

```
bool  OrderSelect(
   ulong    ticket      // Order ticket
   );
```

Parameters

ticket

[in] Order ticket.

Return Value

Value of the bool type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

Function OrderSelect() copies data about an order into the program environment, and further calls of OrderGetDouble(), OrderGetInteger(), OrderGetString() return the earlier copied data. This means that the order itself may no longer exist (or its open price, Stop Loss/Take Profit levels or expiration has changed), but data of this order still can be obtained. To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

Example:

```
#define   EXPERT_MAGIC  123456
#define   OFFSET        50                     // offset from the current price to pl
#define   DIRECTION     ORDER_TYPE_BUY_LIMIT   // order type
#define   VOLUME        1.0                    // volume
#define   DEVIATION     2                      // allowed deviation from the price

OrderGetInteger(), OrderGetDouble(), OrderGetString(), OrderCalcProfit(), OrderGetTicket(), Order Properties

© 2000-2025, MetaQuotes Ltd.

OrderGetDouble

Returns the requested property of an order, pre-selected using OrderGetTicket or OrderSelect. The order property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  OrderGetDouble(
   ENUM_ORDER_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of a function. If successful, the value of the property is placed in a target variable passed by reference by the last parameter.

```
bool  OrderGetDouble(
   ENUM_ORDER_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                     double_var         // Here we accept the property va
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

OrderGetInteger

Returns the requested order property, pre-selected using OrderGetTicket or OrderSelect. Order property must be of the datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  OrderGetInteger(
   ENUM_ORDER_PROPERTY_INTEGER  property_id        // Property identifier
   );
```

2. Returns true or false depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  OrderGetInteger(
   ENUM_ORDER_PROPERTY_INTEGER  property_id,       // Property identifier
   long&                        long_var           // Here we accept the property valu
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type. If the function fails, 0 is returned.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

OrderGetString

Returns the requested order property, pre-selected using OrderGetTicket or OrderSelect. The order property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  OrderGetString(
   ENUM_ORDER_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  OrderGetString(
   ENUM_ORDER_PROPERTY_STRING  property_id,       // Property identifier
   string&                     string_var        // Here we accept the property value
   );
```

Parameters

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type that accepts the value of the requested property.

Return Value

Value of the string type.

Note

Do not confuse current pending orders with positions, which are also displayed on the "Trade" tab of the "Toolbox" of the client terminal.

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol.

To ensure receipt of fresh data about an order, it is recommended to call OrderSelect() right before referring to them.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
```

HistorySelect

Retrieves the history of deals and orders for the specified period of server time.

```
bool  HistorySelect(
   datetime  from_date,      // From date
   datetime  to_date         // To date
   );
```

Parameters

from_date

[in] Start date of the request.

to_date

[in] End date of the request.

Return Value

It returns true if successful, otherwise returns false.

Note

HistorySelect() creates a list of orders and a list of trades in a mql5-program, for further referring to the list elements using corresponding functions. The deals list size can be returned using the HistoryDealsTotal() function; the size of the list of orders in the history can be obtained using HistoryOrdersTotal(). Selection in the list of orders should be better performed by HistoryOrderGetTicket(), for items in the list of deals HistoryDealGetTicket() suits better.

After using HistoryOrderSelect(), the list of history orders available to the mql5 program is reset and filled again by the found order, if the search of an order by the ticket has been completed successfully. The same applies to the list of deals available to the mql5 program - it is reset by HistoryDealSelect() and filled again in case of a successful receipt of a deal by ticket number.

Example:

```
void OnStart()
  {
   color BuyColor =clrBlue;
   color SellColor=clrRed;
//--- request trade history
   HistorySelect(0,TimeCurrent());
//--- create objects
   string   name;
   uint     total=HistoryDealsTotal();
   ulong    ticket=0;
   double   price;
   double   profit;
   datetime time;
   string   symbol;
   long     type;
   long     entry;
//--- for all deals
```

© 2000-2025, MetaQuotes Ltd.

```
   for(uint i=0;i<total;i++)
     {
      //--- try to get deals ticket
      if((ticket=HistoryDealGetTicket(i))>0)
        {
         //--- get deals properties
         price =HistoryDealGetDouble(ticket,DEAL_PRICE);
         time  =(datetime)HistoryDealGetInteger(ticket,DEAL_TIME);
         symbol=HistoryDealGetString(ticket,DEAL_SYMBOL);
         type  =HistoryDealGetInteger(ticket,DEAL_TYPE);
         entry =HistoryDealGetInteger(ticket,DEAL_ENTRY);
         profit=HistoryDealGetDouble(ticket,DEAL_PROFIT);
         //--- only for current symbol
         if(price && time && symbol==Symbol())
           {
            //--- create price object
            name="TradeHistory_Deal_"+string(ticket);
            if(entry) ObjectCreate(0,name,OBJ_ARROW_RIGHT_PRICE,0,time,price,0,0);
            else      ObjectCreate(0,name,OBJ_ARROW_LEFT_PRICE,0,time,price,0,0);
            //--- set object properties
            ObjectSetInteger(0,name,OBJPROP_SELECTABLE,0);
            ObjectSetInteger(0,name,OBJPROP_BACK,0);
            ObjectSetInteger(0,name,OBJPROP_COLOR,type?BuyColor:SellColor);
            if(profit!=0) ObjectSetString(0,name,OBJPROP_TEXT,"Profit: "+string(profit
           }
        }
     }
//--- apply on chart
   ChartRedraw();
  }
```

HistorySelectByPosition

Retrieves the history of deals and orders having the specified position identifier.

```
bool  HistorySelectByPosition(
   ulong   position_id     // position identifier - POSITION_IDENTIFIER
   );
```

Parameters

position_id

[in] Position identifier that is set to every executed order and every deal.

Return Value

It returns true if successful, otherwise returns false.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistorySelectByPosition() creates in a mql5 program a list of orders and a list of deals with a specified position identifier for further reference to the elements of the list using the appropriate functions. To know the size of the list of deals, use function HistoryDealsTotal(), the size of the list of orders in the history can be obtained using HistoryOrdersTotal(). To run through elements of the orders list, use HistoryOrderGetTicket(), for elements of the deals list - HistoryDealGetTicket().

After using HistoryOrderSelect(), list of history orders available to the mql5 program is reset and filled again with the found order, if search of an order by its ticket was successful. The same refers to the list of deals available to the mql5 program - it is reset by function HistoryDealSelect() and is filled out again if a deal was found successfully by the ticket number.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   long  pos_id_array[];          // array for storing position IDs

//--- request the entire history
   if(!HistorySelect(0, TimeCurrent()))
     {
      Print("HistorySelect() failed. Error ", GetLastError());
      return;
     }

HistoryOrderSelect

Selects an order from the history for further calling it through appropriate functions. It returns true if the function has been successfully completed. Returns false if the function has failed. For more details on error call GetLastError().

```
bool  HistoryOrderSelect(
   ulong  ticket      // Order ticket
   );
```

Parameters

ticket

[in] Order ticket.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

HistoryOrderSelect() clears in a mql5-program the list of orders from a history, available for calls, and copies to it a single order, if the execution of HistoryOrderSelect () has been completed successfully. If you need to go through all orders selected by HistorySelect(), you should better use HistoryOrderGetTicket().

Example:

```
#define   TICKET    1819621374   // ticket of any known order, for example, from the a
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- select a historical order by the ticket specified in TICKET
   if(!HistoryOrderSelect(TICKET))
     {
      PrintFormat("HistoryOrderSelect(%I64u) failed. Error %d", TICKET, GetLastError()
      return;
     }

//--- if an order is successfully selected, get its data and display the order descrip
   ENUM_ORDER_TYPE   order_type  = (ENUM_ORDER_TYPE)HistoryOrderGetInteger(TICKET, ORI

HistoryOrdersTotal

Returns the number of orders in the history. Prior to calling HistoryOrdersTotal(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
int  HistoryOrdersTotal();
```

Return Value

Value of the int type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- request all the existing history on the account
   if(!HistorySelect(0, TimeCurrent()))
     {
      Print("HistorySelect() failed. Error ", GetLastError());
      return;
     }

//--- get the number of orders in the list and display it in the journal
   int total=HistoryOrdersTotal();
   Print("Number of historical orders on the account: ", total);
   /*
   result:
   Number of historical orders on the account: 496
   */
  }
```

HistoryOrderGetTicket

Return the ticket of a corresponding order in the history. Prior to calling HistoryOrderGetTicket(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
ulong  HistoryOrderGetTicket(
   int  index      // Number in the list of orders
   );
```

Parameters

index

[in] Number of the order in the list of orders.

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
void OnStart()
  {
   datetime from=0;
   datetime to=TimeCurrent();
//--- request the entire history
   HistorySelect(from,to);
//--- variables for returning values from order properties
   ulong    ticket;
   double   open_price;
   double   initial_volume;
   datetime time_setup;
   datetime time_done;
   string   symbol;
   string   type;
   long     order_magic;
   long     positionID;
//--- number of current pending orders
   uint     total=HistoryOrdersTotal();
//--- go through orders in a loop
   for(uint i=0;i<total;i++)
     {
      //--- return order ticket by its position in the list

HistoryOrderGetDouble

Returns the requested order property. The order property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  HistoryOrderGetDouble(
   ulong                       ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetDouble(
   ulong                       ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                     double_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

HistoryOrderGetInteger

Returns the requested property of an order. The order property must be of datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  HistoryOrderGetInteger(
   ulong                          ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_INTEGER    property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetInteger(
   ulong                          ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_INTEGER    property_id,       // Property identifier
   long&                          long_var           // Here we accept the property valu
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
//+------------------------------------------------------------------+
//| Trade function                                                   |
//+------------------------------------------------------------------+
void OnTrade()
  {
//--- receive the last order's ticket from week's trading history

HistoryOrderGetString

Returns the requested property of an order. The order property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  HistoryOrderGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryOrderGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_ORDER_PROPERTY_STRING  property_id,       // Property identifier
   string&                    string_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Order ticket.

property_id

[in] Identifier of the order property. The value can be one of the values of the ENUM_ORDER_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type.

Return Value

Value of the string type.

Note

Do not confuse orders of a trading history with current pending orders that appear on the "Trade" tab of the "Toolbox" bar. The list of orders that were canceled or have led to a transaction, can be viewed in the "History" tab of "Toolbox" of the client terminal.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- request deal and order history
   if(!HistorySelect(0, TimeCurrent()))
     {
```

© 2000-2025, MetaQuotes Ltd.

```
      Print("HistorySelect() failed. Error ", GetLastError());
      return;
     }

//--- in a loop by the list of all historical orders on the account
   int total=HistoryOrdersTotal();
   for(int i=0; i<total; i++)
     {
      //--- get the order ticket in the list by the loop index
      ulong ticket=HistoryOrderGetTicket(i);
      if(ticket==0)
         continue;

      //--- get the order type and display the header for the list of string propertie
      string type=OrderTypeDescription((ENUM_ORDER_TYPE)HistoryOrderGetInteger(ticket,
      PrintFormat("String properties of an history order %s #%I64u:", type, ticket);

      //--- print all the string properties of the selected order under the header

HistoryDealSelect

Selects a deal in the history for further calling it through appropriate functions. It returns true if the function has been successfully completed. Returns false if the function has failed. For more details on error call GetLastError().

```
bool  HistoryDealSelect(
   ulong  ticket      // Deal ticket
   );
```

Parameters

ticket

[in] Deal ticket.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

HistoryDealSelect() clears in a mql5-program the list of deals available for reference, and copies the single deal, if the execution of HistoryDealSelect() has been completed successfully. If you need to go through all deals selected by the HistorySelect() function, you should better use HistoryDealGetTicket().

Example:

```
#define   TICKET    2620919264   // ticket of any known deal, for example, from the te

long      ExtTicket=TICKET;      // set the specified ticket to the variable from the
                                 // or handle deals in the OnTradeTransaction() handle
//+------------------------------------------------------------------+
//| Expert TradeTransaction handler                                  |
//+------------------------------------------------------------------+
void OnTradeTransaction(const MqlTradeTransaction& trans,
                        const MqlTradeRequest& request,
                        const MqlTradeResult& result)
  {
   //--- if a transaction is adding a deal to history
   if(trans.type==TRADE_TRANSACTION_DEAL_ADD)
     {
      //--- select a deal by ticket, get its data and display the deal description in
      HistoryDealSelectProcess(trans.deal);
     }
  }

//+------------------------------------------------------------------+
//| Script program start function                                    |
```

© 2000-2025, MetaQuotes Ltd.

```
//+------------------------------------------------------------------+
void OnStart()
  {
//--- select a deal by ticket, get its data and display the deal description in the jo
   HistoryDealSelectProcess(ExtTicket);
   /*

HistoryDealsTotal

Returns the number of deal in history. Prior to calling HistoryDealsTotal(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
int  HistoryDealsTotal();
```

Return Value

Value of the int type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- request all the existing history on the account
   if(!HistorySelect(0, TimeCurrent()))
     {
      Print("HistorySelect() failed. Error ", GetLastError());
      return;
     }

//--- get the number of deals in the list and display it in the journal
   int total=HistoryDealsTotal();
   Print("Number of historical deals on the account: ", total);
   /*
   result:
   Number of historical deals on the account: 339
   */
  }
```

HistoryDealGetTicket

The function selects a deal for further processing and returns the deal ticket in history. Prior to calling HistoryDealGetTicket(), first it is necessary to receive the history of deals and orders using the HistorySelect() or HistorySelectByPosition() function.

```
ulong  HistoryDealGetTicket(
   int  index      // ticket deal
   );
```

Parameters

index

[in] Number of a deal in the list of deals

Return Value

Value of the ulong type. If the function fails, 0 is returned.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
void OnStart()
  {
   ulong deal_ticket;            // deal ticket
   ulong order_ticket;           // ticket of the order the deal was executed on
   datetime transaction_time;    // time of a deal execution
   long deal_type ;              // type of a trade operation
   long position_ID;             // position ID
   string deal_description;      // operation description
   double volume;                // operation volume
   string symbol;                // symbol of the deal
//--- set the start and end date to request the history of deals
   datetime from_date=0;         // from the very beginning
   datetime to_date=TimeCurrent();// till the current moment
//--- request the history of deals in the specified period
   HistorySelect(from_date,to_date);
//--- total number in the list of deals
   int deals=HistoryDealsTotal();
//--- now process each trade
   for(int i=0;i<deals;i++)
     {
      deal_ticket=               HistoryDealGetTicket(i);
      volume=                    HistoryDealGetDouble(deal_ticket,DEAL_VOLUME);

HistoryDealGetDouble

Returns the requested property of a deal. The deal property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  HistoryDealGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_DOUBLE  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetDouble(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_DOUBLE  property_id,       // Property identifier
   double&                    double_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Deal ticket.

property_id

[in] Identifier of a deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_DOUBLE enumeration.

double_var

[out] Variable of the double type that accepts the value of the requested property.

Return Value

Value of the double type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- request deal and order history
   if(!HistorySelect(0, TimeCurrent()))
     {
      Print("HistorySelect() failed. Error ", GetLastError());
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }

//--- in a loop by the list of deals in the account history
   int total=HistoryDealsTotal();
   for(int i=0; i<total; i++)
     {

HistoryDealGetInteger

Returns the requested property of a deal. The deal property must be of the datetime, int type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  HistoryDealGetInteger(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_INTEGER property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetInteger(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_INTEGER property_id,       // Property identifier
   long&                      long_var           // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Trade ticket.

property_id

[in] Identifier of the deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_INTEGER enumeration.

long_var

[out] Variable of the long type that accepts the value of the requested property.

Return Value

Value of the long type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
//+------------------------------------------------------------------+
//| Trade function                                                   |
//+------------------------------------------------------------------+
void OnTrade()
  {
//--- receive the last deal's ticket from week's trading history
   ulong last_deal=GetLastDealTicket();
   if(HistoryDealSelect(last_deal))
     {
```

© 2000-2025, MetaQuotes Ltd.

```
      //--- time of deal execution in milliseconds since 01.01.1970
      long deal_time_msc=HistoryDealGetInteger(last_deal,DEAL_TIME_MSC);
      PrintFormat("Deal #%d DEAL_TIME_MSC=%i64 => %s",
                  last_deal,deal_time_msc,TimeToString(deal_time_msc/1000));
     }
   else
      PrintFormat("HistoryDealSelect() failed for #%d. Eror code=%d",
                  last_deal,GetLastError());
//---
  }
//+------------------------------------------------------------------+
//| Returns the last deal ticket in history or -1                    |
//+------------------------------------------------------------------+
ulong GetLastDealTicket()
  {
//--- request history for the last 7 days
   if(!GetTradeHistory(7))
     {
      //--- notify on unsuccessful call and return -1
      Print(__FUNCTION__," HistorySelect() returned false");
      return -1;
     }
//---
   ulong first_deal,last_deal,deals=HistoryDealsTotal();
//--- work with orders if there are any
   if(deals>0)
     {
      Print("Deals = ",deals);
      first_deal=HistoryDealGetTicket(0);
      PrintFormat("first_deal = %d",first_deal);
      if(deals>1)
        {
         last_deal=HistoryDealGetTicket((int)deals-1);
         PrintFormat("last_deal = %d",last_deal);
         return last_deal;
        }
      return first_deal;
     }
//--- no deal found, return -1
   return -1;
  }

HistoryDealGetString

Returns the requested property of a deal. The deal property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  HistoryDealGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_STRING  property_id        // Property identifier
   );
```

2. Returns true or false, depending on the success of the function. If successful, the value of the property is placed into a target variable passed by reference by the last parameter.

```
bool  HistoryDealGetString(
   ulong                      ticket_number,     // Ticket
   ENUM_DEAL_PROPERTY_STRING  property_id,       // Property identifier
   string&                    string_var         // Here we accept the property value
   );
```

Parameters

ticket_number

[in] Deal ticket.

property_id

[in] Identifier of the deal property. The value can be one of the values of the ENUM_DEAL_PROPERTY_STRING enumeration.

string_var

[out] Variable of the string type that accepts the value of the requested property.

Return Value

Value of the string type.

Note

Do not confuse orders, deals and positions. Each deal is the result of the execution of an order, each position is the summary result of one or more deals.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- request deal and order history
   if(!HistorySelect(0, TimeCurrent()))
     {
      Print("HistorySelect() failed. Error ", GetLastError());
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }

//--- in a loop by the list of deals in the account history
   int total=HistoryDealsTotal();
   for(int i=0; i<total; i++)
     {
      //--- get the ticket of the next deal (the deal is automatically selected to get
      ulong ticket=HistoryDealGetTicket(i);

Trade Signals

This is the group of functions intended for managing trade signals. The functions allow:

- get information about trade signals, available for copying,
- get and set the signal copy settings,
- subscribe and unsubscribe to the signal copying using MQL5 language functions.

Function	Action
SignalBaseGetDouble	Returns the value of double type property for selected signal
SignalBaseGetInteger	Returns the value of integer type property for selected signal
SignalBaseGetString	Returns the value of string type property for selected signal
SignalBaseSelect	Selects a signal from signals, available in terminal for further working with it
SignalBaseTotal	Returns the total amount of signals, available in terminal
SignalInfoGetDouble	Returns the value of double type property of signal copy settings
SignalInfoGetInteger	Returns the value of integer type property of signal copy settings
SignalInfoGetString	Returns the value of string type property of signal copy settings
SignalInfoSetDouble	Sets the value of double type property of signal copy settings
SignalInfoSetInteger	Sets the value of integer type property of signal copy settings
SignalSubscribe	Subscribes to the trading signal
SignalUnsubscribe	Cancels subscription

© 2000-2025, MetaQuotes Ltd.

SignalBaseGetDouble

Returns the value of double type property for selected signal.

```
double  SignalBaseGetDouble(
   ENUM_SIGNAL_BASE_DOUBLE     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_DOUBLE enumeration.

Return Value

The value of double type property of the selected signal.

© 2000-2025, MetaQuotes Ltd.

SignalBaseGetInteger

Returns the value of integer type property for selected signal.

```
long  SignalBaseGetInteger(
   ENUM_SIGNAL_BASE_INTEGER     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_INTEGER enumeration.

Return Value

The value of integer type property of the selected signal.

© 2000-2025, MetaQuotes Ltd.

SignalBaseGetString

Returns the value of string type property for selected signal.

```
string  SignalBaseGetString(
   ENUM_SIGNAL_BASE_STRING     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal property identifier. The value can be one of the values of the ENUM_SIGNAL_BASE_STRING enumeration.

Return Value

The value of string type property of the selected signal.

© 2000-2025, MetaQuotes Ltd.

SignalBaseSelect

Selects a signal from signals, available in terminal for further working with it.

```
bool  SignalBaseSelect(
   int      index     // signal index
   );
```

Parameters

index

[in] Signal index in base of trading signals.

Return Value

Returns true if successful, otherwise returns false. To read more about the error call GetLastError().

Example:

```
void OnStart()
  {
//--- get total amount of signals in the terminal
   int total=SignalBaseTotal();
//--- process all signals
   for(int i=0;i<total;i++)
     {
      //--- select the signal by index
      if(SignalBaseSelect(i))
        {
         //--- get signal properties
         long   id    =SignalBaseGetInteger(SIGNAL_BASE_ID);           // signal id
         long   pips  =SignalBaseGetInteger(SIGNAL_BASE_PIPS);         // profit in pi
         long   subscr=SignalBaseGetInteger(SIGNAL_BASE_SUBSCRIBERS); // number of su
         string name  =SignalBaseGetString(SIGNAL_BASE_NAME);          // signal name
         double price =SignalBaseGetDouble(SIGNAL_BASE_PRICE);         // signal price
         string curr  =SignalBaseGetString(SIGNAL_BASE_CURRENCY);      // signal curre
         //--- print all profitable free signals with subscribers
         if(price==0.0 && pips>0 && subscr>0)
            PrintFormat("id=%d, name=\"%s\", currency=%s, pips=%d, subscribers=%d",id,
        }
      else PrintFormat("Error in call of SignalBaseSelect. Error code=%d",GetLastErro
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

SignalBaseTotal

Returns the total amount of signals, available in terminal.

```
int  SignalBaseTotal();
```

Return Value

The total amount of signals, available in terminal.

© 2000-2025, MetaQuotes Ltd.

SignalInfoGetDouble

Returns the value of double type property of signal copy settings.

```
double  SignalInfoGetDouble(
   ENUM_SIGNAL_INFO_DOUBLE     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_DOUBLE enumeration.

Return Value

The value of double type property of signal copy settings.

© 2000-2025, MetaQuotes Ltd.

SignalInfoGetInteger

Returns the value of integer type property of signal copy settings.

```
long  SignalInfoGetInteger(
   ENUM_SIGNAL_INFO_INTEGER     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_INTEGER enumeration.

Return Value

The value of integer type property of signal copy settings.

SignalInfoGetString

Returns the value of string type property of signal copy settings.

```
string  SignalInfoGetString(
   ENUM_SIGNAL_INFO_STRING     property_id,     // property identifier
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_STRING enumeration.

Return Value

The value of string type property of signal copy settings.

© 2000-2025, MetaQuotes Ltd.

SignalInfoSetDouble

Sets the value of double type property of signal copy settings.

```
bool  SignalInfoSetDouble(
   ENUM_SIGNAL_INFO_DOUBLE      property_id,      // property identifier
   double                       value             // new value
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_DOUBLE enumeration.

value

[in] The value of signal copy settings property.

Return Value

Returns true if property has been changed, otherwise returns false. To read more about the error call GetLastError().

© 2000-2025, MetaQuotes Ltd.

SignalInfoSetInteger

Sets the value of integer type property of signal copy settings.

```
bool  SignalInfoSetInteger(
   ENUM_SIGNAL_INFO_INTEGER     property_id,     // property identifier
   long                         value            // new value
   );
```

Parameters

property_id

[in] Signal copy settings property identifier. The value can be one of the values of the ENUM_SIGNAL_INFO_INTEGER enumeration.

value

[in] The value of signal copy settings property.

Return Value

Returns true if property has been changed, otherwise returns false. To read more about the error call GetLastError().

© 2000-2025, MetaQuotes Ltd.

SignalSubscribe

Subscribes to the trading signal.

```
bool  SignalSubscribe(
   long     signal_id     // signal id
   );
```

Parameters

signal_id

[in] Signal identifier.

Return Value

Returns true if subscription was successful, otherwise returns false. To read more about the error call GetLastError().

© 2000-2025, MetaQuotes Ltd.

SignalUnsubscribe

Cancels subscription.

```
bool  SignalUnsubscribe();
```

Return Value

Returns true if subscription has been canceled successfully, otherwise returns false. To read more about the error call GetLastError().

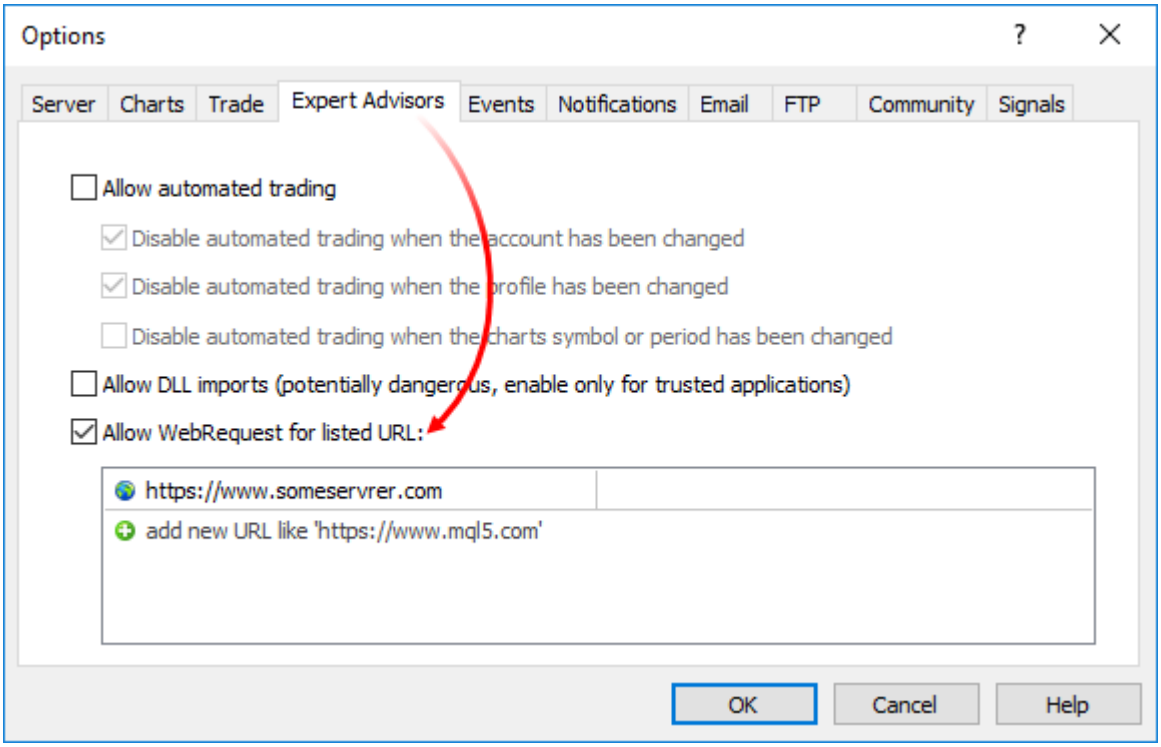
Network functions

MQL5 programs can exchange data with remote servers, as well as send push notifications, emails and data via FTP.

- The Socket* group of functions allows establishing a TCP connection (including a secure TLS) with a remote host via system sockets. The operation principle is simple: create a socket, connect to the server and start reading and writing data.
- The WebRequest function is designed to work with web resources and allows sending HTTP requests (including GET and POST) easily.
- SendFTP, SendMail and SendNotification are more simple functions for sending files, emails and mobile notifications.

For end-user security, the list of allowed IP addresses is implemented on the client terminal side. The list contains IP addresses the MQL5 program is allowed to connect to via the Socket* and WebRequest functions. For example, if the program needs to connect to https://www.someserver.com, this address should be explicitly indicated by a terminal user in the list. An address cannot be added programmatically.



Add an explicit message to the MQL5 program to notify a user of the need for additional configuration. You can do that via #property description, Alert or Print.

Function	Action
SocketCreate	Create a socket with specified flags and return its handle
SocketClose	Close a socket
SocketConnect	Connect to the server with timeout control
SocketIsConnected	Checks if the socket is currently connected

© 2000-2025, MetaQuotes Ltd.

Function	Action
SocketIsReadable	Get a number of bytes that can be read from a socket
SocketIsWritable	Check whether data can be written to a socket at the current time
SocketTimeouts	Set timeouts for receiving and sending data for a socket system object
SocketRead	Read data from a socket
SocketSend	Write data to a socket
SocketTlsHandshake	Initiate secure TLS (SSL) connection to a specified host via TLS Handshake protocol
SocketTlsCertificate	Get data on the certificate used to secure network connection
SocketTlsRead	Read data from secure TLS connection
SocketTlsReadAvailable	Read all available data from secure TLS connection
SocketTlsSend	Send data via secure TLS connection
WebRequest	Send an HTTP request to a specified server
SendFTP	Send a file to an address specified on the FTP tab
SendMail	Send an email to an address specified in the Email tab of the options window
SendNotification	Send push notifications to mobile terminals whose MetaQuotes IDs are specified in the Notifications tab

© 2000-2025, MetaQuotes Ltd.

SocketCreate

Create a socket with specified flags and return its handle.

```
int  SocketCreate(
   uint     flags          // flags
   );
```

Parameters

flags

[in] Combination of flags defining the mode of working with a socket. Currently, only one flag is supported — SOCKET_DEFAULT.

Return Value

In case of a successful socket creation, return its handle, otherwise INVALID_HANDLE.

Notes

To free up computer memory from an unused socket, call SocketClose for it.

You can create a maximum of 128 sockets from one MQL5 program. If the limit is exceeded, the error 5271 (ERR_NETSOCKET_TOO_MANY_OPENED) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketClose

Close a socket.

```
bool  SocketClose(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Handle of a socket to be closed. The handle is returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

Return Value

Returns true if successful, otherwise false.

Note

If a connection via SocketConnect was previously created for a socket, it is discontinued.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketExample.mq5 |

SocketConnect

Connect to the server with timeout control.

```
bool  SocketConnect(
   int           socket,               // socket
   const string  server,               // connection address
   uint          port,                 // connection port
   uint          timeout_receive_ms    // connection timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

server

[in] Domain name of the server you want to connect to or its IP address.

port

[in] Connection port number.

timeout_receive_ms

[in] Connection timeout in milliseconds. If connection is not established within that time interval, attempts are stopped.

Return Value

If connection is successful, return true, otherwise false.

Note

Connection address should be added to the list of allowed ones on the client terminal side (Tools \ Options \ Expert Advisors).

If connection fails, error 5272 (ERR_NETSOCKET_CANNOT_CONNECT) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketIsConnected

Checks if the socket is currently connected.

```
bool  SocketIsConnected(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate() function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

Return Value

Returns true if the socket is connected, otherwise - false.

Note

The SocketIsConnected() function allows checking the current socket connection status.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                            SocketIsConnected.mq5 |

SocketIsReadable

Get a number of bytes that can be read from a socket.

```
uint  SocketIsReadable(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

Return Value

Number of bytes that can be read. In case of an error, 0 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

Before calling SocketRead, check if the socket features data for reading. Otherwise, if there are no data, the SocketRead function waits for data within timeout_ms delaying the program execution.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+

SocketIsWritable

Check whether data can be written to a socket at the current time.

```
bool  SocketIsWritable(
   const int  socket      // socket handle
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

Return Value

Return true if writing is possible, otherwise false.

Note

This function allows you to check whether it is possible to write data to a socket right now.

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                              SocketIsWritable.mq5 |

SocketTimeouts

Set timeouts for receiving and sending data for a socket system object.

```
bool  SocketTimeouts(
   int           socket,               // socket
   uint          timeout_send_ms,      // data sending timeout
   uint          timeout_receive_ms    // data obtaining timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

timeout_send_ms

[in] Data sending timeout in milliseconds.

timeout_receive_ms

[in] Data obtaining timeout in milliseconds.

Return Value

Returns true if successful, otherwise false.

Note

Do not confuse system object timeouts with the ones set when reading data via SocketRead. SocketTimeout sets timeouts once for a socket object in the operating system. These timeouts are to be applied to all functions for reading and sending data via this socket. In SocketRead, the timeout is set for a certain data reading operation.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketTimeouts.mq5 |

SocketRead

Read data from a socket.

```
int  SocketRead(
   int           socket,              // socket
   uchar&        buffer[],            // buffer for reading data from socket
   uint          buffer_maxlen,       // number of bytes to read
   uint          timeout_ms           // reading timeout
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the *buffer[]* array. Data not fitting into the array remain in the socket. They can be received by the next SocketRead call. *buffer_maxlen* cannot exceed INT_MAX (2147483647).

timeout_ms

[in] Data reading timeout in milliseconds. If data is not obtained within this time, attempts are stopped and the function returns -1.

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

SocketSend

Write data to a socket.

```
int  SocketSend(
   int           socket,              // socket
   const uchar&  buffer[],            // data buffer
   uint          buffer_len           // buffer size
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

buffer

[in] Reference to the uchar type array with the data to be sent to the socket.

buffer_len

[in] 'buffer' array size.

Return Value

If successful, return the number of bytes written to a socket. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data writing error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

SocketTlsHandshake

Initiate secure TLS (SSL) connection to a specified host via TLS Handshake protocol. During Handshake, a client and a server agree on connection parameters: applied protocol version and data encryption method.

```
bool  SocketTlsHandshake(
   int           socket,               // socket
   const string  host                  // host address
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

host

[in] Address of a host a secure connection is established with.

Return Value

Returns true if successful, otherwise false.

Notes

Before a secure connection, the program should establish a standard TCP connection with the host using SocketConnect.

If secure connection fails, the error 5274 (ERR_NETSOCKET_HANDSHAKE_FAILED) is written to _LastError.

There is no need to call the function when connecting to the port 443. This is a standard TCP port used for secure TLS (SSL) connections.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+

SocketTlsCertificate

Get data on the certificate used to secure network connection.

```
bool  SocketTlsCertificate(
   int           socket,              // socket
   string&       subject,             // certificate owner
   string&       issuer,              // certificate issuer
   string&       serial,              // certificate serial number
   string&       thumbprint,          // certificate print
   datetime&     expiration           // certificate expiration
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

subject

[in] Certificate owner name. Corresponds to the Subject field.

issuer

[in] Certificate issuer name. Corresponds to the Issuer field.

serial

[in] Certificate serial number. Corresponds to the SerialNumber field.

thumbprint

[in] Certificate print. Corresponds to the SHA-1 hash from the entire certificate file (all fields including the issuer signature).

expiration

[in] Certificate expiration date in the datetime format.

Return Value

Returns true if successful, otherwise false.

Note

Certificate data can be requested only after establishing a secure connection using SocketTlsHandshake.

In case of a certificate obtaining error, the error 5275 (ERR_NETSOCKET_NO_CERTIFICATE) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```

SocketTlsRead

Read data from secure TLS connection.

```
int  SocketTlsRead(
   int           socket,              // socket
   uchar&        buffer[],            // buffer for reading data from socket
   uint          buffer_maxlen        // number of bytes to read
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the *buffer[]* array. Data not fitting into the array remain in the socket. They can be received by the next SocketTLSRead call. *buffer_maxlen* cannot exceed INT_MAX (2147483647).

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

The function is executed till it receives the specified amount of data or the timeout is reached (SocketTimeouts).

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketExample.mq5 |

SocketTlsReadAvailable

Read all available data from secure TLS connection.

```
int  SocketTlsReadAvailable(
   int           socket,               // socket
   uchar&        buffer[],             // buffer for reading data from socket
   const uint    buffer_maxlen         // number of bytes to read
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed to _LastError, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is activated.

buffer

[out] Reference to the uchar type array the data is read in. Dynamic array size is increased by the number of read bytes. The array size cannot exceed INT_MAX (2147483647).

buffer_maxlen

[in] Number of bytes to read to the buffer[] array. Data not fitting into the array remain in the socket. They can be received by the next SocketTlsReadAvailable or SocketTlsRead call. buffer_maxlen cannot exceed INT_MAX (2147483647).

Return Value

If successful, return the number of read bytes. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data reading error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written in _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

       int len=SocketTlsReadAvailable(socket,block,1024);

       if(len>0)
         {
          attempt++;
          //--- merge the obtained data blocks
          ArrayCopy(response,block,response.Size());
          //--- analyze the obtained data, define the header, page body, ending, or loa
          //...
          //...
          //...
          timeout_check=GetTickCount64()+timeout_ms;
         }
       else
          Sleep(10);

       err=GetLastError();
      }
   while(!IsStopped() && GetTickCount()<timeout_check && !err);
//--- were there any errors while reading?
   if(err)
     {
      Print("Error ",err);
      return(false);
     }

   PrintFormat("%s: Document received within %d attempts",__FUNCTION__,attempt);
   return(true);
  }
```

SocketTlsSend

Send data via secure TLS connection.

```
int  SocketTlsSend(
   int           socket,              // socket
   const uchar&  buffer[],            // data buffer
   uint          buffer_len           // buffer size
   );
```

Parameters

socket

[in] Socket handle returned by the SocketCreate function. When an incorrect handle is passed, the error 5270 (ERR_NETSOCKET_INVALIDHANDLE) is written to _LastError.

buffer

[in] Reference to the uchar type array with the data to be sent.

buffer_len

[in] 'buffer' array size.

Return Value

If successful, return the number of bytes written to a socket. In case of an error, -1 is returned.

Note

If an error occurs on a system socket when executing the function, connection established via SocketConnect is discontinued.

In case of a data writing error, the error 5273 (ERR_NETSOCKET_IO_ERROR) is written to _LastError.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If calling from an indicator, GetLastError() returns the error 4014 - "Function is not allowed for call".

Example:

```
//+------------------------------------------------------------------+
//|                                                SocketTlsSend.mq5 |

WebRequest

The function sends an HTTP request to a specified server. The function has two versions:

1. **Sending simple requests** of type "key=value" using the header Content-Type: application/x-www-form-urlencoded.

```
int  WebRequest(
   const string      method,           // HTTP method
   const string      url,              // URL
   const string      cookie,           // cookie
   const string      referer,          // referer
   int               timeout,          // timeout
   const char        &data[],          // the array of the HTTP message body
   int               data_size,        // data[] array size in bytes
   char              &result[],        // an array containing server response data
   string            &result_headers   // headers of server response
   );
```

2. **Sending a request of any type** specifying the custom set of headers for a more flexible interaction with various Web services.

```
int  WebRequest(
   const string      method,           // HTTP method
   const string      url,              // URL
   const string      headers,          // headers
   int               timeout,          // timeout
   const char        &data[],          // the array of the HTTP message body
   char              &result[],        // an array containing server response data
   string            &result_headers   // headers of server response
   );
```

Parameters

method

[in] HTTP method.

url

[in] URL.

headers

[in] Request headers of type "key: value", separated by a line break "\r\n".

cookie

[in] Cookie value.

referer

[in] Value of the Referer header of the HTTP request.

timeout

[in] Timeout in milliseconds.

© 2000-2025, MetaQuotes Ltd.

data[]

[in] Data array of the HTTP message body.

data_size

[in] Size of the data[] array.

result[]

[out] An array containing server response data.

result_headers

[out] Server response headers.

Return Value

HTTP server response code or -1 for an error.

Note

To use the WebRequest() function, add the addresses of the required servers in the list of allowed URLs in the "Expert Advisors" tab of the "Options" window. Server port is automatically selected on the basis of the specified protocol - 80 for "http://" and 443 for "https://".

The WebRequest() function is synchronous, which means its breaks the program execution and waits for the response from the requested server. Since the delays in receiving a response can be large, the function is not available for calls from indicators, because indicators run in a common thread shared by all indicators and charts on one symbol. Indicator performance delay on one of the charts of a symbol may stop updating of all charts of the same symbol.

The function can be called only from Expert Advisors and scripts, as they run in their own execution threads. If you try to call the function from an indicator, GetLastError() will return error 4014 - "Function is not allowed for call".

WebRequest() cannot be executed in the Strategy Tester.

Example:

```
void OnStart()
  {
   string cookie=NULL,headers;
   char   post[],result[];
   string url="https://finance.yahoo.com";
//--- To enable access to the server, you should add URL "https://finance.yahoo.com"
//--- to the list of allowed URLs (Main Menu->Tools->Options, tab "Expert Advisors"):
//--- Resetting the last error code
   ResetLastError();
//--- Downloading a html page from Yahoo Finance
   int res=WebRequest("GET",url,cookie,NULL,500,post,0,result,headers);
   if(res==-1)
     {
      Print("Error in WebRequest. Error code  =",GetLastError());
      //--- Perhaps the URL is not listed, display a message about the necessity to ad
      MessageBox("Add the address '"+url+"' to the list of allowed URLs on tab 'Expert
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   else
     {
      if(res==200)
        {
         //--- Successful download
         PrintFormat("The file has been successfully downloaded, File size %d byte.",A
         //PrintFormat("Server headers: %s",headers);
         //--- Saving the data to a file
         int filehandle=FileOpen("url.htm",FILE_WRITE|FILE_BIN);
         if(filehandle!=INVALID_HANDLE)
           {
            //--- Saving the contents of the result[] array to a file
            FileWriteArray(filehandle,result,0,ArraySize(result));
            //--- Closing the file
            FileClose(filehandle);
           }
         else
            Print("Error in FileOpen. Error code =",GetLastError());
        }
      else
         PrintFormat("Downloading '%s' failed, error code %d",url,res);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

SendFTP

Sends a file at the address, specified in the setting window of the "FTP" tab.

```
bool  SendFTP(
   string  filename,          // file to be send by ftp
   string  ftp_path=NULL      // ftp catalog
   );
```

Parameters

filename

[in] Name of sent file.

ftp_path=NULL

[in] FTP catalog. If a directory is not specified, directory described in settings is used.

Return Value

In case of failure returns 'false'.

Note

Sent file must be located in the folder *terminal_directory\MQL5\files* or its subfolders. Sending isn't performed if FTP address and/or access password are not specified in settings.

SendFTP() function does not work in the Strategy Tester.

Example:

```
//+------------------------------------------------------------------+
//|                                                      SendFTP.mq5 |
//|                                  Copyright 2024, MetaQuotes Ltd. |
//|                                             https://www.mql5.com |
//+------------------------------------------------------------------+
#property copyright "Copyright 2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com
#property version     "1.00"

#define   FILENAME  "SomeFile.bin"
#define   PATH      NULL
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
//--- check permission to send files to the FTP address in the terminal
   if(!TerminalInfoInteger(TERMINAL_FTP_ENABLED))
     {
      Print("Error. The client terminal does not have permission to send messages to t
      return;
     }
```

© 2000-2025, MetaQuotes Ltd.

```
//--- send file
   ResetLastError();
   if(!SendFTP(FILENAME, PATH))
      Print("SendFTP() failed. Error ",GetLastError());
  }
```

© 2000-2025, MetaQuotes Ltd.

SendMail

Sends an email at the address specified in the settings window of the "Email" tab.

```
bool  SendMail(
   string  subject,        // header
   string  some_text       // email text
   );
```

Parameters

subject

[in] Email header.

some_text

[in] Email body.

Return Value

true - if an email is put into the send queue, otherwise - false.

Note

Sending can be prohibited in settings, email address can be omitted as well. For the error information call GetLastError().

SendMail() function does not work in the Strategy Tester.

Example:

```
//+------------------------------------------------------------------+
//|                                                     SendMail.mq5 |
//|                                Copyright 2024, MetaQuotes Ltd. |
//|                                             https://www.mql5.com |

#property copyright "Copyright 2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com
#property version     "1.00"

#define   SUBJECT   "Test SendMail"
#define   TEXT      "Text for SendMail() function"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
//--- check permission to send email in the terminal
   if(!TerminalInfoInteger(TERMINAL_EMAIL_ENABLED))
     {
      Print("Error. The client terminal does not have permission to send email message
      return;
     }
```

© 2000-2025, MetaQuotes Ltd.

```
//--- send mail
   ResetLastError();
   if(!SendMail(SUBJECT, TEXT))
      Print("SendMail() failed. Error ",GetLastError());
  }
```

© 2000-2025, MetaQuotes Ltd.

SendNotification

Sends push notifications to the mobile terminals, whose MetaQuotes IDs are specified in the "Notifications" tab.

```
bool  SendNotification(
   string  text          // Text of the notification
   );
```

Parameters

text

[in] The text of the notification. The message length should not exceed 255 characters.

Return Value

true if a notification has been successfully sent from the terminal; in case of failure returns false. When checking after a failed push of notification, GetLastError () may return one of the following errors:

- 4515 - ERR_NOTIFICATION_SEND_FAILED,
- 4516 - ERR_NOTIFICATION_WRONG_PARAMETER,
- 4517 - ERR_NOTIFICATION_WRONG_SETTINGS,
- 4518 - ERR_NOTIFICATION_TOO_FREQUENT.

Note

Strict use restrictions are set for the SendNotification() function: no more than 2 calls per second and not more than 10 calls per minute. Monitoring the frequency of use is dynamic. The function can be disabled in case of the restriction violation.

SendNotification() function does not work in the Strategy Tester.

Example:

```
//+------------------------------------------------------------------+
//|                                             SendNotification.mq5 |

//+------------------------------------------------------------------+
#property copyright "Copyright 2024, MetaQuotes Ltd."
#property link      "https://www.mql5.com
#property version     "1.00"

#define   MESSAGE   "Test Message"
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart(void)
  {
//--- check permission to send notifications in the terminal
   if(!TerminalInfoInteger(TERMINAL_NOTIFICATIONS_ENABLED))
     {
```

© 2000-2025, MetaQuotes Ltd.

```
      Print("Error. The client terminal does not have permission to send notifications
      return;
     }
//--- send notification
   ResetLastError();
   if(!SendNotification(MESSAGE))
      Print("SendNotification() failed. Error ",GetLastError());
  }
```

Global Variables of the Client Terminal

There is a group set of functions for working with global variables.

Global variables of the client terminal should not be mixed up with variables declared in the global scope of the mql5 program.

Global variables are kept in the client terminal for 4 weeks since the last access, then they will be deleted automatically. An access to a global variable is not only setting of a new value, but reading of the global variable value, as well.

Global variables of the client terminal are accessible simultaneously from all mql5 programs launched in the client terminal.

Function	Action
GlobalVariableCheck	Checks the existence of a global variable with the specified name
GlobalVariableTime	Returns time of the last accessing the global variable
GlobalVariableDel	Deletes a global variable
GlobalVariableGet	Returns the value of a global variable
GlobalVariableName	Returns the name of a global variable by its ordinal number in the list of global variables
GlobalVariableSet	Sets the new value to a global variable
GlobalVariablesFlush	Forcibly saves contents of all global variables to a disk
GlobalVariableTemp	Sets the new value to a global variable, that exists only in the current session of the terminal
GlobalVariableSetOnCondition	Sets the new value of the existing global variable by condition
GlobalVariablesDeleteAll	Deletes global variables with the specified prefix in their names
GlobalVariablesTotal	Returns the total number of global variables

© 2000-2025, MetaQuotes Ltd.

GlobalVariableCheck

Checks the existence of a global variable with the specified name

```
bool  GlobalVariableCheck(
   string  name      // Global variable name
   );
```

Parameters

name

[in] Global variable name.

Return Value

Returns true, if the global variable exists, otherwise returns false.

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

See also

GlobalVariableTime()

© 2000-2025, MetaQuotes Ltd.

GlobalVariableTime

Returns the time when the global variable was last accessed.

```
datetime  GlobalVariableTime(
   string  name      // name
   );
```

Parameters

name

[in] Name of the global variable.

Return Value

The function returns time of last accessing the specified global variable. Addressing a variable for its value, for example using the GlobalVariableGet() and GlobalVariableCheck() functions, also modifies the time of last access. In order to obtain error details, call the GetLastError() function.

Note

Global variables exist in the client terminal during 4 weeks since they were called last. After that they are automatically deleted.

See also

GlobalVariableCheck()

© 2000-2025, MetaQuotes Ltd.

GlobalVariableDel

Deletes a global variable from the client terminal.

```
bool  GlobalVariableDel(
   string  name      // Global variable name
   );
```

Parameters

name

[in] Global variable name.

Return Value

If successful, the function returns true, otherwise it returns false. To obtain an information about the error it is necessary to call the function GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

© 2000-2025, MetaQuotes Ltd.

GlobalVariableGet

Returns the value of an existing global variable of the client terminal. There are 2 variants of the function.

1. Immediately returns the value of the global variable.

```
double  GlobalVariableGet(
   string  name      // Global variable name
   );
```

2. Returns true or false depending on the success of the function run. If successful, the global variable of the client terminal is placed in a variable passed by reference in the second parameter.

```
bool  GlobalVariableGet(
   string  name,              // Global variable name
   double& double_var         // This variable will contain the value of the global va
   );
```

Parameters

name

[in] Global variable name.

double_var

[out] Target variable of the double type, which accepts the value stored in a the global variable of the client terminal.

Return Value

The value of the existing global variable or 0 in case of an error. For more details about the error, call GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

© 2000-2025, MetaQuotes Ltd.

GlobalVariableName

Returns the name of a global variable by its ordinal number.

```
string  GlobalVariableName(
   int  index      // Global variable number in the list of global variables
   );
```

Parameters

index

[in] Sequence number in the list of global variables. It should be greater than or equal to 0 and less than GlobalVariablesTotal().

Return Value

Global variable name by its ordinal number in the list of global variables. For more details about the error, call GetLastError().

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

© 2000-2025, MetaQuotes Ltd.

GlobalVariableSet

Sets a new value for a global variable. If the variable does not exist, the system creates a new global variable.

```
datetime  GlobalVariableSet(
   string  name,      // Global variable name
   double  value      // Value to set
   );
```

Parameters

name

[in] Global variable name.

value

[in] The new numerical value.

Return Value

If successful, the function returns the last modification time, otherwise 0. For more details about the error, call GetLastError().

Note

A global variable name should not exceed 63 characters. Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

© 2000-2025, MetaQuotes Ltd.

GlobalVariablesFlush

Forcibly saves contents of all global variables to a disk.

```
void  GlobalVariablesFlush();
```

Return Value

No return value.

Note

The terminal writes all the global variables when the work is over, but data can be lost at a sudden computer operation failure. This function allows independently controlling the process of saving global variables in case of contingency.

© 2000-2025, MetaQuotes Ltd.

GlobalVariableTemp

The function attempts to create a temporary global variable. If the variable doesn't exist, the system creates a new temporary global variable.

```
bool  GlobalVariableTemp(
   string  name      // Global variable name
   );
```

Parameters

name

[in] The name of a temporary global variable.

Return Value

If successful, the function returns true, otherwise - false. To get details about the error, you should call the GetLastError() function.

Note

Temporary global variables exist only while the client terminal is running; after the terminal shutdown they are automatically deleted. Note that during the execution of GlobalVariablesFlush() temporary global variables are not written to a disk.

After a temporary global variable has been created, it can be accessed and modified the same as global variable of the client terminal.

© 2000-2025, MetaQuotes Ltd.

GlobalVariableSetOnCondition

Sets the new value of the existing global variable if the current value equals to the third parameter check_value. If there is no global variable, the function will generate an error ERR_GLOBALVARIABLE_NOT_FOUND (4501) and return false.

```
bool  GlobalVariableSetOnCondition(
   string  name,            // Global variable name
   double  value,           // New value for variable if condition is true
   double  check_value      // Check value condition
   );
```

Parameters

name

[in] The name of a global variable.

value

[in] New value.

check_value

[in] The value to check the current value of the global variable.

Return Value

If successful, the function returns true, otherwise it returns false. For details about the error call GetLastError(). If the current value of the global variable is different from check_value, the function returns false.

Note

Function provides atomic access to the global variable, so it can be used for providing of a mutex at interaction of several Expert Advisors working simultaneously within one client terminal.

© 2000-2025, MetaQuotes Ltd.

GlobalVariablesDeleteAll

Deletes global variables of the client terminal.

```
int  GlobalVariablesDeleteAll(
   string     prefix_name=NULL,     // All global variables with names beginning with
   datetime   limit_data=0          // All global variables that were changed before t
   );
```

Parameters

prefix_name=NULL

[in] Name prefix global variables to remove. If you specify a prefix NULL or empty string, then all variables that meet the data criterion will be deleted.

limit_data=0

[in] Date to select global variables by the time of their last modification. The function removes global variables, which were changed before this date. If the parameter is zero, then all variables that meet the first criterion (prefix) are deleted.

Return Value

The number of deleted variables.

Note

If both options are equal to zero (prefix_name = NULL and limit_data = 0), then function deletes all global variables of the terminal. If both parameters are specified, then it deletes global variables corresponding to both parameters.

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted.

© 2000-2025, MetaQuotes Ltd.

GlobalVariablesTotal

Returns the total number of global variables of the client terminal.

```
int  GlobalVariablesTotal();
```

Return Value

Number of global variables.

Note

Global variables exist in the client terminal during 4 weeks since their last use, then they are automatically deleted. Call of a global variable is not only setting a new value, but also reading the value of the global variable.

© 2000-2025, MetaQuotes Ltd.

File Functions

This is a group of functions for working with files.

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means cannot be outside the file sandbox.

There are two directories (with subdirectories) in which working files can be located:

- terminal_data_folder\MQL5\FILES\ (in the terminal menu select to view "File" - "Open the data directory");
- the common folder for all the terminals installed on a computer - usually located in the directory C:\Documents and Settings\All Users\Application Data\MetaQuotes\Terminal\Common\Files.

There is a program method to obtain names of these catalogs using the TerminalInfoString() function, using the ENUM_TERMINAL_INFO_STRING enumeration:

```
//--- Folder that stores the terminal data
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
//--- Common folder for all client terminals
   string common_data_path=TerminalInfoString(TERMINAL_COMMONDATA_PATH);
```

Work with files from other directories is prohibited.

If the file is opened for writing using FileOpen(), all subfolders specified in the path will be created if there are no such ones.

File functions allow working with so-called "named pipes". To do this, simply call FileOpen() function with appropriate parameters.

Function	Action
FileSelectDialog	Create a file or folder opening/creation dialog
FileFindFirst	Starts the search of files in a directory in accordance with the specified filter
FileFindNext	Continues the search started by the FileFindFirst() function
FileFindClose	Closes search handle
FileOpen	Opens a file with a specified name and flag
FileDelete	Deletes a specified file
FileFlush	Writes to a disk all data remaining in the input/output file buffer
FileGetInteger	Gets an integer property of a file
FileIsEnding	Defines the end of a file in the process of reading
FileIsLineEnding	Defines the end of a line in a text file in the process of reading
FileClose	Closes a previously opened file
FileIsExist	Checks the existence of a file

© 2000-2025, MetaQuotes Ltd.

Function	Action
FileCopy	Copies the original file from a local or shared folder to another file
FileMove	Moves or renames a file
FileReadArray	Reads arrays of any type except for string from the file of the BIN type
FileReadBool	Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string to a value of bool type
FileReadDatetime	Reads from the file of the CSV type a string of one of the formats: "YYYY.MM.DD HH:MM:SS", "YYYY.MM.DD" or "HH:MM:SS" - and converts it into a datetime value
FileReadDouble	Reads a double value from the current position of the file pointer
FileReadFloat	Reads a float value from the current position of the file pointer
FileReadInteger	Reads int, short or char value from the current position of the file pointer
FileReadLong	Reads a long type value from the current position of the file pointer
FileReadNumber	Reads from the file of the CSV type a string from the current position till a delimiter (or til the end of a text line) and converts the read string into double value
FileReadString	Reads a string from the current position of a file pointer from a file
FileReadStruct	Reads the contents from a binary file into a structure passed as a parameter, from the current position of the file pointer
FileSeek	Moves the position of the file pointer by a specified number of bytes relative to the specified position
FileSize	Returns the size of a corresponding open file
FileTell	Returns the current position of the file pointer of a corresponding open file
FileWrite	Writes data to a file of CSV or TXT type
FileWriteArray	Writes arrays of any type except for string into a file of BIN type
FileWriteDouble	Writes value of the double type from the current position of a file pointer into a binary file
FileWriteFloat	Writes value of the float type from the current position of a file pointer into a binary file
FileWriteInteger	Writes value of the int type from the current position of a file pointer into a binary file
FileWriteLong	Writes value of the long type from the current position of a file pointer into a binary file

© 2000-2025, MetaQuotes Ltd.

Function	Action
FileWriteString	Writes the value of a string parameter into a BIN or TXT file starting from the current position of the file pointer
FileWriteStruct	Writes the contents of a structure passed as a parameter into a binary file, starting from the current position of the file pointer
FileLoad	Reads all data of a specified binary file into a passed array of numeric types or simple structures
FileSave	Writes to a binary file all elements of an array passed as a parameter
FolderCreate	Creates a folder in the Files directory
FolderDelete	Removes a selected directory. If the folder is not empty, then it can't be removed
FolderClean	Deletes all files in the specified folder

© 2000-2025, MetaQuotes Ltd.

FileSelectDialog

Create a file or folder opening/creation dialog.

```
int  FileSelectDialog(
   string   caption,              // window header
   string   initial_dir,          // initial directory
   string   filter,               // extension filter
   uint     flags,                // combination of flags
   string&  filenames[],          // array with file names
   string   default_filename      // default file name
   );
```

Parameters

caption

[in] Dialog window header.

initial_dir

[in] Initial directory name relative to MQL5\Files, the contents of which is to be displayed in the dialog box. If the value is NULL, MQL5\Files is displayed in the dialog.

filter

[in] Extension filter of the files to be displayed in the selection dialog window. Files of other formats are hidden.

flags

[in] Combination of flags defining the dialog window mode. The flags are defined as follows:
FSD_WRITE_FILE - file open dialog;
FSD_SELECT_FOLDER - allow selection of folders only;
FSD_ALLOW_MULTISELECT - allow selection of multiple files;
FSD_FILE_MUST_EXIST - selected files should exist;
FSD_COMMON_FOLDER - file is located in the common folder of all client terminals \Terminal\Common\Files.

filenames[]

[out] Array of strings the names of selected files/folders are placed to.

default_filename

[in] Default file/folder name. If specified, a name is automatically added to the open dialog and returned in the *filenames[]* array when testing.

Return Value

In case of a successful completion, the function returns the number of selected files whose names can be obtained in *filenames[]*. If a user closes the dialog without selecting a file, the function returns 0. In case of unsuccessful execution, a value less than 0 is returned. The error code can be obtained using GetLastError().

Note

© 2000-2025, MetaQuotes Ltd.

For reasons of security, working with files is strictly controlled in MQL5 language. Files used in file operations by means of MQL5 language cannot be located outside the file sandbox (namely, outside the MQL5\Files directory).

The *initial_dir* name is searched in the client terminal's directory in MQL5\Files (or testing_agent_directory\MQL5\Files in case of testing). If FSD_COMMON_FOLDER is set among the flags, the search for the initial directory is performed in the common folder of all client terminals \Terminal\Common\Files.

The *filter* parameter indicates valid files and should be set in the "<description 1>|<extension 1>|<description 2>|<extension 2>..." format, for example, "Text files (*.txt)|*.txt|All files (*.*)|*.*". The first extension "Text files (*.txt)|*.txt" is selected as a default file type.

If *filter*=NULL, the mask of file selection in the dialog window is "All Files (*.*)|*.*|"

If the *default_filename* parameter is set, calling FileSelectDialog() returns 1, while the *default_filename* value itself is copied to the *filenames[]* array during the non-visualized testing.

The function cannot be used in custom indicators since calling FileSelectDialog() suspends the thread of execution for the whole time while waiting for the user's response. Since all indicators for each symbol are executed in a single thread, such suspension makes the operation of all charts on all timeframes for this symbol impossible.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- get the names of text files for downloading from the common folder of the client
   string filenames[];
   if(FileSelectDialog("Select files to download", NULL,
                       "Text files (*.txt)|*.txt|All files (*.*)|*.*",
                       FSD_ALLOW_MULTISELECT|FSD_COMMON_FOLDER, filenames, "data.txt")
     {
      //--- display the name of each selected file
      int total=ArraySize(filenames);
      for(int i=0; i<total; i++)
         Print(i, ": ", filenames[i]);
     }
   else
     {
     Print("Files not selected");
     }
//---
  }
```

FileOpen, FileIsExist, FileDelete, FileMove, FolderCreate, FolderDelete, FolderClean, Flags of opening files

© 2000-2025, MetaQuotes Ltd.

FileFindFirst

The function starts the search of files or subdirectories in a directory in accordance with the specified filter.

```
long  FileFindFirst(
   const string   file_filter,          // String - search filter
   string&        returned_filename,    // Name of the file or subdirectory found
   int            common_flag=0         // Defines the search
   );
```

Parameters

file_filter

[in] Search filter. A subdirectory (or sequence of nested subdirectories) relative to the \Files directory, in which files should be searched for, can be specified in the filter.

returned_filename

[out] The returned parameter, where, in case of success, the name of the first found file or subdirectory is placed. Only the file name is returned (including the extension), the directories and subdirectories are not included no matter if they are specified or not in the search filter.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

Returns handle of the object searched, which should be used for further sorting of files and subdirectories by the FileFindNext() function, or INVALID_HANDLE when there is no file and subdirectory corresponding to the filter (in the particular case - when the directory is empty). After searching, the handle must be closed using the FileFindClose() function.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Example:

© 2000-2025, MetaQuotes Ltd.

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="Dir1\\*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   string int_dir="";
   int    i=1,pos=0,last_pos=-1;
//--- search for the last backslash
   while(!IsStopped())
     {
      pos=StringFind(InpFilter,"\\",pos+1);
      if(pos>=0)
         last_pos=pos;
      else
         break;
     }
//--- the filter contains the folder name
   if(last_pos>=0)
      int_dir=StringSubstr(InpFilter,0,last_pos+1);
//--- get the search handle in the root of the local folder
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if the FileFindFirst() is executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- in a loop, check if the passed strings are the names of files or director
      do
        {
         ResetLastError();
         //--- if it's a file, the function returns true, and if it's a directory, it
         FileIsExist(int_dir+file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==ERR_FILE_IS_DIRECTORY ? "Di
         i++;
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
      Print("Files not found!");
  }
```

See also

FileFindNext, FileFindClose

© 2000-2025, MetaQuotes Ltd.

FileFindNext

The function continues the search started by FileFindFirst().

```
bool  FileFindNext(
   long      search_handle,          // Search handle
   string&   returned_filename       // Name of the file or subdirectory found
   );
```

Parameters

search_handle

[in] Search handle, retrieved by FileFindFirst().

returned_filename

[out] The name of the next file or subdirectory found. Only the file name is returned (including the extension), the directories and subdirectories are not included no matter if they are specified or not in the search filter.

Return Value

If successful returns true, otherwise false.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   int    i=1;
//--- receive search handle in local folder's root
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if FileFindFirst() function executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- check if the passed strings are file or directory names in the loop
      do
        {
         ResetLastError();
         //--- if this is a file, the function will return true, if it is a directory,
         FileIsExist(file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==ERR_FILE_IS_DIRECTORY ? "Di
         i++;
        }
      while(FileFindNext(search_handle,file_name));
```

© 2000-2025, MetaQuotes Ltd.

```
      //--- close search handle
      FileFindClose(search_handle);
     }
   else
      Print("Files not found!");
  }
```

See also

FileFindFirst, FileFindClose

© 2000-2025, MetaQuotes Ltd.

FileFindClose

The function closes the search handle.

```
void  FileFindClose(
   long  search_handle      //  Search handle
   );
```

Parameters

search_handle

[in] Search handle, retrieved by FileFindFirst().

Return Value

No value returned.

Note

Function must be called to free up system resources.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- filter
input string InpFilter="*";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string file_name;
   int    i=1;
//--- receive search handle in local folder's root
   long search_handle=FileFindFirst(InpFilter,file_name);
//--- check if FileFindFirst() function executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- check if the passed strings are file or directory names in the loop
      do
        {
         ResetLastError();
         //--- if this is a file, the function will return true, if it is a directory,
         FileIsExist(file_name);
         PrintFormat("%d : %s name = %s",i,GetLastError()==5018 ? "Directory" : "File"
         i++;
        }
      while(FileFindNext(search_handle,file_name));
      //--- close search handle
      FileFindClose(search_handle);
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   else
      Print("Files not found!");
  }
```

See also

FileFindFirst, FileFindNext

© 2000-2025, MetaQuotes Ltd.

FileIsExist

Checks the existence of a file.

```
bool  FileIsExist(
   const string  file_name,        // File name
   int           common_flag=0     // Search area
   );
```

Parameters

file_name

[in] The name of the file being checked

common_flag=0

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

Returns true, if the specified file exists.

Note

Checked file can turn out to be a subdirectory. In this case, FileIsExist() function will return false, while error 5018 will be logged in _LastError variable - "This is a directory, not a file" (see example for FileFindFirst function).

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If common_flag = FILE_COMMON, then the function looks for the file in a shared folder for all client terminals \Terminal\Common\Files, otherwise the function looks for a file in a local folder (MQL5\Files or MQL5\Tester\Files in the case of testing).

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- date for old files
input datetime InpFilesDate=D'2013.01.01 00:00';
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;      // variable for storing file names
   string   filter="*.txt"; // filter for searching the files
   datetime create_date;    // file creation date
   string   files[];        // list of file names
   int      def_size=25;    // array size by default
   int      size=0;         // number of files
```

© 2000-2025, MetaQuotes Ltd.

```
//--- allocate memory for the array
   ArrayResize(files,def_size);
//--- receive the search handle in the local folder's root
   long search_handle=FileFindFirst(filter,file_name);
//--- check if FileFindFirst() executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- searching files in the loop
      do
        {
         files[size]=file_name;
         //--- increase the array size
         size++;
         if(size==def_size)
           {
            def_size+=25;
            ArrayResize(files,def_size);
           }
         //--- reset the error value
         ResetLastError();
         //--- receive the file creation date
         create_date=(datetime)FileGetInteger(file_name,FILE_CREATE_DATE,false);
         //--- check if the file is old
         if(create_date<InpFilesDate)
           {
            PrintFormat("%s file deleted!",file_name);
            //--- delete the old file
            FileDelete(file_name);
           }
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
     {
      Print("Files not found!");
      return;
     }
//--- check what files have remained
   PrintFormat("Results:");
   for(int i=0;i<size;i++)
     {
      if(FileIsExist(files[i]))
         PrintFormat("%s file exists!",files[i]);
      else
         PrintFormat("%s file deleted!",files[i]);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

See also

FileFindFirst

© 2000-2025, MetaQuotes Ltd.

FileOpen

The function opens the file with the specified name and flag.

```
int  FileOpen(
   string  file_name,           // File name
   int     open_flags,          // Combination of flags
   short   delimiter='\t',      // Delimiter
   uint    codepage=CP_ACP      // Code page
   );
```

Parameters

file_name

[in] The name of the file can contain subfolders. If the file is opened for writing, these subfolders will be created if there are no such ones.

open_flags

[in] combination of flags determining the operation mode for the file. The flags are defined as follows:
FILE_READ file is opened for reading
FILE_WRITE file is opened for writing
FILE_BIN binary read-write mode (no conversion from a string and to a string)
FILE_CSV file of csv type (all recorded items are converted to the strings of unicode or ansi type, and are separated by a delimiter)
FILE_TXT a simple text file (the same as csv, but the delimiter is not taken into account)
FILE_ANSI lines of ANSI type (single-byte symbols)
FILE_UNICODE lines of UNICODE type (double-byte characters)
FILE_SHARE_READ shared reading from several programs
FILE_SHARE_WRITE shared writing from several programs
FILE_COMMON location of the file in a shared folder for all client terminals \Terminal\Common\Files

delimiter='\t'

[in] value to be used as a separator in txt or csv-file. If the csv-file delimiter is not specified, it defaults to a tab. If the txt-file delimiter is not specified, then no separator is used. If the separator is clearly set to 0, then no separator is used.

codepage=CP_ACP

[in] The value of the code page. For the most-used code pages provide appropriate constants.

Return Value

If a file has been opened successfully, the function returns the file handle, which is then used to access the file data. In case of failure returns INVALID_HANDLE.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

© 2000-2025, MetaQuotes Ltd.

Make sure to set the FILE_ANSI flag if the file should be read in a specific encoding (the codepage parameter with a code page value is specified). If there is no specified FILE_ANSI flag, the text file is read in Unicode without any conversion.

The file is opened in the folder of the client terminal in the subfolder MQL5\files (or testing_agent_directory\MQL5\files in case of testing). If FILE_COMMON is specified among flags, the file is opened in a shared folder for all MetaTrader 5 client terminals.

"Named pipes" can be opened according to the following rules:

- Pipe name is a string, which should have the following look: "\\servername\pipe\pipename", where servername - server name in the network, while pipename is a pipe name. If the pipes are used on the same computer, the server name can be omitted but a point should be inserted instead of it: "\\.\pipe\pipename". A client trying to connect the pipe should know its name.
- FileFlush() and FileSeek() should be called to the beginning of a file between sequential operations of reading from the pipe and writing to it.

A special symbol '\' is used in shown strings. Therefore, '\' should be doubled when writing a name in MQL5 application. It means that the above example should have the following look in the code: "\\\\servername\\pipe\\pipename".

More information about working with named pipes can be found in the article "Communicating With MetaTrader 5 Using Named Pipes Without Using DLLs".

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- incorrect file opening method
   string terminal_data_path=TerminalInfoString(TERMINAL_DATA_PATH);
   string filename=terminal_data_path+"\\MQL5\\Files\\"+"fractals.csv";
   int filehandle=FileOpen(filename,FILE_WRITE|FILE_CSV);
   if(filehandle<0)
     {
      Print("Failed to open the file by the absolute path ");
      Print("Error code ",GetLastError());
     }

//--- correct way of working in the "file sandbox"
   ResetLastError();
   filehandle=FileOpen("fractals.csv",FILE_WRITE|FILE_CSV);
   if(filehandle!=INVALID_HANDLE)
     {
      FileWrite(filehandle,TimeCurrent(),Symbol(), EnumToString(_Period));
      FileClose(filehandle);
      Print("FileOpen OK");
     }
   else Print("Operation FileOpen failed, error ",GetLastError());
//--- another example with the creation of an enclosed directory in MQL5\Files\
```

© 2000-2025, MetaQuotes Ltd.

```
   string subfolder="Research";
   filehandle=FileOpen(subfolder+"\\fractals.txt",FILE_WRITE|FILE_CSV);
      if(filehandle!=INVALID_HANDLE)
     {
      FileWrite(filehandle,TimeCurrent(),Symbol(), EnumToString(_Period));
      FileClose(filehandle);
      Print("The file must be created in the folder "+terminal_data_path+"\\"+subfolde
     }
   else Print("File open failed, error ",GetLastError());
  }
```

FileClose

Close the file previously opened by FileOpen().

```
void  FileClose(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

No value returned.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="file.txt";     // file name
input string InpDirectoryName="Data";    // directory name
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the path to the file we are going to use
   PrintFormat("Working %s\\Files\\ folder",TerminalInfoString(TERMINAL_DATA_PATH));
//--- reset the error value
   ResetLastError();
//--- open the file for reading (if the file does not exist, the error will occur)
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_TXT|InpEr
   if(file_handle!=INVALID_HANDLE)
     {
      //--- print the file contents
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      //--- close the file
      FileClose(file_handle);
     }
   else
      PrintFormat("Error, code = %d",GetLastError());
  }
```

© 2000-2025, MetaQuotes Ltd.

FileCopy

The function copies the original file from a local or shared folder to another file.

```
bool  FileCopy(
   const string  src_file_name,     // Name of a source file
   int           common_flag,       // Location
   const string  dst_file_name,     // Name of the destination file
   int           mode_flags         // Access mode
   );
```

Parameters

src_file_name

[in] File name to copy.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder (for example, *common_flag=0*).

dst_file_name

[in] Result file name.

mode_flags

[in] Access flags. The parameter can contain only 2 flags: FILE_REWRITE and/or FILE_COMMON - other flags are ignored. If the file already exists, and the FILE_REWRITE flag hasn't been specified, then the file will not be rewritten, and the function will return false.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the new file already exists, the copy will be made depending on the availability of the FILE_REWRITE flag in the mode_flags parameter.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpSrc="source.txt";       // source
input string InpDst="destination.txt";  // copy
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
  {
//--- display the source contents (it must exist)
   if(!FileDisplay(InpSrc))
      return;
//--- check if the copy file already exists (may not be created)
   if(!FileDisplay(InpDst))
     {
      //--- the copy file does not exist, copying without FILE_REWRITE flag (correct c
      if(FileCopy(InpSrc,0,InpDst,0))
         Print("File is copied!");
      else
         Print("File is not copied!");
     }
   else
     {
      //--- the copy file already exists, try to copy without FILE_REWRITE flag (inco
      if(FileCopy(InpSrc,0,InpDst,0))
         Print("File is copied!");
      else
         Print("File is not copied!");
      //--- InpDst file's contents remains the same
      FileDisplay(InpDst);
      //--- copy once more with FILE_REWRITE flag (correct copying if the file exists)
      if(FileCopy(InpSrc,0,InpDst,FILE_REWRITE))
         Print("File is copied!");
      else
         Print("File is not copied!");
     }
//--- receive InpSrc file copy
   FileDisplay(InpDst);
  }
//+------------------------------------------------------------------+
//| Read the file contents                                           |
//+------------------------------------------------------------------+
bool FileDisplay(const string file_name)
  {
//--- reset the error value
   ResetLastError();
//--- open the file
   int file_handle=FileOpen(file_name,FILE_READ|FILE_TXT|InpEncodingType);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- display the file contents in the loop
      Print("+----------------------+");
      PrintFormat("File name = %s",file_name);
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      Print("+----------------------+");
      //--- close the file
```

© 2000-2025, MetaQuotes Ltd.

```
      FileClose(file_handle);
      return(true);
     }
//--- failed to open the file
   PrintFormat("%s is not opened, error = %d",file_name,GetLastError());
   return(false);
  }
```

© 2000-2025, MetaQuotes Ltd.

FileDelete

Deletes the specified file in a local folder of the client terminal.

```
bool  FileDelete(
   const string  file_name,     // File name to delete
   int           common_flag=0  // Location of the file to delete
   );
```

Parameters

file_name

[in] File name.

common_flag=0

[in] Flag determining the file location. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Deletes the specified file from a local folder of the client terminal (MQL5\Files or MQL5\Tester\Files in case of testing). If common_flag = FILE_COMMON, then the function removes the file from the shared folder for all client terminals \Terminal\Common\Files.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- date for old files
input datetime InpFilesDate=D'2013.01.01 00:00';
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;      // variable for storing file names
   string   filter="*.txt"; // filter for searching the files
   datetime create_date;    // file creation date
   string   files[];        // list of file names
   int      def_size=25;    // array size by default
   int      size=0;         // number of files
//--- allocate memory for the array
   ArrayResize(files,def_size);
//--- receive the search handle in the local folder's root
   long search_handle=FileFindFirst(filter,file_name);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- check if FileFindFirst() executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- searching files in the loop
      do
        {
         files[size]=file_name;
         //--- increase the array size
         size++;
         if(size==def_size)
           {
            def_size+=25;
            ArrayResize(files,def_size);
           }
         //--- reset the error value
         ResetLastError();
         //--- receive the file creation date
         create_date=(datetime)FileGetInteger(file_name,FILE_CREATE_DATE,false);
         //--- check if the file is old
         if(create_date<InpFilesDate)
           {
            PrintFormat("%s file deleted!",file_name);
            //--- delete the old file
            FileDelete(file_name);
           }
        }
      while(FileFindNext(search_handle,file_name));
      //--- close the search handle
      FileFindClose(search_handle);
     }
   else
     {
      Print("Files not found!");
      return;
     }
//--- check what files have remained
   PrintFormat("Results:");
   for(int i=0;i<size;i++)
     {
      if(FileIsExist(files[i]))
         PrintFormat("%s file exists!",files[i]);
      else
         PrintFormat("%s file deleted!",files[i]);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

FileMove

Moves a file from a local or shared folder to another folder.

```
bool  FileMove(
   const string  src_file_name,     // File name for the move operation
   int           common_flag,       // Location
   const string  dst_file_name,     // Name of the destination file
   int           mode_flags         // Access mode
   );
```

Parameters

src_file_name

[in] File name to move/rename.

common_flag

[in] Flag determining the location of the file. If common_flag = FILE_COMMON, then the file is located in a shared folder for all client terminals \Terminal\Common\Files. Otherwise, the file is located in a local folder (*common_flag=0*).

dst_file_name

[in] File name after operation

mode_flags

[in] Access flags. The parameter can contain only 2 flags: FILE_REWRITE and/or FILE_COMMON - other flags are ignored. If the file already exists and the FILE_REWRITE flag isn't specified, the file will not be rewritten, and the function will return false.

Return Value

In case of failure the function returns false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the new file already exists, the copy will be made depending on the availability of the FILE_REWRITE flag in the mode_flags parameter.

Example:

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpSrcName="data.txt";
input string InpDstName="newdata.txt";
input string InpSrcDirectory="SomeFolder";
input string InpDstDirectory="OtherFolder";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
```

© 2000-2025, MetaQuotes Ltd.

```
void OnStart()
  {
   string local=TerminalInfoString(TERMINAL_DATA_PATH);
   string common=TerminalInfoString(TERMINAL_COMMONDATA_PATH);
//--- receive file paths
   string src_path;
   string dst_path;
   StringConcatenate(src_path,InpSrcDirectory,"//",InpSrcName);
   StringConcatenate(dst_path,InpDstDirectory,"//",InpDstName);
//--- check if the source file exists (if not - exit)
   if(FileIsExist(src_path))
      PrintFormat("%s file exists in the %s\\Files\\%s folder",InpSrcName,local,InpSrc
   else
     {
      PrintFormat("Error, %s source file not found",InpSrcName);
      return;
     }
//--- check if the result file already exists
   if(FileIsExist(dst_path,FILE_COMMON))
     {
      PrintFormat("%s file exists in the %s\\Files\\%s folder",InpDstName,common,InpDs
      //--- file exists, moving should be performed with FILE_REWRITE flag
      ResetLastError();
      if(FileMove(src_path,0,dst_path,FILE_COMMON|FILE_REWRITE))
         PrintFormat("%s file moved",InpSrcName);
      else
         PrintFormat("Error! Code = %d",GetLastError());
     }
   else
     {
      PrintFormat("%s file does not exist in the %s\\Files\\%s folder",InpDstName,comm
      //--- the file does not exist, moving should be performed without FILE_REWRITE f
      ResetLastError();
      if(FileMove(src_path,0,dst_path,FILE_COMMON))
         PrintFormat("%s file moved",InpSrcName);
      else
         PrintFormat("Error! Code = %d",GetLastError());
     }
//--- the file is moved; let's check it out
   if(FileIsExist(dst_path,FILE_COMMON) && !FileIsExist(src_path,0))
      Print("Success!");
   else
      Print("Error!");
  }
```

FileIsExist

© 2000-2025, MetaQuotes Ltd.

FileFlush

Writes to a disk all data remaining in the input/output file buffer.

```
void  FileFlush(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

No value returned.

Note

When writing to a file, the data may be actually found there only after some time. To save the data in the file instantly, use FileFlush() function. If the function is not used, part of the data that has not been stored in the disk yet, will be forcibly written there only when the file is closed using FileClose() function.

The function should be used when written data is of a certain value. It should be kept in mind that frequent function call may affect the program operation speed.

Function FileFlush () must be called between the operations of reading from a file and writing to it.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- file name for writing
input string InpFileName="example.csv"; // file name
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- reset error value
   ResetLastError();
//--- open the file
   int file_handle=FileOpen(InpFileName,FILE_READ|FILE_WRITE|FILE_CSV);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- write data to the file
      for(int i=0;i<1000;i++)
        {
         //--- call write function
         FileWrite(file_handle,TimeCurrent(),SymbolInfoDouble(Symbol(),SYMBOL_BID),Sy
         //--- save data on the disk at each 128th iteration
         if((i & 127)==127)
```

© 2000-2025, MetaQuotes Ltd.

```
            {
             //--- now, data will be located in the file and will not be lost in case o
             FileFlush(file_handle);
             PrintFormat("i = %d, OK",i);
            }
          //--- 0.01 second pause
          Sleep(10);
         }
       //--- close the file
       FileClose(file_handle);
      }
    else
       PrintFormat("Error, code = %d",GetLastError());
  }
```

FileClose

© 2000-2025, MetaQuotes Ltd.

FileGetInteger

Gets an integer property of a file. There are two variants of the function.

1. Get a property by the handle of a file.

```
long  FileGetInteger(
   int                          file_handle,    // File handle
   ENUM_FILE_PROPERTY_INTEGER   property_id     // Property ID
   );
```

2. Get a property by the file name.

```
long  FileGetInteger(
   const string                 file_name,             // File name
   ENUM_FILE_PROPERTY_INTEGER   property_id,           // Property ID
   bool                         common_folder=false    // The file is viewed in a local
   );                                                  // or a common folder of all terr
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

file_name

[in] File name.

property_id

[in] File property ID. The value can be one of the values of the ENUM_FILE_PROPERTY_INTEGER enumeration. If the second variant of the function is used, you can receive only the values of the following properties: FILE_EXISTS, FILE_CREATE_DATE, FILE_MODIFY_DATE, FILE_ACCESS_DATE and FILE_SIZE.

common_folder=false

[in] Points to the file location. If the parameter is false, terminal data folder is viewed. Otherwise it is assumed that the file is in the shared folder of all terminals \Terminal\Common\Files (FILE_COMMON).

Return Value

The value of the property. In case of an error, -1 is returned. To get an error code use the GetLastError() function.

If a folder is specified when getting properties by the name, the function will have error 5018 (ERR_MQL_FILE_IS_DIRECTORY) in any case, though the return value will be correct.

Note

The function always changes the error code. In case of successful completion the error code is reset to NULL.

Example:

```
//--- display the window of input parameters when launching the script
```

© 2000-2025, MetaQuotes Ltd.

```
#property script_show_inputs
//--- input parameters
input string InpFileName="data.csv";
input string InpDirectoryName="SomeFolder";
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string path=InpDirectoryName+"//"+InpFileName;
   long   l=0;
//--- open the file
   ResetLastError();
   int handle=FileOpen(path,FILE_READ|FILE_CSV);
   if(handle!=INVALID_HANDLE)
     {
      //--- print all information about the file
      Print(InpFileName," file info:");
      FileInfo(handle,FILE_EXISTS,l,"bool");
      FileInfo(handle,FILE_CREATE_DATE,l,"date");
      FileInfo(handle,FILE_MODIFY_DATE,l,"date");
      FileInfo(handle,FILE_ACCESS_DATE,l,"date");
      FileInfo(handle,FILE_SIZE,l,"other");
      FileInfo(handle,FILE_POSITION,l,"other");
      FileInfo(handle,FILE_END,l,"bool");
      FileInfo(handle,FILE_IS_COMMON,l,"bool");
      FileInfo(handle,FILE_IS_TEXT,l,"bool");
      FileInfo(handle,FILE_IS_BINARY,l,"bool");
      FileInfo(handle,FILE_IS_CSV,l,"bool");
      FileInfo(handle,FILE_IS_ANSI,l,"bool");
      FileInfo(handle,FILE_IS_READABLE,l,"bool");
      FileInfo(handle,FILE_IS_WRITABLE,l,"bool");
      //--- close the file
      FileClose(handle);
     }
   else
      PrintFormat("%s file is not opened, ErrorCode = %d",InpFileName,GetLastError());
  }
//+------------------------------------------------------------------+
//| Display the value of the file property                           |
//+------------------------------------------------------------------+
void FileInfo(const int handle,const ENUM_FILE_PROPERTY_INTEGER id,
              long l,const string type)
  {
//--- receive the property value
   ResetLastError();
   if((l=FileGetInteger(handle,id))!=-1)
     {
      //--- the value received, display it in the correct format
```

© 2000-2025, MetaQuotes Ltd.

```
      if(!StringCompare(type,"bool"))
         Print(EnumToString(id)," = ",l ? "true" : "false");
      if(!StringCompare(type,"date"))
         Print(EnumToString(id)," = ",(datetime)l);
      if(!StringCompare(type,"other"))
         Print(EnumToString(id)," = ",l);
     }
   else
      Print("Error, Code = ",GetLastError());
  }
```

FileIsEnding

Defines the end of a file in the process of reading.

```
bool  FileIsEnding(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The function returns true if the file end has been reached in the process of reading or moving of the file pointer.

Note

To define the end of the file, the function tries to read the next string from it. If the string does not exist, the function returns true, otherwise it returns false.

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="file.txt";     // file name
input string InpDirectoryName="Data";    // directory name
input int    InpEncodingType=FILE_ANSI; // ANSI=32 or UNICODE=64
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- print the path to the file we are going to use
   PrintFormat("Working %s\\Files\\ folder",TerminalInfoString(TERMINAL_DATA_PATH));
//--- reset the error value
   ResetLastError();
//--- open the file for reading (if the file does not exist, the error will occur)
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_TXT|InpEr
   if(file_handle!=INVALID_HANDLE)
     {
      //--- print the file contents
      while(!FileIsEnding(file_handle))
         Print(FileReadString(file_handle));
      //--- close the file
      FileClose(file_handle);
     }
   else
      PrintFormat("Error, code = %d",GetLastError());
```

© 2000-2025, MetaQuotes Ltd.

```
}
```

FileIsLineEnding

Defines the line end in a text file in the process of reading.

```
bool  FileIsLineEnding(
   int  file_handle      // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Returns true if in the process of reading txt or csv-file reached the end of the line (the characters CR-LF).

Example (the file obtained during the execution of an example for FileWriteString function is used here)

```

FileReadArray

Reads from a file of BIN type arrays of any type except string (may be an array of structures, not containing strings, and dynamic arrays).

```
uint  FileReadArray(
   int     file_handle,               // File handle
   void&   array[],                   // Array to record
   int     start=0,                   // start array position to write
   int     count=WHOLE_ARRAY          // count to read
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

array[]

[out] An array where the data will be loaded.

start=0

[in] Start position to read from the array.

count=WHOLE_ARRAY

[in] Number of elements to read. By default, reads the entire array (count=WHOLE_ARRAY).

Return Value

Number of elements read.

Note

String array can be read only from the file of TXT type. If necessary, the function tries to increase the size of the array.

Example (the file obtained after execution of the example for FileWriteArray function is used here)

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input string InpFileName="data.bin";
input string InpDirectoryName="SomeFolder";
//+------------------------------------------------------------------+
//| Structure for storing price data                                 |
//+------------------------------------------------------------------+
struct prices
  {
   datetime          date; // date
   double            bid;  // bid price
   double            ask;  // ask price
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
```

© 2000-2025, MetaQuotes Ltd.

```
//+------------------------------------------------------------------+
void OnStart()
  {
//--- structure array
   prices arr[];
//--- file path
   string path=InpDirectoryName+"//"+InpFileName;
//--- open the file
   ResetLastError();
   int file_handle=FileOpen(path,FILE_READ|FILE_BIN);
   if(file_handle!=INVALID_HANDLE)
     {
      //--- read all data from the file to the array
      FileReadArray(file_handle,arr);
      //--- receive the array size
      int size=ArraySize(arr);
      //--- print data from the array
      for(int i=0;i<size;i++)
         Print("Date = ",arr[i].date," Bid = ",arr[i].bid," Ask = ",arr[i].ask);
      Print("Total data = ",size);
      //--- close the file
      FileClose(file_handle);
     }
   else
      Print("File open failed, error ",GetLastError());
  }
```

FileReadBool

Reads from the file of CSV type string from the current position to a delimiter (or till the end of the text line) and converts the read string to a bool type value.

```
bool  FileReadBool(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Line read may be set to "true", "false" or the symbolic representation of integers "0" or "1". A nonzero value is converted to a logical true. The function returns the converted value.

Example (the file obtained after executing the example for FileWrite function is used here)

FileReadDatetime

Reads from the file of CSV type a string of one of the formats: "YYYY.MM.DD HH:MI:SS", "YYYY.MM.DD" or "HH:MI:SS" - and converts it into a value of datetime type.

```
datetime  FileReadDatetime(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of datetime type.

Example (the file obtained after executing the example for FileWrite function is used here)

```

FileReadDouble

Reads a double-precision floating point number (double) from the current position of the binary file.

```
double  FileReadDouble(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of double type.

Note

For more details about the error, call GetLastError().

Example (the file obtained after executing the example for FileWriteDouble function is used here)

```

FileReadInteger

The function reads int, short or char value from the current position of the file pointer depending on the length specified in bytes.

```
int  FileReadInteger(
   int  file_handle,         // File handle
   int  size=INT_VALUE       // Size of an integer in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

size=INT_VALUE

[in] Number of bytes (up to 4 inclusive) that should be read. The corresponding constants are provided: CHAR_VALUE = 1, SHORT_VALUE = 2 and INT_VALUE = 4, so the function can read the whole value of char, short or int type.

Return Value

A value of the int type. The result of this function must be explicitly cast to a target type, i.e. to the type of data that you need to read. Since a value of the int type is returned, it can be easily converted to any integer value. The file pointer is shifted by the number of bytes read.

Note

When reading less than 4 bytes, the received result is always positive. If one or two bytes are read, the sign of the number can be determined by explicit casting to type char (1 byte) or short (2 bytes). Getting the sign for a three-byte number is not trivial, since there is no corresponding underlying type.

Example (the file obtained after executing the example for FileWriteInteger function is used here)

FileReadLong

The function reads an integer of long type (8 bytes) from the current position of the binary file.

```
long  FileReadLong(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of long type.

FileReadNumber

The function reads from the CSV file a string from the current position till a separator (or till the end of a text string) and converts the read string to a value of double type.

```
double  FileReadNumber(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of double type.

Example (the file obtained during the execution of an example for FileWriteString function is used here)

```

FileReadString

The function reads a string from the current position of a file pointer in a file.

```
string  FileReadString(
   int  file_handle,     // File handle
   int  length=-1        // Length of the string
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

length=-1

[in] Number of characters to read.

Return Value

Line read (string).

Note

When reading from a bin-file. the length of a string to read must be specified. When reading from a txt-file the string length is not required, and the string will be read from the current position to the line feed character "\r\n". When reading from a csv-file, the string length isn't required also, the string will be read from the current position till the nearest delimiter or till the text string end character.

If the file is opened with FILE_ANSI flag, then the line read is converted to Unicode.

Example (the file obtained after executing the example for FileWriteInteger function is used here)

```
//--- display the window of input parameters when launching the script
#property script_show_inputs
//--- parameters for data reading
input string InpFileName="Trend.bin"; // file name
input string InpDirectoryName="Data"; // directory name
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- open the file
   ResetLastError();
   int file_handle=FileOpen(InpDirectoryName+"//"+InpFileName,FILE_READ|FILE_BIN|FILE_
   if(file_handle!=INVALID_HANDLE)
     {
      PrintFormat("%s file is available for reading",InpFileName);
      PrintFormat("File path: %s\\Files\\",TerminalInfoString(TERMINAL_DATA_PATH));
      //--- additional variables
      int    str_size;
      string str;
```

© 2000-2025, MetaQuotes Ltd.

```
      //--- read data from the file
      while(!FileIsEnding(file_handle))
        {
         //--- find out how many symbols are used for writing the time
         str_size=FileReadInteger(file_handle,INT_VALUE);
         //--- read the string
         str=FileReadString(file_handle,str_size);
         //--- print the string
         PrintFormat(str);
        }
      //--- close the file
      FileClose(file_handle);
      PrintFormat("Data is read, %s file is closed",InpFileName);
     }
   else
      PrintFormat("Failed to open %s file, Error code = %d",InpFileName,GetLastError()
  }
```

FileReadStruct

The function reads contents into a structure passed as a parameter from a binary-file, starting with the current position of the file pointer.

```
uint  FileReadStruct(
   int           file_handle,        // file handle
   const void&   struct_object,      // target structure to which the contents are read
   int           size=-1             // structure size in bytes
   );
```

Parameters

file_handle

[in] File descriptor of an open bin-file.

struct_object

[out] The object of this structure. The structure should not contain strings, dynamic arrays or virtual functions.

size=-1

[in] Number of bytes that should be read. If size is not specified or the indicated value is greater than the size of the structure, the exact size of the specified structure is used.

Return Value

If successful the function returns the number of bytes read. File pointer is moved by the same number of bytes.

Example (the file obtained after using the example for FileWriteStruct function is used here)

```

FileSeek

The function moves the position of the file pointer by a specified number of bytes relative to the specified position.

```
bool  FileSeek(
   int                  file_handle,     // File handle
   long                 offset,          // In bytes
   ENUM_FILE_POSITION   origin           // Position for reference
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

offset

[in] The shift in bytes (may take a negative value).

origin

[in] The starting point for the displacement. Can be one of values of ENUM_FILE_POSITION.

Return Value

If successful the function returns true, otherwise false. To obtain information about the error call the GetLastError() function.

Note

If the execution of the FileSeek() function results in a negative shift (going beyond the "level boundary" of the file), the file pointer will be set to the file beginning.

If a position is set beyond the "right boundary" of the file (larger than the file size), the next writing to the file will be performed not from the end of the file, but from the position set. In this case indefinite values will be written for the previous file end and the position set.

Example:

```
//+------------------------------------------------------------------+

FileSize

The function returns the file size in bytes.

```
ulong  FileSize(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

The value of type int.

Note

To obtain information about the error call GetLastError().

Example:

```
//--- show the window of input parameters when launching the script
#property script_show_inputs
//--- input parameters
input ulong  InpThresholdSize=20;        // file threshold size in kilobytes
input string InpBigFolderName="big";     // folder for large files
input string InpSmallFolderName="small"; // folder for small files
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string   file_name;      // variable for storing file names
   string   filter="*.csv"; // filter for searching the files
   ulong    file_size=0;    // file size in bytes
   int      size=0;         // number of files
//--- print the path to the file we are going to work with
   PrintFormat("Working in %s\\Files\\ folder",TerminalInfoString(TERMINAL_COMMONDATA_
//--- receive the search handle in common folder's root of all terminals
   long search_handle=FileFindFirst(filter,file_name,FILE_COMMON);
//--- check if FileFindFirst() has been executed successfully
   if(search_handle!=INVALID_HANDLE)
     {
      //--- move files in the loop according to their size
      do
        {
         //--- open the file
         ResetLastError();
         int file_handle=FileOpen(file_name,FILE_READ|FILE_CSV|FILE_COMMON);
         if(file_handle!=INVALID_HANDLE)
```

FileTell

The file returns the current position of the file pointer of an open file.

```
ulong  FileTell(
   int  file_handle    // File handle
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

Return Value

Current position of the file descriptor in bytes from the beginning of the file.

Note

To obtain information about the error call GetLastError().

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FileTell.mq5 |

FileWrite

The function is intended for writing of data into a CSV file, delimiter being inserted automatically unless it is equal to 0. After writing into the file, the line end character "\r\n" will be added.

```
uint  FileWrite(
   int  file_handle,    // File handle
   ...                  // List of recorded parameters
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

...

[in] The list of parameters separated by commas, to write to the file. The number of written parameters can be up to 63.

Return Value

Number of bytes written.

Note

Numbers will be converted into a text at output (see the Print() function). Data of the double type are output with the accuracy of 16 digits after the decimal point, and the data can be displayed either in traditional or in scientific format - depending on which format will be the most compact. The data of the float type are shown with 5 digits after the decimal point. To output real numbers with different precision or in a clearly specified format, use DoubleToString().

Numbers of the bool type are displayed as "true" or "false" strings. Numbers of the datetime type are displayed as "YYYY.MM.DD HH:MI:SS".

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FileWrite.mq5 |

FileWriteArray

The function writes arrays of any type except for string to a BIN file (can be an array of structures not containing strings or dynamic arrays).

```
uint  FileWriteArray(
   int           file_handle,          // File handle
   const void&   array[],              // Array
   int           start=0,              // Start index in the array
   int           count=WHOLE_ARRAY     // Number of elements
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

array[]

[out] Array for recording.

start=0

[in] Initial index in the array (number of the first recorded element).

count=WHOLE_ARRAY

[in] Number of items to write (WHOLE_ARRAY means that all items starting with the number start until the end of the array will be written).

Return Value

Number of recorded items.

Note

String array can be recorded in a TXT file. In this case, strings are automatically ended by the line end characters "\r\n". Depending on the file type ANSI or UNICODE, strings are either converted to ansi-encoding or not.

FileWriteDouble

The function writes the value of a double parameter to a a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteDouble(
   int     file_handle,     // File handle
   double  value            // Value to write
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] The value of double type.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(double)=8). The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                        Demo_FileWriteDouble.mq5 |

FileWriteFloat

The function writes the value of the float parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteFloat(
   int    file_handle,     // File handle
   float  value            // Value to be written
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] The value of float type.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(float)=4). The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                          Demo_FileWriteFloat.mq5 |

FileWriteInteger

The function writes the value of the int parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteInteger(
   int  file_handle,         // File handle
   int  value,               // Value to be written
   int  size=INT_VALUE       // Size in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] Integer value.

size=INT_VALUE

[in] Number of bytes (up to 4 inclusive), that should be written. The corresponding constants are provided: CHAR_VALUE=1, SHORT_VALUE=2 and INT_VALUE=4, so the function can write the integer value of char, uchar, short, ushort, int, or uint type.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                        Demo_FileWriteInteger.mq5 |

FileWriteLong

The function writes the value of the long-type parameter to a bin-file, starting from the current position of the file pointer.

```
uint  FileWriteLong(
   int   file_handle,     // File handle
   long  value            // Value to be written
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

value

[in] Value of type long.

Return Value

If successful the function returns the number of bytes written (in this case sizeof(long)=8). The file pointer is shifted by the same number of bytes.

Example:

```
//+------------------------------------------------------------------+
//|                                            Demo_FileWriteLong.mq5 |

FileWriteString

The function writes the value of a string-type parameter into a BIN, CSV or TXT file starting from the current position of the file pointer. When writing to a CSV or TXT file: if there is a symbol in the string '\n' (LF) without previous character '\r' (CR), then before '\n' the missing '\r' is added.

```
uint  FileWriteString(
   int           file_handle,     // File handle
   const string  text_string,     // string to write
   int           length=-1        // number of symbols
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

text_string

[in] String.

length=-1

[in] The number of characters that you want to write. This option is needed for writing a string into a BIN file. If the size is not specified, then the entire string without the trailer 0 is written. If you specify a size smaller than the length of the string, then a part of the string without the trailer 0 is written. If you specify a size greater than the length of the string, the string is filled by the appropriate number of zeros. For files of CSV and TXT type, this parameter is ignored and the string is written entirely.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Note

Note that when writing to a file opened by the FILE_UNICODE flag (or without a flag FILE_ANSI), then the number of bytes written will be twice as large as the number of string characters written. When recording to a file opened with the FILE_ANSI flag, the number of bytes written will coincide with the number of string characters written.

Example:

```

FileWriteStruct

The function writes into a bin-file contents of a structure passed as a parameter, starting from the current position of the file pointer.

```
uint  FileWriteStruct(
   int          file_handle,       // File handle
   const void&  struct_object,     // link to an object
   int          size=-1            // size to be written in bytes
   );
```

Parameters

file_handle

[in] File descriptor returned by FileOpen().

struct_object

[in] Reference to the object of this structure. The structure should not contain strings, dynamic arrays or virtual functions.

size=-1

[in] Number of bytes that you want to record. If size is not specified or the specified number of bytes is greater than the size of the structure, the entire structure is written.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Example:

```

FileLoad

Reads all data of a specified binary file into a passed array of numeric types or simple structures. The function allows you to quickly read data of a known type into the appropriate array.

```
long  FileLoad(
   const string  file_name,          // File name
   void&         buffer[],           // An array of numeric types or simple structures
   int           common_flag=0       // A file flag, is searched in <data_folder>\MQL5\
   );
```

Parameters

file_name

[in] The name of the file from which data will be read.

buffer

[out] An array of numeric types or simple structures.

common_flag=0

[in] A file flag indicating the operation mode. If the parameter is not specified, the file is searched in the subfolder MQL5\Files (or in <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

The number of elements read or -1 in case of an error.

Note

The FileLoad() function reads from a file the number of bytes multiple of the array element size. Suppose the file size is 10 bytes, and the function reads data into an array of type double (sizeof(double)=8). In this case the function will read only 8 bytes, the remaining 2 bytes at the end of the file will be dropped, and the function FileLoad() will return 1 (1 element read).

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FileLoad.mq5 |

FileSave

Writes to a binary file all elements of an array passed as a parameter. The function allows you to quickly write arrays of numeric types or simple structures as one string.

```
bool  FileSave(
   const string  file_name,          // File name
   void&         buffer[],           // An array of numeric types or simple structures
   int           common_flag=0       // A file flag, by default files are written to <
   );
```

Parameters

file_name

[in] The name of the file, to the data array will be written.

buffer

[in] An array of numeric types or simple structures.

common_flag=0

[in] A file flag indicating the operation mode. If the parameter is not specified, the file will be written to the subfolder MQL5\Files (or to <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

In case of failure returns false.

Example:

```
//+------------------------------------------------------------------+
//|                                                 Demo_FileSave.mq5 |

FolderCreate

Creates a directory in the Files folder (depending on the common_flag value)

```
bool  FolderCreate(
   string  folder_name,       // line with the created folder name
   int     common_flag=0      // action area
   );
```

Parameters

folder_name

[in] Name of the directory to be created. Contains the relative path to the folder.

common_flag=0

[in] Flag defining the directory location. If common_flag=FILE_COMMON, the directory is located in the common folder of all client terminals \Terminal\Common\Files. Otherwise, the directory is in the local folder (MQL5\Files or MQL5\Tester\Files when testing).

Return Value

Returns true if successful, otherwise false.

Note

For reasons of security, working with files is strictly controlled in MQL5 language. Files used in file operations by means of MQL5 language cannot be located outside the file sandbox.

Example:

```
#property copyright "Copyright 2000-2024, MetaQuotes Ltd."

FileOpen(), FolderClean(), FileCopy()

© 2000-2025, MetaQuotes Ltd.

FolderDelete

The function removes the specified directory. If the folder is not empty, then it can't be removed.

```
bool  FolderDelete(
   string  folder_name,       // String with the name of the folder to delete
   int     common_flag=0      // Scope
   );
```

Parameters

folder_name

[in] The name of the directory you want to delete. Contains the full path to the folder.

common_flag=0

[in] Flag determining the location of the directory. If common_flag=FILE_COMMON, then the directory is in the shared folder for all client terminals \Terminal\Common\Files. Otherwise, the directory is in a local folder (MQL5\Files or MQL5\Tester\Files in the case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the directory contains at least one file and/or subdirectory, then this directory can't be deleted, it must be cleared first. FolderClean() is used to clear a folder of all its files or subfolders.

Example:

```
//+------------------------------------------------------------------+

FolderClean

The function deletes all files in a specified folder.

```
bool  FolderClean(
   string  folder_name,       // String with the name of the deleted folder
   int     common_flag=0      // Scope
   );
```

Parameters

folder_name

[in] The name of the directory where you want to delete all files. Contains the full path to the folder.

common_flag=0

[in] Flag determining the location of the directory. If common_flag = FILE_COMMON, then the directory is in the shared folder for all client terminals \Terminal\Common\Files. Otherwise, the directory is in a local folder(MQL5\Files or MQL5\Tester\Files in case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

This function should be used with caution, since all the files and all subdirectories are deleted irretrievably.

Example:

```
//+------------------------------------------------------------------+
//|                                                Demo_FolderClean.mq5 |

Custom Indicators

This is the group functions used in the creation of custom indicators. These functions can't be used when writing Expert Advisors and Scripts.

Function	Action
SetIndexBuffer	Binds the specified indicator buffer with one-dimensional dynamic array of the double type
IndicatorSetDouble	Sets the value of an indicator property of the double type
IndicatorSetInteger	Sets the value of an indicator property of the int type
IndicatorSetString	Sets the value of an indicator property of the string type
PlotIndexSetDouble	Sets the value of an indicator line property of the type double
PlotIndexSetInteger	Sets the value of an indicator line property of the int type
PlotIndexSetString	Sets the value of an indicator line property of the string type
PlotIndexGetInteger	Returns the value of an indicator line property of the integer type

Indicator properties can be set using the compiler directives or using functions. To better understand this, it is recommended that you study indicator styles in examples.

All the necessary calculations of a custom indicator must be placed in the predetermined function OnCalculate(). If you use a short form of the OnCalculate() function call, like

```
int OnCalculate (const int rates_total, const int prev_calculated, const int begin, co
```

then the *rates_total* variable contains the value of the total number of elements of the price[] array, passed as an input parameter for calculating indicator values.

Parameter *prev_calculated* is the result of the execution of OnCalculate() at the previous call; it allows organizing a saving algorithm for calculating indicator values. For example, if the current value rates_total = 1000, prev_calculated = 999, then perhaps it's enough to make calculations only for one value of each indicator buffer.

If the information about the size of the input array price would have been unavailable, then it would lead to the necessity to make calculations for 1000 values of each indicator buffer. At the first call of OnCalculate() value prev_calculated = 0. If the price[] array has changed somehow, then in this case prev_calculated is also equal to 0.

The *begin* parameter shows the number of initial values of the price array, which don't contain data for calculation. For example, if values of Accelerator Oscillator (for which the first 37 values aren't calculated) were used as an input parameter, then begin = 37. For example, let's consider a simple indicator:

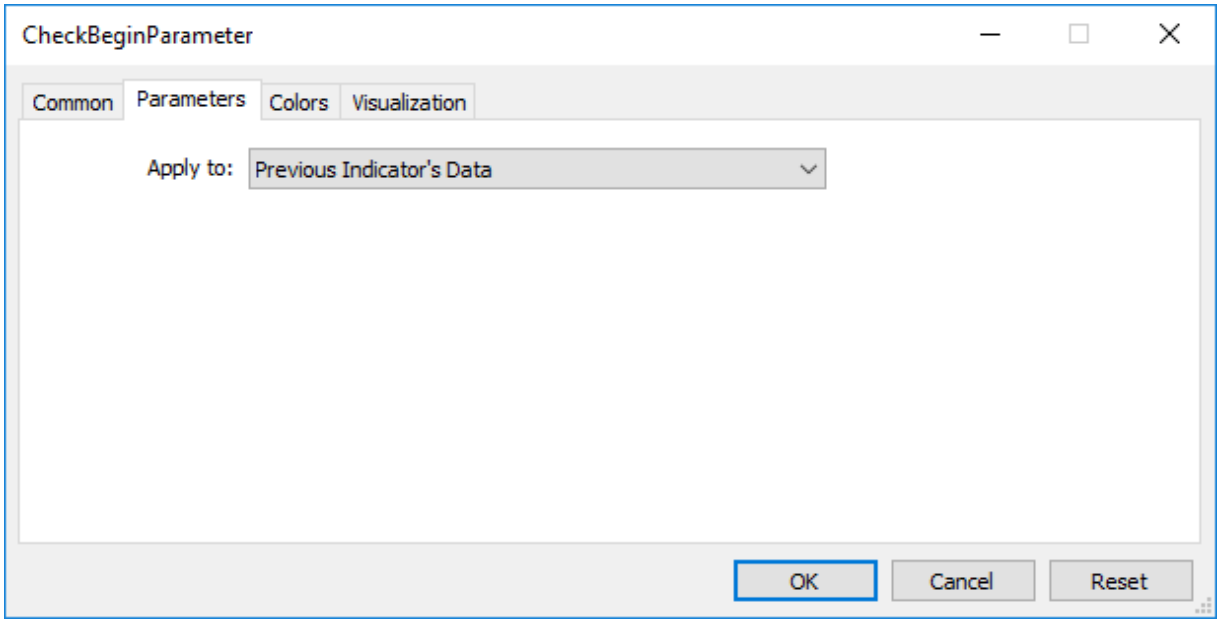
```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots   1
//---- plot Label1
#property indicator_label1  "Label1"
```

© 2000-2025, MetaQuotes Ltd.

```
#property indicator_type1   DRAW_LINE
#property indicator_color1  clrRed
#property indicator_style1  STYLE_SOLID
#property indicator_width1  1
//--- indicator buffers
double         Label1Buffer[];
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+
void OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,Label1Buffer,INDICATOR_DATA);
//---
  }
//+------------------------------------------------------------------+
//| Custom indicator iteration function                              |
//+------------------------------------------------------------------+
int OnCalculate(const int rates_total,
                const int prev_calculated,
                const int begin,
                const double &price[])

  {
//---
   Print("begin = ",begin,"  prev_calculated = ",prev_calculated,"  rates_total = ",ra
//--- return value of prev_calculated for next call
   return(rates_total);
  }
```

Drag it from the "Navigator" window to the window of the Accelerator Oscillator indicator and we indicate that calculations will be made based on the values of the previous indicator:



© 2000-2025, MetaQuotes Ltd.

As a result, the first call of OnCalculate() the value of prev_calculated will be equal to zero, and in further calls it will be equal to the rates_total value (until the number of bars on the price chart increases).

The value of the begin parameter will be exactly equal to the number of initial bars, for which the values of the Accelerator indicator aren't calculated according to the logic of this indicator. If we look at the source code of the custom indicator Accelerator.mq5, we'll see the following lines in the OnInit() function:

```
//--- sets first bar from which index will be drawn
   PlotIndexSetInteger(0,PLOT_DRAW_BEGIN,37);
```

Using the function PlotIndexSetInteger(0, PLOT_DRAW_BEGIN, empty_first_values), we set the number of non-existing first values in the zero indicator array of a custom indicator, which we don't need to accept for calculation (empty_first_values). Thus, we have mechanisms to:

1. set the number of initial values of an indicator, which shouldn't be used for calculations in another custom indicator;
2. get information on the number of first values to be ignored when you call another custom indicator, without going into the logic of its calculations.

Indicator Styles in Examples

The MetaTrader 5 Client Terminal includes 38 technical indicators that can be used in MQL5 programs using appropriate functions. But the main advantage of the MQL5 language is the ability to create custom indicators, which can then be used in Expert Advisors or simply applied on price charts for the purpose of technical analysis.

The entire set of indicators can be derived from several base drawing styles, known as plotting. Plotting denotes a way of displaying data, which the indicator calculates, stores and provides on request. There are seven such basic plotting types:

1. A line
2. A section (segment)
3. Histogram
4. Arrow (symbol)
5. A painted area (filled channel)
6. Bars
7. Japanese candlesticks

Each plotting requires one to five arrays of the double type, in which indicator values are stored. For the purpose of convenience, these arrays are associated with the indicator buffers. The number of buffers in an indicator must be declared in advance using compiler directives, for example:

```
#property indicator_buffers 3 // Number of buffers
#property indicator_plots   2 // number of plots
```

The number of buffers in the indicator is always greater than or equal to the number of plots in the indicator.

Since each basic plotting type can have color variation or construction specifics, the actual number of plotting types in the MQL5 is 18:

Plotting	Description	Value buffers	Color buffers
DRAW_NONE	Is not visually displayed in the chart, but the values of the corresponding buffer can be viewed in the Data Window	1	-

© 2000-2025, MetaQuotes Ltd.

Plotting	Description	Value buffers	Color buffers
DRAW_LINE	A line is plotted on the values of the corresponding buffer (empty values in the buffer are undesirable)	1	-
DRAW_SECTION	Is drawn as line segments between the values of the corresponding buffer (usually has a lot of empty values)	1	-
DRAW_HISTOGRAM	Is drawn as a histogram from the zero line to the values of the corresponding buffer (may have empty values)	1	-

© 2000-2025, MetaQuotes Ltd.

Plotting	Description	Value buffers	Color buffers
DRAW_HISTOGRAM2	Is drawn as a histogram based on two indicator buffers (may have empty values)	2	-
DRAW_ARROW	Is drawn as symbols (may have empty values)	1	-
DRAW_ZIGZAG	Similar to the style DRAW_SECTION, but unlike it, can plot vertical segments on one bar	2	-
DRAW_FILLING	Color fill between two lines. 2 values of the corresponding buffers are shown in the Data Window	2	-
DRAW_BARS	Is drawn as bars. 4 values	4	-

© 2000-2025, MetaQuotes Ltd.

Plotting	Description	Value buffers	Color buffers
	of the corresponding buffers are shown in the Data Window		
DRAW_CANDLES	Drawn as Japanese candlesticks. 4 values of the corresponding buffers are shown in the Data Window	4	-
DRAW_COLOR_LINE	A line for which you can alternate colors on different bars or change its color at any time	1	1
DRAW_COLOR_SECTION	Similar to the style DRAW_SECTION, but the color of each section can be set individually; color can also	1	1

© 2000-2025, MetaQuotes Ltd.

Plotting	Description	Value buffers	Color buffers
	be set dynamically		
DRAW_COLOR_HISTOGRAM	Similar to the style DRAW_HISTOGRAM, but each strip may have a different color, you can set the color dynamically	1	1
DRAW_COLOR_HISTOGRAM2	Similar to the style DRAW_HISTOGRAM2, but each strip may have a different color, you can set the color dynamically	2	1
DRAW_COLOR_ARROW	Similar to the style DRAW_ARROW, but each symbol can have its color. Color can be	1	1

© 2000-2025, MetaQuotes Ltd.

Plotting	Description	Value buffers	Color buffers
	changed dynamically		
DRAW_COLOR_ZIGZAG	The DRAW_ZIGZAG style with the options of individual coloring of sections and dynamic color changing	2	1
DRAW_COLOR_BARS	The DRAW_BARS style with the options of individual coloring of bars and dynamic color changing	4	1
DRAW_COLOR_CANDLES	The DRAW_CANDLES style with the options of individual coloring of candlesticks and dynamic color changing	4	1

© 2000-2025, MetaQuotes Ltd.

The difference between an indicator buffer and an array

In each indicator, on its global level, you should declare one or more arrays of the double type, which then must be used as an indicator buffer using the SetIndexBuffer() function. To draw indicator plots, only the values of the indicator buffers are used, any other arrays cannot be used for this purpose. In addition, buffer values are displayed in the Data Window.

An indicator buffer should be dynamic and does not require specification of the size - the size of the array used as the indicator buffer is set by the terminal execution subsystem automatically.

After the array is bound to the indicator buffer, the indexing direction is set by default like in ordinary arrays, but you can use the ArraySetAsSeries() function to change the way of access to the array elements. By default, the indicator buffer is used to store data used for plotting (INDICATOR_DATA).

If the calculation of indicator values requires holding intermediate calculations and storing the additional values for each bar, then such an array can be declared as a calculation buffer during binding (INDICATOR_CALCULATIONS). For the intermediate values, you can also use a regular array, but in this case, the programmer has to manage the size of the array.

Some plots allow setting a color for each bar. To store the information about color, color buffers are used (INDICATOR_COLOR_INDEX). The color is an integer type color, but all indicator buffers must be of type double. Values of color and auxiliary (INDICATOR_CALCULATIONS) buffers cannot be obtained by using CopyBuffer().

The number of indicator buffers must be specified using the compiler directive #property indicator_buffers number_of_buffers:

```
#property indicator_buffers 3  //  the indicator has 3 buffers
```

The maximum allowed number of buffers in one indicator is 512.

Relevance of Indicator Buffers and Plotting

Each plotting is based on one or more indicator buffers. So, for displaying simple candlesticks, four values are required - Open, High, Low and Close prices. Accordingly, to display an indicator in the form of candlesticks, it is necessary to declare 4 indicator buffers and 4 arrays of the double type for them. For example:

```
//--- The indicator has four indicator buffers
#property indicator_buffers 4
//--- The indicator has one plotting
#property indicator_plots   1
//--- Graphical plotting number 1 will appear as candlesticks
#property indicator_type1   DRAW_CANDLES
//--- Candlestick will be drawn in clrDodgerBlue
#property indicator_color1  clrDodgerBlue
//--- 4 arrays for the indicator buffers
double OBuffer[];
```

© 2000-2025, MetaQuotes Ltd.

```
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

Graphical plots automatically use indicator buffers in accordance with the plot number. Numbering of plots starts with 1, numbering of buffers starts with zero. If the first plotting requires 4 indicator buffers, then the first 4 indicator buffers will be used to draw it. These four buffers should be linked with the appropriate arrays with correct indexing using the SetIndexBuffer() function.

```
//--- Binding arrays with indicator buffers
   SetIndexBuffer(0,OBuffer,INDICATOR_DATA);  // The first buffer corresponds to the z
   SetIndexBuffer(1,HBuffer,INDICATOR_DATA);  // The second buffer corresponds to inde
   SetIndexBuffer(2,LBuffer,INDICATOR_DATA);  // The third buffer corresponds to index
   SetIndexBuffer(3,CBuffer,INDICATOR_DATA);  // The fourth buffer corresponds to inde
```

The plotting candlesticks, the indicator will use just the first four buffers, because plotting of "candlesticks" was announced under the first number.

Change the example, and add plotting of a simple line - DRAW_LINE. Now suppose that the line is numbered 1, and the candlesticks are number 2. The number of buffers and the number of plots has increased.

```
//--- The indicator has 5 indicator buffers
#property indicator_buffers 5
//--- The indicator has 2 plots
#property indicator_plots   2
//--- Plot 1 is a line
#property indicator_type1   DRAW_LINE
//--- The color of the line is clrDodgerRed
#property indicator_color1  clrDodgerRed
//--- Plot 2 is drawn as Japanese candlesticks
#property indicator_type2   DRAW_CANDLES
//--- The color of the candlesticks is clrDodgerBlue
#property indicator_color2  clrDodgerBlue
//--- 5 arrays for indicator buffers
double LineBuffer[];
double OBuffer[];
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

The order of the plots has changed, and now the line comes first, followed by Japanese candlesticks. Therefore, the order of the buffers is appropriate - first we announce a buffer for the line with the zero index, and then four buffers for the candlesticks.

```
   SetIndexBuffer(0,LineBuffer,INDICATOR_DATA);  // The first buffer corresponds to in
//--- Binding arrays with indicator buffers for the candlesticks
   SetIndexBuffer(1,OBuffer,INDICATOR_DATA);     // The second buffer corresponds to i
   SetIndexBuffer(2,HBuffer,INDICATOR_DATA);     // The third buffer corresponds to in
   SetIndexBuffer(3,LBuffer,INDICATOR_DATA);     // The fourth buffer corresponds to i
```

© 2000-2025, MetaQuotes Ltd.

```
   SetIndexBuffer(4,CBuffer,INDICATOR_DATA);     // The fifth buffer corresponds to ir
```

The number of buffers and plots can be set only by using compiler directives, it is impossible to change these properties dynamically using functions.

Color Versions of Styles

As can be seen in the table, the styles are divided into two groups. The first group includes styles in whose name there is no word **COLOR**, we call these styles basic:

- DRAW_LINE
- DRAW_SECTION
- DRAW_HISTOGRAM
- DRAW_HISTOGRAM2
- DRAW_ARROW
- DRAW_ZIGZAG
- DRAW_FILLING
- DRAW_BARS
- DRAW_CANDLES

In the second group, the style names contain the word **COLOR**, let's call them color versions:

- DRAW_COLOR_LINE
- DRAW_COLOR_SECTION
- DRAW_COLOR_HISTOGRAM
- DRAW_COLOR_HISTOGRAM2
- DRAW_COLOR_ARROW
- DRAW_COLOR_ZIGZAG
- DRAW_COLOR_BARS
- DRAW_COLOR_CANDLES

All color versions of styles differ from the basic ones in that they allow specifying a color for each part of the plotting. The minimal part of plotting is a bar, so we can say that the color versions allow setting the color on each bar.

Exceptions are styles DRAW_NONE and DRAW_FILLING, they do not have color versions.

To set the plotting color on each bar, an additional buffer for storing the color index has been added to the color version. These indices indicate the number of a color in a special array, which contains a predefined set of colors. The size of the array of colors is 64. This means that each color version of a style allows painting a plot in 64 different colors.

The set and the number of colors in the special array of colors can be set via a compiler directive #property indicator_color, where you can specify all the necessary colors separated by commas. For example, such an entry in an indicator:

© 2000-2025, MetaQuotes Ltd.

```
//--- Define 8 colors for coloring candlesticks (they are stored in the special array)
#property indicator_color1  clrRed,clrBlue,clrGreen,clrYellow,clrMagenta,clrCyan,clrL
```

It states that for plotting 1, 8 colors are set, which will be placed in a special array. Further in the program we will not specify the color of the plotting, but only its index. If we want to set red color for the bar number K, the color index value from an array should be set in the color buffer of the indicator. The red color is specified first in the directive, it corresponds to the index number 0.

```
   //--- set the candlestick color clrRed
   col_buffer[buffer_index]=0;
```

The set of colors is not given once and for all, it can be changed dynamically using PlotIndexSetInteger(). Example:

```
      //--- Set the color for each index as the property PLOT_LINE_COLOR
      PlotIndexSetInteger(0,                    //  The number of a graphical style
                          PLOT_LINE_COLOR,      //  Property identifier
                          plot_color_ind,       //  The index of the color, where we w
                          color_array[i]);      //  A new color
```

Properties of the indicator and plotting

For indicator plots, properties can be set by means of compiler directives and using the appropriate functions. Read more information about this in Connection between Indicator Properties and Functions. Dynamic change of indicator properties using special functions allows creating more flexible custom indicators.

Start of Indicator Drawing on the Chart

In many cases, according to the conditions of the algorithm, it is impossible to start calculating the indicator values immediately with the current bar, since it is necessary to provide a minimum number of previous bars available in history. For example, many types of smoothing imply using an array of prices over the previous N bars, and on the basis of these values, the indicator value on the current bar is calculated.

In such cases, either there is no way to calculate the indicator values for the first N bars, or these values are not intended to be displayed on the chart and are only subsidiary for calculating further values. To avoid plotting of the indicator on the first N bars of the history, set the N value to the PLOT_DRAW_BEGIN property for the corresponding plot:

```
//--- Binding arrays with indicator buffers for the candlesticks
PlotIndexSetInteger(number_of_plot,PLOT_DRAW_BEGIN,N);
```

Here:

- number_of_plot – a value from zero to indicator_plots-1 (numbering of plots starts with zero).
- N - the number of first bars in the history, on which the indicator should not be displayed on the chart.

© 2000-2025, MetaQuotes Ltd.

© 2000-2025, MetaQuotes Ltd.

DRAW_NONE

The DRAW_NONE style is designed for use in cases where it is necessary to calculate the values of a buffer and show them in the Data Window, but plotting on the chart is not required. To set up the accuracy use the expression IndicatorSetInteger(INDICATOR_DIGITS,num_chars) in the OnInit() function:

```
int OnInit()
  {
//--- indicator buffers mapping
   SetIndexBuffer(0,InvisibleBuffer,INDICATOR_DATA);
//--- Set the accuracy of values to be displayed in the Data Window
   IndicatorSetInteger(INDICATOR_DIGITS,0);
//---
   return(INIT_SUCCEEDED);
  }
```

The number of buffers required for plotting DRAW_NONE is 1.

An example of the indicator that shows the number of the bar on which the mouse currently hovers in the Data Window. The numbering corresponds to the timeseries, meaning the current unfinished bar has the zero index, and the oldest bar has the largest index.

Note that despite the fact that, for red color is set plotting **#1**, the indicator does not draw anything on the chart.

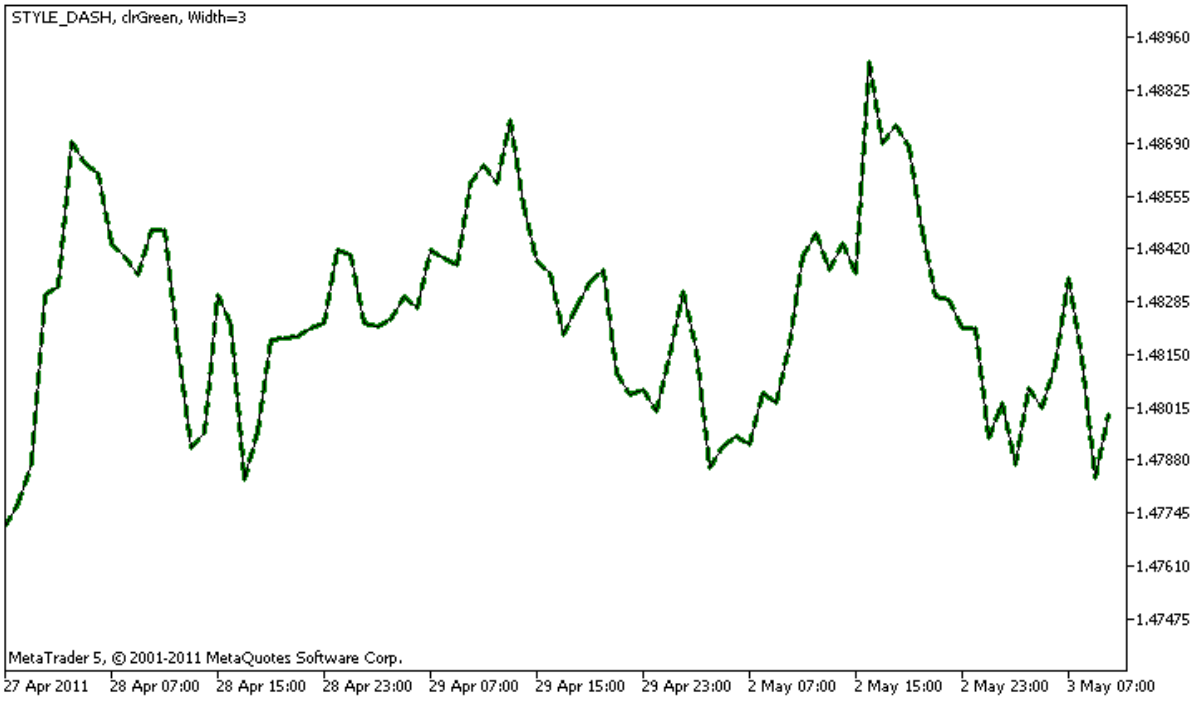
DRAW_LINE

DRAW_LINE draws a line of the specified color by the values of the indicator buffer. The width, style and color of the line can be set using the compiler directives and dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The number of buffers required for plotting DRAW_LINE is 1.

An example of the indicator that draws a line using Close prices of bars. The line color, width and style change randomly every N=5 ticks.



Note that initially for **plot1** with DRAW_LINE the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

DRAW_SECTION

DRAW_SECTION draws sections of the specified color by the values of the indicator buffer. The width, color and style of the line can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

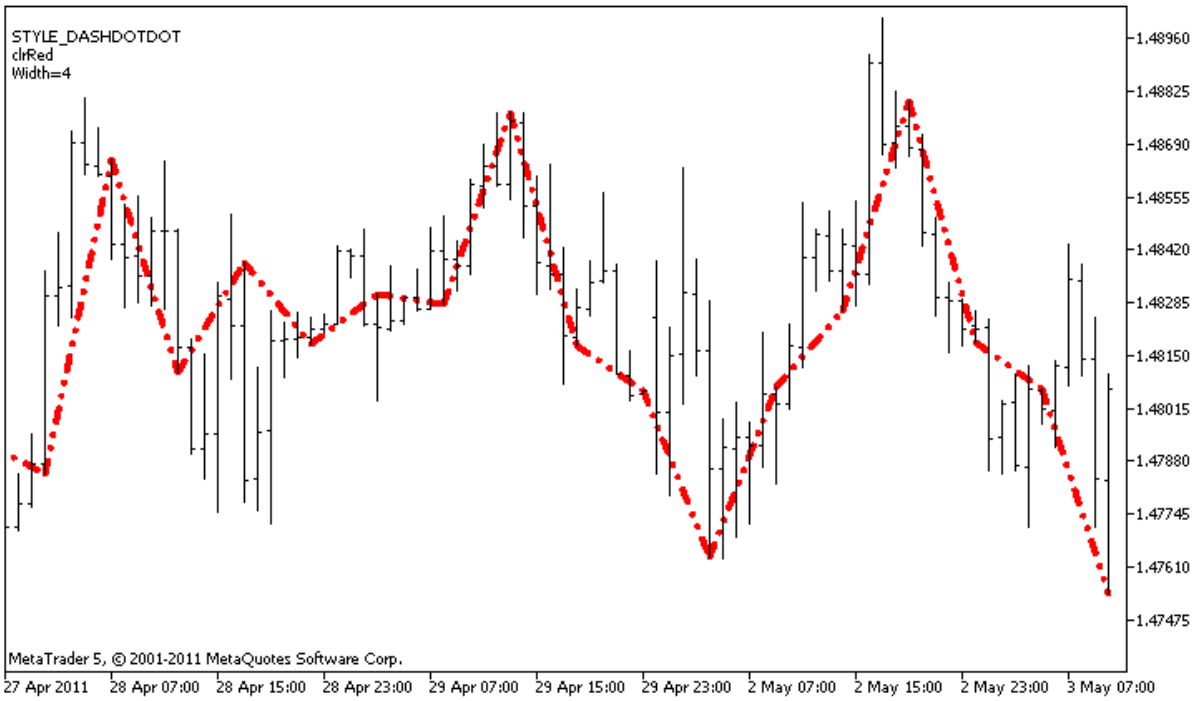
Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

The number of buffers required for plotting DRAW_SECTION is 1.

An example of the indicator that draws sections between the High and Low prices. The color, width and style of **all** sections change randomly every **N** ticks.



Note that initially for **plot1** with DRAW_SECTION the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

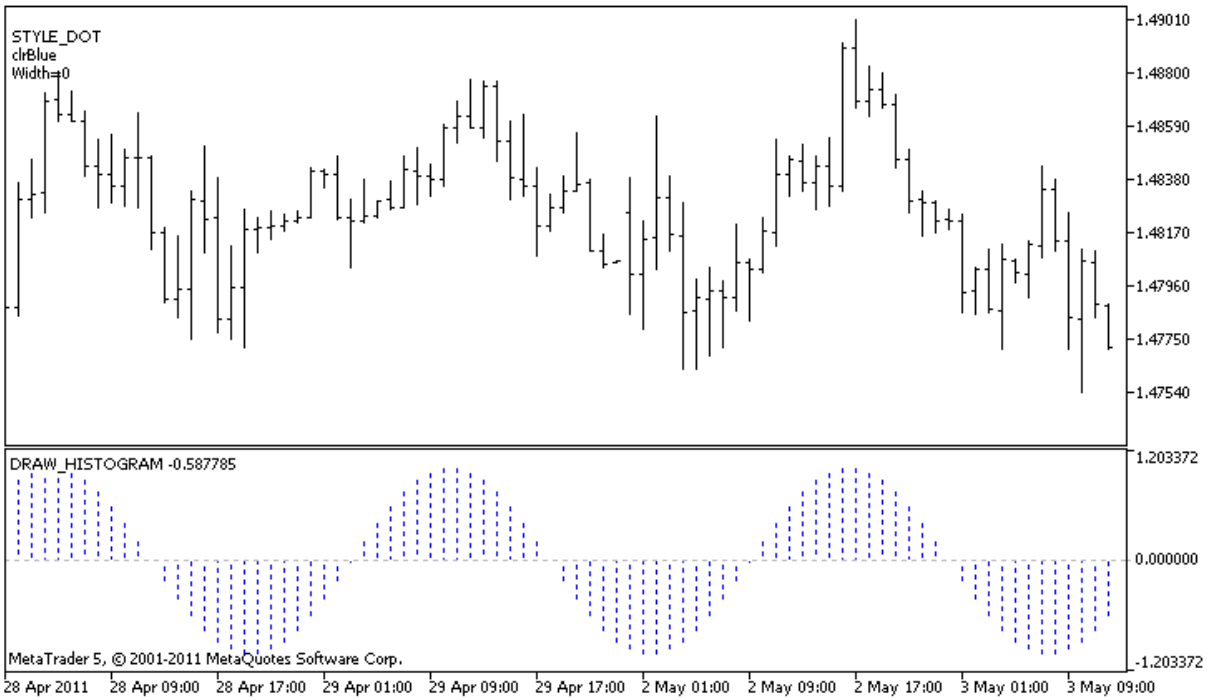
DRAW_HISTOGRAM

The DRAW_HISTOGRAM style draws a histogram as a sequence of columns of a specified color from zero to a specified value. Values are taken from the indicator buffer. The width, color and style of the column can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

Since a column from the zero level is drawn on each bar, DRAW_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, Bears Power or OsMA. For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_HISTOGRAM is 1.

An example of the indicator that draws a sinusoid of a specified color based on the MathSin() function. The color, width and style of **all** histogram columns change randomly each **N** ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.



Note that initially for **plot1** with DRAW_HISTOGRAM the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_HISTOGRAM2

The DRAW_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. The width, color and style of the segments can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with a zero value.

The number of buffers required for plotting DRAW_HISTOGRAM2 is 2.

An example of the indicator that plots a vertical segment of the specified color and width between the Open and Close prices of each bar. The color, width and style of **all** histogram columns change randomly each **N** ticks. During the start of the indicator, in the OnInit() function, the number of the day of week for which the histogram will not be drawn - invisible_day - is set randomly. For this purpose an empty value is set PLOT_EMPTY_VALUE=0:

```
//--- Set an empty value
   PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Note that initially for **plot1** with DRAW_HISTOGRAM2 the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_ARROW

The DRAW_ARROW style draws arrows of the specified color (symbols of the set Wingdings) based on the value of the indicator buffer. The width and color of the symbols can be specified like for the DRAW_LINE style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the PLOT_ARROW property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW
   PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels
   PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

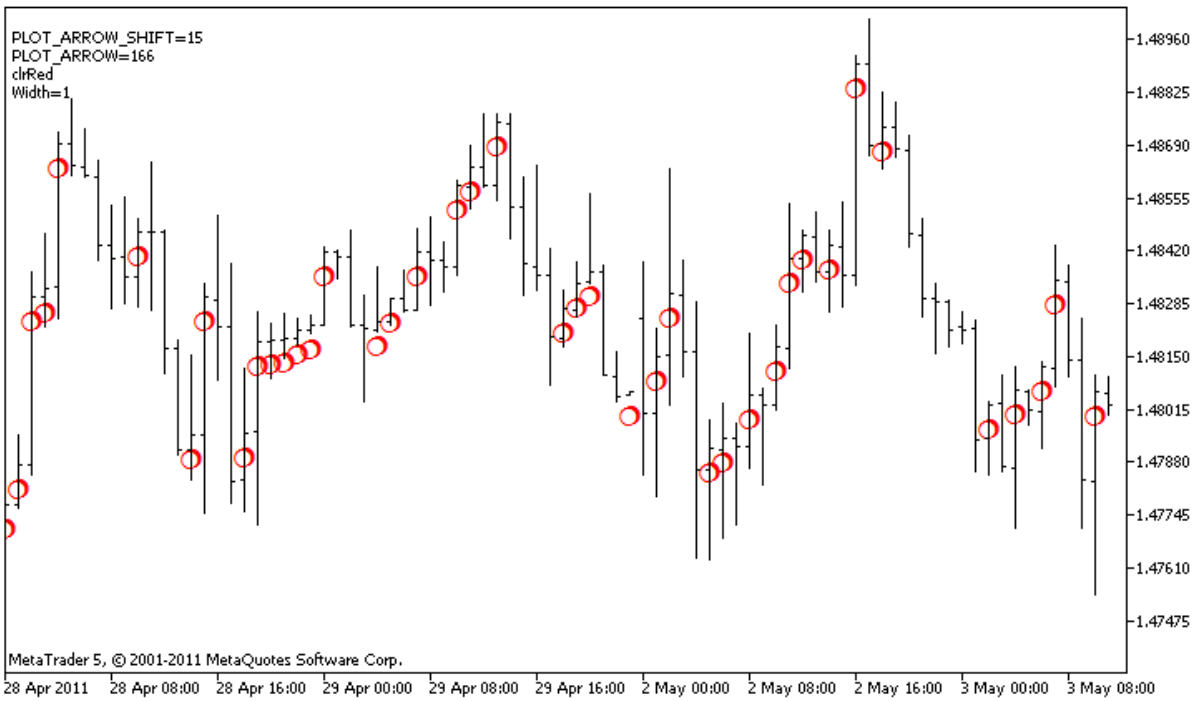
The DRAW_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

```
//--- Set an empty value
   PlotIndexSetDouble(index_of_plot_DRAW_ARROW,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_ARROW is 1.

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The color, width, shift and symbol code of **all** arrows are changed randomly every **N** ticks.

© 2000-2025, MetaQuotes Ltd.



In the example, for **plot1** with the DRAW_ARROW style, the properties, color and size are specified using the compiler directive #property, and then in the OnCalculate() function the properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_ZIGZAG

The DRAW_ZIGZAG style draws segments of a specified color based on the values of two indicator buffers. This style is very similar to DRAW_SECTION, but unlike the latter, it allows drawing vertical segments within one bar, if values of both indicator buffers are set for this bar. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the DRAW_SECTION style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

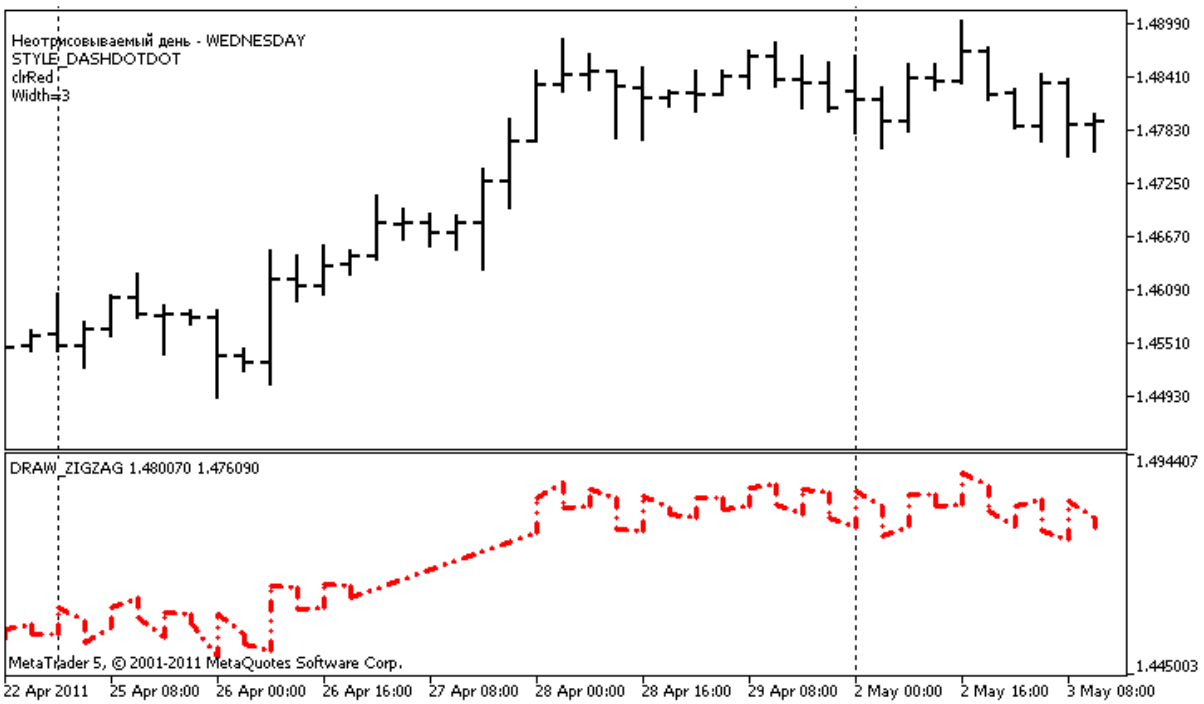
Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_ZIGZAG,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_ZIGZAG is 2.

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every **N** ticks.



Note that initially for **plot1** with DRAW_ZIGZAG the properties are set using the compiler directive #property, and then in the OnCalculate() function these properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_FILLING

The DRAW_FILLING style plots a colored area between the values of two indicator buffers. In fact, this style draws two lines and fills the space between them with one of two specified colors. It is used for creating indicators that draw channels. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set two fill colors:

- the first color is used for the areas where values in the first buffer are greater than the values in the second indicator buffer;
- the second color is used for the areas where values in the second buffer are greater than the values in the first indicator buffer.

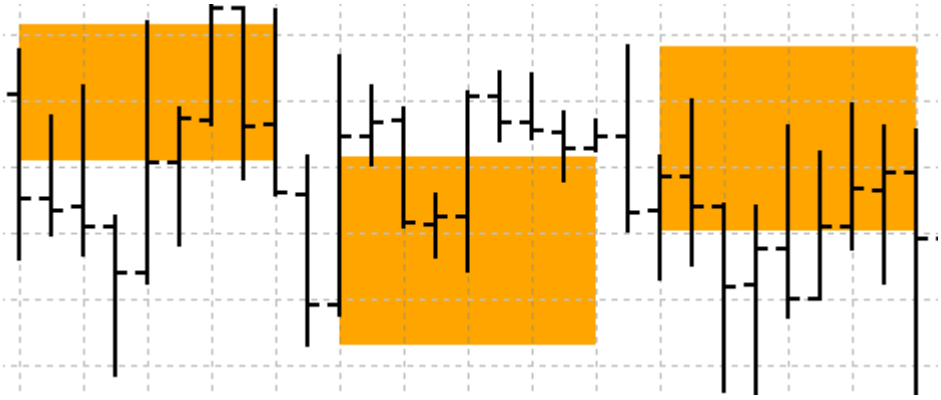
The fill color can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is calculated for all bars, for which the values of the both indicator buffers are equal neither to 0 nor to the empty value. To specify what value should be considered as "empty", set this value in PLOT_EMPTY_VALUE property:

```
   #define INDICATOR_EMPTY_VALUE -1.0
   ...
//--- INDICATOR_EMPTY_VALUE (empty value) will not participate in calculation of
   PlotIndexSetDouble (DRAW_FILLING_creation_index,PLOT_EMPTY_VALUE,INDICATOR_EMPTY_VA
```

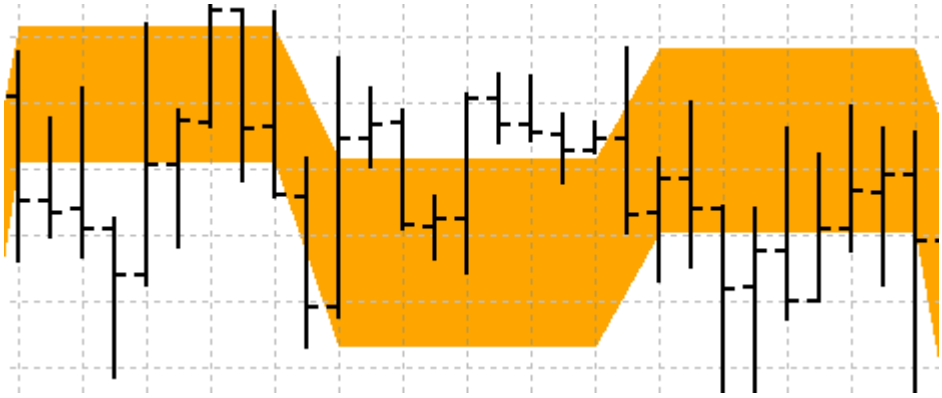
Drawing on the bars that do not participate in the indicator calculation will depend on the values in the indicator buffers:

- Bars, for which the values of both indicator buffers are equal to 0, do not participate in drawing the indicator. It means that the area with zero values is not filled out.



- Bars, for which the values of the indicator buffers are equal to the "empty value", participate in drawing the indicator. The area with empty values will be filled out so that to connect the areas with significant values.

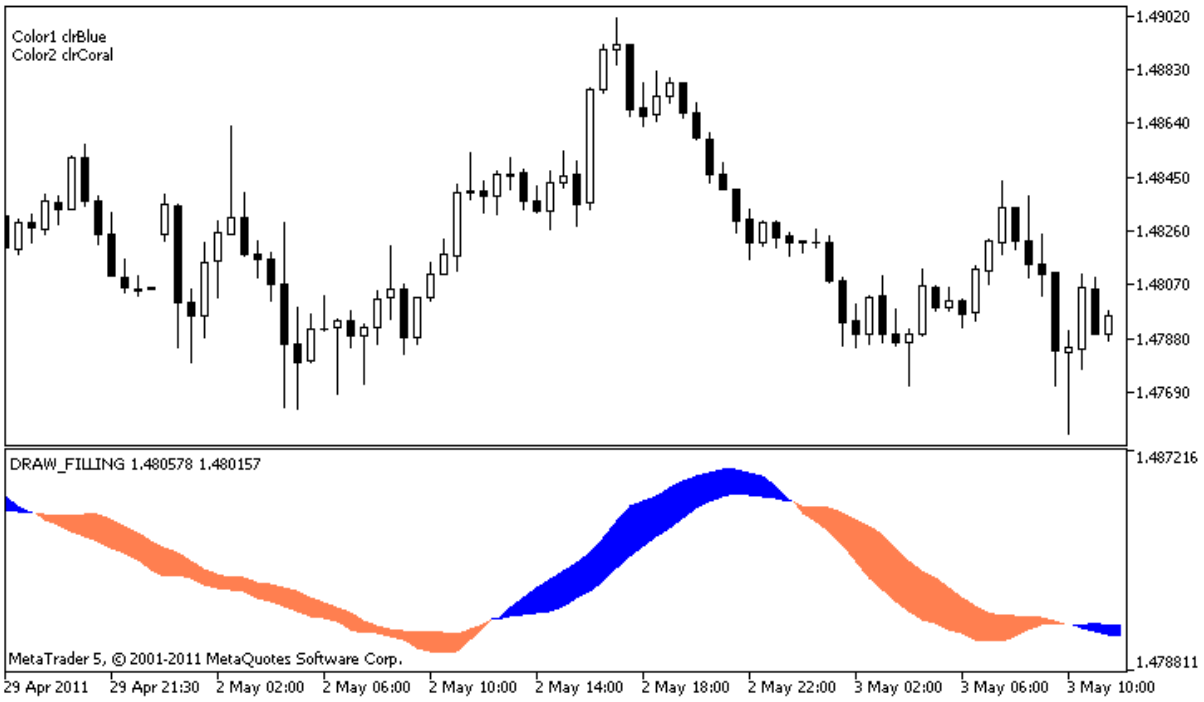
© 2000-2025, MetaQuotes Ltd.



It should be noted that if the "empty value" is equal to zero, the bars that do not participate in the indicator calculation are also filled out.

The number of buffers required for plotting DRAW_FILLING is 2.

An example of the indicator that draws a channel between two MAs with different averaging periods in a separate window. The change of the colors at the crossing of moving averages visually shows the change of the upward and downward trends. The colors change randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).



Note that initially for **plot1** with DRAW_FILLING the properties are set using the compiler directive #property, and then in the OnCalculate() function new colors are set randomly.

DRAW_BARS

The DRAW_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_BARS,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_BARS is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for **plot1** with the DRAW_BARS style, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

DRAW_CANDLES

The DRAW_CANDLES style draws candlesticks on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The color of candlesticks can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_CANDLES,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_CANDLES is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set up to three colors for the DRAW_CANDLES style affecting the candle look. If only one color is set, it is applied to all candles on a chart.

```
//--- identical candles with a single color applied to them
#property indicator_label1  "One color candles"
#property indicator_type1   DRAW_CANDLES
//--- only one color is specified, therefore all candles are of the same color
#property indicator_color1  clrGreen
```

If two comma-separated colors are specified, the first one is applied to candle outlines, while the second one is applied to the body.

```
//--- different colors for candles and wicks
#property indicator_label1  "Two color candles"
#property indicator_type1   DRAW_CANDLES
//--- green is applied to wicks and outlines, while white is applied to the body
#property indicator_color1  clrGreen,clrWhite
```

Specify three comma-separated colors so that rising and falling candles are displayed differently. In that case, the first color is applied to the candle outlines, while the second and third ones - to bullish and bearish candles.

```
//--- different colors for candles and wicks
#property indicator_label1  "One color candles"
#property indicator_type1   DRAW_CANDLES
//--- wicks and outlines are green, bullish candle body is white, while bearish candle
#property indicator_color1  clrGreen,clrWhite,clrRed
```

Thus, the DRAW_CANDLES style allows you to create custom candle coloring options. Besides, all colors can be changed dynamically during the indicator operation using the PlotIndexSetInteger function

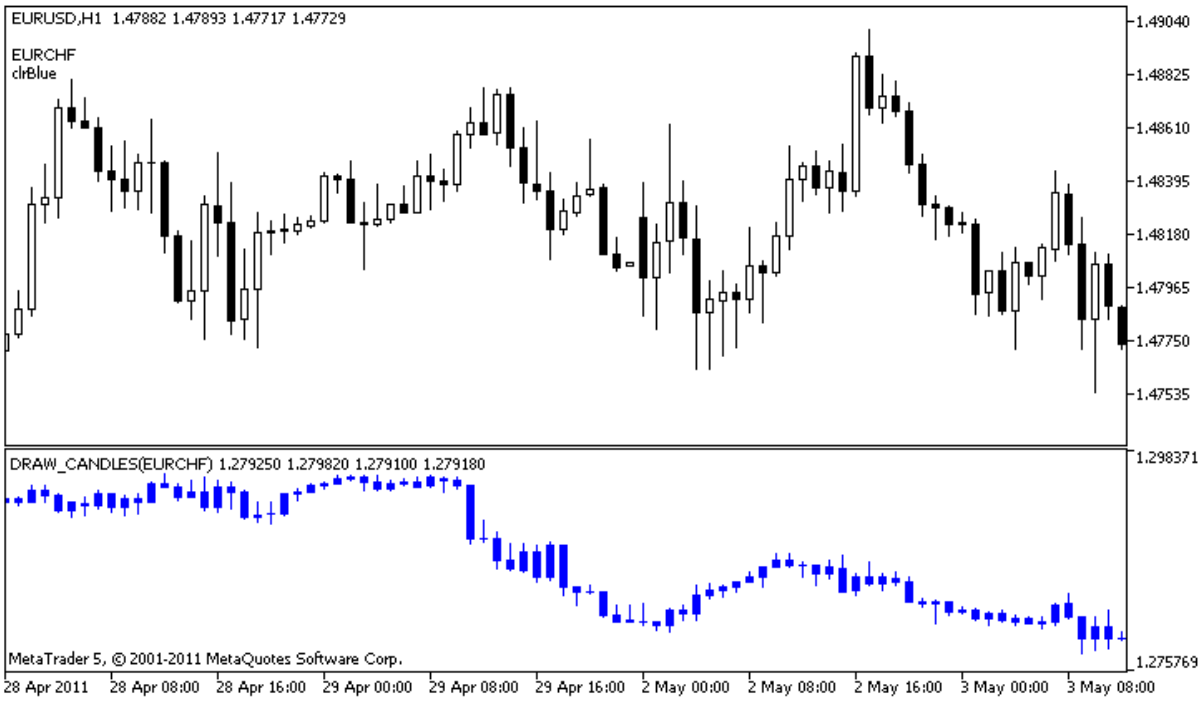
© 2000-2025, MetaQuotes Ltd.

(composition_index_DRAW_CANDLES, PLOT_LINE_COLOR, modifier_index, color), where modifier_index may have the following values:

- 0 - colors of outlines and wicks
- 1- bullish candle body color
- 2 - bearish candle body color

```
//--- set the color of outlines and wicks
PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrBlue);
//--- set the bullish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrGreen);
//--- set the bearish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrRed);
```

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).



Please note that for **plot1**, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

DRAW_COLOR_LINE

The DRAW_COLOR_LINE value is a colored variant of the DRAW_LINE style; it also draws a line using the values of the indicator buffer. But this style, like all color styles with the word **COLOR** in their title has an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each line segment can be defined by specifying the color index of the index to draw the line at this bar.

The width, style and colors of lines can be set using the compiler directives and dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

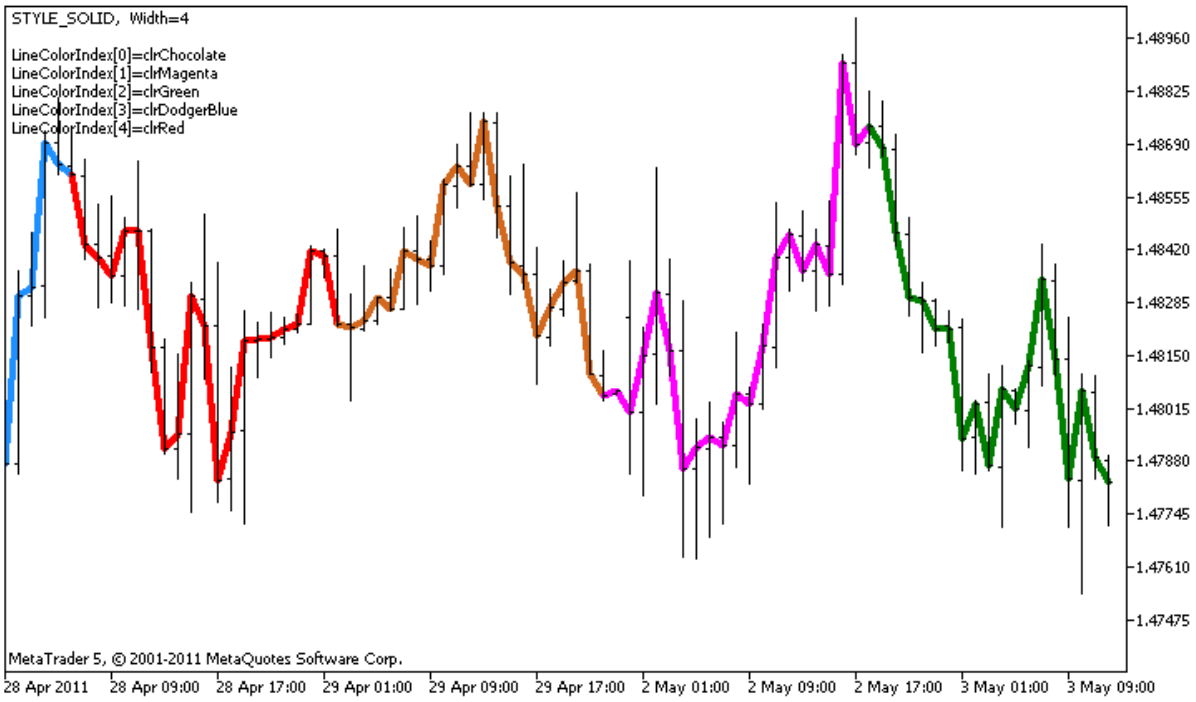
The number of buffers required for plotting DRAW_COLOR_LINE is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the index of the color of the line on each bar.

Colors can be specified by the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

```
//--- Define 5 colors for coloring each bar (they are stored in the special array)
#property indicator_color1  clrRed,clrBlue,clrGreen,clrOrange,clrDeepPink // (Up to 6
```

An example of the indicator that draws a line using Close prices of bars. The line width and style change randomly every N=5 ticks.



The colors of the line segments also change randomly in the custom function ChangeColors().

```
//+------------------------------------------------------------------+
//| Changes the color of line segments                               |
//+------------------------------------------------------------------+
void  ChangeColors(color  &cols[],int plot_colors)
```

© 2000-2025, MetaQuotes Ltd.

```
  {
//--- The number of colors
   int size=ArraySize(cols);
//---
   string comm=ChartGetString(0,CHART_COMMENT)+"\r\n\r\n";

//--- For each color index define a new color randomly
   for(int plot_color_ind=0;plot_color_ind<plot_colors;plot_color_ind++)
     {
      //--- Get a random value
      int number=MathRand();
      //--- Get an index in the col[] array as a remainder of the integer devision
      int i=number%size;
      //--- Set the color for each index as the property PLOT_LINE_COLOR
      PlotIndexSetInteger(0,                    //  The number of a graphical style
                          PLOT_LINE_COLOR,      //  Property identifier
                          plot_color_ind,       //  The index of the color, where we w
                          cols[i]);             //  A new color
      //--- Write the colors
      comm=comm+StringFormat("LineColorIndex[%d]=%s \r\n",plot_color_ind,ColorToString
      ChartSetString(0,CHART_COMMENT,comm);
     }
//---
  }
```

The example shows the feature of the "color" versions of indicators - to change the color of a line segment, you do not need to change values in the ColorLineColors[] buffer (which contains the color indexes). All you need to do is set new colors in a special array. This allows you to quickly change the color once for the entire plotting, changing only a small array of colors using the PlotIndexSetInteger() function.

Note that initially for **plot1** with DRAW_COLOR_LINE the properties are set using the compiler directive #property, and then in the OnCalculate() function these three properties are set randomly.

The N and Length (the length of color segments in bars) parameters are set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_SECTION

The DRAW_COLOR_SECTION style is a color version of DRAW_SECTION, but unlike the latter, it allows drawing sections of different colors. The DRAW_COLOR_SECTION style, like all color styles with the word **COLOR** in their title, contains an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each section can be defined by specifying the color index of the index of the bar that corresponds to the section end.

The width, color and style of the sections can be specified like for the DRAW_SECTION style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_SECTION,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

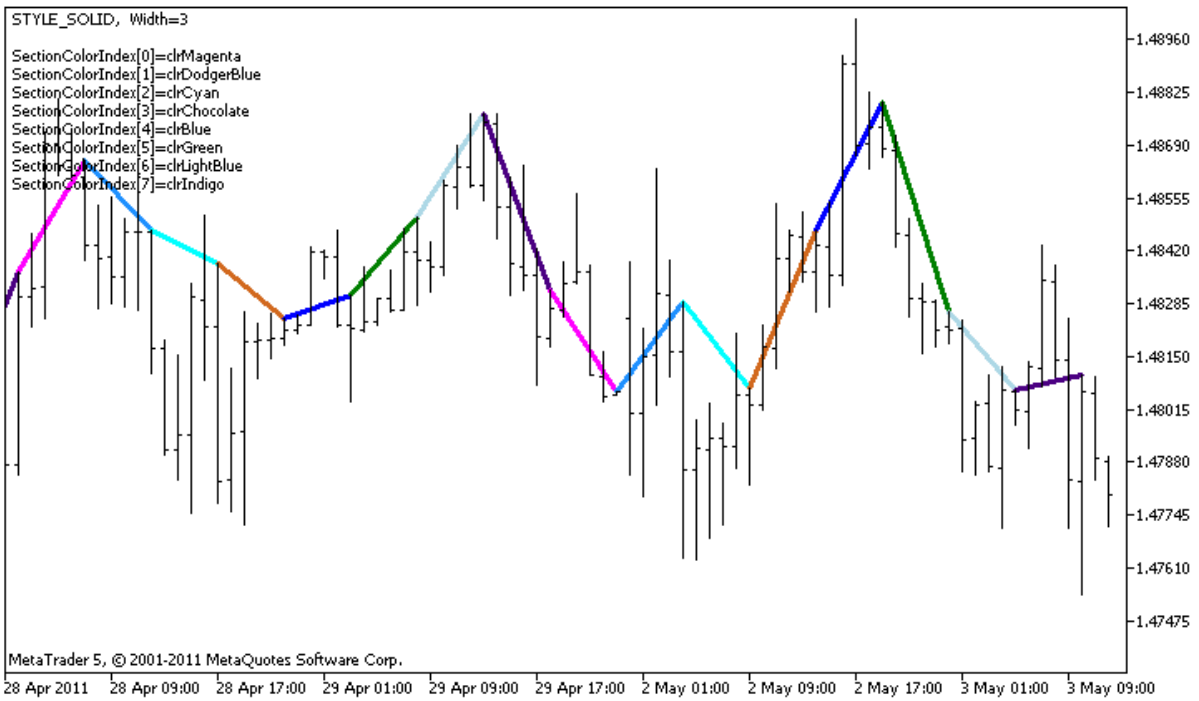
The number of buffers required for plotting DRAW_COLOR_SECTION is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified by the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws colored sections each 5 bars long, using the High price values. The color, width and style of sections change randomly every **N** ticks.

© 2000-2025, MetaQuotes Ltd.



Note that initially for **plot1** with DRAW_COLOR_SECTION 8 colors are set using the compiler directive #property. Then in the OnCalculate() function, colors are set randomly from the array of colors colors[].

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_HISTOGRAM

The DRAW_COLOR_HISTOGRAM style draws a histogram as a sequence of colored columns from zero to a specified value. Values are taken from the indicator buffer. Each column can have its own color from a predefined set of colors.

The width, color and style of the histogram can be specified like for the DRAW_HISTOGRAM style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

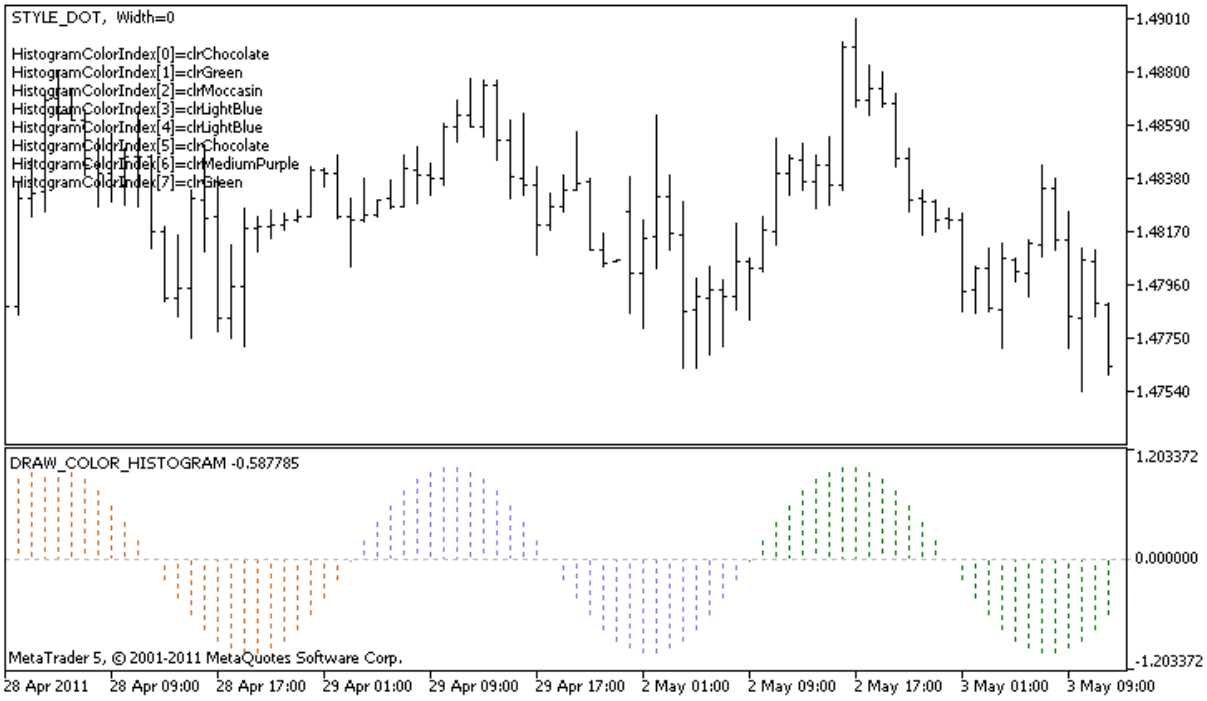
Since a column from the zero level is drawn on each bar, DRAW_COLOR_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, Awesome Oscillator or Market Facilitation Index. For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM is 2.

- one buffer for storing a non-zero value of the vertical segment on each bar, the second end of the segment is always on the zero line of the indicator;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified using the compiler directive #property indicator_color1 separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws a sinusoid of a specified color based on the MathSin() function. The color, width and style of **all** histogram columns change randomly each **N** ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.



Please note that for **plot1** with the DRAW_COLOR_HISTOGRAM style, 5 colors are set using the compiler directive #property, and then in the OnCalculate() function the colors are selected randomly

© 2000-2025, MetaQuotes Ltd.

from the 14 colors stored in the colors[] array. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_HISTOGRAM2

The DRAW_COLOR_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. But unlike the one-color DRAW_HISTOGRAM2, in this style each column of the histogram can have its own color from a predefined set. The values of all the segments are taken from the indicator buffer.

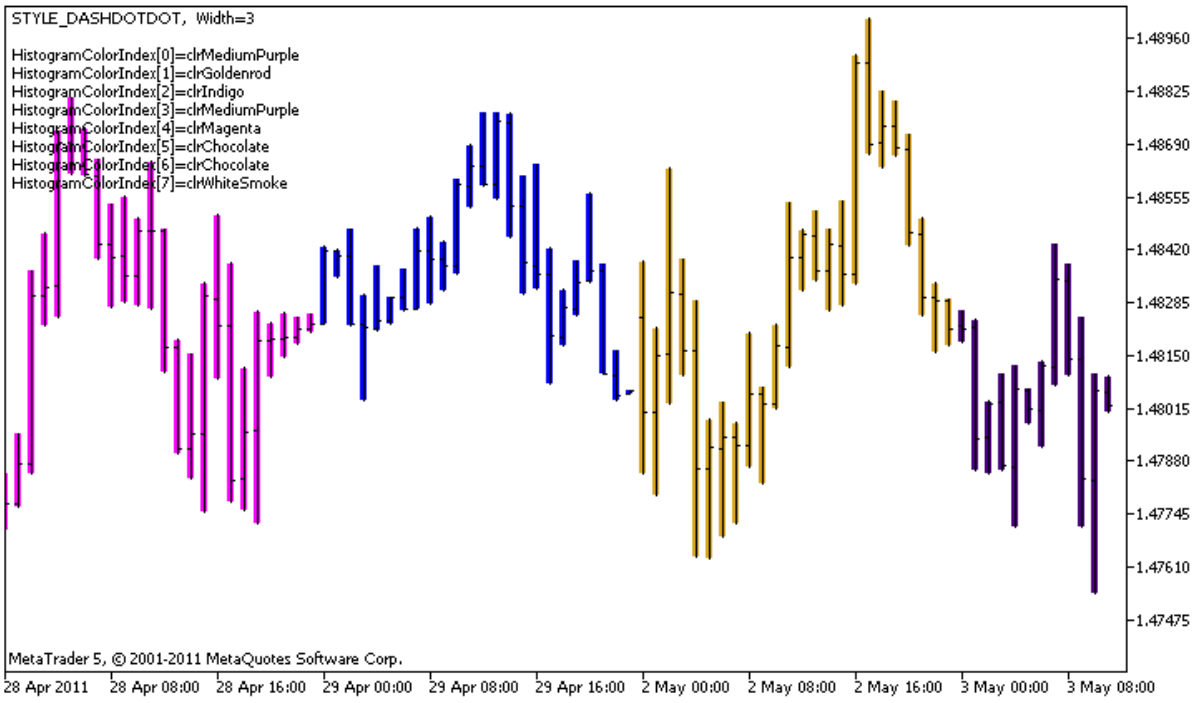
The width, style and color of the histogram can be specified like for theDRAW_HISTOGRAM2 style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_COLOR_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with empty values.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM2 is 3:

- two buffers to store the upper and lower end of the vertical segment on each bar;
- one buffer to store the color index, which is used to draw the segment (it makes sense to set only non-empty values).

An example of the indicator that draws a histogram of a specified color between the High and Low prices. For each day of week, the histogram lines have a different color. The color of the day, width and style of the histogram change randomly each **N** ticks.



Please note that for **plot1** with the DRAW_COLOR_HISTOGRAM2 style, 5 colors are set using the compiler directive #property, and then in the OnCalculate() function the colors are selected randomly from the 14 colors stored in the colors[] array.

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_ARROW

The DRAW_COLOR_ARROW style draws colored arrows (symbols of the set Wingdings) based on the value of the indicator buffer. In contrast to DRAW_ARROW, in this style it is possible to set a color from a predefined set of colors specified by the indicator_color1 property for each symbol.

The width and color of the symbols can be specified like for theDRAW_ARROW style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the PLOT_ARROW property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW
   PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels
   PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

The DRAW_COLOR_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

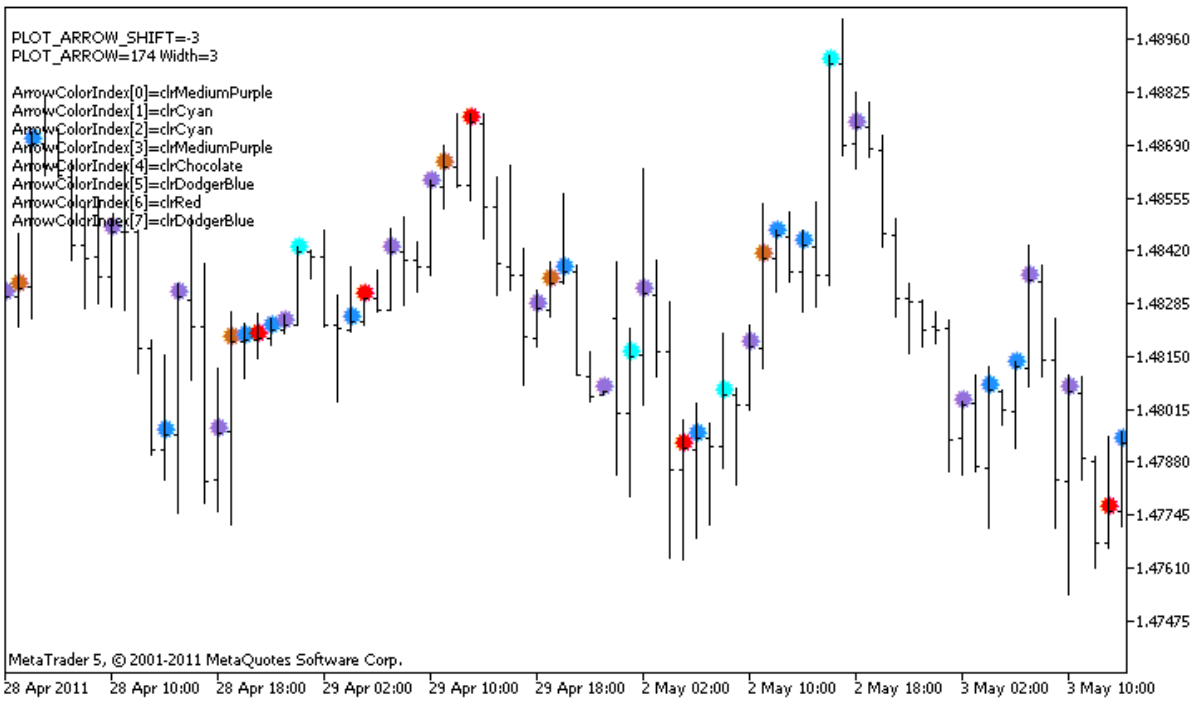
```
//--- Set an empty value
   PlotIndexSetDouble(DRAW_COLOR_ARROW_plot_index,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_COLOR_ARROW is 2.

- a buffer to store the value of the price which is used to draw the symbol (plus a shift in pixels, given in the PLOT_ARROW_SHIFT property);
- a buffer to store the color index, which is used to draw an arrow (it makes sense to set only non-empty values).

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The width, shift and symbol code of **all** arrows are changed randomly every **N** ticks. The color of the symbol depends on the number of the bar on which it is drawn.

© 2000-2025, MetaQuotes Ltd.



In the example, for **plot1** with the DRAW_COLOR_ARROW style, the properties, color and size are specified using the compiler directive #property, and then in the OnCalculate() function the properties are set randomly. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that initially 8 colors are set using the compiler directive #property, and then in the OnCalculate() function, the color is set randomly from the 14 colors that are stored in the colors[] array.

DRAW_COLOR_ZIGZAG

The DRAW_COLOR_ZIGZAG style draws segments of different colors, using the values of two indicator buffers. This style is a colored version of DRAW_ZIGZAG, i.e. allows specifying for each segment an individual color from the predefined set of colors. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the DRAW_ZIGZAG style - using compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

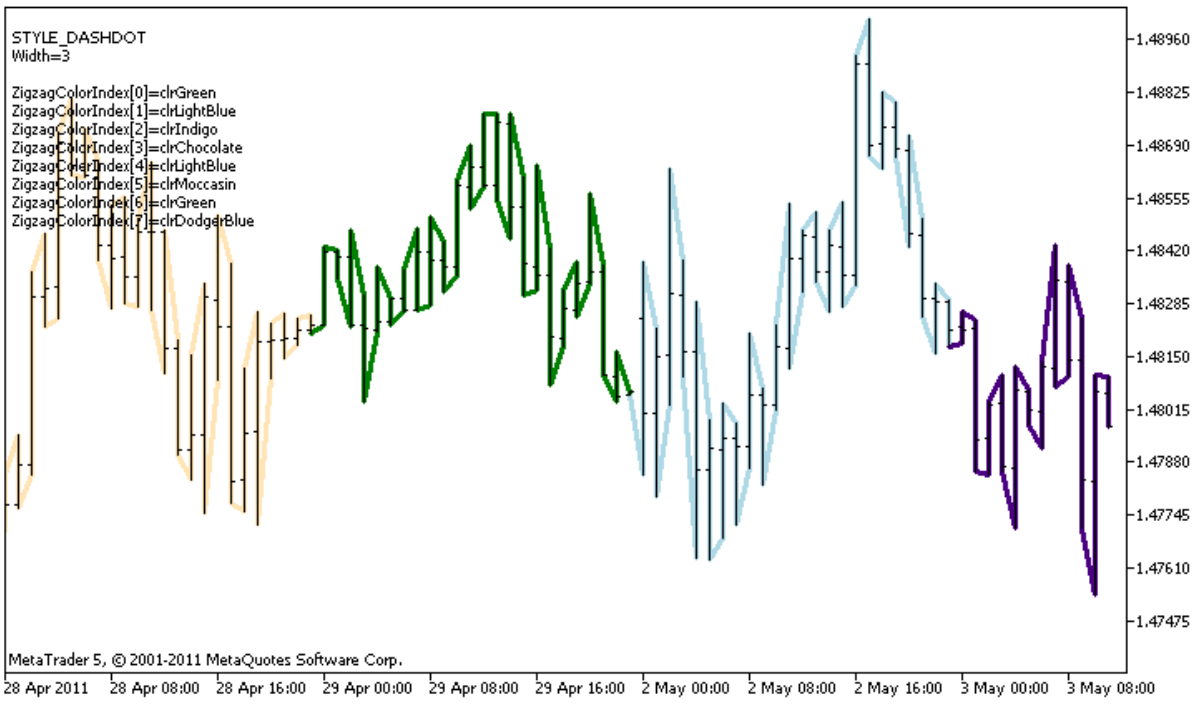
```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_ZIGZAG,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_COLOR_ZIGZAG is 3:

- two buffers to store the values of ends of the zigzag sections;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every N ticks.



© 2000-2025, MetaQuotes Ltd.

Please note that for **plot1** with the DRAW_COLOR_ZIGZAG style, 8 colors are set using the compiler directive #property, and then in the OnCalculate() function the color is selected randomly from the 14 colors stored in the colors[] array.

The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_BARS

The DRAW_COLOR_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. This style is an advanced version of DRAW_BARS and allows specifying for each bar an individual color from the predefined set of colors. It used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_BARS,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

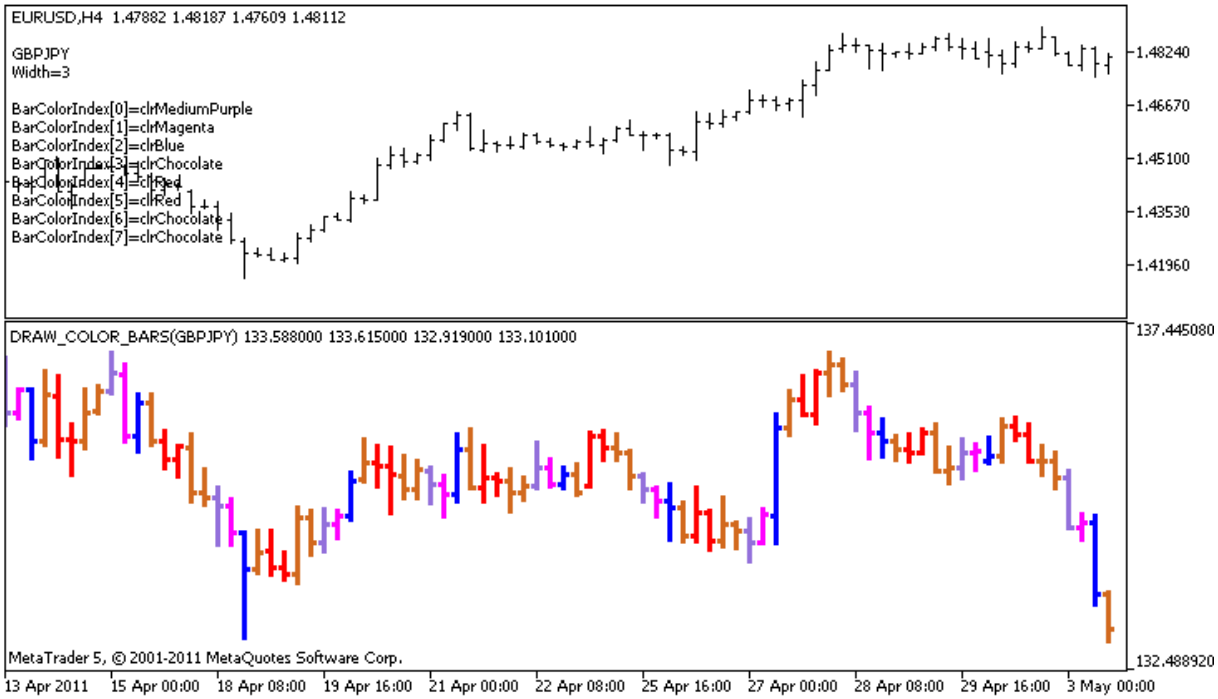
The number of buffers required for plotting DRAW_COLOR_BARS is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a bar (it makes sense to set it only for the bars that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only null values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

© 2000-2025, MetaQuotes Ltd.



Please note that for **plot1** with the DRAW_COLOR_BARS style, 8 colors are set using the compiler directive #property, and then in the OnCalculate() function the color is selected randomly from the 14 colors stored in the colors[] array.

DRAW_COLOR_CANDLES

The DRAW_COLOR_CANDLES style, like DRAW_CANDLES, draws candlesticks using the values of four indicator buffers, which contain Open, High, Low and Close prices. In addition, it allows specifying a color for each candlestick from a given set. For this purpose, the style has a special color buffer that stores color indexes for each bar. It used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The number of colors of candlesticks can be set using the compiler directives or dynamically using the PlotIndexSetInteger() function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of four price buffers of the indicator are set. To specify what value should be considered as "empty", set this value in the PLOT_EMPTY_VALUE property:

```
//--- The 0 (empty) value will mot participate in drawing
   PlotIndexSetDouble(index_of_plot_DRAW_COLOR_CANDLES,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_COLOR_CANDLES is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a candlestick (it makes sense to set it only for the candlesticks that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every **N** ticks. The N parameter is set in external parameters of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

© 2000-2025, MetaQuotes Ltd.

Please note that for **plot1**, the color is set using the compiler directive #property, and then in the OnCalculate() function the color is set randomly from an earlier prepared list.

Connection between Indicator Properties and Corresponding Functions

Every custom indicator has numerous properties, some of which are obligatory and are always positioned at the beginning of description. They are the following properties:

- indication of a window to plot the indicator – indicator_separate_window or indicator_chart_window;
- number of indicator buffers – indicator_buffers;
- number of plots of the indicator – indicator_plots.

Also there are other properties that can be set both through preprocessor directives and through functions intended for custom indicator creation. These properties and corresponding functions are described in the following table.

Directives for properties of indicator subwindow	Functions of IndicatorSet...() type	Description of the adjusted property of the subwindow
indicator_height	IndicatorSetInteger (INDICATOR_INDICATOR_HEIGHT, nHeight)	The fixed value of the subwindow height
indicator_minimum	IndicatorSetDouble (INDICATOR_MINIMUM, dMaxValue)	Minimal value of the vertical axis
indicator_maximum	IndicatorSetDouble (INDICATOR_MAXIMUM, dMinValue)	Maximal value of the vertical axis
indicator_levelN	IndicatorSetDouble (INDICATOR_LEVELVALUE, N-1, nLevelValue)	Vertical axis value for N level
no preprocessor directive	IndicatorSetString (INDICATOR_LEVELTEXT, N-1, sLevelName)	Name of a displayed level
indicator_levelcolor	IndicatorSetInteger (INDICATOR_LEVELCOLOR, N-1, nLevelColor)	Color of N level
indicator_levelwidth	IndicatorSetInteger (INDICATOR_LEVELWIDTH, N-1, nLevelWidth)	Line width for N level
indicator_levelstyle	IndicatorSetInteger (INDICATOR_LEVELSTYLE, N-1, nLevelStyle)	Line style for N level
Directives for plotting properties	**Functions of PlotIndexSet...() type**	**Description of the adjusted property of a plot**
indicator_labelN	PlotIndexSetString(N-1,PLOT_LABEL,sLabel)	Short name of the number N plot. It is displayed in

© 2000-2025, MetaQuotes Ltd.

Directives for properties of indicator subwindow	Functions of IndicatorSet...() type	Description of the adjusted property of the subwindow
		DataWindow and in the pop-up tooltip when pointing the mouse cursor over it
indicator_colorN	PlotIndexSetInteger(N-1, PLOT_LINE_COLOR, nColor)	Line color for N plot
indicator_styleN	PlotIndexSetInteger(N-1, PLOT_LINE_STYLE, nType)	Line style for N plot
indicator_typeN	PlotIndexSetInteger(N-1, PLOT_DRAW_TYPE, nType)	Line type for N plot
indicator_widthN	PlotIndexSetInteger(N-1, PLOT_LINE_WIDTH, nWidth)	Line width for N plot
Common indicator properties	**Functions of IndicatorSet...() type**	**Description**
no preprocessor directive	IndicatorSetString (INDICATOR_SHORTNAME, sShortName)	Sets the convenient short name of the indicator that will be displayed in the list of indicators (opened in the terminal by pressing **Ctrl+I**).
no preprocessor directive	IndicatorSetInteger (INDICATOR_DIGITS, nDigits)	Sets required accuracy of display of indicator values - number of decimal places
no preprocessor directive	IndicatorSetInteger (INDICATOR_LEVELS, nLevels)	Sets number of levels in the indicator window
indicator_applied_price	No function, the property can be set only by the preprocessor directive.	Default price type used for the indicator calculation. It is specified when necessary, only if OnCalculate() of the first type is used. The property value can also be set from the dialog of indicator properties in the "Parameters" tab - "Apply to".

It should be noted that numeration of levels and plots in preprocessor terms starts with one, while numeration of the same properties at using functions starts with zero, i.e. the indicated value must be by 1 less than that indicated for #property.

There are several directives, for which there are no corresponding functions:

Directive	Description
indicator_chart_window	Indicator is displayed in the main window

© 2000-2025, MetaQuotes Ltd.

Directive	Description
indicator_separate_window	Indicator is displayed in a separate subwindow
indicator_buffers	Number of required indicator buffers
indicator_plots	Number of plots in the indicator

© 2000-2025, MetaQuotes Ltd.

SetIndexBuffer

The function binds a specified indicator buffer with one-dimensional dynamic array of the double type.

```
bool  SetIndexBuffer(
   int                   index,          // buffer index
   double                buffer[],       // array
   ENUM_INDEXBUFFER_TYPE  data_type      // what will be stored
   );
```

Parameters

index

[in] Number of the indicator buffer. The numbering starts with 0. The number must be less than the value declared in #property indicator_buffers.

buffer[]

[in] An array declared in the custom indicator program.

data_type

[in] Type of data stored in the indicator array. By default it is INDICATOR_DATA (values of the calculated indicator). It may also take the value of INDICATOR_COLOR_INDEX; in this case this buffer is used for storing color indexes for the previous indicator buffer. You can specify up to 64 colors in the #property indicator_colorN line. The INDICATOR_CALCULATIONS value means that the buffer is used in intermediate calculations of the indicator and is not intended for drawing.

Return Value

If successful, returns true, otherwise - false.

Note

After binding, the dynamic array buffer[] will be indexed as in common arrays, even if the indexing of timeseries is pre-installed for the bound array. If you want to change the order of access to elements of the indicator array, use the ArraySetAsSeries() function **after binding the array using the SetIndexBuffer() function**. Please note that you can't change the size for dynamic arrays set as indicator buffers by the function SetIndexBuffer(). For indicator buffers, all operations of size changes are performed by the executing sub-system of the terminal.

Example:

```

IndicatorSetDouble

The function sets the value of the corresponding indicator property. Indicator property must be of the double type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetDouble(
   int     prop_id,           // identifier
   double  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetDouble(
   int     prop_id,           // identifier
   int     prop_modifier,     // modifier
   double  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier. Numbering of levels starts from 0. It means that in order to set property for the second level you need to specify 1 (1 less than when using compiler directive).

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

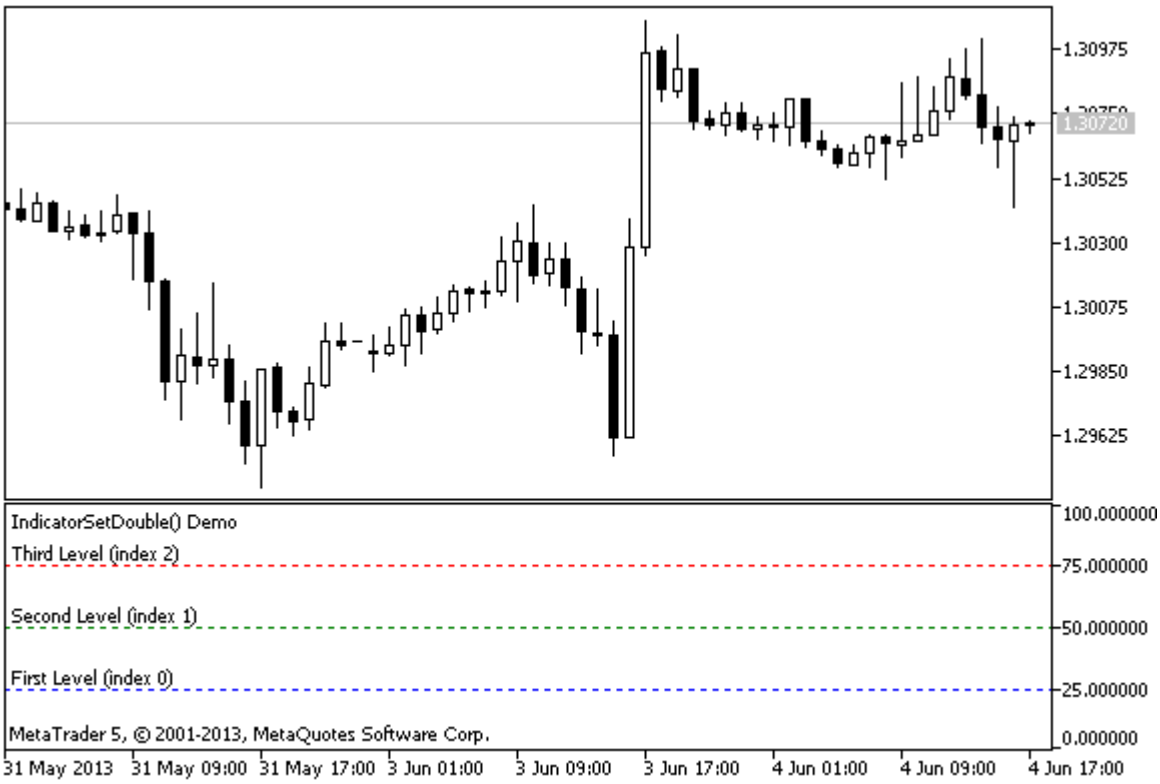
Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, the first level value for the indicator in a separate subwindow can be set in two ways:

- property indicator_level**1** 50 - the value of 1 is used for specifying the level number,
- IndicatorSetDouble(INDICATOR_LEVELVALUE, **0**, 50) - 0 is used for specifying the first level.

Example: indicator that turns upside down the maximum and minimum values of the indicator window and values of levels on which the horizontal lines are placed.

© 2000-2025, MetaQuotes Ltd.



```
#property indicator_separate_window
//--- set the maximum and minimum values for the indicator window
#property indicator_minimum  0
#property indicator_maximum  100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 25
#property indicator_level2 50
#property indicator_level3 75
//--- set thickness of horizontal levels
#property indicator_levelwidth 1
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_DOT
//+------------------------------------------------------------------+
//| Custom indicator initialization function                         |
//+------------------------------------------------------------------+

Indicator Styles in Examples, Connection between Indicator Properties and Functions, Drawing Styles

© 2000-2025, MetaQuotes Ltd.

IndicatorSetInteger

The function sets the value of the corresponding indicator property. Indicator property must be of the int or color type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetInteger(
   int  prop_id,           // identifier
   int  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetInteger(
   int  prop_id,           // identifier
   int  prop_modifier,     // modifier
   int  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, in order to set thickness of the first horizontal line use zeroth index:

- IndicatorSetInteger(INDICATOR_LEVELWIDTH, **0**, 5) - index 0 is used to set thickness of the first level.

Example: indicator that sets color, style and thickness of the indicator horizontal lines.

IndicatorSetString

The function sets the value of the corresponding indicator property. Indicator property must be of the string type. There are two variants of the function.

Call with specifying the property identifier.

```
bool  IndicatorSetString(
   int     prop_id,           // identifier
   string  prop_value         // value to be set
   );
```

Call with specifying the property identifier and modifier.

```
bool  IndicatorSetString(
   int     prop_id,           // identifier
   int     prop_modifier,     // modifier
   string  prop_value         // value to be set
   )
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the ENUM_CUSTOMIND_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, indicator display can differ from the intended one.

For example, in order to set description of the first horizontal line use zeroth index:

- IndicatorSetString(INDICATOR_LEVELTEXT, **0**, "First Level") - index 0 is used to set text description of the first level.

Example: indicator that sets text labels to the indicator horizontal lines.

PlotIndexSetDouble

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the double type.

```
bool  PlotIndexSetDouble(
   int     plot_index,     // plotting style index
   int     prop_id,        // property identifier
   double  prop_value      // value to be set
   );
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_DOUBLE enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

© 2000-2025, MetaQuotes Ltd.

PlotIndexSetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, char, bool or color type. There are 2 variants of the function.

Call indicating identifier of the property.

```
bool  PlotIndexSetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   int  prop_value          // value to be set
   );
```

Call indicating the identifier and modifier of the property.

```
bool  PlotIndexSetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   int  prop_modifier,      // property modifier
   int  prop_value          // value to be set
   )
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

Example: an indicator that draws a three-color line. The color scheme changes every 5 ticks.

            case 0:// first color scheme
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrRed);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrBlue);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrGreen);
               Print("Color scheme "+modified);
               break;
            case 1:// second color scheme
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrYellow);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrPink);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLightSlateGray);
               Print("Color scheme "+modified);
               break;
            default:// third color scheme
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrLightGoldenrod);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrOrchid);
               PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLimeGreen);
               Print("Color scheme "+modified);
           }
        }
      else
        {
         //--- set start position
         limit=prev_calculated-1;
         //--- now we set line color for every bar
         for(int i=limit;i<rates_total;i++)
            ColorBuffer[i]=getIndexOfColor(i);
        }
     }
//--- return value of prev_calculated for next call
   return(rates_total);
  }
//+------------------------------------------------------------------+
```

© 2000-2025, MetaQuotes Ltd.

PlotIndexSetString

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the string type.

```
bool  PlotIndexSetString(
   int     plot_index,     // plotting style index
   int     prop_id,        // property identifier
   string  prop_value      // value to be set
   );
```

Parameters

plot_index

[in] Index of graphical plot

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_STRING enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns true, otherwise false.

© 2000-2025, MetaQuotes Ltd.

PlotIndexGetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, color, bool or char type. There are 2 variants of the function.

Call indicating identifier of the property.

```
int  PlotIndexGetInteger(
   int  plot_index,         // plotting style index
   int  prop_id,            // property identifier
   );
```

Call indicating the identifier and modifier of the property.

```
int  PlotIndexGetInteger(
   int  plot_index,         // plotting index
   int  prop_id,            // property identifier
   int  prop_modifier       // property modifier
   )
```

Parameters

plot_index

[in] Index of the graphical plotting

prop_id

[in] The value can be one of the values of the ENUM_PLOT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

Note

Function is designed to extract the settings of drawing of the appropriate indicator line. The function works in tandem with the function PlotIndexSetInteger to copy the drawing properties of one line to another.

Example: an indicator that colors candles depending on the day of the week. Colors for each day are set in a programmatically.

Object Functions

This is the group of functions intended for working with graphic objects relating to any specified chart.

The functions defining the properties of graphical objects, as well as ObjectCreate() and ObjectMove() operations for creating and moving objects along the chart are actually used for sending commands to the chart. If these functions are executed successfully, the command is included in the common queue of the chart events. Visual changes in the properties of graphical objects are implemented when handling the queue of the chart events.

Thus, do not expect an immediate visual update of graphical objects after calling these functions. Generally, the graphical objects on the chart are updated automatically by the terminal following the change events - a new quote arrival, resizing the chart window, etc. Use ChartRedraw() function to forcefully update the graphical objects.

Function	Action
ObjectCreate	Creates an object of the specified type in a specified chart
ObjectName	Returns the name of an object of the corresponding type in the specified chart (specified chart subwindow)
ObjectDelete	Removes the object with the specified name from the specified chart (from the specified chart subwindow)
ObjectsDeleteAll	Removes all objects of the specified type from the specified chart (from the specified chart subwindow)
ObjectFind	Searches for an object with the specified ID by the name
ObjectGetTimeByValue	Returns the time value for the specified object price value
ObjectGetValueByTime	Returns the price value of an object for the specified time
ObjectMove	Changes the coordinates of the specified object anchor point
ObjectsTotal	Returns the number of objects of the specified type in the specified chart (specified chart subwindow)
ObjectGetDouble	Returns the double value of the corresponding object property
ObjectGetInteger	Returns the integer value of the corresponding object property
ObjectGetString	Returns the string value of the corresponding object property
ObjectSetDouble	Sets the value of the corresponding object property
ObjectSetInteger	Sets the value of the corresponding object property
ObjectSetString	Sets the value of the corresponding object property
TextSetFont	Sets the font for displaying the text using drawing methods (Arial 20 used by default)
TextOut	Transfers the text to the custom array (buffer) designed for creation of a graphical resource

© 2000-2025, MetaQuotes Ltd.

Function	Action
TextGetSize	Returns the string's width and height at the current font settings

Every graphical object should have a name unique within one chart, including its subwindows. Changing of a name of a graphic object generates two events: event of deletion of an object with the old name, and event of creation of an object with a new name.

After an object is created or an object property is modified it is recommended to call the ChartRedraw() function, which commands the client terminal to forcibly draw a chart (and all visible objects in it).

© 2000-2025, MetaQuotes Ltd.

ObjectCreate

The function creates an object with the specified name, type, and the initial coordinates in the specified chart subwindow. During creation up to 30 coordinates can be specified.

```
bool  ObjectCreate(
   long          chart_id,      // chart identifier
   string        name,          // object name
   ENUM_OBJECT   type,          // object type
   sub_window    nwin,          // window index
   datetime      time1,         // time of the first anchor point
   double        price1,        // price of the first anchor point
   ...
   datetime      timeN=0,       // time of the N-th anchor point
   double        priceN=0,      // price of the N-th anchor point
   ...
   datetime      time30=0,      // time of the 30th anchor point
   double        price30=0      // price of the 30th anchor point
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object. The name must be unique within a chart, including its subwindows.

type

[in] Object type. The value can be one of the values of the ENUM_OBJECT enumeration.

sub_window

[in] Number of the chart subwindow. 0 means the main chart window. The specified subwindow must exist, otherwise the function returns false.

time1

[in] The time coordinate of the first anchor.

price1

[in] The price coordinate of the first anchor point.

timeN=0

[in] The time coordinate of the N-th anchor point.

priceN=0

[in] The price coordinate of the N-th anchor point.

time30=0

[in] The time coordinate of the thirtieth anchor point.

price30=0

[in] The price coordinate of the thirtieth anchor point.

© 2000-2025, MetaQuotes Ltd.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise. If an object has already been created, an attempt is made to change its coordinates.

Note

An asynchronous call is always used for ObjectCreate(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use the ObjectFind() function or any other function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object name should not exceed 63 characters.

The numbering of the chart subwindows (if there are subwindows with indicators in the chart) starts with 1. The main chart window of the chart is and always has index 0.

The large number of anchor points (up to 30) is implemented for future use. At the same time, the limit of 30 possible anchor points for graphical objects is determined by the limit on the number of parameters (not more than 64) that can be used when calling a function.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

There is a certain number of anchor points that must be specified when creating each object type:

ID	Description	Anchor Points
OBJ_VLINE	Vertical Line	One anchor point. Actually only the time coordinate is used.
OBJ_HLINE	Horizontal Line	One anchor point. Actually only the price coordinate is used.
OBJ_TREND	Trend Line	Two anchor points.
OBJ_TRENDBYANGLE	Trend Line By Angle	Two anchor points.
OBJ_CYCLES	Cycle Lines	Two anchor points.
OBJ_ARROWED_LINE	Arrowed Line	Two anchor points.
OBJ_CHANNEL	Equidistant Channel	Three anchor points.
OBJ_STDDEVCHANNEL	Standard Deviation Channel	Two anchor points.
OBJ_REGRESSION	Linear Regression Channel	Two anchor points.

© 2000-2025, MetaQuotes Ltd.

ID	Description	Anchor Points
OBJ_PITCHFORK	Andrews' Pitchfork	Three anchor points.
OBJ_GANNLINE	Gann Line	Two anchor points.
OBJ_GANNFAN	Gann Fan	Two anchor points.
OBJ_GANNGRID	Gann Grid	Two anchor points.
OBJ_FIBO	Fibonacci Retracement	Two anchor points.
OBJ_FIBOTIMES	Fibonacci Time Zones	Two anchor points.
OBJ_FIBOFAN	Fibonacci Fan	Two anchor points.
OBJ_FIBOARC	Fibonacci Arcs	Two anchor points.
OBJ_FIBOCHANNEL	Fibonacci Channel	Three anchor points.
OBJ_EXPANSION	Fibonacci Expansion	Three anchor points.
OBJ_ELLIOTWAVE5	Elliott Motive Wave	Five anchor points.
OBJ_ELLIOTWAVE3	Elliott Correction Wave	Three anchor points.
OBJ_RECTANGLE	Rectangle	Two anchor points.
OBJ_TRIANGLE	Triangle	Three anchor points.
OBJ_ELLIPSE	Ellipse	Three anchor points.
OBJ_ARROW_THUMB_UP	Thumbs Up	One anchor point.
OBJ_ARROW_THUMB_DOWN	Thumbs Down	One anchor point.
OBJ_ARROW_UP	Arrow Up	One anchor point.
OBJ_ARROW_DOWN	Arrow Down	One anchor point.
OBJ_ARROW_STOP	Stop Sign	One anchor point.
OBJ_ARROW_CHECK	Check Sign	One anchor point.
OBJ_ARROW_LEFT_PRICE	Left Price Label	One anchor point.
OBJ_ARROW_RIGHT_PRICE	Right Price Label	One anchor point.
OBJ_ARROW_BUY	Buy Sign	One anchor point.
OBJ_ARROW_SELL	Sell Sign	One anchor point.
OBJ_ARROW	Arrow	One anchor point.
OBJ_TEXT	Text	One anchor point.
OBJ_LABEL	Label	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.

© 2000-2025, MetaQuotes Ltd.

ID	Description	Anchor Points
OBJ_BUTTON	Button	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_CHART	Chart	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_BITMAP	Bitmap	One anchor point.
OBJ_BITMAP_LABEL	Bitmap Label	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_EDIT	Edit	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.
OBJ_EVENT	The "Event" object corresponding to an event in the economic calendar	One anchor point. Actually only the time coordinate is used.
OBJ_RECTANGLE_LABEL	The "Rectangle label" object for creating and designing the custom graphical interface.	Position is set using the OBJPROP_XDISTANCE and OBJPROP_YDISTANCE properties.

© 2000-2025, MetaQuotes Ltd.

ObjectName

The function returns the name of the corresponding object in the specified chart, in the specified subwindow, of the specified type.

```
string  ObjectName(
   long  chart_id,           // chart identifier
   int   pos,                // number in the list of objects
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

pos

[in] Ordinal number of the object according to the specified filter by the number and type of the subwindow.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

Name of the object is returned in case of success.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

© 2000-2025, MetaQuotes Ltd.

ObjectDelete

The function removes the object with the specified name from the specified chart.

```
bool  ObjectDelete(
   long    chart_id,      // chart identifier
   string  name           // object name
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of object to be deleted.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise.

Note

An asynchronous call is always used for ObjectDelete(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use the ObjectFind() function or any other function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

© 2000-2025, MetaQuotes Ltd.

ObjectsDeleteAll

Removes all objects from the specified chart, specified chart subwindow, of the specified type.

```
int  ObjectsDeleteAll(
   long  chart_id,           // chart identifier
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Removes all objects of the specified type using prefix in object names.

```
int  ObjectsDeleteAll(
   long           chart_id,   // chart ID
   const string     prefix,   // prefix in object name
   int        sub_window=-1,  // window index
   int      object_type=-1    // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

prefix

[in] Prefix in object names. All objects whose names start with this set of characters will be removed from chart. You can specify prefix as 'name' or 'name*' - both variants will work the same. If an empty string is specified as the prefix, objects with all possible names will be removed.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

Returns the number of deleted objects. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

© 2000-2025, MetaQuotes Ltd.

ObjectFind

The function searches for an object with the specified name in the chart with the specified ID.

```
int  ObjectFind(
   long    chart_id,      // chart identifier
   string  name           // object name
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] The name of the searched object.

Return Value

If successful the function returns the number of the subwindow (0 means the main window of the chart), in which the object is found. If the object is not found, the function returns a negative number. To read more about the error call GetLastError().

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

© 2000-2025, MetaQuotes Ltd.

ObjectGetTimeByValue

The function returns the time value for the specified price value of the specified object.

```
datetime  ObjectGetTimeByValue(
   long     chart_id,      // chart identifier
   string   name,          // object name
   double   value,         // Price
   int      line_id        // Line number
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

value

[in] Price value.

line_id

[in] Line identifier.

Return Value

The time value for the specified price value of the specified object.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLINE)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

ObjectGetValueByTime

The function returns the price value for the specified time value of the specified object.

```
double  ObjectGetValueByTime(
   long      chart_id,     // chart identifier
   string    name,         // object name
   datetime  time,         // Time
   int       line_id       // Line number
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

time

[in] Time value.

line_id

[in] Line ID.

Return Value

The price value for the specified time value of the specified object.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLINE)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

ObjectMove

The function changes coordinates of the specified anchor point of the object.

```
bool  ObjectMove(
   long      chart_id,         // chart identifier
   string    name,             // object name
   int       point_index,      // anchor point number
   datetime  time,             // Time
   double    price             // Price
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

point_index

[in] Index of the anchor point. The number of anchor points depends on the type of object.

time

[in] Time coordinate of the selected anchor point.

price

[in] Price coordinate of the selected anchor point.

Return Value

The function returns true if the command has been successfully added to the queue of the specified chart, or false otherwise.

Note

An asynchronous call is always used for ObjectMove(), that is why the function only returns the results of adding the command to a chart queue. In this case, true only means that the command has been successfully enqueued, but the result of its execution is unknown.

To check the command execution result, you can use a function that requests object properties, such as ObjectGetXXX. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result (due to the synchronous call), and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

© 2000-2025, MetaQuotes Ltd.

ObjectsTotal

The function returns the number of objects in the specified chart, specified subwindow, of the specified type.

```
int  ObjectsTotal(
   long  chart_id,           // chart identifier
   int   sub_window=-1,      // window index
   int   type=-1             // object type
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the ENUM_OBJECT enumeration. -1 means all types.

Return Value

The number of objects.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

© 2000-2025, MetaQuotes Ltd.

ObjectSetDouble

The function sets the value of the corresponding object property. The object property must be of the double type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property
   double                        prop_value         // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property
   int                           prop_modifier,     // modifier
   double                        prop_value         // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

© 2000-2025, MetaQuotes Ltd.

The function uses an asynchronous call, which means that the function does not wait for the execution of the command that has been added to the queue of the specified chart. Instead, it immediately returns control.

To check the command execution result, you can use a function that requests the specified object property. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result, and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

Example of creating a Fibonacci object and adding a new level in it

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- auxiliary arrays
   double high[],low[],price1,price2;
   datetime time[],time1,time2;
//--- Copy the open prices - 100 latest bars are enough
   int copied=CopyHigh(Symbol(),0,0,100,high);
   if(copied<=0)
     {
      Print("Failed to copy the values of the High price series");
      return;
     }
//--- Copy the close price - 100 latest bars are enough
   copied=CopyLow(Symbol(),0,0,100,low);
   if(copied<=0)
     {
      Print("Failed to copy the values of the Low price series");
      return;
     }
//--- Copy the open time for the last 100 bars
   copied=CopyTime(Symbol(),0,0,100,time);
   if(copied<=0)
     {
      Print("Failed to copy the values of the price series of Time");
      return;
     }
//--- Organize access to the copied data as to timeseries - backwards
   ArraySetAsSeries(high,true);
   ArraySetAsSeries(low,true);
   ArraySetAsSeries(time,true);

//--- Coordinates of the first anchor point of the Fibo object
   price1=high[70];
   time1=time[70];
//--- Coordinates of the second anchor point of the Fibo object
   price2=low[50];
```

© 2000-2025, MetaQuotes Ltd.

```
   time2=time[50];

//--- Time to create the Fibo object
   bool created=ObjectCreate(0,"Fibo",OBJ_FIBO,0,time1,price1,time2,price2);
   if(created) // If the object is created successfully
     {
      //--- set the color of Fibo levels
      ObjectSetInteger(0,"Fibo",OBJPROP_LEVELCOLOR,Blue);
      //--- by the way, how much Fibo levels do we have?
      int levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
      Print("Fibo levels before = ",levels);
      //---output to the Journal => number of level:value level_desription
      for(int i=0;i<levels;i++)
        {
         Print(i,": ",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
               "  ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
        }
      //--- Try to increase the number of levels per unit
      bool modified=ObjectSetInteger(0,"Fibo",OBJPROP_LEVELS,levels+1);
      if(!modified) // failed to change the number of levels
        {
         Print("Failed to change the number of levels of Fibo, error ",GetLastError())
        }
      //--- just inform
      Print("Fibo levels after = ",ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS));
      //--- set a value for a newly created level
      bool added=ObjectSetDouble(0,"Fibo",OBJPROP_LEVELVALUE,levels,133);
      if(added) // managed to set a value for the level
        {
         Print("Successfully set one more Fibo level");
         //--- Also do not forget to set the level description
         ObjectSetString(0,"Fibo",OBJPROP_LEVELTEXT,levels,"my level");
         ChartRedraw(0);
         //--- Get the actual value of the number of levels in the Fibo object
         levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
         Print("Fibo levels after adding = ",levels);
         //--- once again output all levels - just to make sure
         for(int i=0;i<levels;i++)
           {
            Print(i,":",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
                  "  ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
           }
        }
      else // Fails if you try to increase the number of levels in the Fibo object
        {
         Print("Failed to set one more Fibo level. Error ",GetLastError());
        }
     }
  }
```

ObjectSetInteger

The function sets the value of the corresponding object property. The object property must be of the datetime, int, color, bool or char type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetInteger(
   long                          chart_id,       // chart identifier
   string                        name,           // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,        // property
   long                          prop_value      // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetInteger(
   long                          chart_id,       // chart identifier
   string                        name,           // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,        // property
   int                           prop_modifier,  // modifier
   long                          prop_value      // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

ObjectSetString

The function sets the value of the corresponding object property. The object property must be of the string type. There are 2 variants of the function.

Setting property value, without modifier

```
bool  ObjectSetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property
   string                        prop_value         // value
   );
```

Setting a property value indicating the modifier

```
bool  ObjectSetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property
   int                           prop_modifier,     // modifier
   string                        prop_value         // value
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the error call GetLastError().

Note

The function uses an asynchronous call, which means that the function does not wait for the execution of the command that has been added to the queue of the specified chart. Instead, it immediately returns control.

To check the command execution result, you can use a function that requests the specified object property. However, you should keep in mind that such functions are added to the end of the queue of that chart, and they wait for the execution result, and can therefore be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectGetDouble

The function returns the value of the corresponding object property. The object property must be of the double type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double  ObjectGetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if require
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetDouble(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   double&                       double_var         // here we accept the property v
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_DOUBLE enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

double_var

[out] Variable of the double type that received the value of the requested property.

Return Value

Value of the double type for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the double_var variable, otherwise returns false. To read more about the error call GetLastError().

ObjectGetInteger

The function returns the value of the corresponding object property. The object property must be of the datetime, int, color, bool or char type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long  ObjectGetInteger(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if requi
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetInteger(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   long&                         long_var           // here we accept the property
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_INTEGER enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

long_var

[out] Variable of the long type that receives the value of the requested property.

Return Value

The long value for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the long_var variable, otherwise returns false. To read more about the error call GetLastError().

© 2000-2025, MetaQuotes Ltd.

Note

The function uses a synchronous call, which means that the function waits for the execution of all commands that have been enqueued for this chart prior to its call, that is why this function can be time consuming. This feature should be taken into account when working with a large number of objects on a chart.

© 2000-2025, MetaQuotes Ltd.

ObjectGetString

The function returns the value of the corresponding object property. The object property must be of the string type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string  ObjectGetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property identifier
   int                           prop_modifier=0    // property modifier, if require
   );
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool  ObjectGetString(
   long                          chart_id,          // chart identifier
   string                        name,              // object name
   ENUM_OBJECT_PROPERTY_STRING   prop_id,           // property identifier
   int                           prop_modifier,     // property modifier
   string&                       string_var         // here we accept the property v
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the ENUM_OBJECT_PROPERTY_STRING enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in Fibonacci tools and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

string_var

[out] Variable of the string type that receives the value of the requested properties.

Return Value

String value for the first version of the call.

For the second version of the call returns true, if this property is maintained and the value has been placed into the string_var variable, otherwise returns false. To read more about the error call GetLastError().

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the OnChartEvent() function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

© 2000-2025, MetaQuotes Ltd.

TextSetFont

The function sets the font for displaying the text using drawing methods and returns the result of that operation. Arial font with the size -120 (12 pt) is used by default.

```
bool  TextSetFont(
   const string  name,            // font name or path to font file on the disk
   int           size,            // font size
   uint          flags,           // combination of flags
   int           orientation=0    // text slope angle
   );
```

Parameters

name

[in] Font name in the system or the name of the resource containing the font or the path to font file on the disk.

size

[in] The font size that can be set using positive and negative values. In case of positive values, the size of a displayed text does not depend on the operating system's font size settings. In case of negative values, the value is set in tenths of a point and the text size depends on the operating system settings ("standard scale" or "large scale"). See the Note below for more information about the differences between the modes.

flags

[in] Combination of flags describing font style.

orientation

[in] Text's horizontal inclination to X axis, the unit of measurement is 0.1 degrees. It means that *orientation=450* stands for inclination equal to 45 degrees.

Return Value

Returns true if the current font is successfully installed, otherwise false. Possible code errors:

- ERR_INVALID_PARAMETER(4003) - *name* presents NULL or "" (empty string),
- ERR_INTERNAL_ERROR(4001) - operating system error (for example, an attempt to create a non-existent font).

Note

If "::" is used in font name, the font is downloaded from EX5 resource. If *name* font name is specified with an extension, the font is downloaded from the file, if the path starts from "\" or "/", the file is searched relative to MQL5 directory. Otherwise, it is searched relative to the path of EX5 file which called TextSetFont() function.

The font size is set using positive or negative values. This fact defines the dependence of the text size from the operating system settings (size scale).

- If the size is specified using a positive number, this size is transformed into physical measurement units of a device (pixels) when changing a logical font into a physical one, and this size corresponds to the height of the symbol glyphs picked from the available fonts. This case is not recommended when the texts displayed by TextOut() function and the ones displayed by OBJ_LABEL ("Label") graphical object are to be used together on the chart.

© 2000-2025, MetaQuotes Ltd.

- If the size is specified using a negative number, this number is supposed to be set in tenths of a logical point and is divided by 10 (for example, -350 is equal to 35 logical points). An obtained value is then transformed into physical measurement units of a device (pixels) and corresponds to the absolute value of the height of a symbol picked from the available fonts. Multiply the font size specified in the object properties by -10 to make the size of a text on the screen similar to the one in OBJ_LABEL object.

The flags can be used as the combination of style flags with one of the flags specifying the font width. Flag names are shown below.

Flags for specifying font style

Flag	Description
FONT_ITALIC	Italic
FONT_UNDERLINE	Underline
FONT_STRIKEOUT	Strikeout

Flags for specifying font width

Flag
FW_DONTCARE
FW_THIN
FW_EXTRALIGHT
FW_ULTRALIGHT
FW_LIGHT
FW_NORMAL
FW_REGULAR
FW_MEDIUM
FW_SEMIBOLD
FW_DEMIBOLD
FW_BOLD
FW_EXTRABOLD
FW_ULTRABOLD
FW_HEAVY
FW_BLACK

TextOut

The function displays a text in a custom array (buffer) and returns the result of that operation. The array is designed to create the graphical resource.

```
bool  TextOut(
   const string       text,          // displayed text
   int                x,             // X coordinate
   int                y,             // Y coordinate
   uint               anchor,        // anchor type
   uint               &data[],       // output buffer
   uint               width,         // buffer width in pixels
   uint               height,        // buffer height in pixels
   uint               color,         // text color
   ENUM_COLOR_FORMAT  color_format   // color format for output
   );
```

Parameters

text

[in] Displayed text that will be written to the buffer. Only one-lined text is displayed.

x

[in] X coordinate of the anchor point of the displayed text.

y

[in] Y coordinate of the anchor point of the displayed text.

anchor

[in] The value out of the 9 pre-defined methods of the displayed text's anchor point location. The value is set by a combination of two flags - flags of horizontal and vertical text align. Flag names are listed in the Note below.

data[]

[in] Buffer, in which text is displayed. The buffer is used to create the graphical resource.

width

[in] Buffer width in pixels.

height

[in] Buffer height in pixels.

color

[in] Text color.

color_format

[in] Color format is set by ENUM_COLOR_FORMAT enumeration value.

Return Value

Returns true if successful, otherwise false.

Note

© 2000-2025, MetaQuotes Ltd.

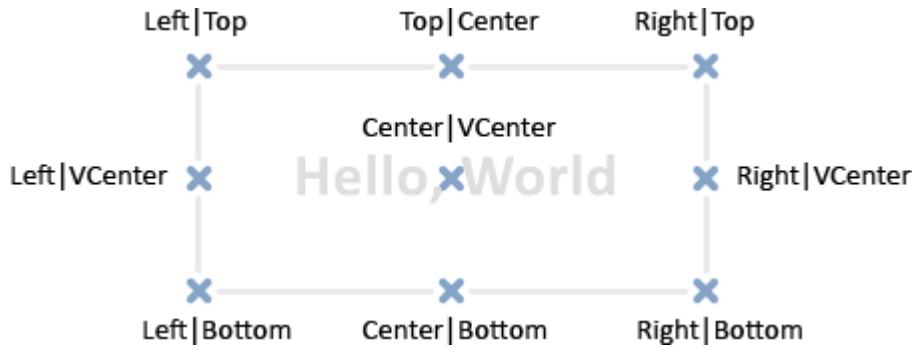
Anchor point specified by *anchor* is a combination of two flags of horizontal and vertical text align.
Horizontal text align flags:

- TA_LEFT - anchor point on the left side of the bounding box
- TA_CENTER - horizontal anchor point is located at the center of the bounding box
- TA_RIGHT - anchor point on the right side of the bounding box

Vertical text align flags:

- TA_TOP - anchor point at the upper side of the bounding box
- TA_VCENTER - vertical anchor point is located at the center of the bounding box
- TA_BOTTOM - anchor point at the lower side of the bounding box

Possible combinations of flags and specified anchor points are shown in the image.



Example:

```
//--- width and height of the canvas (used for drawing)
#define IMG_WIDTH  200
#define IMG_HEIGHT 200
//--- display the parameter window before launching the script
#property script_show_inputs
//--- enable to set color format
input ENUM_COLOR_FORMAT clr_format=COLOR_FORMAT_XRGB_NOALPHA;
//--- drawing array (buffer)
uint ExtImg[IMG_WIDTH*IMG_HEIGHT];
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create OBJ_BITMAP_LABEL object for drawing
   ObjectCreate(0,"CLOCK",OBJ_BITMAP_LABEL,0,0,0);
//--- specify the name of the graphical resource for writing in CLOCK object
   ObjectSetString(0,"CLOCK",OBJPROP_BMPFILE,"::IMG");

//--- auxiliary variables
   double a;            // arrow corner
   uint   nm=2700;      // minute corner
   uint   nh=2700*12;   // hour counter
   uint   w,h;          // variables for receiving text string sizes
```

© 2000-2025, MetaQuotes Ltd.

```
   int    x,y;          // variables for calculation of the current coordinates of tex

//--- rotate clock hands in an infinite loop, till the script is stopped
   while(!IsStopped())
     {
      //--- clear the clock drawing buffer array
      ArrayFill(ExtImg,0,IMG_WIDTH*IMG_HEIGHT,0);
      //--- set the font for drawing digits for the clock-face
      TextSetFont("Arial",-200,FW_EXTRABOLD,0);
      //--- draw the clock-face
      for(int i=1;i<=12;i++)
        {
         //--- receive the size of the current hour on the clock-face
         TextGetSize(string(i),w,h);
         //--- calculate the coordinates of the current hour on the clock-face
         a=-((i*300)%3600*M_PI)/1800.0;
         x=IMG_WIDTH/2-int(sin(a)*80+0.5+w/2);
         y=IMG_HEIGHT/2-int(cos(a)*80+0.5+h/2);
         //--- output the hour on the clock-face to ExtImg[] buffer
         TextOut(string(i),x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,c
        }
      //--- now, specify the font for drawing the minute hand
      TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nm%3600));
      //--- receive the size of the minute hand
      TextGetSize("----->",w,h);
      //--- calculate the coordinates of the minute hand on the clock-face
      a=-(nm%3600*M_PI)/1800.0;
      x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
      y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
      //--- output of the minute hand to the clock-face in ExtImg[]buffer
      TextOut("----->",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_f

      //--- now, set the font for drawing the minute hand
      TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nh/12%3600));
      TextGetSize("==>",w,h);
      //--- calculate the coordinates of the hour hand on the clock-face
      a=-(nh/12%3600*M_PI)/1800.0;
      x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
      y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
      //--- output of the hour hand on the clock-face to ExtImg[] buffer
      TextOut("==>",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_forn

      //--- update the graphical resource
      ResourceCreate("::IMG",ExtImg,IMG_WIDTH,IMG_HEIGHT,0,0,IMG_WIDTH,clr_format);
      //--- forced chart update
      ChartRedraw();

      //--- increase hour and minute counters
      nm+=60;
      nh+=60;
```

TextGetSize

The function returns the line width and height at the current font settings.

```
bool  TextGetSize(
   const string       text,          // text string
   uint&               width,        // buffer width in pixels
   uint&               height        // buffer height in pixels
   );
```

Parameters

text

[in] String, for which length and width should be obtained.

width

[out] Input parameter for receiving width.

height

[out] Input parameter for receiving height.

Return Value

Returns true if successful, otherwise false. Possible code errors:

- ERR_INTERNAL_ERROR(4001) - operating system error.

Technical Indicator Functions

All functions like iMA, iAC, iMACD, iIchimoku etc. create a copy of the corresponding technical indicator in the global cache of the client terminal. If a copy of the indicator with such parameters already exists, the new copy is not created, and the counter of references to the existing copy increases.

These functions return the handle of the appropriate copy of the indicator. Further, using this handle, you can receive data calculated by the corresponding indicator. The corresponding buffer data (technical indicators contain calculated data in their internal buffers, which can vary from 1 to 5, depending on the indicator) can be copied to a mql5-program using the CopyBuffer() function.

You can't refer to the indicator data right after it has been created, because calculation of indicator values requires some time, so it's better to create indicator handles in OnInit(). Function iCustom() creates the corresponding custom indicator, and returns its handle in case it is successfully create. Custom indicators can contain up to 512 indicator buffers, the contents of which can also be obtained by the CopyBuffer() function, using the obtained handle.

There is a universal method for creating any technical indicator using the IndicatorCreate() function. This function accepts the following data as input parameters:

- symbol name;
- timeframe;
- type of the indicator to create;
- number of input parameters of the indicator;
- an array of MqlParam type containing all the necessary input parameters.

The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note. Repeated call of the indicator function with the same parameters within one mql5-program does not lead to a multiple increase of the reference counter; the counter will be increased only once by 1. However, it's recommended to get the indicators handles in function OnInit() or in the class constructor, and further use these handles in other functions. The reference counter decreases when a mql5-program is deinitialized.

All indicator functions have at least 2 parameters - symbol and period. The NULL value of the symbol means the current symbol, the 0 value of the period means the current timeframe.

Function	Returns the handle of the indicator:
iAC	Accelerator Oscillator
iAD	Accumulation/Distribution
iADX	Average Directional Index
iADXWilder	Average Directional Index by Welles Wilder
iAlligator	Alligator
iAMA	Adaptive Moving Average

© 2000-2025, MetaQuotes Ltd.

Function	Returns the handle of the indicator:
iAO	Awesome Oscillator
iATR	Average True Range
iBearsPower	Bears Power
iBands	Bollinger Bands®
iBullsPower	Bulls Power
iCCI	Commodity Channel Index
iChaikin	Chaikin Oscillator
iCustom	Custom indicator
iDEMA	Double Exponential Moving Average
iDeMarker	DeMarker
iEnvelopes	Envelopes
iForce	Force Index
iFractals	Fractals
iFrAMA	Fractal Adaptive Moving Average
iGator	Gator Oscillator
iIchimoku	Ichimoku Kinko Hyo
iBWMFI	Market Facilitation Index by Bill Williams
iMomentum	Momentum
iMFI	Money Flow Index
iMA	Moving Average
iOsMA	Moving Average of Oscillator (MACD histogram)
iMACD	Moving Averages Convergence-Divergence
iOBV	On Balance Volume
iSAR	Parabolic Stop And Reverse System
iRSI	Relative Strength Index
iRVI	Relative Vigor Index
iStdDev	Standard Deviation
iStochastic	Stochastic Oscillator
iTEMA	Triple Exponential Moving Average
iTriX	Triple Exponential Moving Averages Oscillator

© 2000-2025, MetaQuotes Ltd.

Function	Returns the handle of the indicator:
iWPR	Williams' Percent Range
iVIDyA	Variable Index Dynamic Average
iVolumes	Volumes

© 2000-2025, MetaQuotes Ltd.

iAC

The function creates Accelerator Oscillator in a global cache of the client terminal and returns its handle. It has only one buffer.

```
int  iAC(
   string           symbol,      // symbol name
   ENUM_TIMEFRAMES  period       // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES enumeration values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+
