iAD

The function returns the handle of the Accumulation/Distribution indicator. It has only one buffer.

```
int  iAD(
   string                symbol,              // symbol name
   ENUM_TIMEFRAMES       period,              // period
   ENUM_APPLIED_VOLUME   applied_volume       // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES enumeration values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+
//|                                                    Demo_iAD.mq5 |

iADX

The function returns the handle of the Average Directional Movement Index indicator.

```
int  iADX(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              adx_period       // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

iADXWilder

The function returns the handle of Average Directional Movement Index by Welles Wilder.

```
int  iADXWilder(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              adx_period       // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

Example:

```

iAlligator

The function returns the handle of the Alligator indicator.

```
int  iAlligator(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  jaw_period,        // period for the calculation of jaws
   int                  jaw_shift,         // horizontal shift of jaws
   int                  teeth_period,      // period for the calculation of teeth
   int                  teeth_shift,       // horizontal shift of teeth
   int                  lips_period,       // period for the calculation of lips
   int                  lips_shift,        // horizontal shift of lips
   ENUM_MA_METHOD       ma_method,         // type of smoothing
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw)

jaw_shift

[in] The shift of the blue line relative to the price chart.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price chart.

ma_method

[in] The method of averaging. Can be any of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

© 2000-2025, MetaQuotes Ltd.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - GATORJAW_LINE, 1 - GATORTEETH_LINE, 2 - GATORLIPS_LINE.

Example:

```

iAMA

The function returns the handle of the Adaptive Moving Average indicator. It has only one buffer.

```
int  iAMA(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  ama_period,          // average period for AMA
   int                  fast_ma_period,      // fast MA period
   int                  slow_ma_period,      // slow MA period
   int                  ama_shift,           // horizontal shift of the indicator
   ENUM_APPLIED_PRICE   applied_price        // type of the price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ama_period

[in] The calculation period, on which the efficiency coefficient is calculated.

fast_ma_period

[in] Fast period for the smoothing coefficient calculation for a rapid market.

slow_ma_period

[in] Slow period for the smoothing coefficient calculation in the absence of trend.

ama_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+
//|                                                   Demo_iAMA.mq5 |

iAO

The function returns the handle of the Awesome Oscillator indicator. It has only one buffer.

```
int  iAO(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period      // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

iATR

The function returns the handle of the Average True Range indicator. It has only one buffer.

```
int  iATR(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The value of the averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iBearsPower

The function returns the handle of the Bears Power indicator. It has only one buffer.

```
int  iBearsPower(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The value of the averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iBands

The function returns the handle of the Bollinger Bands® indicator.

```
int  iBands(
   string               symbol,           // symbol name
   ENUM_TIMEFRAMES      period,           // period
   int                  bands_period,     // period for average line calculation
   int                  bands_shift,      // horizontal shift of the indicator
   double               deviation,        // number of standard deviations
   ENUM_APPLIED_PRICE   applied_price     // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

bands_period

[in] The averaging period of the main line of the indicator.

bands_shift

[in] The shift the indicator relative to the price chart.

deviation

[in] Deviation from the main line.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - BASE_LINE, 1 - UPPER_BAND, 2 - LOWER_BAND

Example:

```

iBullsPower

The function returns the handle of the Bulls Power indicator. It has only one buffer.

```
int  iBullsPower(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iCCI

The function returns the handle of the Commodity Channel Index indicator. It has only one buffer.

```
int  iCCI(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iChaikin

The function returns the handle of the Chaikin Oscillator indicator. It has only one buffer.

```
int  iChaikin(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ma_period,      // fast period
   int                  slow_ma_period,      // slow period
   ENUM_MA_METHOD       ma_method,           // smoothing type
   ENUM_APPLIED_VOLUME  applied_volume       // type of volume
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ma_period

[in] Fast averaging period for calculations.

slow_ma_period

[in] Slow averaging period for calculations.

ma_method

[in] Smoothing type. Can be one of the averaging constants of ENUM_MA_METHOD.

applied_volume

[in] The volume used. Can be one of the constants of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iCustom

The function returns the handle of a specified custom indicator.

```
int  iCustom(
   string           symbol,      // symbol name
   ENUM_TIMEFRAMES  period,      // period
   string           name         // folder/custom_indicator_name
   ...                           // list of indicator input parameters
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

name

[in] Custom indicator name. If the name starts with the reverse slash '\', the EX5 indicator file is searched for relative to the MQL5 root directory. So, for a call of iCustom(Symbol(), Period(), "\FirstIndicator"...), the indicator will be loaded as MQL5\FirstIndicator.ex5. If the file is not found at this path, error 4802 (ERR_INDICATOR_CANNOT_CREATE) is returned.

If the path does not start with '\', the indicator is searched and downloaded as follows:

- First, the indicator EX5 file is searched for in the folder where the EX5 file of the calling program is located. For example, the CrossMA.EX5 EA is located in MQL5\Experts\MyExperts and contains the iCustom call (Symbol(), Period(), "SecondIndicator"...). In this case, the indicator is searched for in MQL5\Experts\MyExperts\SecondIndicator.ex5.
- If the indicator is not found in the same directory, the search is performed relative to the MQL5\Indicators indicator root directory. In other words, the search for the MQL5\Indicators\SecondIndicator.ex5 file is performed. If the indicator is still not found, the function returns INVALID_HANDLE and the error 4802 (ERR_INDICATOR_CANNOT_CREATE) is triggered.

If the path to the indicator is set in the subdirectory (for example, MyIndicators\ThirdIndicator), the search is first performed in the calling program folder (the EA is located in MQL5\Experts\MyExperts) in MQL5\Experts\MyExperts\MyIndicators\ThirdIndicator.ex5. If unsuccessful, the search for the MQL5\Indicators\MyIndicators\ThirdIndicator.ex5 file is performed. Make sure to use the double reverse slash '\\' as a separator in the path, for example iCustom(Symbol(), Period(), "MyIndicators\\ThirdIndicator"...)

...

[in] input-parameters of a custom indicator, separated by commas. Type and order of parameters must match. If there is no parameters specified, then default values will be used.

Return Value

© 2000-2025, MetaQuotes Ltd.

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

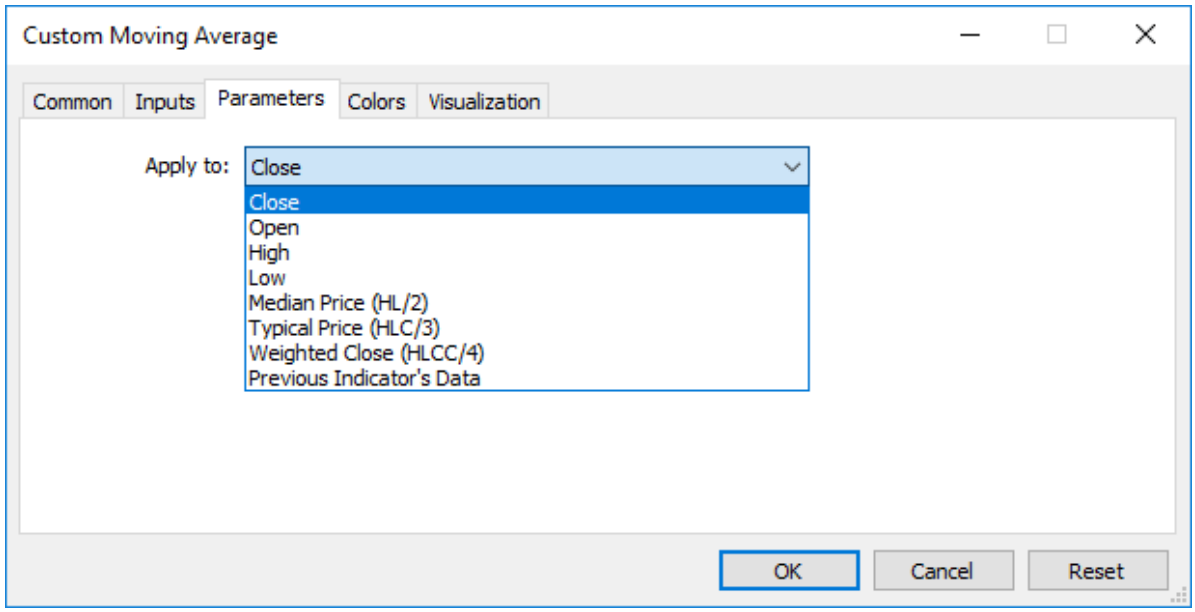
Note

A custom indicator must be compiled (with extension EX5) and located in the directory MQL5/Indicators of the client terminal or its subdirectory.

Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a constant string. For all other cases (use of the IndicatorCreate() function or use of a non-constant string in the parameter that sets the indicator name) the property #property tester_indicator is required:

```
#property tester_indicator "indicator_name.ex5"
```

If the first call form is used in the indicator, then at the custom indicator start you can additionally indicate data for calculation in its "Parameters" tab. If the "Apply to" parameter is not selected explicitly, the default calculation is based on the values of "Close" prices.



When you call a custom indicator from mql5-program, the Applied_Price parameter or a handle of another indicator should be passed last, after all input variables of the custom indicator.

iDEMA

The function returns the handle of the Double Exponential Moving Average indicator. It has only one buffer.

```
int  iDEMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iDeMarker

The function returns the handle of the DeMarker indicator. It has only one buffer.

```
int  iDeMarker(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iEnvelopes

The function returns the handle of the Envelopes indicator.

```
int  iEnvelopes(
   string               symbol,           // symbol name
   ENUM_TIMEFRAMES      period,           // period
   int                  ma_period,        // period for the average line calculation
   int                  ma_shift,         // horizontal shift of the indicator
   ENUM_MA_METHOD       ma_method,        // type of smoothing
   ENUM_APPLIED_PRICE   applied_price,    // type of price or handle
   double               deviation         // deviation of boundaries from the midline
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the main line.

ma_shift

[in] The shift of the indicator relative to the price chart.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

deviation

[in] The deviation from the main line (in percents).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - UPPER_LINE, 1 - LOWER_LINE.

iForce

The function returns the handle of the Force Index indicator. It has only one buffer.

```
int  iForce(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_MA_METHOD       ma_method,         // smoothing type
   ENUM_APPLIED_VOLUME  applied_volume     // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

applied_volume

[in] The volume used. Can be one of the values of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iFractals

The function returns the handle of the Fractals indicator.

```
int  iFractals(
   string           symbol,     // symbol name
   ENUM_TIMEFRAMES  period      // period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - UPPER_LINE, 1 - LOWER_LINE.

Example:

```

iFrAMA

The function returns the handle of the Fractal Adaptive Moving Average indicator. It has only one buffer.

```
int  iFrAMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift on the chart
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Period (bars count) for the indicator calculations.

ma_shift

[in] Shift of the indicator in the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+
//|                                                  Demo_iFrAMA.mq5 |

iGator

The function returns the handle of the Gator indicator. The Oscillator shows the difference between the blue and red lines of Alligator (upper histogram) and difference between red and green lines (lower histogram).

```
int  iGator(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  jaw_period,        // period for the calculation of the jaws
   int                  jaw_shift,         // jaws horizontal shift
   int                  teeth_period,      // period for the calculation of the teeth
   int                  teeth_shift,       // teeth horizontal shift
   int                  lips_period,       // period for the calculation of the lips
   int                  lips_shift,        // lips horizontal shift
   ENUM_MA_METHOD       ma_method,         // type of smoothing
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw).

jaw_shift

[in] The shift of the blue line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price charts. It isn't directly connected with the visual shift of the indicator histogram.

ma_method

[in] Smoothing type. Can be one of the values of ENUM_MA_METHOD.

© 2000-2025, MetaQuotes Ltd.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

Buffer numbers: 0 - UPPER_HISTOGRAM, 1 - color buffer of the upper histogram, 2 - LOWER_HISTOGRAM, 3 - color buffer of the lower histogram.

iIchimoku

The function returns the handle of the Ichimoku Kinko Hyo indicator.

```
int  iIchimoku(
   string           symbol,           // symbol name
   ENUM_TIMEFRAMES  period,           // period
   int              tenkan_sen,       // period of Tenkan-sen
   int              kijun_sen,        // period of Kijun-sen
   int              senkou_span_b     // period of Senkou Span B
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

tenkan_sen

[in] Averaging period for Tenkan Sen.

kijun_sen

[in] Averaging period for Kijun Sen.

senkou_span_b

[in] Averaging period for Senkou Span B.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - TENKANSEN_LINE, 1 - KIJUNSEN_LINE, 2 - SENKOUSPANA_LINE, 3 - SENKOUSPANB_LINE, 4 - CHIKOUSPAN_LINE.

Example:

```

iBWMFI

The function returns the handle of the Market Facilitation Index indicator. It has only one buffer.

```
int  iBWMFI(
   string               symbol,             // symbol name
   ENUM_TIMEFRAMES      period,             // period
   ENUM_APPLIED_VOLUME  applied_volume      // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be one of the constants of ENUM_APPLIED_VOLUME.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iMomentum

The function returns the handle of the Momentum indicator. It has only one buffer.

```
int  iMomentum(
   string                symbol,            // symbol name
   ENUM_TIMEFRAMES       period,            // period
   int                   mom_period,        // averaging period
   ENUM_APPLIED_PRICE    applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

mom_period

[in] Averaging period (bars count) for the calculation of the price change.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iMFI

The function returns the handle of the Money Flow Index indicator.

```
int  iMFI(
   string                symbol,              // symbol name
   ENUM_TIMEFRAMES       period,              // period
   int                   ma_period,           // averaging period
   ENUM_APPLIED_VOLUME   applied_volume       // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for the calculation.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iMA

The function returns the handle of the Moving Average indicator. It has only one buffer.

```
int  iMA(
   string                symbol,            // symbol name
   ENUM_TIMEFRAMES       period,            // period
   int                   ma_period,         // averaging period
   int                   ma_shift,          // horizontal shift
   ENUM_MA_METHOD        ma_method,         // smoothing type
   ENUM_APPLIED_PRICE    applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the calculation of the moving average.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Smoothing type. Can be one of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iOsMA

The function returns the handle of the Moving Average of Oscillator indicator. The OsMA oscillator shows the difference between values of MACD and its signal line. It has only one buffer.

```
int  iOsMA(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ema_period,     // period for Fast Moving Average
   int                  slow_ema_period,     // period for Slow Moving Average
   int                  signal_period,       // averaging period for their difference
   ENUM_APPLIED_PRICE   applied_price        // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Averaging period for signal line calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

In some systems this oscillator is also known as MACD histogram.

iMACD

The function returns the handle of the Moving Averages Convergence/Divergence indicator. In systems where OsMA is called MACD Histogram, this indicator is shown as two lines. In the client terminal the Moving Averages Convergence/Divergence looks like a histogram.

```
int  iMACD(
   string               symbol,              // symbol name
   ENUM_TIMEFRAMES      period,              // period
   int                  fast_ema_period,     // period for Fast average calculation
   int                  slow_ema_period,     // period for Slow average calculation
   int                  signal_period,       // period for their difference averaging
   ENUM_APPLIED_PRICE   applied_price        // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Period for Signal line calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

Example:

```

iOBV

The function returns the handle of the On Balance Volume indicator. It has only one buffer.

```
int  iOBV(
   string                symbol,             // symbol name
   ENUM_TIMEFRAMES       period,             // period
   ENUM_APPLIED_VOLUME   applied_volume      // volume type for calculation
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iSAR

The function returns the handle of the Parabolic Stop and Reverse system indicator. It has only one buffer.

```
int  iSAR(
   string           symbol,      // symbol name
   ENUM_TIMEFRAMES  period,      // period
   double           step,        // price increment step - acceleration factor
   double           maximum      // maximum value of step
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

step

[in] The step of price increment, usually 0.02.

maximum

[in] The maximum step, usually 0.2.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iRSI

The function returns the handle of the Relative Strength Index indicator. It has only one buffer.

```
int  iRSI(
   string               symbol,           // symbol name
   ENUM_TIMEFRAMES      period,           // period
   int                  ma_period,        // averaging period
   ENUM_APPLIED_PRICE   applied_price     // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RSI calculation.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iRVI

The function returns the handle of the Relative Vigor Index indicator.

```
int  iRVI(
   string           symbol,        // symbol name
   ENUM_TIMEFRAMES  period,        // period
   int              ma_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RVI calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

Example:

```

iStdDev

The function returns the handle of the Standard Deviation indicator. It has only one buffer.

```
int  iStdDev(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift
   ENUM_MA_METHOD       ma_method,         // smoothing type
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Type of averaging. Can be any of the ENUM_MA_METHOD values.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iStochastic

The function returns the handle of the Stochastic Oscillator indicator.

```
int  iStochastic(
   string            symbol,          // symbol name
   ENUM_TIMEFRAMES   period,          // period
   int               Kperiod,         // K-period (number of bars for calculations)
   int               Dperiod,         // D-period (period of first smoothing)
   int               slowing,         // final smoothing
   ENUM_MA_METHOD    ma_method,       // type of smoothing
   ENUM_STO_PRICE    price_field      // stochastic calculation method
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

Kperiod

[in] Averaging period (bars count) for the %K line calculation.

Dperiod

[in] Averaging period (bars count) for the %D line calculation.

slowing

[in] Slowing value.

ma_method

[in] Type of averaging. Can be any of the ENUM_MA_METHOD values.

price_field

[in] Parameter of price selection for calculations. Can be one of the ENUM_STO_PRICE values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

iTEMA

The function returns the handle of the Triple Exponential Moving Average indicator. It has only one buffer.

```
int  iTEMA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   int                  ma_shift,          // horizontal shift of indicator
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculation.

ma_shift

[in] Shift of indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iTriX

The function returns the handle of the Triple Exponential Moving Averages Oscillator indicator. It has only one buffer.

```
int  iTriX(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  ma_period,         // averaging period
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```

iWPR

The function returns the handle of the Larry Williams' Percent Range indicator. It has only one buffer.

```
int  iWPR(
   string           symbol,          // symbol name
   ENUM_TIMEFRAMES  period,          // period
   int              calc_period      // averaging period
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

calc_period

[in] Period (bars count) for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+

iVIDyA

The function returns the handle of the Variable Index Dynamic Average indicator. It has only one buffer.

```
int  iVIDyA(
   string               symbol,            // symbol name
   ENUM_TIMEFRAMES      period,            // period
   int                  cmo_period,        // period for Chande Momentum
   int                  ema_period,        // EMA smoothing period
   int                  ma_shift,          // horizontal shift on the price chart
   ENUM_APPLIED_PRICE   applied_price      // type of price or handle
   );
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

cmo_period

[in] Period (bars count) for the Chande Momentum Oscillator calculation.

ema_period

[in] EMA period (bars count) for smoothing factor calculation.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants ENUM_APPLIED_PRICE or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

iVolumes

The function returns the handle of the Volumes indicator. It has an only one buffer.

```
int  iVolumes(
   string                symbol,              // symbol name
   ENUM_TIMEFRAMES       period,              // period
   ENUM_APPLIED_VOLUME   applied_volume       // volume type for calculation
   )
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the ENUM_TIMEFRAMES values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the ENUM_APPLIED_VOLUME values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns INVALID_HANDLE. The computer memory can be freed from an indicator that is no more utilized, using the IndicatorRelease() function, to which the indicator handle is passed.

Example:

```
//+------------------------------------------------------------------+
//|                                                 Demo_iVolumes.mq5 |

Working with Optimization Results

Functions for organizing custom processing of the optimization results in the strategy tester. They can be called during optimization in testing agents, as well as locally in Expert Advisors and scripts.

When you run an Expert Advisor in the strategy tester, you can create your own data array based on the simple types or simple structures (they do not contain strings, class objects or objects of dynamic arrays). This data set can be saved using the FrameAdd() function in a special structure called a frame. During the optimization of an Expert Advisor, each agent can send a series of frames to the terminal. All the received frames are written in the *.MQD file named as the Expert Advisor in the terminal_directory\MQL5\Files\Tester folder. They are written in the order they are received from the agents. Receipt of a frame in the client terminal from a testing agent generates the TesterPass event.

Frames can be stored in the computer memory and in a file with the specified name. The MQL5 language sets no limitations on the number of frames.

Memory and disk space limits in MQL5 Cloud Network

The following limitation applies to optimizations run in the MQL5 Cloud Network: the Expert Advisor must not write to disk more than 4GB of information or use more than 4GB of RAM. If the limit is exceeded, the network agent will not be able to complete the calculation correctly, and you will not receive the result. However, you will be charged for all the time spent on the calculations.

If you need to get information from each optimization pass, send frames without writing to disk. To avoid using file operations in Expert Advisors during calculations in the MQL5 Cloud Network, you can use the following check:

```
int handle=INVALID_HANDLE;
bool file_operations_allowed=true;
if(MQLInfoInteger(MQL_OPTIMIZATION) || MQLInfoInteger(MQL_FORWARD))
   file_operations_allowed=false;

if(file_operations_allowed)
  {
   ...
   handle=FileOpen(...);
   ...
  }
```

Function	Action
FrameFirst	Moves a pointer of frame reading to the beginning and resets the previously set filter
FrameFilter	Sets the frame reading filter and moves the pointer to the beginning
FrameNext	Reads a frame and moves the pointer to the next one
FrameInputs	Receives input parameters, on which the frame is formed
FrameAdd	Adds a frame with data

© 2000-2025, MetaQuotes Ltd.

Function	Action
ParameterGetRange	Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester
ParameterSetRange	Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values

© 2000-2025, MetaQuotes Ltd.

FrameFirst

Moves a pointer of frame reading to the beginning and resets a set filter.

```
bool  FrameFirst();
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

FrameFilter

Sets the frame reading filter and moves the pointer to the beginning.

```
bool  FrameFilter(
   const string  name,          // Public name/label
   long          id             // Public ID
   );
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

If an empty string is passed as the first parameter, the filter will work only with a numeric parameter, i.e. only frames with the specified id will be viewed. If the value of the second parameter is ULONG_MAX, only a text filter works.

Call of FrameFilter("", ULONG_MAX) is equivalent to calling FrameFirst(), i.e. equal to not using any filter.

© 2000-2025, MetaQuotes Ltd.

FrameNext

Reads a frame and moves the pointer to the next one. There are two variants of the function.

1. Calling to receive one numeric value

```
bool  FrameNext(
   ulong&   pass,      // The number of a pass in the optimization, during which the
   string&  name,      // Public name/label
   long&    id,        // Public ID
   double&  value      // Value
   );
```

2. Calling to receive all the data of a frame

```
bool  FrameNext(
   ulong&   pass,      // The number of a pass in the optimization, during which the
   string&  name,      // Public name/label
   long&    id,        // Public ID
   double&  value,     // Value
   void&    data[]     // Array of any type
   );
```

Parameters

pass

[out] The number of a pass during optimization in the strategy tester.

name

[out] The name of the identifier.

id

[out] The value of the identifier.

value

[out] A single numeric value.

data

[out] An array of any type.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

In the second version of the call, you must correctly handle the received data in the *data[]* array.

© 2000-2025, MetaQuotes Ltd.

FrameInputs

Receives input parameters, on which the frame with the specified pass number is formed.

```
bool  FrameInputs(
   ulong    pass,                // The number of a pass in the optimization
   string&  parameters[],        // An array of strings of form "parameterN=valueN"
   uint&    parameters_count     // The total number of parameters
   );
```

Parameters

pass

[in] The number of a pass during optimization in the strategy tester.

parameters

[out] A string array with the description of names and parameter values

parameters_count

[out] The number of elements in the array *parameters[]*.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

Note

Having obtained the number of strings *parameters_count* in the *parameters[]* array, you can organize a loop to go through all records. This will help you find the values of input parameters of an Expert Advisor for the specified pass number.

© 2000-2025, MetaQuotes Ltd.

FrameAdd

Adds a frame with data. There are two variants of the function.

1. Adding data from a file

```
bool  FrameAdd(
   const string  name,         // Public name/label
   long          id,           // Public ID
   double        value,        // Value
   const string  filename      // Name of a data file
   );
```

2. Adding data from an array of any type

```
bool  FrameAdd(
   const string  name,         // Public name/label
   long          id,           // Public ID
   double        value,        // Value
   const void&   data[]        // Array of any type
   );
```

Parameters

name

[in] Public frame label. It can be used for a filter in the FrameFilter() function.

id

[in] A public identifier of the frame. It can be used for a filter in the FrameFilter() function.

value

[in] A numeric value to write into the frame. It is used to transmit a single pass result like in the OnTester() function.

filename

[in] The name of the file that contains data to add to the frame. The file must be locate in the folder MQL5/Files.

data

[in] An array of any type to write into the frame. Passed by reference.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

ParameterGetRange

Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester. There are 2 variants of the function.

1. Receiving data for the integer type input parameter

```
bool  ParameterGetRange(
   const string  name,           // parameter (input variable) name
   bool&         enable,         // parameter optimization enabled
   long&         value,          // parameter value
   long&         start,          // initial value
   long&         step,           // change step
   long&         stop            // final value
   );
```

2. Receiving data for the real type input parameter

```
bool  ParameterGetRange(
   const string  name,           // parameter (input variable) name
   bool&         enable,         // parameter optimization enabled
   double&       value,          // parameter value
   double&       start,          // initial value
   double&       step,           // change step
   double&       stop            // final value
   );
```

Parameters

name

[in] input variable ID. These variables are external parameters of an application. Their values can be specified when launching on a chart or during a single test.

enable

[out] Flag that this parameter can be used to enumerate the values during the optimization in the Strategy Tester.

value

[out] Parameter value.

start

[out] Initial parameter value during the optimization.

step

[out] Parameter change step when enumerating its values.

stop

[out] Final parameter value during the optimization.

Return Value

© 2000-2025, MetaQuotes Ltd.

Returns true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

The function can be called only from OnTesterInit(), OnTesterPass() and OnTesterDeinit() handlers. It has been introduced to receive Expert Advisor input parameters' values and variation ranges during the optimization in the Strategy Tester.

When called in OnTesterInit(), the obtained data can be used to redefine the rules for enumeration of any input variable using ParameterSetRange() function. Therefore, new Start, Stop and Step values can be set and the input parameter can even be completely excluded from optimization regardless of the Strategy Tester settings. This allows you to manage the area of the input parameters during the optimization by excluding some parameters from the optimization depending on the Expert Advisor's key parameters' values.

Example:

```
#property description "Expert Advisor for ParameterGetRange() function demonstration."
#property description "Should be launched in the optimization mode of the Strategy Tes
//--- input parameters
input int                  Input1=1;
input double               Input2=2.0;

               EnumToString((ENUM_DAY_OF_WEEK)par4_start),
               EnumToString((ENUM_DAY_OF_WEEK)par4_stop));
  }
//+------------------------------------------------------------------+
//| TesterDeinit function                                            |
//+------------------------------------------------------------------+
void OnTesterDeinit()
  {
//--- this message will be shown after optimization is complete
   Print(__FUNCTION__," Optimization completed");
  }
```

© 2000-2025, MetaQuotes Ltd.

ParameterSetRange

Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values. There are 2 variants of the function.

1. Specifying the values for the integer type input parameter

```
bool  ParameterSetRange(
   const string  name,           // parameter (input variable) name
   bool          enable,         // parameter optimization enabled
   long          value,          // parameter value
   long          start,          // initial value
   long          step,           // change step
   long          stop            // final value
   );
```

2. Specifying the values for the real type input parameter

```
bool  ParameterSetRange(
   const string  name,           // parameter (input variable) name
   bool          enable,         // parameter optimization enabled
   double        value,          // parameter value
   double        start,          // initial value
   double        step,           // change step
   double        stop            // final value
   );
```

Parameters

name

[in] input or sinput variable ID. These variables are external parameters of an application. Their values can be specified when launching the program.

enable

[in] Enable this parameter to enumerate the values during the optimization in the Strategy Tester.

value

[in] Parameter value.

start

[in] Initial parameter value during the optimization.

step

[in] Parameter change step when enumerating its values.

stop

[in] Final parameter value during the optimization.

Return Value

© 2000-2025, MetaQuotes Ltd.

Returns true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

The function can be called only from OnTesterInit() handler when launching optimization from the Strategy Tester. It is designed for specifying the parameter's range and change step. The parameter can be completely excluded from optimization regardless of the Strategy Tester settings. It also allows using the variables declared with sinput modifier in the optimization process.

ParameterSetRange() function allows you to manage an Expert Advisor optimization in the Strategy Tester depending on its key parameters' values by including or excluding required input parameters from the optimization and setting the required range and the change step.

© 2000-2025, MetaQuotes Ltd.

Event Functions

This group contains functions for working with custom events and timer events. Besides this group, there are special functions for handling predefined events.

Function	Action
EventSetMillisecondTimer	Launches event generator of the high-resolution timer with a period less than 1 second for the current chart
EventSetTimer	Starts the timer event generator with the specified periodicity for the current chart
EventKillTimer	Stops the generation of events by the timer in the current chart
EventChartCustom	Generates a custom event for the specified chart

See also

Types of Chart Events

© 2000-2025, MetaQuotes Ltd.

EventSetMillisecondTimer

The function indicates to the client terminal that timer events should be generated at intervals less than one second for this Expert Advisor or indicator.

```
bool  EventSetMillisecondTimer(
   int  milliseconds      // number of milliseconds
   );
```

Parameters

milliseconds

[in] Number of milliseconds defining the frequency of timer events.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, GetLastError() function should be called.

Note

This feature is designed for the cases when high-resolution timer is required. In other words, timer events should be received more frequently than once per second. If a conventional timer with the period of more than one second is enough for you, use EventSetTimer().

In general, when the timer period is reduced, the testing time is increased, as the handler of timer events is called more often. When working in real-time mode, timer events are generated no more than 1 time in 10-16 milliseconds due to hardware limitations.

Usually, this function should be called from OnInit() function or in class constructor. To handle events coming from the timer, an Expert Advisor or an indicator should have OnTimer() function.

Each Expert Advisor and each indicator work with its own timer receiving events solely from this timer. During mql5 application shutdown, the timer is forcibly destroyed in case it has been created but has not been disabled by EventKillTimer() function.

Only one timer can be launched for each program. Each mql5 application and chart have their own queue of events where all newly arrived events are placed. If the queue already contains Timer event or this event is in the processing stage, then the new Timer event is not added to mql5 application queue.

© 2000-2025, MetaQuotes Ltd.

EventSetTimer

The function indicates to the client terminal, that for this indicator or Expert Advisor, events from the timer must be generated with the specified periodicity.

```
bool  EventSetTimer(
   int  seconds      // number of seconds
   );
```

Parameters

seconds

[in] Number of seconds that determine the frequency of the timer event occurrence.

Return Value

In case of success returns true, otherwise false. In order to get an error code, the GetLastError() function should be called.

Note

Normally, this function must be called from the OnInit() function or from a class constructor. In order to handle events coming from the timer, the Expert Advisor must have the OnTimer() function.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the EventKillTimer() function.

For each program no more than one timer can be run. Each mql5 program and each chart has its own queue of events, in which all the newly received events are placed. If the Timer event is present in the queue or is being processed, the new Timer event will not be placed in the queue of the mql5 program.

© 2000-2025, MetaQuotes Ltd.

EventKillTimer

Specifies the client terminal that is necessary to stop the generation of events from Timer.

```
void  EventKillTimer();
```

Return Value

No return value.

Note

Typically, this function must be called from a function OnDeinit(), if the EventSetTimer() function has been called from OnInit(). This function can also be called form the class destructor, if the EventSetTimer() function has been called in the constructor of this class.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the EventKillTimer() function

© 2000-2025, MetaQuotes Ltd.

EventChartCustom

The function generates a custom event for the specified chart.

```
bool  EventChartCustom(
   long    chart_id,            // identifier of the event receiving chart
   ushort  custom_event_id,     // event identifier
   long    lparam,              // parameter of type long
   double  dparam,              // parameter of type double
   string  sparam               // string parameter of the event
   );
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

custom_event_id

[in] ID of the user events. This identifier is automatically added to the value CHARTEVENT_CUSTOM and converted to the integer type.

lparam

[in] Event parameter of the long type passed to the OnChartEvent function.

dparam

[in] Event parameter of the double type passed to the OnChartEvent function.

sparam

[in] Event parameter of the string type passed to the OnChartEvent function. If the string is longer than 63 characters, it is truncated.

Return Value

Returns true if a custom event has been successfully placed in the events queue of the chart that receives the events. In case of failure, it returns false. Use GetLastError() to get an error code.

Note

An Expert Advisor or indicator attached to the specified chart handles the event using the function OnChartEvent(int event_id, long& lparam, double& dparam, string& sparam).

For each type of event, the input parameters of the OnChartEvent() function have definite values that are required for the processing of this event. The events and values passed through this parameters are listed in the below table.

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
Event of a keystroke	CHARTEVENT_KEYDOWN	code of a pressed key	Repeat count (the number of times the keystroke is	The string value of a bit mask describing the

Working with OpenCL

OpenCL programs are used for performing computations on video cards that support OpenCL 1.1 or higher. Modern video cards contain hundreds of small specialized processors that can simultaneously perform simple mathematical operations with incoming data streams. The OpenCL language organizes parallel computing and provides greater speed for a certain class of tasks.

In some graphic cards working with the double type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: #pragma OPENCL EXTENSION cl_khr_fp64 : enable. However if a graphic card doesn't support double, enabling this directive won't be of help.

It is recommended to write the source code for OpenCL in separate CL files, which can later be included in the MQL5 program using the resource variables.

Handling errors in OpenCL programs

To get information about the last error in an OpenCL program, use the CLGetInfoInteger and CLGetInfoStringfunctions that allow getting the error code and text description.

OpenCL last error code: To get the latest OpenCL error, call CLGetInfoInteger, while the*handle*parameter is ignored (can be set to zero). Description of errors: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS.

For an unknown error code, the"unknown OpenCL error N" string is returned where N is an error code. Example:

```
//--- the first 'handle' parameter is ignored when getting the last error code
intcode= (int)CLGetInfoInteger(0,CL_LAST_ERROR);
```

Text description of the OpenCL error: To get the latest OpenCL error, call CLGetInfoString. The error code should be passed as the*handle*parameter.

Description of errors: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS. If CL_LAST_ERROR is passed instead of the error code, then the function returns the description of the last error. For example:

```
//--- get the code of the last OpenCL error
int   code= (int)CLGetInfoInteger(0,CL_LAST_ERROR);
stringdesc;// to get an error text description

//--- use the error code to get an error text description
if(!CLGetInfoString(code,CL_ERROR_DESCRIPTION,desc))
 desc="cannot get OpenCL error description,"+ (string)GetLastError();
Print(desc);

//--- in order to get the description of the last OpenCL error without getting the coc
if(!CLGetInfoString(CL_LAST_ERROR,CL_ERROR_DESCRIPTION,desc))
 desc="cannot get OpenCL error description,"+ (string)GetLastError();
Print(desc);;
```

© 2000-2025, MetaQuotes Ltd.

So far, the name of the internal enumeration is given as an error description. You can find its decoding here: https://registry.khronos.org/OpenCL/specs/3.0-unified/html/OpenCL_API.html#CL_SUCCESS. For example, the CL_INVALID_KERNEL_ARGS value means "Returned when enqueuing a kernel when some kernel arguments have not been set or are invalid."

Functions for running programs in OpenCL:

Function	Action
CLHandleType	Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration
CLGetInfoInteger	Returns the value of an integer property for an OpenCL object or device
CLContextCreate	Creates an OpenCL context
CLContextFree	Removes an OpenCL context
CLGetDeviceInfo	Receives device property from OpenCL driver
CLProgramCreate	Creates an OpenCL program from a source code
CLProgramFree	Removes an OpenCL program
CLKernelCreate	Creates an OpenCL start function
CLKernelFree	Removes an OpenCL start function
CLSetKernelArg	Sets a parameter for the OpenCL function
CLSetKernelArgMem	Sets an OpenCL buffer as a parameter of the OpenCL function
CLSetKernelArgMemLocal	Sets the local buffer as an argument of the kernel function
CLBufferCreate	Creates an OpenCL buffer
CLBufferFree	Deletes an OpenCL buffer
CLBufferWrite	Writes an array into an OpenCL buffer
CLBufferRead	Reads an OpenCL buffer into an array
CLExecute	Runs an OpenCL program
CLExecutionStatus	Returns the OpenCL program execution status

OpenCL, Resources

© 2000-2025, MetaQuotes Ltd.

CLHandleType

Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration.

```
ENUM_OPENCL_HANDLE_TYPE  CLHandleType(
   int  handle     // Handle of an OpenCL object
   );
```

Parameters

handle

[in] A handle to an OpenCL object: a context, a kernel or an OpenCL program.

Return Value

The type of the OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration.

ENUM_OPENCL_HANDLE_TYPE

Identifier	Description
OPENCL_INVALID	Incorrect handle
OPENCL_CONTEXT	A handle of the OpenCL context
OPENCL_PROGRAM	A handle of the OpenCL program
OPENCL_KERNEL	A handle of the OpenCL kernel
OPENCL_BUFFER	A handle of the OpenCL buffer

© 2000-2025, MetaQuotes Ltd.

CLGetInfoInteger

Returns the value of an integer property for an OpenCL object or device.

```
long  CLGetInfoInteger(
   int  handle,                          // The handle of the OpenCL object or the nu
   ENUM_OPENCL_PROPERTY_INTEGER  prop    // Requested property
   );
```

Parameters

handle

[in] A handle to the OpenCL object or number of the OpenCL device. Numbering of OpenCL devices starts with zero.

prop

[in] The type of a requested property from the ENUM_OPENCL_PROPERTY_INTEGER enumeration, the value of which you want to obtain.

Return Value

The value of the property if successful or -1 in case of an error. For information about the error, use the GetLastError() function.

ENUM_OPENCL_PROPERTY_INTEGER

Identifier	Description	Type
CL_DEVICE_COUNT	The number of devices with OpenCL support. This property does not require specification of the first parameter, i.e. you can pass a zero value for the *handle* parameter.	int
CL_DEVICE_TYPE	Type of device	ENUM_CL_DEVICE_TYPE
CL_DEVICE_VENDOR_ID	Unique vendor identifier	uint
CL_DEVICE_MAX_COMPUTE_UNITS	Number of parallel calculated tasks in OpenCL device. One working group solves one computational task. The lowest value is 1	uint
CL_DEVICE_MAX_CLOCK_FREQUENCY	Highest set frequency of the device in MHz.	uint
CL_DEVICE_GLOBAL_MEM_SIZE	Size of the global memory of the device in bytes	ulong
CL_DEVICE_LOCAL_MEM_SIZE	Size of the processed data (scene) local memory in bytes	uint

© 2000-2025, MetaQuotes Ltd.

Identifier	Description	Type
CL_BUFFER_SIZE	Actual size of the OpenCL buffer in bytes	ulong
CL_DEVICE_MAX_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL device.	ulong
CL_KERNEL_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL program.	ulong
CL_KERNEL_LOCAL_MEM_SIZE	Size of the local memory (in bytes) used by an OpenCL program for solving all parallel tasks in a group. Use CL_DEVICE_LOCAL_MEM_SIZE to receive the maximum available value	ulong
CL_KERNEL_PRIVATE_MEM_SIZE	The minimum size of the private memory (in bytes) used by each task in the OpenCL program kernel.	ulong
CL_LAST_ERROR	The value of the last OpenCL error	int

The ENUM_CL_DEVICE_TYPE enumeration contains possible types of devices supporting OpenCL. You can receive the type of device by its number or the handle of the OpenCL object by calling CLGetInfoInteger(handle_or_deviceN, CL_DEVICE_TYPE).

ENUM_CL_DEVICE_TYPE

Identifier	Description
CL_DEVICE_ACCELERATOR	Dedicated OpenCL accelerators (for example, the IBM CELL Blade). These devices communicate with the host processor using a peripheral interconnect such as PCIe.
CL_DEVICE_CPU	An OpenCL device that is the host processor. The host processor runs the OpenCL implementations and is a single or multi-core CPU.
CL_DEVICE_GPU	An OpenCL device that is a GPU.
CL_DEVICE_DEFAULT	The default OpenCL device in the system. The default device cannot be a CL_DEVICE_TYPE_CUSTOM device.

© 2000-2025, MetaQuotes Ltd.

Identifier	Description
CL_DEVICE_CUSTOM	Dedicated accelerators that do not support programs written in OpenCL C.

Example:

```
void OnStart()
  {
   int cl_ctx;
//--- initialize OpenCL context
   if((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY))==INVALID_HANDLE)
     {
      Print("OpenCL not found");
      return;
     }
//--- Display general information about OpenCL device
   Print("OpenCL type: ",EnumToString((ENUM_CL_DEVICE_TYPE)CLGetInfoInteger(cl_ctx,CL_
   Print("OpenCL vendor ID: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_VENDOR_ID));
   Print("OpenCL units: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_COMPUTE_UNITS));
   Print("OpenCL freq: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_CLOCK_FREQUENCY)," MHz"
   Print("OpenCL global mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_GLOBAL_MEM_SIZE)," by
   Print("OpenCL local mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_LOCAL_MEM_SIZE)," byte
//--- free OpenCL context
   CLContextFree(cl_ctx);
  }
```

© 2000-2025, MetaQuotes Ltd.

CLGetInfoString

Returns string value of a property for OpenCL object or device.

```
bool  CLGetInfoString(
   int  handle,                          // OpenCL object handle or OpenCL device nu
   ENUM_OPENCL_PROPERTY_STRING  prop,    // requested property
   string&  value                        // referenced string
   );
```

Parameters

handle

[in] OpenCL object handle or OpenCL device number. The numbering of OpenCL devices starts with zero.

prop

[in] Type of requested property from ENUM_OPENCL_PROPERTY_STRING enumeration, the value of which should be obtained.

value

[out] String for receiving the property value.

Return Value

true if successful, otherwise false. For information about the error, use the GetLastError() function.

ENUM_OPENCL_PROPERTY_STRING

Identifier	Description
CL_PLATFORM_PROFILE	CL_PLATFORM_PROFILE - OpenCL Profile. Profile name may be one of the following values: • FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support); • EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_PLATFORM_VERSION	OpenCL version
CL_PLATFORM_VENDOR	Platform vendor name
CL_PLATFORM_EXTENSIONS	List of extensions supported by the platform. Extension names should be supported by all devices related to this platform
CL_DEVICE_NAME	Device name
CL_DEVICE_VENDOR	Vendor name

© 2000-2025, MetaQuotes Ltd.

Identifier	Description
CL_DRIVER_VERSION	OpenCL driver version in major_number.minor_number format
CL_DEVICE_PROFILE	OpenCL device profile. Profile name may be one of the following values: • FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support); • EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_DEVICE_VERSION	OpenCL version in "OpenCL<space><major_version.minor_version><space><vendor-specific information>" format
CL_DEVICE_EXTENSIONS	List of extensions supported by the device. The list may contain extensions supported by the vendor, as well as one or more approved names: cl_khr_int64_base_atomics cl_khr_int64_extended_atomics cl_khr_fp16 cl_khr_gl_sharing cl_khr_gl_event cl_khr_d3d10_sharing cl_khr_dx9_media_sharing cl_khr_d3d11_sharing
CL_DEVICE_BUILT_IN_KERNELS	The list of supported kernels separated by ";".
CL_DEVICE_OPENCL_C_VERSION	The maximum version supported by the compiler for this device. Version format: "OpenCL<space>C<space><major_version.minor_version><space><vendor-specific information> "
CL_ERROR_DESCRIPTION	Text description of an OpenCL error

Example:

```
void OnStart()
  {
   int cl_ctx;
   string str;
//--- initialize OpenCL context
   if((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY))==INVALID_HANDLE)
     {
      Print("OpenCL not found");
      return;
     }
```

//--- free OpenCL context
   CLContextFree(cl_ctx);
  }
```

© 2000-2025, MetaQuotes Ltd.

CLContextCreate

Creates an OpenCL context and returns its handle.

```
int  CLContextCreate(
   int  device=CL_USE_ANY     // Serial number of the OpenCL device or macro
   );
```

Parameter

device

[in] The ordinal number of the OpenCL-device in the system. Instead of a specific number, you can specify one of the following values:

- CL_USE_ANY - any available device with OpenCL support is allowed;
- CL_USE_CPU_ONLY - only OpenCL emulation on CPU is allowed;
- CL_USE_GPU_ONLY - OpenCL emulation is prohibited and only specialized devices with OpenCL support (video cards) can be used;
- CL_USE_GPU_DOUBLE_ONLY - only the GPUs that support type double are allowed.

Return Value

A handle to the OpenCL context if successful, otherwise -1. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLContextFree

Removes an OpenCL context.

```
void  CLContextFree(
   int  context     // Handle to an OpenCL context
   );
```

Parameters

context

[in] Handle of the OpenCL context.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLGetDeviceInfo

The function receives device property from OpenCL driver.

```
bool  CLGetDeviceInfo(
   int     handle,          // OpenCL device handle
   int     property_id,     // requested property ID
   uchar&  data[],          // array for receiving data
   uint&   size             // shift in the array elements, default value is 0
   );
```

Parameters

handle

[in] OpenCL device index or OpenCL handle created by CLContextCreate() function.

property_id

[in] ID of the OpenCL device property that should be received. The values can be of one of the predetermined ones listed in the table below.

data[]

[out] The array for receiving data on the requested property.

size

[out] Size of the received data in the array *data[]*.

Return Value

true if successful, otherwise false. For information about the error, use the GetLastError() function.

Note

For one-dimensional arrays, the number of the element, from which data reading for OpenCL buffer starts, is calculated considering AS_SERIES flag.

The list of available IDs of OpenCL device properties

Exact description of the property and its functions can be found at the official OpenCL web site.

CLProgramCreate

Creates an OpenCL program from a source code.

```
int  CLProgramCreate(
   int           context,     // Handle to an OpenCL context
   const string  source       // Source code
   );
```

An overloaded function version creates an OpenCL program and writes compiler messages into the passed string.

```
int  CLProgramCreate(
   int           context,     // Handle to an OpenCL context
   const string  source,      // Source code
   string       &build_log    // A string for receiving the compilation log
   );
```

Parameters

context

[in] Handle of the OpenCL context.

source

[in] String with the source code of the OpenCL program.

&build_log

[in] A string for receiving the OpenCL compiler messages.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to the context OpenCL.
- ERR_INVALID_PARAMETER - invalid string parameter.
- ERR_NOT_ENOUGH_MEMORY - not enough memory to complete operation.
- ERR_OPENCL_PROGRAM_CREATE - internal error of OpenCL or compilation error.

In some graphic cards working with the double type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: #pragma OPENCL EXTENSION cl_khr_fp64 : enable. However if a graphic card doesn't support double, enabling this directive won't be of help.

Example:

```
//+------------------------------------------------------------------+
//| OpenCL kernel                                                    |
//+------------------------------------------------------------------+
const string
```

© 2000-2025, MetaQuotes Ltd.

```
cl_src=
       //--- by default some GPU doesn't support doubles
       //--- cl_khr_fp64 directive is used to enable work with doubles
       "#pragma OPENCL EXTENSION cl_khr_fp64 : enable      \r\n"
       //--- OpenCL kernel function
       "__kernel void Test_GPU(__global double *data,      \r\n"

CLProgramFree

Removes an OpenCL program.

```
void  CLProgramFree(
   int  program     // Handle to an OpenCL object
   );
```

Parameters

program

[in] Handle of the OpenCL object.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLKernelCreate

Creates the OpenCL program kernel and returns its handle.

```
int  CLKernelCreate(
   int           program,        // Handle to an OpenCL object
   const string  kernel_name     // Kernel name
   );
```

Parameters

program

[in] Handle to an object of the OpenCL program.

kernel_name

[in] The name of the kernel function in the appropriate OpenCL program, in which execution begins.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL program.
- ERR_INVALID_PARAMETER - invalid string parameter.
- ERR_OPENCL_TOO_LONG_KERNEL_NAME - kernel name contains more than 127 characters.
- ERR_OPENCL_KERNEL_CREATE - internal error occurred while creating an OpenCL object.

© 2000-2025, MetaQuotes Ltd.

CLKernelFree

Removes an OpenCL start function.

```
void  CLKernelFree(
   int  kernel     // Handle to the kernel of an OpenCL program
   );
```

Parameters

kernel_name

[in] Handle of the kernel object.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLSetKernelArg

Sets a parameter for the OpenCL function.

```
bool  CLSetKernelArg(
   int   kernel,        // Handle to the kernel of an OpenCL program
   uint  arg_index,     // The number of the argument of the OpenCL function
   void  arg_value      // Source code
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

arg_value

[in] The value of the function argument.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_INVALID_PARAMETER,
- ERR_OPENCL_INVALID_HANDLE - invalid handle to the OpenCL kernel.
- ERR_OPENCL_SET_KERNEL_PARAMETER - internal error of OpenCL.

© 2000-2025, MetaQuotes Ltd.

CLSetKernelArgMem

Sets an OpenCL buffer as a parameter of the OpenCL function.

```
bool  CLSetKernelArgMem(
   int   kernel,           // Handle to the kernel of an OpenCL program
   uint  arg_index,        // The number of the argument of the OpenCL function
   int   cl_mem_handle     // Handle to OpenCL buffer
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

cl_mem_handle

[in] A handle to an OpenCL buffer.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLSetKernelArgMemLocal

Sets the local buffer as an argument of the kernel function.

```
bool  CLSetKernelArgMemLocal(
   int    kernel,           // handle to a kernel of an OpenCL program
   uint   arg_index,        // number of the OpenCL function argument
   ulong  local_mem_size    // buffer size
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

local_mem_size

[in] Buffer size in bytes.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLBufferCreate

Creates an OpenCL buffer and returns its handle.

```
int  CLBufferCreate(
   int   context,     // Handle to an OpenCL context
   uint  size,        // Buffer size
   uint  flags        // Flags combination which specify properties of OpenCL buffer
   );
```

Parameters

context

[in] A handle to context OpenCL.

size

[in] Buffer size in bytes.

flags

[in] Buffer properties that are set using a combination of flags: CL_MEM_READ_WRITE, CL_MEM_WRITE_ONLY, CL_MEM_READ_ONLY, CL_MEM_ALLOC_HOST_PTR.

Return Value

A handle to an OpenCL buffer if successful. In case of error -1 is returned. For information about the error, use the GetLastError() function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL context.
- ERR_NOT_ENOUGH_MEMORY - insufficient memory.
- ERR_OPENCL_BUFFER_CREATE - internal error creating buffers.

© 2000-2025, MetaQuotes Ltd.

CLBufferFree

Deletes an OpenCL buffer.

```
void  CLBufferFree(
   int   buffer     // Handle to an OpenCL buffer
   );
```

Parameters

buffer

[in] A handle to an OpenCL buffer.

Return Value

None. In the case of an internal error the value of _LastError changes. For information about the error, use the GetLastError() function.

© 2000-2025, MetaQuotes Ltd.

CLBufferWrite

Writes into the OpenCL buffer and returns the number of written elements.

```
uint  CLBufferWrite(
   int           buffer,                    // A handle to the OpenCL buffer
   const void&   data[],                    // An array of values
   uint          buffer_offset=0,           // An offset in the OpenCL buffer in bytes,
   uint          data_offset=0,             // An offset in the array in elements, 0 by
   uint          data_count=WHOLE_ARRAY     // The number of values from the array for
   );
```

There are also versions for handling matrices and vectors.

Writes the values from the matrix to the buffer and returns true if successful.

```
uint  CLBufferWrite(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   matrix<T>     &mat                       // the values matrix for writing to the bu
   );
```

Writes the values from the vector to the buffer and returns true if successful.

```
uint  CLBufferWrite(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   vector<T>     &vec                       // the values vector for writing to the bu
   );
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array of values that should be written in the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which writing begins. By default, writing start with the very beginning of the buffer.

data_offset

[in] The index of the first array element, starting from which values from the array are written in the OpenCL buffer. By default, values from the very beginning of the array are taken.

data_count

[in] The number of values that should be written. All the values of the array, by default.

mat

[out] The matrix for reading data from the buffer can be any of the three types — matrix, matrixf or matrixc.

© 2000-2025, MetaQuotes Ltd.

vec

[out] The vector for reading data from the buffer can be of any of the three types — vector, vectorf or vectorc.

Return Value

The number of written elements. 0 is returned in case of an error. For information about the error, use the GetLastError() function.

true if a matrix or a vector is handled successfully, otherwise false.

Note

For one-dimensional arrays, the number of the element, with which reading of data for writing into an OpenCL buffer begins, is calculated taking into account the AS_SERIES flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

Example of matrix multiplication using the MatMul method and parallel computing in OpenCL

```
#define M       3000      // the number of rows in the first matrix
#define K       2000      // the number of columns in the first matrix is equal to the
#define N       3000      // the number of columns in the second matrix

//+------------------------------------------------------------------+
const string clSrc=
  "#define N     "+IntegerToString(N)+"                                \r\n"
  "#define K     "+IntegerToString(K)+"                                \r\n"
  "                                                                   \r\n"
  "__kernel void matricesMul( __global float *in1,                    \r\n"
  "                           __global float *in2,                    \r\n"
  "                           __global float *out  )                  \r\n"
  "{                                                                  \r\n"
  "  int m = get_global_id( 0 );                                      \r\n"
  "  int n = get_global_id( 1 );                                      \r\n"
  "  float sum = 0.0;                                                 \r\n"
  "  for( int k = 0; k < K; k ++ )                                    \r\n"
  "     sum += in1[ m * K + k ] * in2[ k * N + n ];                   \r\n"
  "  out[ m * N + n ] = sum;                                          \r\n"
  "}                                                                  \r\n";
//+------------------------------------------------------------------+
//| Script program start function                                    |

CLBufferRead

Reads an OpenCL buffer into an array and returns the number of read elements.

```
uint  CLBufferRead(
   int           buffer,                    // A handle to the OpenCL buffer
   const void&   data[],                    // An array of values
   uint          buffer_offset=0,           // An offset in the OpenCL buffer in bytes,
   uint          data_offset=0,             // An offset in the array in elements, 0 by
   uint          data_count=WHOLE_ARRAY     // The number of values from the buffer for
   );
```

There are also versions for handling matrices and vectors.

Reads the OpenCL buffer to the matrix and returns true if successful.

```
uint  CLBufferRead(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   const matrix& mat,                       // the matrix for receiving the values fro
   ulong         rows=-1,                   // the number of rows in the matrix
   ulong         cols=-1                    // the number of columns in the matrix
   );
```

Reads the OpenCL buffer to the vector and returns true if successful.

```
uint  CLBufferRead(
   int           buffer,                    // a handle to the OpenCL buffer
   uint          buffer_offset,             // an offset in the OpenCL buffer in bytes
   const vector& vec,                       // the vector for receiving the values fro
   ulong         size-1,                    // vector length
   );
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array for receiving values from the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which reading begins. By default, reading start with the very beginning of the buffer.

data_offset

[in] The index of the first array element for writing the values of the OpenCL buffer. By default, writing of the read values into an array starts from the zero index.

data_count

[in] The number of values that should be read. The whole OpenCL buffer is read by default.

mat

© 2000-2025, MetaQuotes Ltd.

[out] The matrix for reading data from the buffer can be any of the three types — matrix, matrixf or matrixc.

vec

[out] The vector for reading data from the buffer can be of any of the three types — vector, vectorf or vectorc.

rows=-1

[in] If the parameter is specified, the *cols* parameter should be specified as well. If the new matrix dimensions are not specified, the current ones are used. If the value is -1, then the number of rows does not change.

cols=-1

[in] If the parameter is not specified, the *rows* parameter should be skipped as well. The matrix adheres to the rule: either both parameters are specified, or none, otherwise an error will occur. If both parameters (*rows* and *cols*) are specified, the matrix size is changed. In case of -1, the number of columns does not change.

size=-1

[in] If the parameter is not specified or its value is -1, the vector length does not change.

Return Value

The number of read elements. 0 is returned in case of an error. For information about the error, use the GetLastError() function.

true if a matrix or a vector is handled successfully, otherwise false.

Note

For one-dimensional arrays, the number of the element, into which writing of data into an OpenCL buffer begins, is calculated taking into account the AS_SERIES flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

Example of calculating Pi using the equation:

$$\pi = \lim_{N\to\infty}\frac{1}{N}\sum_{k=0}^{N-1}\frac{4}{1+\left(\frac{2k+1}{2N}\right)^2} = 16\lim_{N\to\infty}N\sum_{k=0}^{N-1}\frac{1}{4N^2+(2k+1)^2}$$

```
#define  _num_steps        1000000000
#define  _divisor          40000
#define  _step             1.0 / _num_steps
#define  _intrnCnt         _num_steps / _divisor
```

CLExecute

The function runs an OpenCL program. There are 3 versions of the function:

1. Launching kernel functions using one kernel

```
bool  CLExecute(
   int           kernel                    // Handle to the kernel of an OpenCL prograr
   );
```

2. Launching several kernel copies (OpenCL function) with task space description

```
bool  CLExecute(
   int           kernel,                   // Handle to the kernel of an OpenCL prograr
   uint          work_dim,                 // Dimension of the tasks space
   const uint&   global_work_offset[],     // Initial offset in the tasks space
   const uint&   global_work_size[]        // Total number of tasks
   );
```

3. Launching several kernel copies (OpenCL function) with task space description and specification of the size of the group's local task subset

```
bool  CLExecute(
   int           kernel,                   // Handle to the kernel of an OpenCL prograr
   uint          work_dim,                 // Dimension of the tasks space
   const uint&   global_work_offset[],     // Initial offset in the tasks space
   const uint&   global_work_size[],       // Total number of tasks
   const uint&   local_work_size[]         // Number of tasks in the local group
   );
```

Parameters

kernel

[in] Handle to the OpenCL kernel.

work_dim

[in] Dimension of the tasks space.

global_work_offset[]

[in] Initial offset in the tasks space.

global_work_size[]

[in] The size of a subset of tasks.

local_work_size[]

[in] The size of the group's local task subset.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the GetLastError() function.

Note

© 2000-2025, MetaQuotes Ltd.

Consider the use of the parameters in the following example:

- *work_dim* specifies the size of *work_items[]* array that describes the tasks. If *work_dim*=3, three-dimensional array *work_items[N1, N2, N3]* is used.
- *global_work_size[]* contains the values that set the *work_items[]* array size. If work_dim=3, *global_work_size[3]* array can be {40, 100, 320}. Then we have *work_items[40, 100, 320]*. So, the total number of tasks is 40 x 100 x 320 = 1 280 000.
- *local_work_size[]* sets the subset of the tasks that will be executed by the specified kernel of OpenCL program. Its size is equal to *work_items[]* size and allows to split the common task subset into smaller subsets without loss of remainder in division. In fact, the size of *local_work_size[]* array should be selected so that the *work_items[]* global task set will be split into smaller subsets. In this example *local_work_size[3]={10, 10, 10}* will be OK, as *work_items[40, 100, 320]* can be gathered from *local_items[10, 10, 10]* array without division remainder.

CLExecutionStatus

Returns the OpenCL program execution status.

```
int  CLExecutionStatus(
   int   kernel            // handle to a kernel of an OpenCL program
   );
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

Return Value

Returns the OpenCL program status. The value can be one of the following:

- CL_COMPLETE=0 - program complete,
- CL_RUNNING=1 - running,
- CL_SUBMITTED=2 - submitted for execution,
- CL_QUEUED=3 - queued,
- -1 (minus one) - error occurred when executing CLExecutionStatus().

Working with databases

The functions for working with databases apply the popular and easy-to-use SQLite engine. The convenient feature of this engine is that the entire database is located in a single file on a user PC's hard disk.

The functions allow for convenient creation of tables, adding data to them, performing modifications and sampling using simple SQL requests:

- receiving trading history and quotes from any formats,
- saving optimization and test results,
- preparing and exchanging data with other analysis packages,
- storing MQL5 application settings and status.

Queries allow using statistical and mathematical functions.

The functions for working with databases allow you to replace the most repetitive large data array handling operations with SQL requests, so that it is often possible to use the DatabaseExecute/DatabasePrepare calls instead of programming complex loops and comparisons. Use the DatabaseReadBind function to conveniently obtain query results in a ready-made structure. The function allows reading all record fields at once within a single call.

To accelerate reading, writing and modification, a database can be opened/created in RAM with the DATABASE_OPEN_MEMORY flag, although such a database is available only to a specific application and is not shared. When working with databases located on the hard disk, bulk data inserts/changes should be wrapped in transactions using DatabaseTransactionBegin/DatabaseTransactionCommit/DatabaseTransactionRollback. This accelerates the process hundreds of times.

To start working with the functions, read the article SQLite: Native handling of SQL databases in MQL5.

Function	Action
DatabaseOpen	Opens or creates a database in a specified file
DatabaseClose	Closes a database
DatabaseImport	Imports data from a file into a table
DatabaseExport	Exports a table or an SQL request execution result to a CSV file
DatabasePrint	Prints a table or an SQL request execution result in the Experts journal
DatabaseTableExists	Checks the presence of the table in a database
DatabaseExecute	Executes a request to a specified database
DatabasePrepare	Creates a handle of a request, which can then be executed using DatabaseRead()
DatabaseReset	Resets a request, like after calling DatabasePrepare()
DatabaseBind	Sets a parameter value in a request

© 2000-2025, MetaQuotes Ltd.

Function	Action
DatabaseBindArray	Sets an array as a parameter value
DatabaseRead	Moves to the next entry as a result of a request
DatabaseReadBind	Moves to the next record and reads data into the structure from it
DatabaseFinalize	Removes a request created in DatabasePrepare()
DatabaseTransactionBegin	Starts transaction execution
DatabaseTransactionCommit	Completes transaction execution
DatabaseTransactionRollback	Rolls back transactions
DatabaseColumnsCount	Gets the number of fields in a request
DatabaseColumnName	Gets a field name by index
DatabaseColumnType	Gets a field type by index
DatabaseColumnSize	Gets a field size in bytes
DatabaseColumnText	Gets a field value as a string from the current record
DatabaseColumnInteger	Gets the int type value from the current record
DatabaseColumnLong	Gets the long type value from the current record
DatabaseColumnDouble	Gets the double type value from the current record
DatabaseColumnBlob	Gets a field value as an array from the current record

Statistical functions:

- mode - mode
- median - median (50th percentile)
- percentile_25 - 25th percentile
- percentile_75
- percentile_90
- percentile_95
- percentile_99
- stddev or stddev_samp — sample standard deviation
- stddev_pop — population standard deviation
- variance or var_samp — sample variance
- var_pop — population variance

Mathematical functions

- acos(X) - arccosine in radians
- acosh(X) - hyperbolic arccosine
- asin(X) - arcsine in radians

© 2000-2025, MetaQuotes Ltd.

- asinh(X) - hyperbolic arcsine
- atan(X) - arctangent in radians
- atan2(X,Y) - arctangent in radians of the X/Y ratio
- atanh(X) - hyperbolic arctangent
- ceil(X) - rounding up to an integer
- ceiling(X) - rounding up to an integer
- cos(X) - angle cosine in radians
- cosh(X) - hyperbolic cosine
- degrees(X) - convert radians into the angle
- exp(X) - exponent
- floor(X) - rounding down to an integer
- ln(X) - natural logarithm
- log(B,X) - logarithm to the indicated base
- log(X) - decimal logarithm
- log10(X) - decimal logarithm
- log2(X) - logarithm to base 2
- mod(X,Y) - remainder of division
- pi() - approximate Pi
- pow(X,Y) - power by the indicated base
- power(X,Y) - power by the indicated base
- radians(X) - convert the angle into radians
- sin(X) - angle sine in radians
- sinh(X) - hyperbolic sine
- sqrt(X) - square root
- tan(X) - angle tangent in radians
- tanh(X) - hyperbolic tangent
- trunc(X) - truncate to an integer closest to 0

Example:

```
select
  count(*) as book_count,
  cast(avg(parent) as integer) as mean,
  cast(median(parent) as integer) as median,
  mode(parent) as mode,
  percentile_90(parent) as p90,
  percentile_95(parent) as p95,
  percentile_99(parent) as p99
from moz_bookmarks;
```

© 2000-2025, MetaQuotes Ltd.

DatabaseOpen

Opens or creates a database in a specified file.

```
int  DatabaseOpen(
   string  filename,       // file name
   uint    flags           // combination of flags
   );
```

Parameters

filename

[in] File name relative to the "MQL5\Files" folder.

flags

[in] Combination of flags from the ENUM_DATABASE_OPEN_FLAGS enumeration.

Return Value

If executed successfully, the function returns the database handle, which is then used to access the database. Otherwise, it returns INVALID_HANDLE. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_WRONG_INTERNAL_PARAMETER (4002) - internal error, while accessing the "MQL5\Files" folder;
- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_FILENAME (5002) - wrong database file name;
- ERR_TOO_LONG_FILENAME (5003) - absolute path to the database file exceeds the maximum length;
- ERR_DATABASE_TOO_MANY_OBJECTS (5122) - exceeded the maximum acceptable number of Database objects;
- ERR_DATABASE_CONNECT (5123) - database connection error;
- ERR_DATABASE_MISUSE (5621) - incorrect use of the SQLite library.

Note

If the *filename* parameter features NULL or the empty string "", a temporary file is created on the disk. It is automatically deleted after closing the database connection.

If the *filename* parameter features ":memory:", the database is created in the memory and is automatically deleted after the connection to it is closed.

If the *flags* parameter features none of the DATABASE_OPEN_READONLY or DATABASE_OPEN_READWRITE flags, the DATABASE_OPEN_READWRITE flag is used.

If the file extension is not specified, ".sqlite" is used.

ENUM_DATABASE_OPEN_FLAGS

© 2000-2025, MetaQuotes Ltd.

ID	Description
DATABASE_OPEN_READONLY	Read only
DATABASE_OPEN_READWRITE	Open for reading and writing
DATABASE_OPEN_CREATE	Create the file on a disk if necessary
DATABASE_OPEN_MEMORY	Create a database in RAM
DATABASE_OPEN_COMMON	The file is in the common folder of all terminals

See also

DatabaseClose

© 2000-2025, MetaQuotes Ltd.

DatabaseClose

Closes a database.

```
void  DatabaseClose(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return Value

None.

Note

After calling DatabaseClose, all handles of requests to the database are automatically removed and become invalid.

If the handle is invalid, the function sets the ERR_DATABASE_INVALID_HANDLE error. You can check the error using GetLastError().

DatabaseOpen, DatabasePrepare

© 2000-2025, MetaQuotes Ltd.

DatabaseImport

Imports data from a file into a table.

```
long  DatabaseImport(
   int           database,          // database handle received in DatabaseOpen
   const string  table,             // name of a table to insert data
   const string  filename,          // name of a file to import data
   uint          flags,             // combination of flags
   const string  separator,         // data separator
   ulong         skip_rows,         // how many initial strings to skip
   const string  skip_comments      // string of characters defining comments
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table

[in] Name of a table the data from a file is to be added to.

filename

[in] CSV file or ZIP archive for reading data. The name may contain subdirectories and is set relative to the MQL5\Files folder.

flags

[in] Combination of flags from the ENUM_DATABASE_IMPORT_FLAGS enumeration.

separator

[in] Data separator in CSV file.

skip_rows

[in] Number of initial strings to be skipped when reading data from the file.

skip_comments

[in] String of characters for designating strings as comments. If any character from *skip_comments* is detected at the beginning of a string, such a string is considered a comment and is not imported.

Return Value

Return the number of imported strings or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle.

Note

If there is no table named *table*, it is generated automatically. Names and field types in the created table are defined automatically based on the file data.

© 2000-2025, MetaQuotes Ltd.

If there is no table named *table*, it is generated automatically. Names and field types in the created table are defined automatically based on the file data.

ENUM_DATABASE_IMPORT_FLAGS

ID	Description
DATABASE_IMPORT_HEADER	The first line contains the names of the table fields
DATABASE_IMPORT_CRLF	CRLF (the default is LF) is considered a string break
DATABASE_IMPORT_APPEND	Add data to the end of an existing table
DATABASE_IMPORT_QUOTED_STRINGS	String values enclosed in double quotes
DATABASE_IMPORT_COMMON_FOLDER	The file is stored in the common folder of all client terminals \Terminal\Common\File.

Example of reading the table from the file created by the code from the DatabaseExport example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
  string csv_filename;
//--- get the names of text files for downloading from the common folder of the client
  string filenames[];
  if(FileSelectDialog("Select a CSV file to download a table", NULL,
                      "Text files (*.csv)|*.csv",
                      FSD_WRITE_FILE|FSD_COMMON_FOLDER, filenames, "data.csv")>0)
   {
    //--- display the name of each selected file
    if(ArraySize(filenames)==1)
      csv_filename=filenames[0];
    else
     {
      Print("Unknown error while selecting file. Error code ", GetLastError());
      return;
     }
   }
  else
   {
    Print("CSV file not selected");
    return;
   }
//--- create or open a database
  string db_filename="test.sqlite";
  int db=DatabaseOpen(db_filename, DATABASE_OPEN_READWRITE|DATABASE_OPEN_CREATE);
//--- check if the TEST table exists
```

© 2000-2025, MetaQuotes Ltd.

```
  if(DatabaseTableExists(db, "TEST"))
   {
    //--- remove the TEST table
    if(!DatabaseExecute(db, "DROP TABLE IF EXISTS TEST"))
     {
      Print("Failed to drop the TEST table with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
   }
  //--- import entries from the file to the TEST table
  long imported=DatabaseImport(db, "TEST", csv_filename, DATABASE_IMPORT_HEADER|DATABA
  if(imported>0)
   {
    Print(imported," lines imported in table TEST");
    DatabasePrint(db,"SELECT * FROM TEST",DATABASE_PRINT_NO_INDEX);
   }
  else
    {
     Print("DatabaseImport() failed. Error ",GetLastError());
    }
//--- close the database file and inform of that
  DatabaseClose(db);
  PrintFormat("Database: %s closed", db_filename);
 }
```

See also

DatabaseOpen, DatabasePrint

© 2000-2025, MetaQuotes Ltd.

DatabaseExport

Exports a table or an SQL request execution result to a CSV file. The file is created in the UTF-8 encoding.

```
long  DatabaseExport(
   int           database,          // database handle received in DatabaseOpen
   const string  table_or_sql,      // a table name or an SQL request
   const string  filename,          // a name of a CSV file for data export
   uint          flags,             // combination of flags
   const string  separator          // data separator in the CSV file
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table_or_sql

[in] A name of a table or a text of an SQL request whose results are to be exported to a specified file.

filename

[in] A file name for data export. The path is set relative to the MQL5\Files folder.

flags

[in] Combination of flags from the ENUM_DATABASE_EXPORT_FLAGS enumeration.

separator

[in] Data separator. If NULL is specified, the '\t' tabulation character is used as a separator. An empty string "" is considered a valid separator but the obtained CSV file cannot be read as a table - it is considered as a set of strings.

Return Value

Return the number of exported entries or a negative value in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_FUNCTION_NOT_ALLOWED(4014) - specified pipe is not allowed;
- ERR_PROGRAM_STOPPED(4022) - operation canceled (MQL program stopped);
- ERR_WRONG_FILENAME (5002) - invalid file name;
- ERR_TOO_LONG_FILENAME (5003) - absolute path to the file exceeds the maximum length;
- ERR_CANNOT_OPEN_FILE(5004) - unable to open the file for writing;
- ERR_FILE_WRITEERROR(5026) - unable to write to the file;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;

© 2000-2025, MetaQuotes Ltd.

- ERR_DATABASE_QUERY_PREPARE(5125) - request generation error;
- ERR_DATABASE_QUERY_NOT_READONLY - read-only request is allowed.

Note

If request results are exported, the SQL request should begin with "SELECT" or "select". In other words, the SQL request cannot alter the database status, otherwise DatabaseExport() fails with an error.

Database string values may contain the conversion character ('\r' or '\r\n'), as well as the value separator character set in the *separator* parameter. In this case, be sure to use the DATABASE_EXPORT_QUOTED_STRINGS flag in the 'flags' parameter. If this flag is present, all displayed strings are enclosed in double quotes. If a string contains a double quote, it is replaced by two double quotes.

ENUM_DATABASE_EXPORT_FLAGS

ID	Description
DATABASE_EXPORT_HEADER	Display field names in the first string
DATABASE_EXPORT_INDEX	Display string indices
DATABASE_EXPORT_NO_BOM	Do not insert BOM mark at the beginning of the file (BOM is inserted by default)
DATABASE_EXPORT_CRLF	Use CRLF for string break (the default is LF)
DATABASE_EXPORT_APPEND	Add data to the end of an existing file (by default, the file is overwritten). If the file does not exist, it will be created.
DATABASE_EXPORT_QUOTED_STRINGS	Display string values in double quotes.
DATABASE_EXPORT_COMMON_FOLDER	A CSV file is created in the common folder of all client terminals \Terminal\Common\File.

Example:

```
input int InpRates=100;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
 {
  MqlRates rates[];
//--- remember the start time before receiving bars
  ulong start=GetMicrosecondCount();
//--- request the last 100 bars on H1
  if(CopyRates(Symbol(), PERIOD_H1, 1, InpRates, rates)<InpRates)
   {
    Print("CopyRates() failed,, Error ", GetLastError());
```

© 2000-2025, MetaQuotes Ltd.

```
    return;
   }
  else
   {
    //--- how many bars were received and how much time it took to receive them
    PrintFormat("%s: CopyRates received %d bars in %d ms ",
                _Symbol, ArraySize(rates), (GetMicrosecondCount()-start)/1000);
   }
//--- set the file name for storing the database
  string filename=_Symbol+"_"+EnumToString(PERIOD_H1)+"_"+TimeToString(TimeCurrent())+
  StringReplace(filename, ":", "-"); // ":" character is not allowed in file names
//--- open/create the database in the common terminal folder
  int db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE|DATABASE_OPEN_CREATE|DATABASE_
  if(db==INVALID_HANDLE)
   {
    Print("Database: ", filename, " open failed with code ", GetLastError());
    return;
   }
  else
    Print("Database: ", filename, " opened successfully");

//--- check if the RATES table exists
  if(DatabaseTableExists(db, "RATES"))
   {
    //--- remove the RATES table
    if(!DatabaseExecute(db, "DROP TABLE IF EXISTS RATES"))
     {
      Print("Failed to drop the RATES table with code ", GetLastError());
      DatabaseClose(db);
      return;
     }
   }
//--- create the RATES table
  if(!DatabaseExecute(db, "CREATE TABLE RATES("
                      "SYMBOL             CHAR(10),"
                      "TIME               INT NOT NULL,"
                      "OPEN               REAL,"
                      "HIGH               REAL,"
                      "LOW                REAL,"
                      "CLOSE              REAL,"
                      "TICK_VOLUME        INT,"
                      "SPREAD             INT,"
                      "REAL_VOLUME        INT);"))
   {
    Print("DB: ", filename, " create table RATES with code ", GetLastError());
    DatabaseClose(db);
    return;
   }

DatabasePrint, DatabaseImport

© 2000-2025, MetaQuotes Ltd.

DatabasePrint

Prints a table or an SQL request execution result in the Experts journal.

```
long  DatabasePrint(
   int           database,          // database handle received in DatabaseOpen
   const string  table_or_sql,      // a table or an SQL request
   uint          flags              // combination of flags
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table_or_sql

[in] A name of a table or a text of an SQL request whose results are displayed in the Experts journal.

flags

[in] Combination of flags defining the output formatting. The flags are defined as follows:

DATABASE_PRINT_NO_HEADER - do not display table column names (field names)
DATABASE_PRINT_NO_INDEX - do not display string indices
DATABASE_PRINT_NO_FRAME - do not display a frame separating a header and data
DATABASE_PRINT_STRINGS_RIGHT - align strings to the right.

If flags=0, the columns and the strings are displayed, the header and the data are separated by the frame, while the strings are aligned to the left.

Return Value

Return the number of exported strings or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;

Note

If the journal displays request results, the SQL request should begin with "SELECT" or "select". In other words, the SQL request cannot alter the database status, otherwise DatabasePrint() fails with an error.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
   string filename="departments.sqlite";
```

DatabaseTableExists

Checks the presence of the table in a database.

```
bool  DatabaseTableExists(
   int     database,      // database handle received in DatabaseOpen
   string  table          // table name
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

table

[in] Table name.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

DatabaseExecute

Executes a request to a specified database.

```
bool  DatabaseExecute(
   int     database,      // database handle received in DatabaseOpen
   string  sql            // SQL request
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

sql

[in] SQL request.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

DatabasePrepare, DatabaseFinalize

© 2000-2025, MetaQuotes Ltd.

DatabasePrepare

Creates a handle of a request, which can then be executed using DatabaseRead().

```
int  DatabasePrepare(
   int     database,      // database handle received in DatabaseOpen
   string  sql,           // SQL request
           ...            // request parameters
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

sql

[in] SQL request that may contain automatically substituted parameters named ?1,?2,...

...

[in] Automatically substituted request parameters.

Return Value

If successful, the function returns a handle for the SQL request. Otherwise, it returns INVALID_HANDLE. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - path to the database file contains an empty string, or an incompatible combination of flags is set;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_TOO_MANY_OBJECTS (5122) - exceeded the maximum acceptable number of Database objects;
- ERR_DATABASE_PREPARE (5125) - request generation error.

Note

The DatabasePrepare() function does not perform a request to a database. Its purpose is to verify the request parameters and return the handle for executing the SQL request based on the verification results. The request itself is set during the DatabaseRead() first call.

Example:

```
//--- Structure to store the deal
struct Deal
  {
   ulong             ticket;           // DEAL_TICKET
   long              order_ticket;     // DEAL_ORDER
   long              position_ticket;  // DEAL_POSITION_ID
   datetime          time;             // DEAL_TIME
   char              type;             // DEAL_TYPE
   char              entry;            // DEAL_ENTRY

DatabaseExecute, DatabaseFinalize

© 2000-2025, MetaQuotes Ltd.

DatabaseReset

Resets a request, like after calling DatabasePrepare().

```
int  DatabaseReset(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] The handle of the request obtained in DatabasePrepare().

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- SQLite error codes starting with ERR_DATABASE_ERROR(5601).

Note

The DatabaseReset() function is intended for multiple execution of a request with different parameter values. For example, when adding data to the table in bulk using the INSERT command, a custom set of field values should be formed for each entry.

Unlike DatabasePrepare(), the DatabaseReset() call does not compile the string with SQL commands into a new request, therefore DatabaseReset() is executed much faster than DatabasePrepare().

DatabaseReset() is used together with the DatabaseBind() functions and/or DatabaseBindArray() if the request parameter values should be changed after executing DatabaseRead(). This means that before setting new values of the request parameters (before the block of DatabaseBind/DatabaseBindArray calls), DatabaseReset() should be called to reset it. The parametrized request itself should be created using DatabasePrepare().

Just like DatabasePrepare(), DatabaseReset() does not make a database request. A direct request execution is performed when calling DatabaseRead() or DatabaseReadBind().

DatabaseReset() call does not lead to resetting parameter values in the request if they were set by calling DatabaseBind()/DatabaseBindArray(), i.e. the parameters retain their values. Thus, the value of only a single parameter can be changed. There is no need to set all request parameters anew after calling DatabaseReset().

A handle of a request removed using DatabaseFinalize() cannot be passed to DatabaseReset(). This will result in an error.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- create or open a database
```

DatabaseBind

Sets a parameter value in a request.

```
bool  DatabaseBind(
   int  request,      // the handle of a request created in DatabasePrepare
   int  index,        // the parameter index in the request
   T    value         // the value of a simple type parameter
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

index

[in] The parameter index in the request a value should be set for. The numbering starts with zero.

value

[in] The value to be set. Extended types: bool, char, uchar, short, ushart, int, uint, color, datetime, long, ulong, float, double, string.

Return Value

Returns true if successful, otherwise - false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - unsupported type;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_NOT_READY (5128) - cannot use the function to make a request at the moment. The request is being executed or already complete. DatabaseReset() should be called.

Note

The function is used in case an SQL request contains "?" or "?N" parameterizable values where N means the parameter index (starting from one). At the same time, parameters indexing in DatabaseBind() starts from zero.

For example:

```
INSERT INTO table VALUES (?,?,?)
SELECT * FROM table WHERE id=?
```

The function may be called immediately after a parametrized request is created in DatabasePrepare() or after the request is reset using DatabaseReset().

Use this function together with DatabaseReset() to execute the request as many times as needed with different parameter values.

The function is designed to work with simple type parameters. If a parameter should be checked against an array, use the DatabaseBindArray() function.

Example:

DatabaseBindArray

Sets an array as a parameter value.

```
bool  DatabaseBind(
   int   request,       // the handle of a request created in DatabasePrepare
   int   index,         // the parameter index in the request
   T&    array[]        // parameter value as an array
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

index

[in] The parameter index in the request a value should be set for. The numbering starts with zero.

array[]

[in] The array to be set as a request parameter value.

Return Value

Returns true if successful, otherwise - false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - unsupported type;
- ERR_ARRAY_BAD_SIZE (4011) - array size in bytes exceeds INT_MAX;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_NOT_READY (5128) - cannot use the function to make a request at the moment (the request is being executed or already complete, DatabaseReset should be called).

Note

The function is used in case an SQL request contains "?" or "?N" parameterizable values where N means the parameter index (starting from one). At the same time, parameters indexing in DatabaseBindArray() starts from zero.

For example:

```
INSERT INTO table VALUES (?,?,?)
```

The function may be called immediately after a parametrized request is created in DatabasePrepare() or after the request is reset using DatabaseReset().

Use this function together with DatabaseReset() to execute the request as many times as needed with different parameter values.

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

DatabaseRead

Moves to the next entry as a result of a request.

```
bool  DatabaseRead(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

DatabaseReadBind

Moves to the next record and reads data into the structure from it.

```
bool  DatabaseReadBind(
   int    request,           // the handle of a request created in DatabasePrepare
   void&  struct_object      // the reference to the structure for reading the record
   );
```

Parameters

request

[in] The handle of a request created in DatabasePrepare().

struct_object

[out] The reference to the structure the data from the current record is to be read to. The structure should only have numerical types and/or strings (arrays are not allowed) as members and cannot be a descendant.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INVALID_PARAMETER (4003) - no table name specified (empty string or NULL);
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error;
- ERR_DATABASE_NO_MORE_DATA (5126) - no table exists (not an error, normal completion).

Note

A number of fields in the *struct_object* structure should not exceed DatabaseColumnsCount(). If the number of fields in the *struct_object* structure is less than the number of fields in the record, the partial reading is performed. The remaining data can be explicitly obtained using the corresponding DatabaseColumnText(), DatabaseColumnInteger() and other functions.

Example:

```
struct Person
  {
   int               id;
   string            name;
   int               age;
   string            address;
   double            salary;
  };
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
  {
   int db;
   string filename="company.sqlite";
//--- open
   db=DatabaseOpen(filename, DATABASE_OPEN_READWRITE | DATABASE_OPEN_CREATE |DATABASE_
   if(db==INVALID_HANDLE)
     {
      Print("DB: ", filename, " open failed with code ", GetLastError());
      return;
     }
//--- if the table COMPANY exists then drop the table
   if(DatabaseTableExists(db, "COMPANY"))
     {
      //--- delete the table
      if(!DatabaseExecute(db, "DROP TABLE COMPANY"))
        {
         Print("Failed to drop table COMPANY with code ", GetLastError());
         DatabaseClose(db);
         return;
        }
     }
//--- create table

DatabaseFinalize

Removes a request created in DatabasePrepare().

```
void  DatabaseFinalize(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

None.

Note

If the handle is invalid, the function sets the ERR_DATABASE_INVALID_HANDLE error. You can check the error using GetLastError().

See also

DatabasePrepare, DatabaseExecute

© 2000-2025, MetaQuotes Ltd.

DatabaseTransactionBegin

Starts transaction execution.

```
bool  DatabaseTransactionBegin(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

The DatabaseTransactionBegin() function should be called before a transaction execution. Any transaction should start with calling DatabaseTransactionBegin() and end with calling DatabaseTransactionCommit().

Example:

```
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

DatabaseTransactionCommit

Completes transaction execution.

```
bool  DatabaseTransactionCommit(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

The DatabaseTransactionCommit() function completes all transactions executed after calling the DatabaseBeginTransaction() function. Any transaction should start with calling DatabaseTransactionBegin() and end with calling DatabaseTransactionCommit() for successful completion.

See also

DatabaseExecute, DatabasePrepare, DatabaseTransactionBegin, DatabaseTransactionRollback

© 2000-2025, MetaQuotes Ltd.

DatabaseTransactionRollback

Rolls back transactions.

```
bool  DatabaseTransactionRollback(
   int  database      // database handle received in DatabaseOpen
   );
```

Parameters

database

[in] Database handle received in DatabaseOpen().

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_INTERNAL_ERROR (4001) - critical runtime error;
- ERR_INVALID_PARAMETER (4003) - sql parameter contains an empty string;
- ERR_NOT_ENOUGH_MEMORY (4004) - insufficient memory;
- ERR_WRONG_STRING_PARAMETER (5040) - error converting a request into a UTF-8 string;
- ERR_DATABASE_INTERNAL (5120) - internal database error;
- ERR_DATABASE_INVALID_HANDLE (5121) - invalid database handle;
- ERR_DATABASE_EXECUTE (5124) - request execution error.

Note

DatabaseTransactionRollback() call cancels all transactions executed after calling the DatabaseTransactionBegin() function. The DatabaseTransactionRollback() function is necessary for rolling back changes in a database in case errors occur when executing a transaction.

DatabaseColumnsCount

Gets the number of fields in a request.

```
int  DatabaseColumnsCount(
   int  request      // request handle received in DatabasePrepare
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

Return Value

Number of fields or -1 in case of an error. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle.

Note

There is no need to call the DatabaseRead() function to get the number of fields of a request created in DatabasePrepare(). For the remaining DatabaseColumnXXX() functions, DatabaseRead() should be preliminarily called.

See also

DatabasePrepare, DatabaseFinalize, DatabaseClose

© 2000-2025, MetaQuotes Ltd.

DatabaseColumnName

Gets a field name by index.

```
bool  DatabaseColumnName(
   int       request,      // request handle received in DatabasePrepare
   int       column,       // field index in the request
   string&   name          // the reference to the variable for receiving the field name
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

name

[out] Variable for writing the field name.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnType

© 2000-2025, MetaQuotes Ltd.

DatabaseColumnType

Gets a field type by index.

```
ENUM_DATABASE_FIELD_TYPE  DatabaseColumnType(
   int  request,     // request handle received in DatabasePrepare
   int  column       // field index in the request
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

Return Value

Return the field type from the ENUM_DATABASE_FIELD_TYPE enumeration. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

ENUM_DATABASE_FIELD_TYPE

ID	Description
DATABASE_FIELD_TYPE_INVALID	Error getting type, the error code can be obtained using int GetLastError()
DATABASE_FIELD_TYPE_INTEGER	Integer type
DATABASE_FIELD_TYPE_FLOAT	Real type
DATABASE_FIELD_TYPE_TEXT	String type
DATABASE_FIELD_TYPE_BLOB	Binary type
DATABASE_FIELD_TYPE_NULL	Special NULL type

See also

DatabasePrepare, DatabaseColumnsCount, DatabaseColumnName

© 2000-2025, MetaQuotes Ltd.

DatabaseColumnSize

Gets a field size in bytes.

```
int  DatabaseColumnSize(
   int  request,     // request handle received in DatabasePrepare
   int  column       // field index in the request
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

Return Value

If successful, the field size in bytes is returned, otherwise -1. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

See also

DatabasePrepare, DatabaseColumnBlob, DatabaseColumnsCount, DatabaseColumnName, DatabaseColumnType

© 2000-2025, MetaQuotes Ltd.

DatabaseColumnText

Gets a field value as a string from the current record.

```
bool  DatabaseColumnText(
   int      request,     // request handle received in DatabasePrepare
   int      column,      // field index in the request
   string&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

DatabaseColumnInteger

Gets the int type value from the current record.

```
bool  DatabaseColumnInteger(
   int   request,     // request handle received in DatabasePrepare
   int   column,      // field index in the request
   int&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

DatabaseColumnLong

Gets the long type value from the current record.

```
bool  DatabaseColumnLong(
   int     request,      // request handle received in DatabasePrepare
   int     column,       // field index in the request
   long&   value         // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

DatabaseColumnDouble

Gets the double type value from the current record.

```
bool  DatabaseColumnDouble(
   int      request,     // request handle received in DatabasePrepare
   int      column,      // field index in the request
   double&  value        // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

value

[out] Reference to the variable for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

DatabaseColumnBlob

Gets a field value as an array from the current record.

```
bool  DatabaseColumnBlob(
   int    request,     // request handle received in DatabasePrepare
   int    column,      // field index in the request
   void&  data[]       // the reference to the variable for receiving the value
   );
```

Parameters

request

[in] Request handle received in DatabasePrepare().

column

[in] Field index in the request. Field numbering starts from zero and cannot exceed DatabaseColumnsCount() - 1.

data[]

[out] Reference to the array for writing the field value.

Return Value

Return true if successful, otherwise false. To get the error code, use GetLastError(), the possible responses are:

- ERR_DATABASE_INVALID_HANDLE (5121) - invalid request handle;
- ERR_DATABASE_NO_MORE_DATA (5126) - 'column' index exceeds DatabaseColumnsCount() -1.

Note

The value can be obtained only if at least one DatabaseRead() call has been preliminarily made for 'request'.

To read the value from the next record, call DatabaseRead() preliminarily.

Working with DirectX

DirectX 11 functions and shaders are designed for 3D visualization directly on a price chart.

Creating 3D graphics requires a graphic context (DXContextCreate) with the necessary image size. Besides, it is necessary to prepare vertex and index buffers (DXBufferCreate), as well as create vertex and pixel shaders (DXShaderCreate). This is enough to display graphics in color.

The next level of graphics requires the inputs (DXInputSet) for passing additional rendering parameters to shaders. This allows setting the camera and 3D object positions, describe light sources and implement mouse and keyboard control.

Thus, the built-in MQL5 functions enable you to create animated 3D charts directly in MetaTrader 5 with no need for third-party tools. A video card should support DX 11 and Shader Model 5.0 for the functions to work.

To start working with the library, simply read the article How to create 3D graphics using DirectX in MetaTrader 5.

Function	Action
DXContextCreate	Creates a graphic context for rendering frames of a specified size
DXContextSetSize	Changes a frame size of a graphic context created in DXContextCreate()
DXContextSetSize	Gets a frame size of a graphic context created in DXContextCreate()
DXContextClearColors	Sets a specified color to all pixels for the rendering buffer
DXContextClearDepth	Clears the depth buffer
DXContextGetColors	Gets an image of a specified size and offset from a graphic context
DXContextGetDepth	Gets the depth buffer of a rendered frame
DXBufferCreate	Creates a buffer of a specified type based on a data array
DXTextureCreate	Creates a 2D texture out of a rectangle of a specified size cut from a passed image
DXInputCreate	Creates shader inputs
DXInputSet	Sets shader inputs
DXShaderCreate	Creates a shader of a specified type
DXShaderSetLayout	Sets vertex layout for the vertex shader
DXShaderInputsSet	Sets shader inputs
DXShaderTexturesSet	Sets shader textures
DXDraw	Renders the vertices of the vertex buffer set in DXBufferSet()

© 2000-2025, MetaQuotes Ltd.

Function	Action
DXDrawIndexed	Renders graphic primitives described by the index buffer from DXBufferSet()
DXPrimiveTopologySet	Sets the type of primitives for rendering using DXDrawIndexed()
DXBufferSet	Sets a buffer for the current rendering
DXShaderSet	Sets a shader for rendering
DXHandleType	Returns a handle type
DXRelease	Releases a handle

© 2000-2025, MetaQuotes Ltd.

DXContextCreate

Creates a graphic context for rendering frames of a specified size.

```
int  DXContextCreate(
   uint  width,      // width in pixels
   uint  height      // height in pixels
   );
```

Parameters

width

[in] Frame width in pixels.

height

[in] Frame height in pixels.

Return Value

A handle for a created context or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

All graphical objects created using the DXBufferCreate, DXInputCreate, DXShaderCreate and DXTextureCreate functions can be used only in a graphic context they were created in.

A frame size can subsequently be changed to DXContextSetSize().

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

© 2000-2025, MetaQuotes Ltd.

DXContextSetSize

Changes a frame size of a graphic context created in DXContextCreate().

```
bool  DXContextSetSize(
   int    context,      // graphic context handle
   uint&  width,        // width in pixels
   uint&  height        // height in pixels
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

width

[in] Frame width in pixels.

height

[in] Frame height in pixels.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

A frame size of a graphic context should be changed only between frame renderings.

© 2000-2025, MetaQuotes Ltd.

DXContextGetSize

Gets a frame size of a graphic context created in DXContextCreate().

```
bool  DXContextGetSize(
   int    context,      // graphic context handle
   uint&  width,        // width in pixels
   uint&  height        // height in pixels
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

width

[out] Frame width in pixels.

height

[out] Frame height in pixels.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

© 2000-2025, MetaQuotes Ltd.

DXContextClearColors

Sets a specified color to all pixels for the rendering buffer.

```
bool  DXContextClearColors(
   int              context,      // graphic context handle
   const DXVector&  color         // color
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

color

[in] Rendering color.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXContextClearColors() function can be used for clearing the color buffer before rendering the next frame.

© 2000-2025, MetaQuotes Ltd.

DXContextClearDepth

Clears the depth buffer.

```
bool  DXContextClearDepth(
   int  context      // graphic context handle
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXContextClearDepth() function can be used for clearing the depth buffer before rendering the next frame.

© 2000-2025, MetaQuotes Ltd.

DXContextGetColors

Gets an image of a specified size and offset from a graphic context.

```
bool  DXContextGetColors(
   int    context,                      // graphic context handle
   uint&  image[],                      // image pixels array
   int    image_width=WHOLE_ARRAY,      // image width in pixels
   int    image_height=WHOLE_ARRAY,     // image height in pixels
   int    image_offset_x=0,             // X offset
   int    image_offset_y=0              // Y offset
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

image

[out] The array of *image_width*image_height* pixels in ARGB format.

image_width=WHOLE_ARRAY

[in] Image width in pixels.

image_height=WHOLE_ARRAY

[in] Image height in pixels.

image_offset_x=0

[in] X offset.

image_offset_y=0

[in] Y offset.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

© 2000-2025, MetaQuotes Ltd.

DXContextGetDepth

Gets the depth buffer of a rendered frame.

```
bool  DXContextGetDepth(
   int     context,      // graphic context handle
   float&  image[]       // depth value array
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

image

[out] Array of the rendered frame depth buffer values.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The returned buffer contains the depth of each pixel of a rendered frame that can be obtained in DXContextGetColors() in relative units (from 0.0 to 1.0).

© 2000-2025, MetaQuotes Ltd.

DXBufferCreate

Creates a buffer of a specified type based on a data array.

```
int  DXBufferCreate(
   int                  context,              // graphic context handle
   ENUM_DX_BUFFER_TYPE  buffer_type,          // type of a created buffer
   const void&          data[],               // buffer data
   uint                 start=0,              // initial index
   uint                 count=WHOLE_ARRAY     // number of elements
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

buffer_type

[in] Buffer type from the ENUM_DX_BUFFER_TYPE enumeration.

data[]

[in] Data for creating a buffer.

start=0

[in] Index of the first element of the array, starting from which the array values are used to create a buffer. By default, the data is taken from the beginning of the array.

count=WHOLE_ARRAY

[in] Number of values. By default, the entire array is used (count=WHOLE_ARRAY).

Return Value

The handle for a created buffer or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

For the index buffer, the *data[]* array should be of 'uint' type, while the vertex buffer receives the array of structures describing vertices.

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

ENUM_DX_BUFFER_TYPE

ID	Value	Description
DX_BUFFER_VERTEX	1	Vertex buffer
DX_BUFFER_INDEX	2	Index buffer

© 2000-2025, MetaQuotes Ltd.

DXTextureCreate

Creates a 2D texture out of a rectangle of a specified size cut from a passed image.

```
int  DXTextureCreate(
   int              context,          // graphic context handle
   ENUM_DX_FORMAT   format,           // pixel color format
   uint             width,            // source image width
   uint             height,           // source image height
   const void&      data[],           // array of source image pixels
   uint             data_x,           // X coordinate of a rectangle used to create a te
   uint             data_y,           // Y coordinate of a rectangle used to create a te
   uint             data_width,       // rectangle width for creating a texture
   uint             data_height       // rectangle height for creating a texture
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

format

[in] Pixel color format set from the ENUM_DX_FORMAT enumeration.

width

[in] Width of an image a texture is based on.

height

[in] Height of an image a texture is based on.

data

[in] Pixel array of an image a texture is based on.

data_x

[in] X coordinate of a rectangle (X offset) used to create a texture.

data_y

[in] Y coordinate of a rectangle (Y offset) used to create a texture.

data_width

[in] Width of a rectangle used to create a texture.

data_height

[in] Height of a rectangle used to create a texture.

Return Value

Texture handle or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

DXInputCreate

Creates shader inputs.

```
int  DXInputCreate(
   int   context,        // graphic context handle
   uint  input_size      // size of inputs in bytes
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

input_size

[in] Size of the parameter structure in bytes.

Return Value

The handle for shader inputs or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

© 2000-2025, MetaQuotes Ltd.

DXInputSet

Sets shader inputs.

```
bool  DXInputSet(
   int           input,       // graphic context handle
   const void&   data         // data for setting
   );
```

Parameters

input

[in] Handle of inputs for a shader obtained in DXInputCreate().

data

[in] Data for setting shader inputs.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

© 2000-2025, MetaQuotes Ltd.

DXShaderCreate

Creates a shader of a specified type.

```
int  DXShaderCreate(
   int                  context,           // graphic context handle
   ENUM_DX_SHADER_TYPE  shader_type,       // shader type
   const string         source,            // shader source code
   const string         entry_point,       // entry point
   string&              compile_error      // string for receiving compiler messages
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

shader_type

[out] The value from the ENUM_DX_SHADER_TYPE enumeration.

source

[in] Shader source code in HLSL 5.

entry_point

[in] Entry point - function name in a source code.

compile_error

[in] String for receiving compilation errors.

Return Value

Handle for shader or INVALID_HANDLE in case of an error. To receive an error code, the GetLastError() function should be called.

Note

A created handle that is no longer in use should be explicitly released by the DXRelease() function.

ENUM_DX_SHADER_TYPE

ID	Value	Description
DX_SHADER_VERTEX	0	Vertex shader
DX_SHADER_GEOMETRY	1	Geometry shader
DX_SHADER_PIXEL	2	Pixel shader

© 2000-2025, MetaQuotes Ltd.

DXShaderSetLayout

Sets vertex layout for the vertex shader.

```
bool  DXShaderSetLayout(
   int                     shader,        // shader handle
   const DXVertexLayout&   layout[]       //
   );
```

Parameters

shader

[in] Handle of a vertex shader created in DXShaderCreate().

layout[]

[in] Array of vertex fields description. The description is set by the DXVertexLayout structure:

```
struct DXVertexLayout
  {
   string          semantic_name;        // The HLSL semantic associated with this e
   uint            semantic_index;       // The semantic index for the element. A se
   ENUM_DX_FORMAT  format;               // The data type of the element data.
  };
```

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The layout should match the type of vertices in a specified vertex buffer. It should also match the input type of vertices used at the entry point in the vertex shader code.

The vertex buffer for a shader is set in DXBufferSet().

The DXVertexLayout structure is a version of the D3D11_INPUT_ELEMENT_DESC MSDN structure.

© 2000-2025, MetaQuotes Ltd.

DXShaderInputsSet

Sets shader inputs.

```
bool  DXShaderInputsSet(
   int          shader,        // shader handle
   const int&   inputs[]       // array of input handles
   );
```

Parameters

shader

[in] Handle of a shader created in DXShaderCreate().

inputs[]

[in] Array of input handles created using DXInputCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The size of the input parameter should be equal to the number of cbuffer objects declared in the shader code.

© 2000-2025, MetaQuotes Ltd.

DXShaderTexturesSet

Sets shader textures.

```
bool  DXShaderTexturesSet(
   int          shader,          // shader handle
   const  int&  textures[]       // array of structure handles
   );
```

Parameters

shader

[in] Handle of a shader created in DXShaderCreate().

textures[]

[in] Array of texture handles created using DXTextureCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The size of the texture array should be equal to the number of Texture2D objects declared in the shader code.

© 2000-2025, MetaQuotes Ltd.

DXDraw

Renders the vertices of the vertex buffer set in DXBufferSet().

```
bool  DXDraw(
   int   context,               // graphic context handle
   uint  start=0,               // first vertex index
   uint  count=WHOLE_ARRAY      // number of vertices
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

start=0

[in] Index of the first vertex for rendering.

count=WHOLE_ARRAY

[in] Number of vertices to render.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Shaders should be preliminarily set using DXShaderSet() for rendering vertices.

© 2000-2025, MetaQuotes Ltd.

DXDrawIndexed

Renders graphic primitives described by the index buffer from DXBufferSet().

```
bool  DXDrawIndexed(
   int   context,               // graphic context handle
   uint  start=0,               // first primitive index
   uint  count=WHOLE_ARRAY      // number of primitives
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

start=0

[in] Index of the first primitive for rendering.

count=WHOLE_ARRAY

[in] Number of primitives for rendering.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The type of primitives described by the index buffer is set using DXPrimiveTopologySet().

The vertex buffer in DXBufferSet() should be preliminarily set to render primitives.

Also, shaders should be preliminarily set using DXShaderSet().

© 2000-2025, MetaQuotes Ltd.

DXPrimiveTopologySet

Sets the type of primitives for rendering using DXDrawIndexed().

```
bool  DXPrimiveTopologySet(
   int                          context,               // graphic context handle
   ENUM_DX_PRIMITIVE_TOPOLOGY   primitive_topology     // primitive type
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

primitive_topology

[in] The value from the ENUM_DX_PRIMITIVE_TOPOLOGY enumeration.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

ENUM_DX_PRIMITIVE_TOPOLOGY

ID	Value	Match in D3D11_PRIMITIVE_TOPOLOGY
DX_PRIMITIVE_TOPOLOGY_POINTLIST	1	D3D11_PRIMITIVE_TOPOLOGY_POINTLIST
DX_PRIMITIVE_TOPOLOGY_LINELIST	2	D3D11_PRIMITIVE_TOPOLOGY_LINELIST
DX_PRIMITIVE_TOPOLOGY_LINESTRIP	3	D3D11_PRIMITIVE_TOPOLOGY_LINESTRIP
DX_PRIMITIVE_TOPOLOGY_TRIANGLELIST	4	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLELIST
DX_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP	5	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP
DX_PRIMITIVE_TOPOLOGY_LINELIST_ADJ	6	D3D11_PRIMITIVE_TOPOLOGY_LINELIST_ADJ
DX_PRIMITIVE_TOPOLOGY_LINESTRIP_ADJ	7	D3D11_PRIMITIVE_TOPOLOGY_LINESTRIP_ADJ
DX_PRIMITIVE_TOPOLOGY_TRIANGLELIST_ADJ	8	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLELIST_ADJ
DX_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP_ADJ	9	D3D11_PRIMITIVE_TOPOLOGY_TRIANGLESTRIP_ADJ

© 2000-2025, MetaQuotes Ltd.

DXBufferSet

Sets a buffer for the current rendering.

```
bool  DXBufferSet(
   int   context,               // graphic context handle
   int   buffer,                // vertex or index buffer handle
   uint  start=0,               // initial index
   uint  count=WHOLE_ARRAY      // number of elements
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

buffer

[in] Handle of the vertex or index buffer created in DXBufferCreate().

start=0

[in] Index of the buffer first element. The data from the beginning of the buffer is used by default.

count=WHOLE_ARRAY

[in] Number of values to be used. The default is all buffer values.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

The DXBufferSet() function should be called to set vertex and index buffers for rendering using DXDraw().

© 2000-2025, MetaQuotes Ltd.

DXShaderSet

Sets a shader for rendering.

```
bool  DXShaderSet(
   int  context,      // graphic context handle
   int  shader        // shader handle
   );
```

Parameters

context

[in] Handle for a graphic context created in DXContextCreate().

shader

[in] Handle of a shader created in DXShaderCreate().

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

Several types of shaders can simultaneously be used for rendering (vertex, geometry and pixel ones).

© 2000-2025, MetaQuotes Ltd.

DXHandleType

Returns a handle type.

```
ENUM_DX_HANDLE_TYPE  DXHandleType(
   int  handle      // handle
   );
```

Parameters

handle

[in] Handle.

Return Value

The value from the ENUM_DX_HANDLE_TYPE enumeration

ENUM_DX_HANDLE_TYPE

ID	Value	Description
DX_HANDLE_INVALID	0	Invalid handle
DX_HANDLE_CONTEXT	1	Graphic context handle
DX_HANDLE_SHADER	2	Shader handle
DX_HANDLE_BUFFER	3	Vertex or index buffer handle
DX_HANDLE_INPUT	4	Handle for shader inputs
DX_HANDLE_TEXTURE	5	Texture handle

© 2000-2025, MetaQuotes Ltd.

DXRelease

Releases a handle.

```
bool  DXRelease(
   int  handle      // handle
   );
```

Parameters

context

[in] Released handle.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an error code, the GetLastError() function should be called.

Note

All created handles that are no longer in use should be explicitly released by the DXRelease() function.

MetaTrader module for integration with Python

MQL5 is designed for the development of high-performance trading applications in the financial markets and is unparalleled among other specialized languages used in the algorithmic trading. The syntax and speed of MQL5 programs are very close to C++, there is support for OpenCL and integration with MS Visual Studio. Statistics, fuzzy logic and ALGLIB libraries are available as well. MetaEditor development environment features native support for .NET libraries with "smart" functions import eliminating the need to develop special wrappers. Third-party C++ DLLs can also be used. C++ source code files (CPP and H) can be edited and compiled into DLL directly from the editor. Microsoft Visual Studio installed on user's PC can be used for that.

Python is a modern high-level programming language for developing scripts and applications. It contains multiple libraries for machine learning, process automation, as well as data analysis and visualization.

MetaTrader package for Python is designed for convenient and fast obtaining of exchange data via interprocessor communication directly from the MetaTrader 5 terminal. The data received this way can be further used for statistical calculations and machine learning.

Installing the package from the command line:

```
pip install MetaTrader5
```

Updating the package from the command line:

```
pip install --upgrade MetaTrader5
```

Functions for integrating MetaTrader 5 and Python

Function	Action
initialize	Establish a connection with the MetaTrader 5 terminal
login	Connect to a trading account using specified parameters
shutdown	Close the previously established connection to the MetaTrader 5 terminal
version	Return the MetaTrader 5 terminal version
last_error	Return data on the last error
account_info	Get info on the current trading account
terminal_Info	Get status and parameters of the connected MetaTrader 5 terminal
symbols_total	Get the number of all financial instruments in the MetaTrader 5 terminal
symbols_get	Get all financial instruments from the MetaTrader 5 terminal
symbol_info	Get data on the specified financial instrument
symbol_info_tick	Get the last tick for the specified financial instrument
symbol_select	Select a symbol in the MarketWatch window or remove a symbol from the window

© 2000-2025, MetaQuotes Ltd.

Function	Action
market_book_add	Subscribes the MetaTrader 5 terminal to the Market Depth change events for a specified symbol
market_book_get	Returns a tuple from BookInfo featuring Market Depth entries for the specified symbol
market_book_release	Cancels subscription of the MetaTrader 5 terminal to the Market Depth change events for a specified symbol
copy_rates_from	Get bars from the MetaTrader 5 terminal starting from the specified date
copy_rates_from_pos	Get bars from the MetaTrader 5 terminal starting from the specified index
copyrates_range	Get bars in the specified date range from the MetaTrader 5 terminal
copy_ticks_from	Get ticks from the MetaTrader 5 terminal starting from the specified date
copy_ticks_range	Get ticks for the specified date range from the MetaTrader 5 terminal
orders_total	Get the number of active orders.
orders_get	Get active orders with the ability to filter by symbol or ticket
order_calc_margin	Return margin in the account currency to perform a specified trading operation
order_calc_profit	Return profit in the account currency for a specified trading operation
order_check	Check funds sufficiency for performing a required trading operation
order_send	Send a request to perform a trading operation.
positions_total	Get the number of open positions
positions_get	Get open positions with the ability to filter by symbol or ticket
history_orders_total	Get the number of orders in trading history within the specified interval
history_orders_get	Get orders from trading history with the ability to filter by ticket or position
history_deals_total	Get the number of deals in trading history within the specified interval
history_deals_get	Get deals from trading history with the ability to filter by ticket or position

Example of connecting Python to MetaTrader 5

1. Download the latest version of Python 3.8 from https://www.python.org/downloads/windows
2. When installing Python, check "Add Python 3.8 to PATH%" to be able to run Python scripts from the command line.

© 2000-2025, MetaQuotes Ltd.

3. Install the MetaTrader 5 module from the command line

```
pip install MetaTrader5
```

4. Add matplotlib and pandas packages

```
pip install matplotlib
pip install pandas
```

5. Launch the test script

```
from datetime import datetime
import matplotlib.pyplot as plt
import pandas as pd
from pandas.plotting import register_matplotlib_converters
register_matplotlib_converters()
import MetaTrader5 as mt5

# connect to MetaTrader 5
if not mt5.initialize():
    print("initialize() failed")
    mt5.shutdown()

# request connection status and parameters
print(mt5.terminal_info())
# get data on MetaTrader 5 version
print(mt5.version())

# request 1000 ticks from EURAUD
euraud_ticks = mt5.copy_ticks_from("EURAUD", datetime(2020,1,28,13), 1000, mt5.COPY_TI
# request ticks from AUDUSD within 2019.04.01 13:00 - 2019.04.02 13:00
audusd_ticks = mt5.copy_ticks_range("AUDUSD", datetime(2020,1,27,13), datetime(2020,1,

# get bars from different symbols in a number of ways
eurusd_rates = mt5.copy_rates_from("EURUSD", mt5.TIMEFRAME_M1, datetime(2020,1,28,13),
eurgbp_rates = mt5.copy_rates_from_pos("EURGBP", mt5.TIMEFRAME_M1, 0, 1000)
eurcad_rates = mt5.copy_rates_range("EURCAD", mt5.TIMEFRAME_M1, datetime(2020,1,27,13)

# shut down connection to MetaTrader 5
mt5.shutdown()

#DATA
print('euraud_ticks(', len(euraud_ticks), ')')
for val in euraud_ticks[:10]: print(val)

print('audusd_ticks(', len(audusd_ticks), ')')

initialize

Establish a connection with the MetaTrader 5 terminal. There are three call options.

Call without parameters. The terminal for connection is found automatically.

```
initialize()
```

Call specifying the path to the MetaTrader 5 terminal we want to connect to.

```
initialize(
   path                       // path to the MetaTrader 5 terminal EXE file
   )
```

Call specifying the trading account path and parameters.

```
initialize(
   path,                      // path to the MetaTrader 5 terminal EXE file
   login=LOGIN,               // account number
   password="PASSWORD",       // password
   server="SERVER",           // server name as it is specified in the terminal
   timeout=TIMEOUT,           // timeout
   portable=False             // portable mode
   )
```

Parameters

path

[in] Path to the metatrader.exe or metatrader64.exe file. Optional unnamed parameter. It is indicated first without a parameter name. If the path is not specified, the module attempts to find the executable file on its own.

login=LOGIN

[in] Trading account number. Optional named parameter. If not specified, the last trading account is used.

password="PASSWORD"

[in] Trading account password. Optional named parameter. If the password is not set, the password for a specified trading account saved in the terminal database is applied automatically.

server="SERVER"

[in] Trade server name. Optional named parameter. If the server is not set, the server for a specified trading account saved in the terminal database is applied automatically.

timeout=TIMEOUT

[in] Connection timeout in milliseconds. Optional named parameter. If not specified, the value of 60 000 (60 seconds) is applied.

portable=False

[in] Flag of the terminal launch in portable mode. Optional named parameter. If not specified, the value of False is used.

Return Value

© 2000-2025, MetaQuotes Ltd.

Returns True in case of successful connection to the MetaTrader 5 terminal, otherwise - False.

Note

If required, the MetaTrader 5 terminal is launched to establish connection when executing the initialize() call.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish MetaTrader 5 connection to a specified trading account
if not mt5.initialize(login=25115284, server="MetaQuotes-Demo",password="4zatlbqx"):
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on connection status, server name and trading account
print(mt5.terminal_info())
# display data on MetaTrader 5 version
print(mt5.version())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

shutdown, terminal_info, version

© 2000-2025, MetaQuotes Ltd.

login

Connect to a trading account using specified parameters.

```
login(
   login,                    // account number
   password="PASSWORD",      // password
   server="SERVER",          // server name as it is specified in the terminal
   timeout=TIMEOUT           // timeout
   )
```

Parameters

login

[in] Trading account number. Required unnamed parameter.

password

[in] Trading account password. Optional named parameter. If the password is not set, the password saved in the terminal database is applied automatically.

server

[in] Trade server name. Optional named parameter. If no server is set, the last used server is applied automatically.

timeout=TIMEOUT

[in] Connection timeout in milliseconds. Optional named parameter. If not specified, the value of 60 000 (60 seconds) is applied. If the connection is not established within the specified time, the call is forcibly terminated and the exception is generated.

Return Value

True in case of a successful connection to the trade account, otherwise - False.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on MetaTrader 5 version
print(mt5.version())
# connect to the trade account without specifying a password and a server
account=17221085
authorized=mt5.login(account)  # the terminal database password is applied if connecti
if authorized:
    print("connected to account #{}".format(account))
else:
```

shutdown

Close the previously established connection to the MetaTrader 5 terminal.

```
shutdown()
```

Return Value

None.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed")
    quit()

# display data on connection status, server name and trading account
print(mt5.terminal_info())
# display data on MetaTrader 5 version
print(mt5.version())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

See also

initialize, login_py, terminal_info, version

© 2000-2025, MetaQuotes Ltd.

version

Return the MetaTrader 5 terminal version.

```
version()
```

Return Value

Return the MetaTrader 5 terminal version, build and release date. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The version() function returns the terminal version, build and release date as a tuple of three values:

Type	Description	Sample value
integer	MetaTrader 5 terminal version	500
integer	Build	2007
string	Build release date	'25 Feb 2019'

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on MetaTrader 5 version
print(mt5.version())

# display data on connection status, server name and trading account 'as is'
print(mt5.terminal_info())
print()

# get properties in the form of a dictionary
terminal_info_dict=mt5.terminal_info()._asdict()
# convert the dictionary into DataFrame and print
df=pd.DataFrame(list(terminal_info_dict.items()),columns=['property','value'])
print("terminal_info() as dataframe:")
print(df[:-1])
```

last_error

Return data on the last error.

```
last_error()
```

Return Value

Return the last error code and description as a tuple.

Note

last_error() allows obtaining an error code in case of a failed execution of a MetaTrader 5 library function. It is similar to GetLastError(). However, it applies its own error codes. Possible values:

Constant	Value	Description
RES_S_OK	1	generic success
RES_E_FAIL	-1	generic fail
RES_E_INVALID_PARAMS	-2	invalid arguments/parameters
RES_E_NO_MEMORY	-3	no memory condition
RES_E_NOT_FOUND	-4	no history
RES_E_INVALID_VERSION	-5	invalid version
RES_E_AUTH_FAILED	-6	authorization failed
RES_E_UNSUPPORTED	-7	unsupported method
RES_E_AUTO_TRADING_DISABLED	-8	auto-trading disabled
RES_E_INTERNAL_FAIL	-10000	internal IPC general error
RES_E_INTERNAL_FAIL_SEND	-10001	internal IPC send failed
RES_E_INTERNAL_FAIL_RECEIVE	-10002	internal IPC recv failed
RES_E_INTERNAL_FAIL_INIT	-10003	internal IPC initialization fail
RES_E_INTERNAL_FAIL_CONNECT	-10003	internal IPC no ipc
RES_E_INTERNAL_FAIL_TIMEOUT	-10005	internal timeout

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()
```

account_info

Get info on the current trading account.

```
account_info()
```

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function returns all data that can be obtained using AccountInfoInteger, AccountInfoDouble and AccountInfoString in one call.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

terminal_info

Get the connected MetaTrader 5 client terminal status and settings.

```
terminal_info()
```

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function returns all data that can be obtained using TerminalInfoInteger, TerminalInfoDouble and TerminalInfoDouble in one call.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on MetaTrader 5 version
print(mt5.version())
# display info on the terminal settings and status
terminal_info=mt5.terminal_info()
if terminal_info!=None:
    # display the terminal data 'as is'
    print(terminal_info)
    # display data in the form of a list
    print("Show terminal_info()._asdict():")
    terminal_info_dict = mt5.terminal_info()._asdict()
    for prop in terminal_info_dict:
        print("  {}={}".format(prop, terminal_info_dict[prop]))
    print()

initialize, shutdown, version

© 2000-2025, MetaQuotes Ltd.

symbols_total

Get the number of all financial instruments in the MetaTrader 5 terminal.

```
symbols_total()
```

Return Value

Integer value.

Note

The function is similar to SymbolsTotal(). However, it returns the number of all symbols including custom ones and the ones disabled in MarketWatch.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get the number of financial instruments
symbols=mt5.symbols_total()
if symbols>0:
    print("Total symbols =",symbols)
else:
    print("symbols not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

symbols_get

Get all financial instruments from the MetaTrader 5 terminal.

```
symbols_get(
   group="GROUP"      // symbol selection filter
)
```

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional parameter. If the group is specified, the function returns only symbols meeting a specified criteria.

Return Value

Return symbols in the form of a tuple. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The *group* parameter allows sorting out symbols by name. '*' can be used at the beginning and the end of a string.

The *group* parameter can be used as a named or an unnamed one. Both options work the same way. The named option (group="GROUP") makes the code easier to read.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that all symbols should be selected first and the ones containing "EUR" in their names should be excluded afterwards.

Unlike symbol_info(), the symbols_get() function returns data on all requested symbols within a single call.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get all symbols
symbols=mt5.symbols_get()
print('Symbols: ', len(symbols))
count=0
# display the first five ones
for s in symbols:
    count+=1
```

© 2000-2025, MetaQuotes Ltd.

```
    print("{}. {}".format(count,s.name))
    if count==5: break
print()

# get symbols containing RU in their names
ru_symbols=mt5.symbols_get("*RU*")
print('len(*RU*): ', len(ru_symbols))
for s in ru_symbols:
    print(s.name)
print()

# get symbols whose names do not contain USD, EUR, JPY and GBP
group_symbols=mt5.symbols_get(group="*,!*USD*,!*EUR*,!*JPY*,!*GBP*")
print('len(*,!*USD*,!*EUR*,!*JPY*,!*GBP*):', len(group_symbols))
for s in group_symbols:
    print(s.name,":",s)

# shut down connection to the MetaTrader 5 terminal

symbol_info

Get data on the specified financial instrument.

```
symbol_info(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function returns all data that can be obtained using SymbolInfoInteger, SymbolInfoDouble and SymbolInfoString in one call.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

symbol_info_tick

Get the last tick for the specified financial instrument.

```
symbol_info_tick(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

Return info in the form of a tuple. Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function is similar to SymbolInfoTick.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to the MetaTrader 5 terminal

symbol_select

Select a symbol in the MarketWatch window or remove a symbol from the window.

```
symbol_select(
   symbol,      // financial instrument name
   enable=None  // enable or disable
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

enable

[in] Switch. Optional unnamed parameter. If 'false', a symbol should be removed from the MarketWatch window. Otherwise, it should be selected in the MarketWatch window. A symbol cannot be removed if open charts with this symbol are currently present or positions are opened on it.

Return Value

True if successful, otherwise - False.

Note

The function is similar to SymbolSelect.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

symbol_info

© 2000-2025, MetaQuotes Ltd.

market_book_add

Subscribes the MetaTrader 5 terminal to the Market Depth change events for a specified symbol.

```
market_book_add(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

True if successful, otherwise - False.

Note

The function is similar to MarketBookAdd.

See also

market_book_get, market_book_release, Market Depth structure

© 2000-2025, MetaQuotes Ltd.

market_book_get

Returns a tuple from BookInfo featuring Market Depth entries for the specified symbol.

```
market_book_get(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

Returns the Market Depth content as a tuple from BookInfo entries featuring order type, price and volume in lots. BookInfo is similar to the MqlBookInfo structure.

Return None in case of an error. The info on the error can be obtained using last_error().

Note

The subscription to the Market Depth change events should be preliminarily performed using the market_book_add() function.

The function is similar to MarketBookGet.

Example:

```
import MetaTrader5 as mt5
import time
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print("")

# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
   # shut down connection to the MetaTrader 5 terminal
    mt5.shutdown()
    quit()

# subscribe to market depth updates for EURUSD (Depth of Market)
if mt5.market_book_add('EURUSD'):

market_book_release

Cancels subscription of the MetaTrader 5 terminal to the Market Depth change events for a specified symbol.

```
market_book_release(
   symbol      // financial instrument name
)
```

symbol

[in] Financial instrument name. Required unnamed parameter.

Return Value

True if successful, otherwise - False.

Note

The function is similar to MarketBookRelease.

See also

market_book_add, market_book_get, Market Depth structure

© 2000-2025, MetaQuotes Ltd.

copy_rates_from

Get bars from the MetaTrader 5 terminal starting from the specified date.

```
copy_rates_from(
   symbol,       // symbol name
   timeframe,    // timeframe
   date_from,    // initial bar open date
   count         // number of bars
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

date_from

[in] Date of opening of the first bar from the requested sample. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

count

[in] Number of bars to receive. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

Only data whose date is less than (earlier) or equal to the date specified will be returned. It means, the open time of any bar is always less or equal to the specified one.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

TIMEFRAME is an enumeration with possible chart period values

ID	Description
TIMEFRAME_M1	1 minute

© 2000-2025, MetaQuotes Ltd.

ID	Description
TIMEFRAME_M2	2 minutes
TIMEFRAME_M3	3 minutes
TIMEFRAME_M4	4 minutes
TIMEFRAME_M5	5 minutes
TIMEFRAME_M6	6 minutes
TIMEFRAME_M10	10 minutes
TIMEFRAME_M12	12 minutes
TIMEFRAME_M12	15 minutes
TIMEFRAME_M20	20 minutes
TIMEFRAME_M30	30 minutes
TIMEFRAME_H1	1 hour
TIMEFRAME_H2	2 hours
TIMEFRAME_H3	3 hours
TIMEFRAME_H4	4 hours
TIMEFRAME_H6	6 hours
TIMEFRAME_H8	8 hours
TIMEFRAME_H12	12 hours
TIMEFRAME_D1	1 day
TIMEFRAME_W1	1 week
TIMEFRAME_MN1	1 month

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz
```

© 2000-2025, MetaQuotes Ltd.

```
# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' object in UTC time zone to avoid the implementation of a local tir
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
# get 10 EURUSD H4 bars starting from 01.10.2020 in UTC time zone
rates = mt5.copy_rates_from("EURUSD", mt5.TIMEFRAME_H4, utc_from, 10)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
# display each element of obtained data in a new line
print("Display obtained data 'as is'")
for rate in rates:
    print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the datetime format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame)

CopyRates, copy_rates_from_pos, copy_rates_range, copy_ticks_from, copy_ticks_range

© 2000-2025, MetaQuotes Ltd.

copy_rates_from_pos

Get bars from the MetaTrader 5 terminal starting from the specified index.

```
copy_rates_from_pos(
   symbol,       // symbol name
   timeframe,    // timeframe
   start_pos,    // initial bar index
   count         // number of bars
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

start_pos

[in] Initial index of the bar the data are requested from. The numbering of bars goes from present to past. Thus, the zero bar means the current one. Required unnamed parameter.

count

[in] Number of bars to receive. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Returns None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
```

© 2000-2025, MetaQuotes Ltd.

```
# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get 10 GBPUSD D1 bars from the current day
rates = mt5.copy_rates_from_pos("GBPUSD", mt5.TIMEFRAME_D1, 0, 10)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
# display each element of obtained data in a new line
print("Display obtained data 'as is'")
for rate in rates:
    print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the datetime format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame)

CopyRates, copy_rates_from, copy_rates_range, copy_ticks_from, copy_ticks_range

© 2000-2025, MetaQuotes Ltd.

copy_rates_range

Get bars in the specified date range from the MetaTrader 5 terminal.

```
copy_rates_range(
   symbol,       // symbol name
   timeframe,    // timeframe
   date_from,    // date the bars are requested from
   date_to       // date, up to which the bars are requested
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

timeframe

[in] Timeframe the bars are requested for. Set by a value from the TIMEFRAME enumeration. Required unnamed parameter.

date_from

[in] Date the bars are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Bars with the open time >= date_from are returned. Required unnamed parameter.

date_to

[in] Date, up to which the bars are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Bars with the open time <= date_to are returned. Required unnamed parameter.

Return Value

Returns bars as the numpy array with the named time, open, high, low, close, tick_volume, spread and real_volume columns. Returns None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyRates() function for more information.

MetaTrader 5 terminal provides bars only within a history available to a user on charts. The number of bars available to users is set in the "Max. bars in chart" parameter.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
```

© 2000-2025, MetaQuotes Ltd.

```
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' objects in UTC time zone to avoid the implementation of a local ti
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
utc_to = datetime(2020, 1, 11, hour = 13, tzinfo=timezone)
# get bars from USDJPY M5 within the interval of 2020.01.10 00:00 - 2020.01.11 13:00 i
rates = mt5.copy_rates_range("USDJPY", mt5.TIMEFRAME_M5, utc_from, utc_to)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

# display each element of obtained data in a new line
print("Display obtained data 'as is'")
counter=0
for rate in rates:
    counter+=1
    if counter<=10:
        print(rate)

# create DataFrame out of the obtained data
rates_frame = pd.DataFrame(rates)
# convert time in seconds into the 'datetime' format
rates_frame['time']=pd.to_datetime(rates_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with data")
print(rates_frame.head(10))
```

Result:

CopyRates, copy_rates_from, copy_rates_range, copy_ticks_from, copy_ticks_range

© 2000-2025, MetaQuotes Ltd.

copy_ticks_from

Get ticks from the MetaTrader 5 terminal starting from the specified date.

```
copy_ticks_from(
   symbol,       // symbol name
   date_from,    // date the ticks are requested from
   count,        // number of requested ticks
   flags         // combination of flags defining the type of requested ticks
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

from

[in] Date the ticks are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

count

[in] Number of ticks to receive. Required unnamed parameter.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. Flag values are described in the COPY_TICKS enumeration. Required unnamed parameter.

Return Value

Returns ticks as the numpy array with the named time, bid, ask, last and flags columns. The 'flags' value can be a combination of flags from the TICK_FLAG enumeration. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyTicks function for more information.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. Data received from the MetaTrader 5 terminal has UTC time.

COPY_TICKS defines the types of ticks that can be requested using the copy_ticks_from() and copy_ticks_range() functions.

ID	Description
COPY_TICKS_ALL	all ticks
COPY_TICKS_INFO	ticks containing Bid and/or Ask price changes
COPY_TICKS_TRADE	ticks containing Last and/or Volume price changes

© 2000-2025, MetaQuotes Ltd.

TICK_FLAG defines possible flags for ticks. These flags are used to describe ticks obtained by the copy_ticks_from() and copy_ticks_range() functions.

ID	Description
TICK_FLAG_BID	Bid price changed
TICK_FLAG_ASK	Ask price changed
TICK_FLAG_LAST	Last price changed
TICK_FLAG_VOLUME	Volume changed
TICK_FLAG_BUY	last Buy price changed
TICK_FLAG_SELL	last Sell price changed

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# import the 'pandas' module for displaying data obtained in the tabular form
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# import pytz module for working with time zone
import pytz

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# set time zone to UTC
timezone = pytz.timezone("Etc/UTC")
# create 'datetime' object in UTC time zone to avoid the implementation of a local tir
utc_from = datetime(2020, 1, 10, tzinfo=timezone)
# request 100 000 EURUSD ticks starting from 10.01.2019 in UTC time zone
ticks = mt5.copy_ticks_from("EURUSD", utc_from, 100000, mt5.COPY_TICKS_ALL)
print("Ticks received:",len(ticks))

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

# display data on each tick on a new line
print("Display obtained ticks 'as is'")
count = 0
for tick in ticks:
```

© 2000-2025, MetaQuotes Ltd.

```
    count+=1
    print(tick)
    if count >= 10:
        break

# create DataFrame out of the obtained data
ticks_frame = pd.DataFrame(ticks)
# convert time in seconds into the datetime format
ticks_frame['time']=pd.to_datetime(ticks_frame['time'], unit='s')

# display data
print("\nDisplay dataframe with ticks")
print(ticks_frame.head(10))

Result:

CopyRates, copy_rates_from_pos, copy_rates_range, copy_ticks_from, copy_ticks_range

© 2000-2025, MetaQuotes Ltd.

copy_ticks_range

Get ticks for the specified date range from the MetaTrader 5 terminal.

```
copy_ticks_range(
   symbol,       // symbol name
   date_from,    // date the ticks are requested from
   date_to,      // date, up to which the ticks are requested
   flags         // combination of flags defining the type of requested ticks
   )
```

Parameters

symbol

[in] Financial instrument name, for example, "EURUSD". Required unnamed parameter.

date_from

[in] Date the ticks are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the ticks are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

flags

[in] A flag to define the type of the requested ticks. COPY_TICKS_INFO - ticks with Bid and/or Ask changes, COPY_TICKS_TRADE - ticks with changes in Last and Volume, COPY_TICKS_ALL - all ticks. Flag values are described in the COPY_TICKS enumeration. Required unnamed parameter.

Return Value

Returns ticks as the numpy array with the named time, bid, ask, last and flags columns. The 'flags' value can be a combination of flags from the TICK_FLAG enumeration. Return None in case of an error. The info on the error can be obtained using last_error().

Note

See the CopyTicks function for more information.

When creating the 'datetime' object, Python uses the local time zone, while MetaTrader 5 stores tick and bar open time in UTC time zone (without the shift). Therefore, 'datetime' should be created in UTC time for executing functions that use time. The data obtained from MetaTrader 5 have UTC time, but Python applies the local time shift again when trying to print them. Thus, the obtained data should also be corrected for visual presentation.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
```

© 2000-2025, MetaQuotes Ltd.

```
# import the 'pandas' module for displaying data obtained in the tabular form

orders_total

Get the number of active orders.

```
orders_total()
```

Return Value

Integer value.

Note

The function is similar to OrdersTotal.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# check the presence of active orders
orders=mt5.orders_total()
if orders>0:
    print("Total orders=",orders)
else:
    print("Orders not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

orders_get

Get active orders with the ability to filter by symbol or ticket. There are three call options.

Call without parameters. Return active orders on all symbols.

```
orders_get()
```

Call specifying a symbol active orders should be received for.

```
orders_get(
   symbol="SYMBOL"       // symbol name
)
```

Call specifying a group of symbols active orders should be received for.

```
orders_get(
   group="GROUP"         // filter for selecting orders for symbols
)
```

Call specifying the order ticket.

```
orders_get(
   ticket=TICKET         // ticket
)
```

symbol="SYMBOL"

[in] Symbol name. Optional named parameter. If a symbol is specified, the *ticket* parameter is ignored.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only active orders meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Order ticket (ORDER_TICKET). Optional named parameter.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all active orders within one call similar to the OrdersTotal and OrderSelect tandem.

The *group* parameter allows sorting out orders by symbols. '*' can be used at the beginning and the end of a string.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that orders for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

```
import MetaTrader5 as mt5
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)
print()
# establish connection to the MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# display data on active orders on GBPUSD
orders=mt5.orders_get(symbol="GBPUSD")
if orders is None:
    print("No orders on GBPUSD, error code={}".format(mt5.last_error()))
else:
    print("Total orders on GBPUSD:",len(orders))
    # display all active orders
    for order in orders:
        print(order)
print()

# get the list of orders on symbols whose names contain "*GBP*"
gbp_orders=mt5.orders_get(group="*GBP*")
if gbp_orders is None:
    print("No orders with group=\"*GBP*\", error code={}".format(mt5.last_error()))
else:
    print("orders_get(group=\"*GBP*\")={}".format(len(gbp_orders)))
    # display these orders as a table using pandas.DataFrame
    df=pd.DataFrame(list(gbp_orders),columns=gbp_orders[0]._asdict().keys())
    df.drop(['time_done', 'time_done_msc', 'position_id', 'position_by_id', 'reason',
    df['time_setup'] = pd.to_datetime(df['time_setup'], unit='s')
    print(df)

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

orders_total, positions_get

© 2000-2025, MetaQuotes Ltd.

order_calc_margin

Return margin in the account currency to perform a specified trading operation.

```
order_calc_margin(
   action,      // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
   symbol,      // symbol name
   volume,      // volume
   price        // open price
   )
```

Parameters

action

[in] Order type taking values from the ORDER_TYPE enumeration. Required unnamed parameter.

symbol

[in] Financial instrument name. Required unnamed parameter.

volume

[in] Trading operation volume. Required unnamed parameter.

price

[in] Open price. Required unnamed parameter.

Return Value

Real value if successful, otherwise None. The error info can be obtained using last_error().

Note

The function allows estimating the margin necessary for a specified order type on the current account and in the current market environment without considering the current pending orders and open positions. The function is similar to OrderCalcMargin.

ORDER_TYPE

ID	Description
ORDER_TYPE_BUY	Market buy order
ORDER_TYPE_SELL	Market sell order
ORDER_TYPE_BUY_LIMIT	Buy Limit pending order
ORDER_TYPE_SELL_LIMIT	Sell Limit pending order
ORDER_TYPE_BUY_STOP	Buy Stop pending order
ORDER_TYPE_SELL_STOP	Sell Stop pending order
ORDER_TYPE_BUY_STOP_LIMIT	Upon reaching the order price, Buy Limit pending order is placed at StopLimit price
ORDER_TYPE_SELL_STOP_LIMIT	Upon reaching the order price, Sell Limit pending order is placed at StopLimit price

© 2000-2025, MetaQuotes Ltd.

ID	Description
ORDER_TYPE_CLOSE_BY	Order for closing a position by an opposite one

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# get account currency
account_currency=mt5.account_info().currency
print("Account currency:",account_currency)

# arrange the symbol list
symbols=("EURUSD","GBPUSD","USDJPY", "USDCHF","EURJPY","GBPJPY")
print("Symbols to check margin:", symbols)
action=mt5.ORDER_TYPE_BUY
lot=0.1
for symbol in symbols:
    symbol_info=mt5.symbol_info(symbol)
    if symbol_info is None:
        print(symbol,"not found, skipped")
        continue
    if not symbol_info.visible:
        print(symbol, "is not visible, trying to switch on")
        if not mt5.symbol_select(symbol,True):
            print("symbol_select({}}) failed, skipped",symbol)
            continue
    ask=mt5.symbol_info_tick(symbol).ask
    margin=mt5.order_calc_margin(action,symbol,lot,ask)
    if margin != None:
        print("   {} buy {} lot margin: {} {}".format(symbol,lot,margin,account_currer
    else:
        print("order_calc_margin failed: , error code =", mt5.last_error())

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()

order_calc_profit, order_check

© 2000-2025, MetaQuotes Ltd.

order_calc_profit

Return profit in the account currency for a specified trading operation.

```
order_calc_profit(
   action,          // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
   symbol,          // symbol name
   volume,          // volume
   price_open,      // open price
   price_close      // close price
   );
```

Parameters

action

[in] Order type may take one of the two ORDER_TYPE enumeration values: ORDER_TYPE_BUY or ORDER_TYPE_SELL. Required unnamed parameter.

symbol

[in] Financial instrument name. Required unnamed parameter.

volume

[in] Trading operation volume. Required unnamed parameter.

price_open

[in] Open price. Required unnamed parameter.

price_close

[in] Close price. Required unnamed parameter.

Return Value

Real value if successful, otherwise None. The error info can be obtained using last_error().

Note

The function allows estimating a trading operation result on the current account and in the current trading environment. The function is similar to OrderCalcProfit.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal

```

See also

order_calc_margin, order_check

© 2000-2025, MetaQuotes Ltd.

order_check

Check funds sufficiency for performing a required trading operation. Check result are returned as the MqlTradeCheckResult structure.

```
order_check(
   request      // request structure
   );
```

Parameters

request

[in] MqlTradeRequest type structure describing a required trading action. Required unnamed parameter. Example of filling in a request and the enumeration content are described below.

Return Value

Check result as the MqlTradeCheckResult structure. The *request* field in the answer contains the structure of a trading request passed to order_check().

Note

Successful sending of a request **does not entail that the requested trading operation will be executed successfully**. The order_check function is similar to OrderCheck.

TRADE_REQUEST_ACTIONS

ID	Description
TRADE_ACTION_DEAL	Place an order for an instant deal with the specified parameters (set a market order)
TRADE_ACTION_PENDING	Place an order for performing a deal at specified conditions (pending order)
TRADE_ACTION_SLTP	Change open position Stop Loss and Take Profit
TRADE_ACTION_MODIFY	Change parameters of the previously placed trading order
TRADE_ACTION_REMOVE	Remove previously placed pending order
TRADE_ACTION_CLOSE_BY	Close a position by an opposite one

ORDER_TYPE_FILLING

ID	Description
ORDER_FILLING_FOK	This execution policy means that an order can be executed only in the specified volume. If the necessary amount of a financial instrument is currently unavailable in the market, the order will not be executed. The desired volume can be made up of several available offers.
ORDER_FILLING_IOC	An agreement to execute a deal at the maximum volume available in the market within the volume specified in the order. If the request cannot be filled completely, an order

© 2000-2025, MetaQuotes Ltd.

ID	Description
	with the available volume will be executed, and the remaining volume will be canceled.
ORDER_FILLING_RETURN	This policy is used only for market (ORDER_TYPE_BUY and ORDER_TYPE_SELL), limit and stop limit orders (ORDER_TYPE_BUY_LIMIT, ORDER_TYPE_SELL_LIMIT, ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT) and only for the symbols with Market or Exchange execution modes. If filled partially, a market or limit order with the remaining volume is not canceled, and is processed further. During activation of the ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT orders, an appropriate limit order ORDER_TYPE_BUY_LIMIT/ORDER_TYPE_SELL_LIMIT with the ORDER_FILLING_RETURN type is created.

ORDER_TYPE_TIME

ID	Description
ORDER_TIME_GTC	The order stays in the queue until it is manually canceled
ORDER_TIME_DAY	The order is active only during the current trading day
ORDER_TIME_SPECIFIED	The order is active until the specified date
ORDER_TIME_SPECIFIED_DAY	The order is active until 23:59:59 of the specified day. If this time appears to be out of a trading session, the expiration is processed at the nearest trading time.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal

order_send

Send a request to perform a trading operation from the terminal to the trade server. The function is similar to OrderSend.

```
order_send(
   request      // request structure
   );
```

Parameters

request

[in] MqlTradeRequest type structure describing a required trading action. Required unnamed parameter. Example of filling in a request and the enumeration content are described below.

Return Value

Execution result as the MqlTradeResult structure. The *request* field in the answer contains the structure of a trading request passed to order_send(). The info on the error can be obtained using last_error().

The MqlTradeRequest **trading request structure**

Field	Description
action	Trading operation type. The value can be one of the values of the TRADE_REQUEST_ACTIONS enumeration
magic	EA ID. Allows arranging the analytical handling of trading orders. Each EA can set a unique ID when sending a trading request
order	Order ticket. Required for modifying pending orders
symbol	The name of the trading instrument, for which the order is placed. Not required when modifying orders and closing positions
volume	Requested volume of a deal in lots. A real volume when making a deal depends on an order execution type.
price	Price at which an order should be executed. The price is not set in case of market orders for instruments of the "Market Execution" (SYMBOL_TRADE_EXECUTION_MARKET) type having the TRADE_ACTION_DEAL type
stoplimit	A price a pending Limit order is set at when the price reaches the 'price' value (this condition is mandatory). The pending order is not passed to the trading system until that moment
sl	A price a Stop Loss order is activated at when the price moves in an unfavorable direction
tp	A price a Take Profit order is activated at when the price moves in a favorable direction
deviation	Maximum acceptable deviation from the requested price, specified in points

© 2000-2025, MetaQuotes Ltd.

Field	Description
type	Order type. The value can be one of the values of the ORDER_TYPE enumeration
type_filling	Order filling type. The value can be one of the ORDER_TYPE_FILLING values
type_time	Order type by expiration. The value can be one of the ORDER_TYPE_TIME values
expiration	Pending order expiration time (for TIME_SPECIFIED type orders)
comment	Comment to an order
position	Position ticket. Fill it when changing and closing a position for its clear identification. Usually, it is the same as the ticket of the order that opened the position.
position_by	Opposite position ticket. It is used when closing a position by an opposite one (opened at the same symbol but in the opposite direction).

Note

A trading request passes several verification stages on the trade server. First, the validity of all the necessary *request* fields is checked. If there are no errors, the server accepts the order for further handling. See the OrderSend function description for the details about executing trading operations.

Example:

```
import time
import MetaTrader5 as mt5

# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ", mt5.__author__)
print("MetaTrader5 package version: ", mt5.__version__)

positions_total

Get the number of open positions.

```
positions_total()
```

Return Value

Integer value.

Note

The function is similar to PositionsTotal.

Example:

```
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())
    quit()

# check the presence of open positions
positions_total=mt5.positions_total()
if positions_total>0:
    print("Total positions=",positions_total)
else:
    print("Positions not found")

# shut down connection to the MetaTrader 5 terminal
mt5.shutdown()
```

positions_get, orders_total

© 2000-2025, MetaQuotes Ltd.

positions_get

Get open positions with the ability to filter by symbol or ticket. There are three call options.

Call without parameters. Return open positions for all symbols.

```
positions_get()
```

Call specifying a symbol open positions should be received for.

```
positions_get(
   symbol="SYMBOL"      // symbol name
)
```

Call specifying a group of symbols open positions should be received for.

```
positions_get(
   group="GROUP"        // filter for selecting positions by symbols
)
```

Call specifying a position ticket.

```
positions_get(
   ticket=TICKET        // ticket
)
```

Parameters

symbol="SYMBOL"

[in] Symbol name. Optional named parameter. If a symbol is specified, the *ticket* parameter is ignored.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only positions meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Position ticket (POSITION_TICKET). Optional named parameter.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

The function allows receiving all open positions within one call similar to the PositionsTotal and PositionSelect tandem.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that positions for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

history_orders_total

Get the number of orders in trading history within the specified interval.

```
history_orders_total(
   date_from,     // date the orders are requested from
   date_to        // date, up to which the orders are requested
   )
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

Return Value

Integer value.

Note

The function is similar to HistoryOrdersTotal.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

history_orders_get

Get orders from trading history with the ability to filter by ticket or position. There are three call options.

Call specifying a time interval. Return all orders falling within the specified interval.

```
history_orders_get(
   date_from,                 // date the orders are requested from
   date_to,                   // date, up to which the orders are requested
   group="GROUP"         // filter for selecting orders by symbols
   )
```

Call specifying the order ticket. Return an order with the specified ticket.

```
history_orders_get(
   ticket=TICKET         // order ticket
)
```

Call specifying the position ticket. Return all orders with a position ticket specified in the ORDER_POSITION_ID property.

```
history_orders_get(
   position=POSITION     // position ticket
)
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified first.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified second.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only orders meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Order ticket that should be received. Optional parameter. If not specified, the filter is not applied.

position=POSITION

[in] Ticket of a position (stored in ORDER_POSITION_ID) all orders should be received for. Optional parameter. If not specified, the filter is not applied.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

Note

© 2000-2025, MetaQuotes Ltd.

The function allows receiving all history orders within a specified period in a single call similar to the HistoryOrdersTotal and HistoryOrderSelect tandem.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. history_deals_total

Get the number of deals in trading history within the specified interval.

```
history_deals_total(
   date_from,     // date the deals are requested from
   date_to        // date, up to which the deals are requested
   )
```

Parameters

date_from

[in] Date the deals are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

date_to

[in] Date, up to which the deals are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter.

Return Value

Integer value.

Note

The function is similar to HistoryDealsTotal.

Example:

```
from datetime import datetime
import MetaTrader5 as mt5
# display data on the MetaTrader 5 package
print("MetaTrader5 package author: ",mt5.__author__)
print("MetaTrader5 package version: ",mt5.__version__)

# establish connection to MetaTrader 5 terminal
if not mt5.initialize():
    print("initialize() failed, error code =",mt5.last_error())

history_deals_get

Get deals from trading history within the specified interval with the ability to filter by ticket or position.

Call specifying a time interval. Return all deals falling within the specified interval.

```
history_deals_get(
   date_from,                 // date the deals are requested from
   date_to,                   // date, up to which the deals are requested
   group="GROUP"          // filter for selecting deals for symbols
   )
```

Call specifying the order ticket. Return all deals having the specified order ticket in the DEAL_ORDER property.

```
history_deals_get(
   ticket=TICKET          // order ticket
)
```

Call specifying the position ticket. Return all deals having the specified position ticket in the DEAL_POSITION_ID property.

```
history_deals_get(
   position=POSITION      // position ticket
)
```

Parameters

date_from

[in] Date the orders are requested from. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified first.

date_to

[in] Date, up to which the orders are requested. Set by the 'datetime' object or as a number of seconds elapsed since 1970.01.01. Required unnamed parameter is specified second.

group="GROUP"

[in] The filter for arranging a group of necessary symbols. Optional named parameter. If the group is specified, the function returns only deals meeting a specified criteria for a symbol name.

ticket=TICKET

[in] Ticket of an order (stored in DEAL_ORDER) all deals should be received for. Optional parameter. If not specified, the filter is not applied.

position=POSITION

[in] Ticket of a position (stored in DEAL_POSITION_ID) all deals should be received for. Optional parameter. If not specified, the filter is not applied.

Return Value

Return info in the form of a named tuple structure (namedtuple). Return None in case of an error. The info on the error can be obtained using last_error().

© 2000-2025, MetaQuotes Ltd.

Note

The function allows receiving all history deals within a specified period in a single call similar to the HistoryDealsTotal and HistoryDealSelect tandem.

The *group* parameter allows sorting out deals by symbols. '*' can be used at the beginning and the end of a string.

The *group* parameter may contain several comma separated conditions. A condition can be set as a mask using '*'. The logical negation symbol '!' can be used for an exclusion. All conditions are applied sequentially, which means conditions of including to a group should be specified first followed by an exclusion condition. For example, *group*="*, !EUR" means that deals for all symbols should be selected first and the ones containing "EUR" in symbol names should be excluded afterwards.

Example:

```
import MetaTrader5 as mt5
from datetime import datetime
import pandas as pd
pd.set_option('display.max_columns', 500) # number of columns to be displayed
pd.set_option('display.width', 1500)      # max table width to display
# display data on the MetaTrader 5 package

ONNX Models in Machine Learning

ONNX (Open Neural Network Exchange) is an open-source format for machine learning models. This project has several major advantages:

- ONNX is supported by large companies such as Microsoft, Facebook, Amazon and other partners.
- Its open format enables format conversions between different machine learning toolkits, while Microsoft's ONNXMLTools allows converting models to the ONNX format.
- MQL5 provides automatic data type conversion for model inputs and outputs if the passed parameter type does not match the model.
- ONNX models can be created using various machine learning tools. They are currently supported in Caffe2, Microsoft Cognitive Toolkit, MXNet, PyTorch and OpenCV. Interfaces for other popular frameworks and libraries are also available.
- With the MQL5 language, you can implement an ONNX model in a trading strategy and use it along with all the advantages of the MetaTrader 5 platform for efficient operations in the financial markets.
- Before tunning a model for live trading, you can test the model behavior on historical data in the Strategy Tester, without using third-party tools.

MQL5 provides the following functions for working with ONNX:

Function	Action
OnnxCreate	Create an ONNX session, loading a model from an *.onnx file
OnnxCreateFromBuffer	Create an ONNX session, loading a model from a data array
OnnxRelease	Close an ONNX session
OnnxRun	Run an ONNX model
OnnxGetInputCount	Get the number of inputs in an ONNX model
OnnxGetOutputCount	Get the number of outputs in an ONNX model
OnnxGetInputName	Get the name of a model's input by index
OnnxGetOutputName	Get the name of a model's output by index
OnnxGetInputTypeInfo	Get the description of the input type from the model
OnnxGetOutputTypeInfo	Get the description of the output type from the model
OnnxSetInputShape	Set the shape of a model's input data by index
OnnxSetOutputShape	Set the shape of a model's output data by index

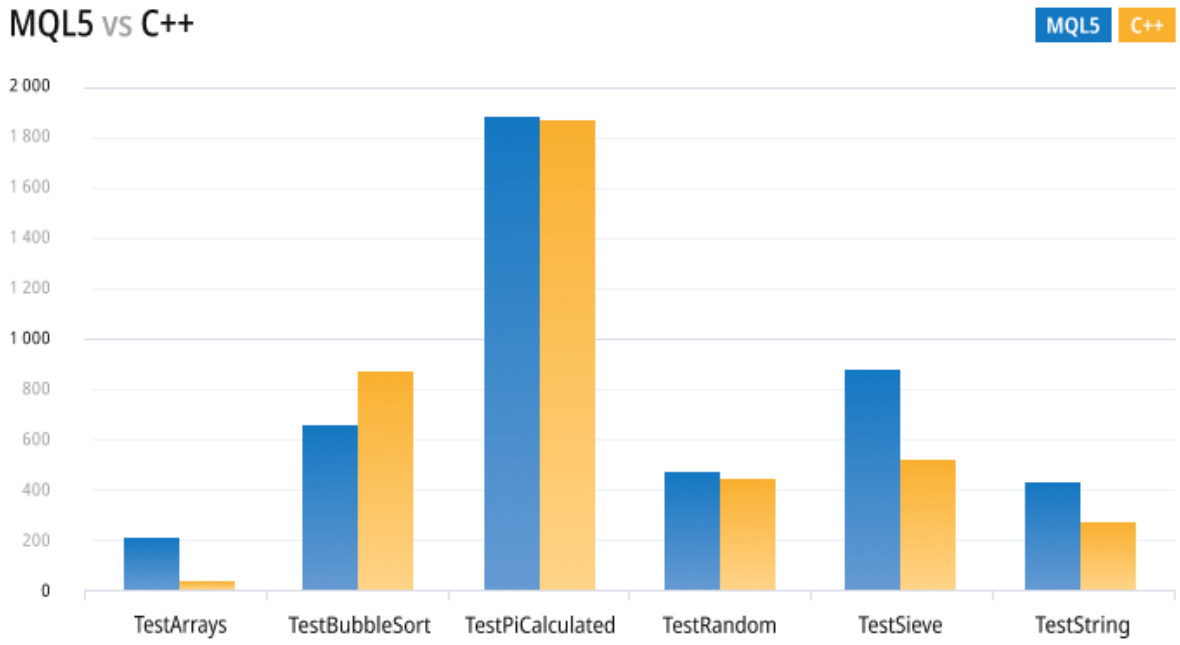
ONNX Support in MQL5

ONNX is an open format build to represent machine learning models. This standard defines a common set of operators and a common file format to enable developers to use models with different frameworks, tools, runtimes and compilers.

Thus, the open ONNX format allows you to receive and transfer machine learning models between different platforms and machine learning toolkits. The ONNX is implemented in the MQL5 language to enable AI developers to run created models in the high-performance execution environment provided by the MetaTrader 5 platform.

The MQL5 execution speed is comparable to that of C++ applications. This is proved by the execution results of standard tests on MQL5 and C++. The lower the bar, the less time (in milliseconds) spent on execution and the better the result. The tests have been conducted on Windows 10 (build 17763) x64, Xeon E5-2630 v4 @ 2.20GHz, Memory: 65457 Mb.



The new asynchronous trading operations and the native ONNX support provide you with new opportunities which were previously available only to a handful of professional AI developers and institutional traders. ONNX support in MQL5 enables traders to train models for financial market trading in their preferred development environment and then to trade with low network costs, high order book update speeds and asynchronous order submission.

Currently, ONNX is being developed and maintained by partner companies such as Microsoft, Facebook, Amazon and others, which guarantees the further development of this open project.

Format Conversion

ONNX is an open format, which allows using models from different machine learning toolkits. This format is supported by many frameworks, including Chainer, Caffee2 and PyTorch.

One of the most popular tools for converting models to the ONNX format is Microsoft's ONNXMLTools.

ONNXMLTools installation and use instructions are available at the GitHub repo. The following toolkits are currently supported:

- Keras (a wrapper of keras2onnx converter)
- Tensorflow (a wrapper of tf2onnx converter)
- scikit-learn (a wrapper of skl2onnx converter)
- Apple Core ML
- Spark ML (experimental)
- LightGBM
- libscm;
- XGBoost;
- H2O
- CatBoost

ONNXMLTools can be easily installed. For installation details and model conversion examples, please see the project page at https://github.com/onnx/onnxmltools#install.

Autoconvert input and output values when running ONNX models

The current ONNX version in MQL5 supports only tensors for input/output values. Tensors are data arrays with the elements of the following data types:

ONNX type	Corresponds to MQL5 type
ONNX_DATA_TYPE_BOOL	bool
ONNX_DATA_TYPE_FLOAT	float
ONNX_DATA_TYPE_UINT8	uchar
ONNX_DATA_TYPE_INT8	char
ONNX_DATA_TYPE_UINT16	ushort
ONNX_DATA_TYPE_INT16	short
ONNX_DATA_TYPE_INT32	int
ONNX_DATA_TYPE_INT64	long
ONNX_DATA_TYPE_FLOAT16	—
ONNX_DATA_TYPE_DOUBLE	double
ONNX_DATA_TYPE_UINT32	uint
ONNX_DATA_TYPE_UINT64	ulong
ONNX_DATA_TYPE_COMPLEX64	—
ONNX_DATA_TYPE_COMPLEX128	complex
ONNX_DATA_TYPE_BFLOAT16	—
ONNX_DATA_TYPE_STRING	—

Only arrays, vectors and matrices (we will refer to them as the **Data**) can be fed into ONNX models as input/output values.

If the parameter types does not match the ONNX model's parameter type, and the OnnxRun is called without the ONNX_NO_CONVERSION flag specified, automatic data conversion will be applied. Autoconversion implies that before running an ONNX model, user **Data** will be copied into ONNX tensors with the relevant conversion.

When an ONNX model is run without the autoconversion, the model will be calculated using the **Data** without any additional copying.

> **IMPORTANT!** Autoconversion does not control overflow (truncate), therefore you should carefully monitor the data and the data types input into the ONNX model.

Autoconversion supports the following ONNX types:

© 2000-2025, MetaQuotes Ltd.

- ONNX_DATA_TYPE_BOOL
- ONNX_DATA_TYPE_FLOAT
- ONNX_DATA_TYPE_UINT8
- ONNX_DATA_TYPE_INT8
- ONNX_DATA_TYPE_UINT16
- ONNX_DATA_TYPE_INT16
- ONNX_DATA_TYPE_INT32
- ONNX_DATA_TYPE_INT64
- ONNX_DATA_TYPE_FLOAT16
- ONNX_DATA_TYPE_DOUBLE
- ONNX_DATA_TYPE_UINT32
- ONNX_DATA_TYPE_UINT64
- ONNX_DATA_TYPE_COMPLEX64
- ONNX_DATA_TYPE_COMPLEX128

Unsupported types:

- ONNX_DATA_TYPE_BFLOAT16
- ONNX_DATA_TYPE_STRING

Autoconversion Rules by Tensor Types

If the MQL5 type is not included into the list of types supported by the model, running the ONNX model will return the ERR_ONNX_NOT_SUPPORTED error (error code 5802).

Note: During autoconversion, the color type is processed as uint, while datetime is processed as long.

Autoconversion of input values

ONNX type (tensor item type)	MQL5 type supported by autoconversion
ONNX_DATA_TYPE_BOOL	bool, char, uchar, short, ushort, int, color, uint, datetime, long, folat, double, complex During conversion, **Data** elements are checked by a simple comparison against 0
ONNX_DATA_TYPE_FLOAT16	float, double
ONNX_DATA_TYPE_FLOAT	char, uchar, short, ushort, int, color, uint, datetime, long, ulong, float, double
ONNX_DATA_TYPE_UINT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT8	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT16	See ONNX_DATA_TYPE_FLOAT

© 2000-2025, MetaQuotes Ltd.

ONNX type (tensor item type)	MQL5 type supported by autoconversion
ONNX_DATA_TYPE_INT16	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT32	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_INT64	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_DOUBLE	See ONNX_DATA_TYPE_FLOAT
ONNX_DATA_TYPE_UINT32	See ONNX_DATA_TYPE_FLOAT

Creating a Model

Multiple methods are available to obtain a ready model in the ONNX format. The popular ONNX Model Zoo library contains several pre-trained ONNX models for different types of tasks. The advantage of this collection is that each model's notebook contains links to the training dataset and references to the original paper that describes the model architecture.

Most machine learning frameworks use Python. To install the ONNX runtime for Python, use one of the following commands:

```
pip install onnxruntime        # CPU build
pip install onnxruntime-gpu    # GPU build
```

To invoke the ONNX runtime in Python, use the following command

```
import onnxruntime
session = onnxruntime.InferenceSession("path to model")
```

For model inputs and outputs, check out the relevant model's documentation. You can also use visualization tools to view the model, such as Netron or WinML Dashboard. In the ONNX runtime, you can also query a model's metadata and its inputs and outputs:

```
results = session.run(["output1", "output2"], {
                      "input1": indata1, "input2": indata2})
results = session.run([], {"input1": indata1, "input2": indata2})
```

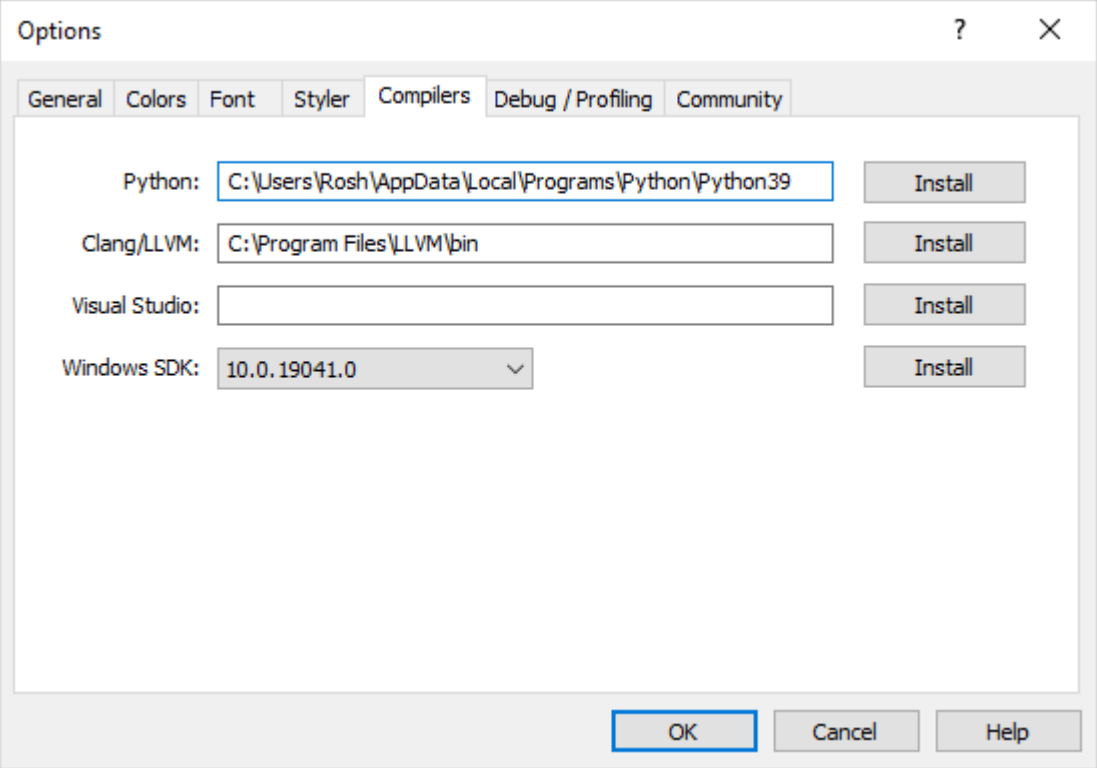
You can create ONNX models directly in the MetaTrader 5 terminal or in MetaEditor using Python.

Python in MetaTrader 5

The MetaTrader 5 provides out-of-the-box support for Python scripts. To enable these operations, the terminal developers provide MetaTrader5 module for Python: https://pypi.org/project/MetaTrader5.

In the MetaEditor integrated development environment, in addition to creating applications in MQL5, you can also run Python scripts directly from the editor. To do this, specify the path to the executable in MetaEditor settings:

© 2000-2025, MetaQuotes Ltd.



If Python is not installed on your computer, click Install to download the installation file.

You can create a Python script in MetaEdtior or upload it to the terminal's data folder and immediately run it using the F7 (Compile) key. This will open the MetaTrader 5 terminal with the script running on the current chart. Messages from the Python console (stdout, stderr) will be displayed under the Errors section.

Operations with models in MetaTrader 5

The MQL5 language allows you to run ONNX models directly in the MetaTrader 5 terminal. This is done in three steps:

1. Train the model in a third-party platform, such as Python.
2. Convert the model to ONNX.
3. Include the ONNX model into an Expert Advisor using ONNX function and run in the MetaTrader 5 terminal.

Python integration in MQL5 allows running a python script and saving an ONNX model in the MetaEditor or run it directly on a chart in MetaTrader 5. You can train the model using a pre-written Python script as often as you need right in the terminal. The library includes ready-made functions for obtaining price data, which can be input into an ONNX model:

- copy_rates_from - get bars starting from the specified date
- copy_rates_from_pos - get bars starting from the specified index
- copy_rates_range - get bars for the specified date range
- copy_ticks_from - get ticks starting from the specified date
- copy_ticks_range - get ticks for the specified date range

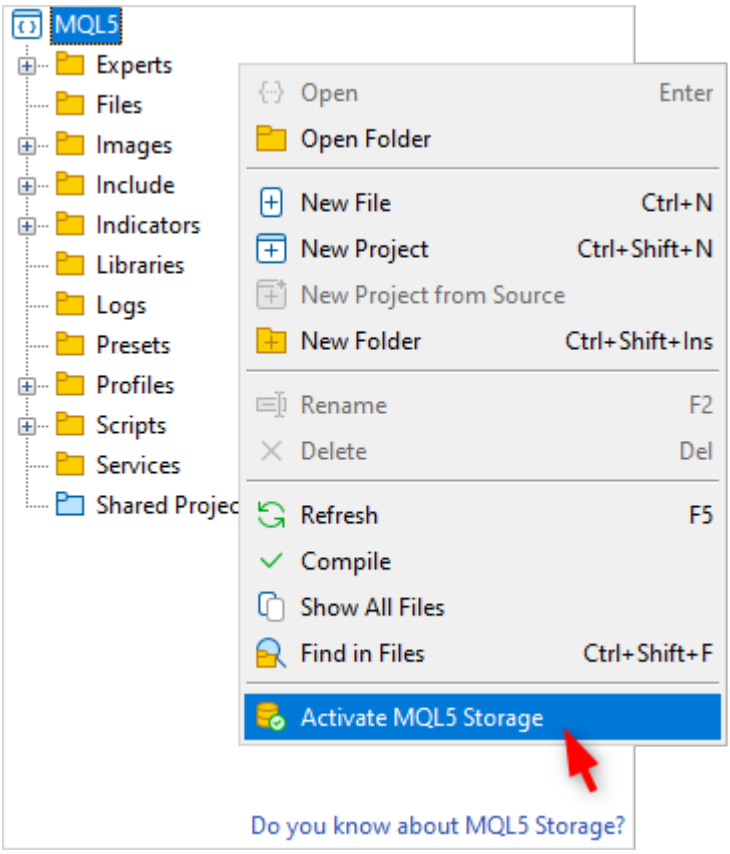
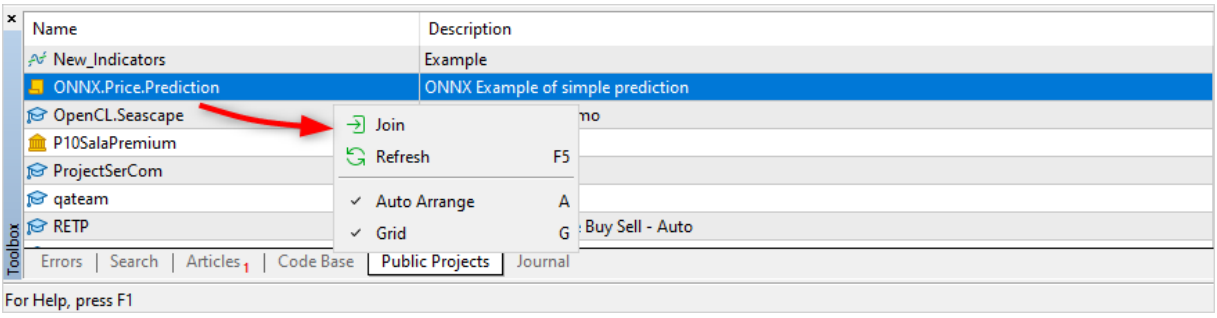
Model example

En example of a finished ONNX model is available in public projects. You should first activate MQL5 Storage in the Navigator by specifying you MQL5 login in MetaEditor settings (case sensitive).

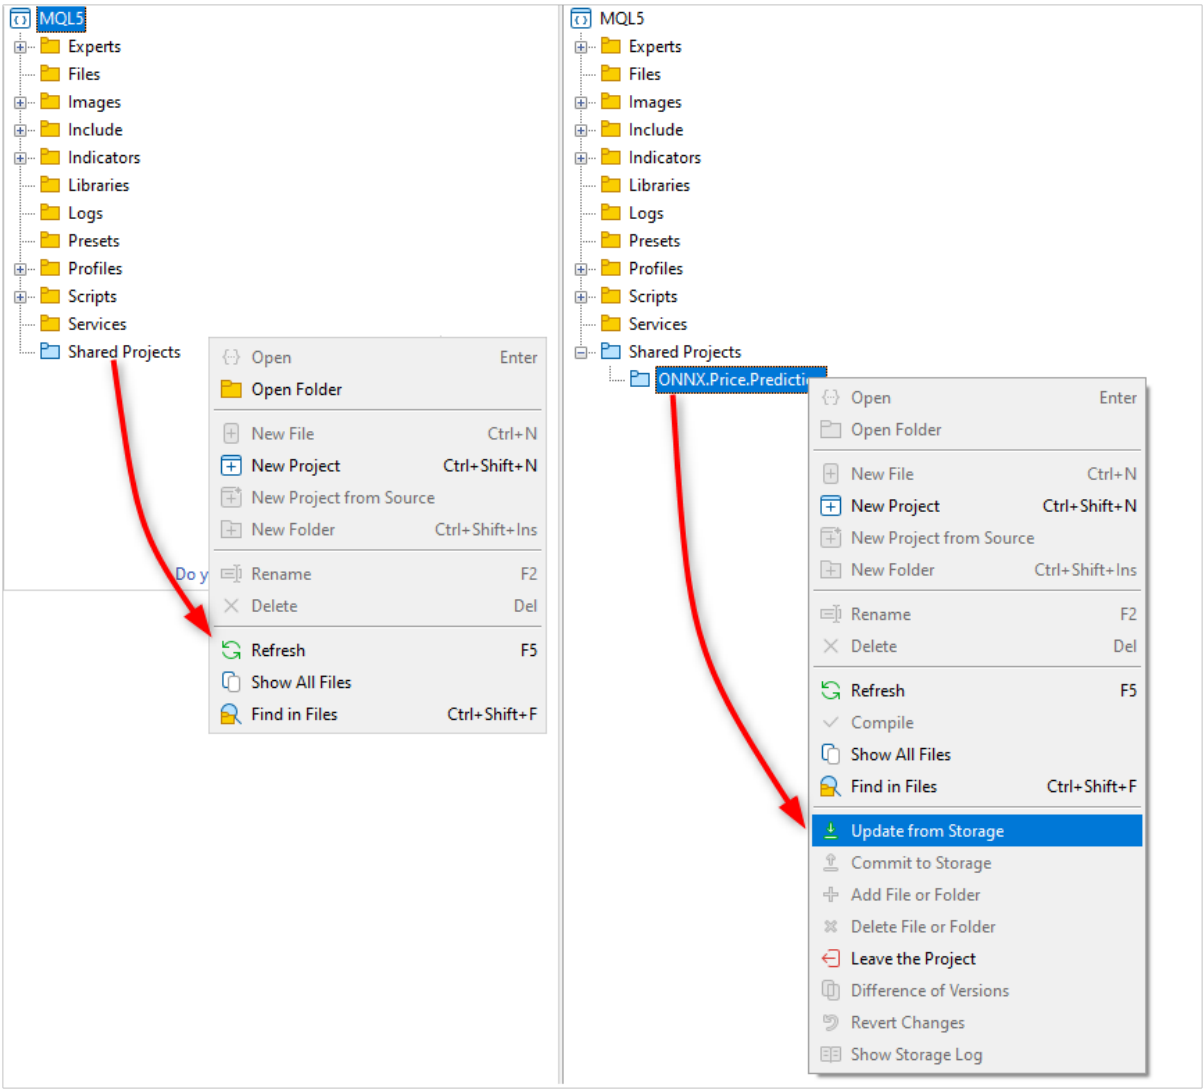


After activation, find the ONNX.Price.Prediction project and join it via the context menu command.

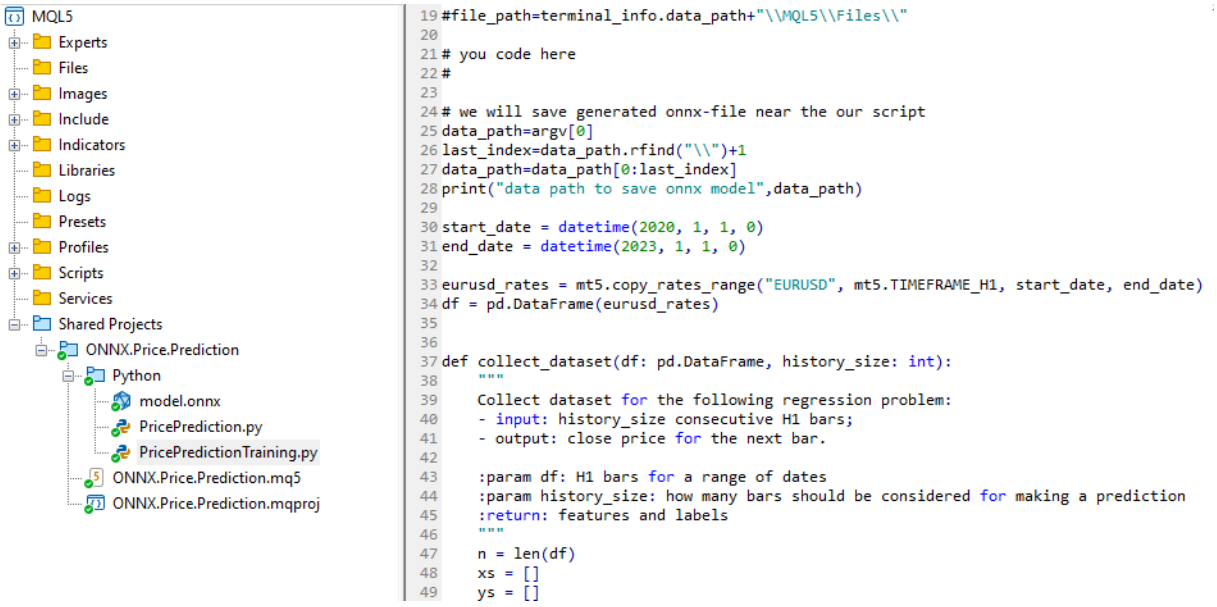


Next, update the project from MQL5 Storage.

© 2000-2025, MetaQuotes Ltd.



The project contains an ONNX model, two python scripts, an MQL5 script for project operation, and an MQL5 project file (ONNX.Price.Prediction.mqproj).



```
#file_path=terminal_info.data_path+"\\MQL5\\Files\\"

# you code here
#

# we will save generated onnx-file near the our script
data_path=argv[0]
last_index=data_path.rfind("\\")+1
data_path=data_path[0:last_index]
print("data path to save onnx model",data_path)

start_date = datetime(2020, 1, 1, 0)
end_date = datetime(2023, 1, 1, 0)

eurusd_rates = mt5.copy_rates_range("EURUSD", mt5.TIMEFRAME_H1, start_date, end_date)
df = pd.DataFrame(eurusd_rates)

def collect_dataset(df: pd.DataFrame, history_size: int):
    """
    Collect dataset for the following regression problem:
    - input: history_size consecutive H1 bars;
    - output: close price for the next bar.

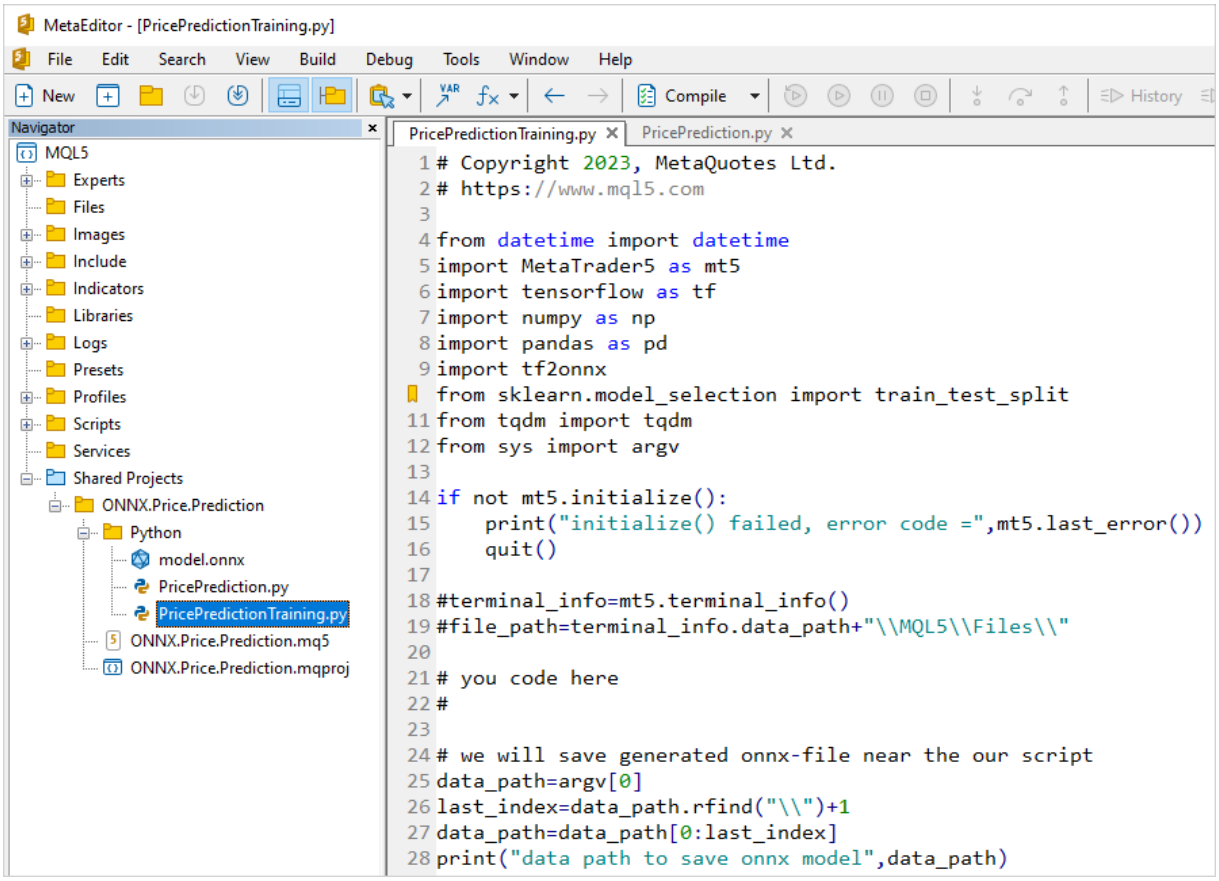
    :param df: H1 bars for a range of dates
    :param history_size: how many bars should be considered for making a prediction
    :return: features and labels
    """
    n = len(df)
    xs = []
    ys = []
```

© 2000-2025, MetaQuotes Ltd.

You can create the ONNX model yourself using the PricePredictionTraining.py script included in the project. To do this, you should first install the required modules from the command line.

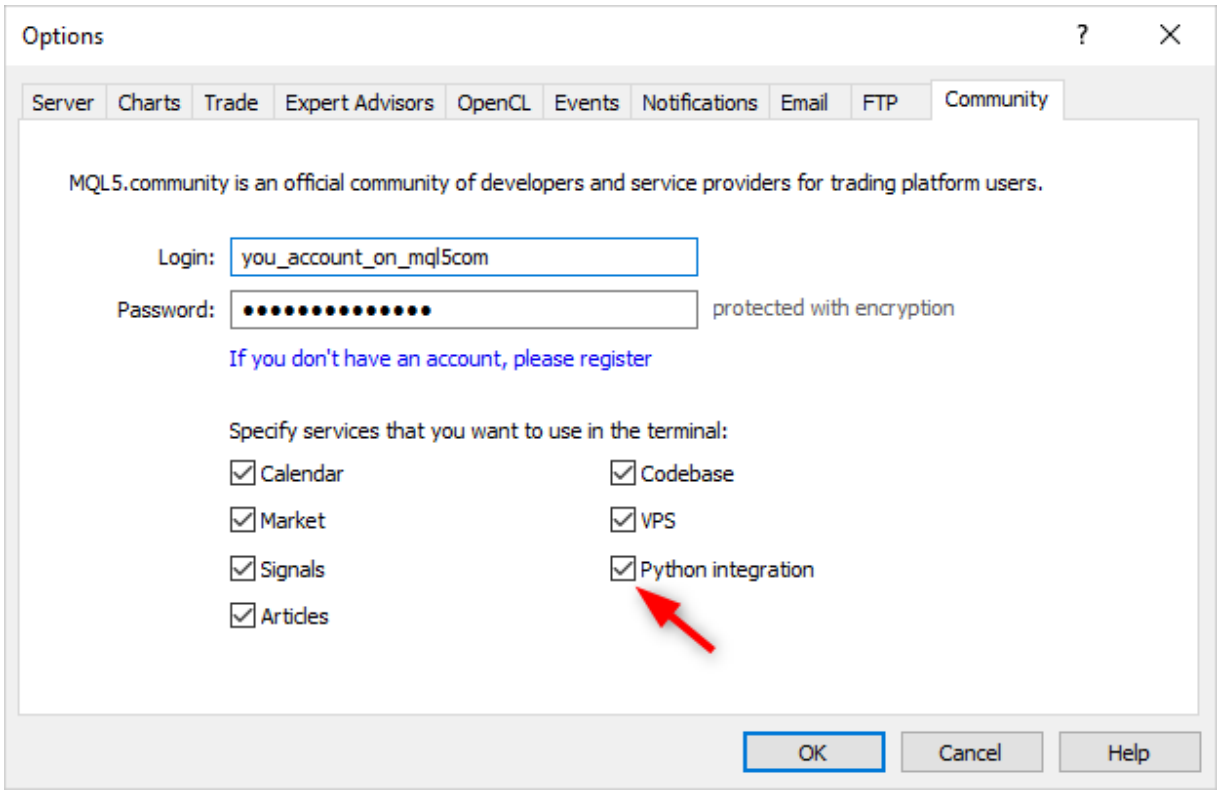
```
python.exe -m pip install --upgrade pip
python -m pip install --upgrade tensorflow
python -m pip install --upgrade pandas
python -m pip install --upgrade scikit-learn
python -m pip install --upgrade matplotlib
python -m pip install --upgrade tqdm
python -m pip install --upgrade metatrader5
python -m pip install --upgrade onnx==1.12
python -m pip install --upgrade tf2onnx
python -m pip install --upgrade numpy
python -m pip install onnxruntime
```

After installing the modules, open the PricePredictionTraining.py script in MetaEditor and run it with the Compile button or with the F7 key.



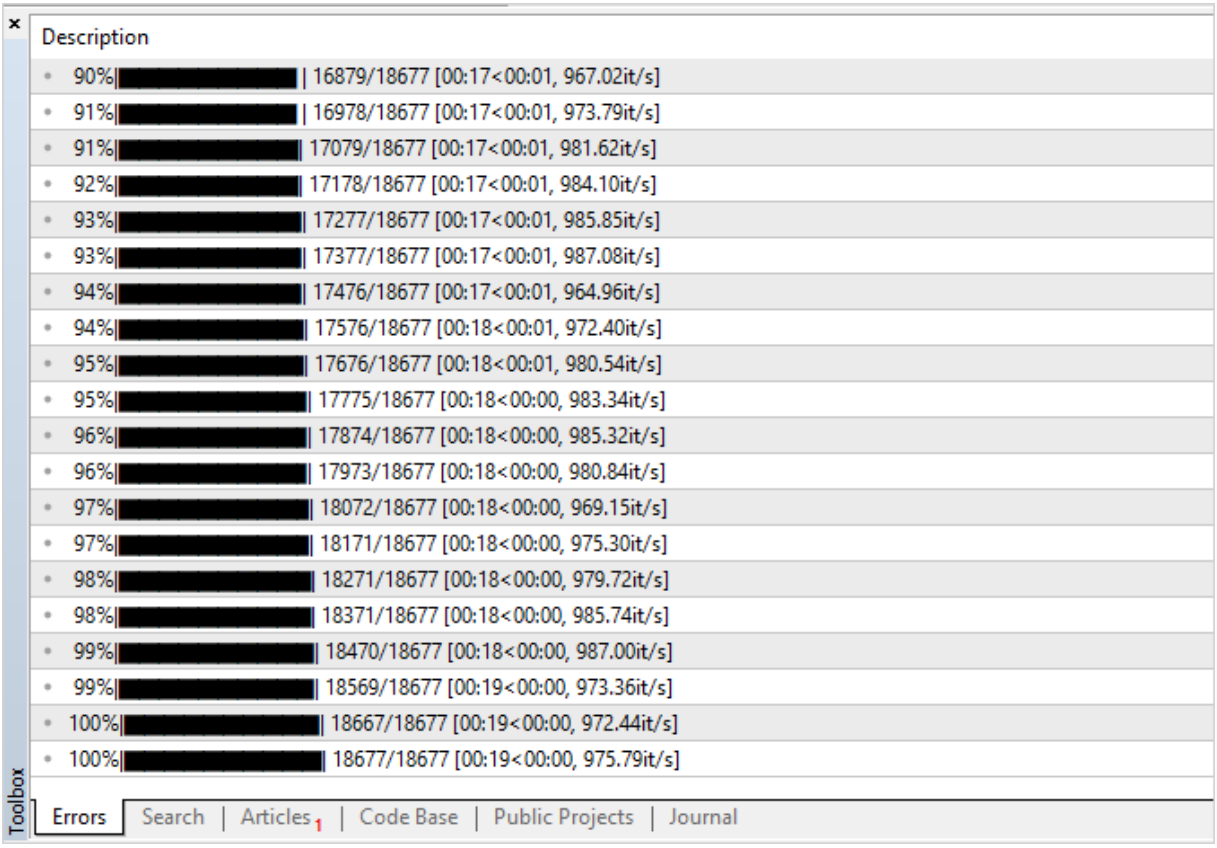
© 2000-2025, MetaQuotes Ltd.

Before running the Python script, make sure that the MetaTrader 5 terminal is connected to a server with the EURUSD symbol available. For example, connect to the MetaQuotes-Demo server and check "Integration with Python" in terminal settings.



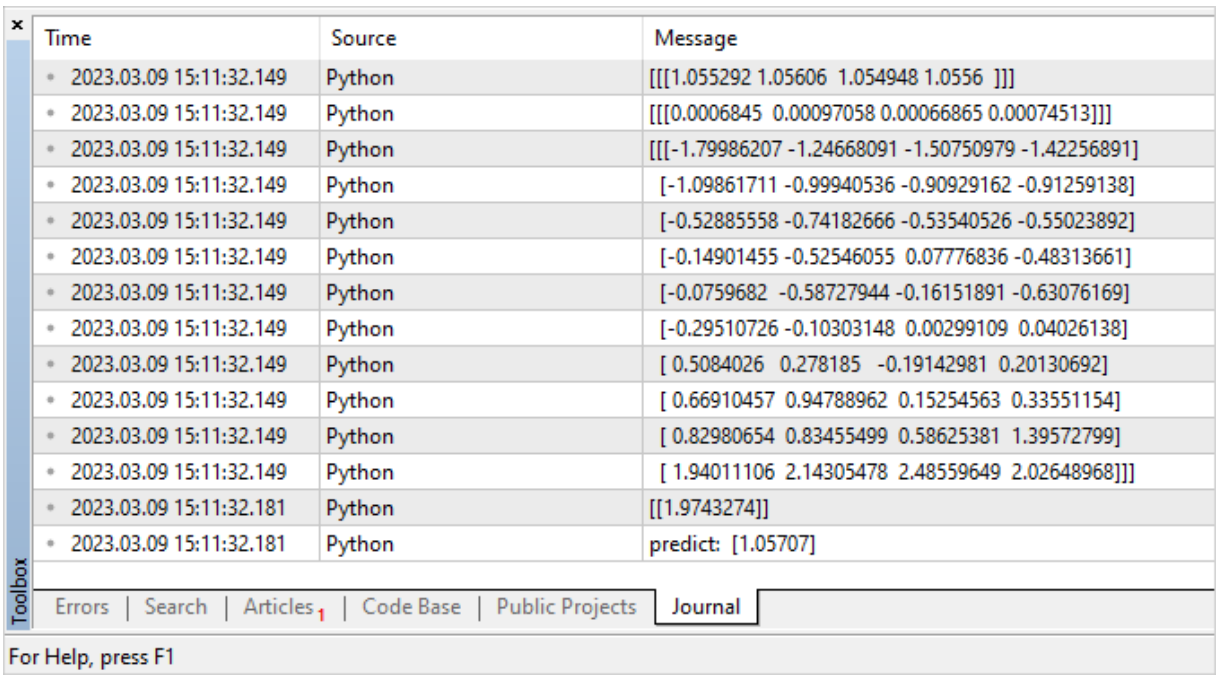
While training the network, MetaEditor will print messages from the Python script until the training is complete.

© 2000-2025, MetaQuotes Ltd.



When the result is 100%, the ONNX model is ready and it is saved to the project folder at <terminal data directory>\MQL5\Shared Projects\ONNX.Price.Prediction\Python.

You can check the resulting model by running the second script PricePrediction.py, pressing **F7**.



© 2000-2025, MetaQuotes Ltd.

Running a model

To run an ONNX model in MQL5, complete 3 steps:

1. Load the model from an *.onnx file using the OnnxCreate function or from an array using OnnxCreateFromBuffer.
2. Specify input and output data shapes using OnnxSetInputShape and OnnxSetOutputShape functions.
3. Run the model using the OnnxRun function, passing to it the relevant input and output parameters.
4. When needed, you can terminate the model operation using the OnnxRelease function.

When creating an ONNX model, you should consider the existing limits and restrictions, which are described at https://github.com/microsoft/onnxruntime/blob/rel-1.14.0/docs/OperatorKernels.md

Some of the examples of such restrictions are shown below:

Operation	Supported data types
ReduceSum	tensor(double), tensor(float), tensor(int32), tensor(int64)
Mul	tensor(bfloat16), tensor(double), tensor(float), tensor(float16), tensor(int32), tensor(int64), tensor(uint32), tensor(uint64)

Below is an MQL5 code example from the public project ONNX.Price.Prediction.

```
const long   ExtOutputShape[] = {1,1};     // model's output shape
const long   ExtInputShape [] = {1,10,4}; // model's input shape
#resource "Python/model.onnx" as uchar ExtModel[]// model as a resource
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart(void)
  {
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,2,10))
      return(-1);
//--- input a set of OHLC vectors
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
```

© 2000-2025, MetaQuotes Ltd.

```
   x_norm-=mm;
   x_norm/=ms;
//--- create the model
   long handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- print the output value of the model to the log
   Print(y_norm);
//--- do the reverse transformation to get the predicted price
   double y_pred=y_norm[0]*s[3]+m[3];
   Print("price predicted:",y_pred);
//--- complete operation
   OnnxRelease(handle);
   return(0);
  }
```

Script run example:

```
ONNX: Creating and using per session threadpools since use_per_session_threads_ is tru
ONNX: Dynamic block base set to 0
ONNX: Initializing session.
ONNX: Adding default CPU execution provider.
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Total shared scalar initializer count: 0
```

© 2000-2025, MetaQuotes Ltd.

```
ONNX: Total fused reshape node count: 0
ONNX: Use DeviceBasedPartition as default
ONNX: Saving initialized tensors.
ONNX: Done saving initialized tensors
ONNX: Session successfully initialized.
[0.28188983]
predicted 1.0559258806393044
```

The MetaTrader 5 terminal has selected the optimal executor for calculations — ONNX Runtime Execution Provider. In this example, the model was executed on the CPU.

Let's modify the script to calculate the percentage of successful Close price predictions made based on the values of the preceding 10 bars.

```
#resource "Python/model.onnx" as uchar ExtModel[]// model as a resource

#define TESTS 10000  // number of test datasets
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart()
  {
//--- create the model
   long session_handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
   if(session_handle==INVALID_HANDLE)
     {
      Print("Cannot create model. Error ",GetLastError());
      return(-1);
     }

//--- since the input tensor size is not defined for the model, specify it explicitly
//--- first index is batch size, second index is series size, third index is number of
   const long input_shape[]={1,10,4};
   if(!OnnxSetInputShape(session_handle,0,input_shape))
     {
      Print("OnnxSetInputShape error ",GetLastError());
      return(-2);
     }

//--- since the output tensor size is not defined for the model, specify it explicitly
//--- first index is batch size, must match the batch size in the input tensor
//--- second index is number of predicted prices (only Close is predicted here)
   const long output_shape[]={1,1};
   if(!OnnxSetOutputShape(session_handle,0,output_shape))
     {
      Print("OnnxSetOutputShape error ",GetLastError());
      return(-3);
     }
//--- run tests
   vector closes(TESTS);      // vector to store validation prices
```

© 2000-2025, MetaQuotes Ltd.

```
   vector predicts(TESTS);     // vector to store obtained predictions
   vector prev_closes(TESTS); // vector to store preceding prices

   matrix rates;              // matrix to get the OHLC series
   matrix splitted[2];        // two submatrices to divide the series into test and va
   ulong  parts[]={10,1};     // sizes of divided submatrices

//--- start from the previous bar
   for(int i=1; i<=TESTS; i++)
     {
      //--- get 11 bars
      rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,i,11);
      //--- divide the matrix into test and validation
      rates.Vsplit(parts,splitted);
      //--- take the Close price from the validation matrix
      closes[i-1]=splitted[1][3][0];
      //--- last Close in the tested series
      prev_closes[i-1]=splitted[0][3][9];

      //--- submit the test matrix of 10 bars to testing
      predicts[i-1]=PricePredictionTest(session_handle,splitted[0]);
      //--- runtime error
      if(predicts[i-1]<=0)
        {
         OnnxRelease(session_handle);
         return(-4);
        }
     }
//--- complete operation
   OnnxRelease(session_handle);
//--- evaluate if price movement was predicted correctly
   int    right_directions=0;
   vector delta_predicts=prev_closes-predicts;
   vector delta_actuals=prev_closes-closes;

   for(int i=0; i<TESTS; i++)
      if((delta_predicts[i]>0 && delta_actuals[i]>0) || (delta_predicts[i]<0 && delta_
         right_directions++;
   PrintFormat("right direction predictions = %.2f%%",(right_directions*100.0)/double
//---
   return(0);
  }
//+------------------------------------------------------------------+
//|  Prepare the data and run the model                              |
//+------------------------------------------------------------------+
double PricePredictionTest(const long session_handle,matrix& rates)
  {
   static matrixf input_data(10,4); // matrix for the transformed input
   static vectorf output_data(1);   // vector to receive the result
```

© 2000-2025, MetaQuotes Ltd.

```
   static matrix mm(10,4);          // matrix of horizontal vectors Mean
   static matrix ms(10,4);          // matrix of horizontal vectors Std

//--- a set of OHLC vertical vectors must be input into the model
   matrix x_norm=rates.Transpose();
//--- normalize prices
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
   x_norm-=mm;
   x_norm/=ms;

//--- run the model
   input_data.Assign(x_norm);
   if(!OnnxRun(session_handle,ONNX_DEBUG_LOGS,input_data,output_data))
     {
      Print("OnnxRun error ",GetLastError());
      return(0);
     }
//--- unnormalize the price from the output value
   double y_pred=output_data[0]*s[3]+m[3];

   return(y_pred);
  }
```

Run the script: the prediction accuracy is about 51%

```
ONNX: Creating and using per session threadpools since use_per_session_threads_ is tru
ONNX: Dynamic block base set to 0
ONNX: Initializing session.
ONNX: Adding default CPU execution provider.
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Total shared scalar initializer count: 0
ONNX: Total fused reshape node count: 0
ONNX: Use DeviceBasedPartition as default
ONNX: Saving initialized tensors.
ONNX: Done saving initialized tensors
ONNX: Session successfully initialized.
right direction predictions = 51.34 %
```

Model validation in the Strategy Tester

Models created for operations in the financial markets can be validated in the MetaTrader 5 terminal Strategy Tester. This is the fastest and most convenient option, which eliminates the need to additionally emulate the market environment and trading conditions.

To test the model, let us create an Expert Advisor based on the code from the public project ONNX.Price.Prediction. This will require some edits.

Move the model creation to the OnInit function. The onnx session will be closed in OnDeinit. Locate the main model operations block to the OnTick handler.

Also, add obtaining of the Close price of the previous two bars, which is needed to compare the actual Close price and the prediction.

The Expert Advisor code is small and easy to read.

```
const long   ExtInputShape [] = {1,10,4}; // model's input shape
const long   ExtOutputShape[] = {1,1};    // model's output shape
#resource "Python/model.onnx" as uchar ExtModel[];// model as a resource

long handle;          // model handle
ulong predictions=0; // predictions counter
ulong confirmed=0;   // successful predictions counter
//+------------------------------------------------------------------+
//| Expert initialization function                                   |
//+------------------------------------------------------------------+
int OnInit()
  {
//--- basic checks
   if(_Symbol!="EURUSD")
     {
      Print("Symbol must be EURUSD, testing aborted");
      return(-1);
     }
   if(_Period!=PERIOD_H1)
     {
      Print("Timeframe must be H1, testing aborted");
      return(-1);
     }
//--- create the model
   handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

© 2000-2025, MetaQuotes Ltd.

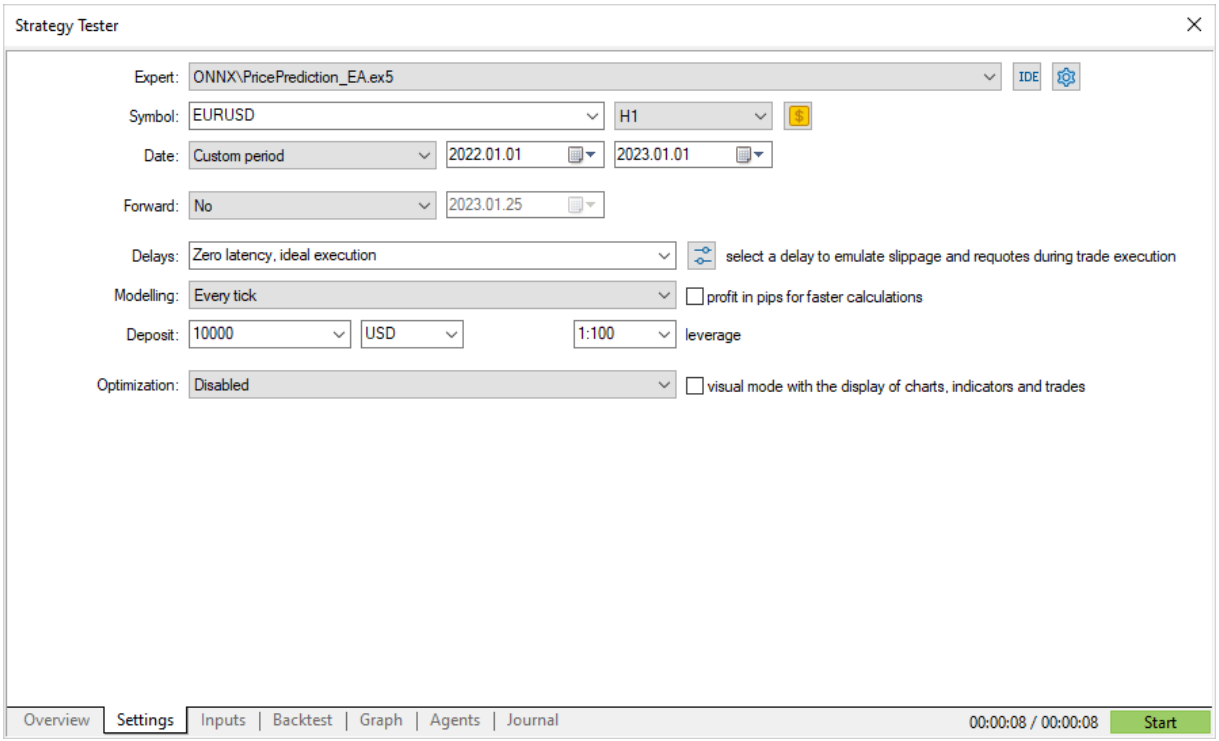
```
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//---
   return(INIT_SUCCEEDED);
  }
//+------------------------------------------------------------------+
//| Expert deinitialization function                                 |
//+------------------------------------------------------------------+
void OnDeinit(const int reason)
  {
//--- complete model operation
   OnnxRelease(handle);
//--- calculate and output prediction statistics
   PrintFormat("Successfull predictions = %.2f %%",confirmed*100./double(predictions));
  }
//+------------------------------------------------------------------+
//| Expert tick function                                             |
//+------------------------------------------------------------------+
void OnTick()
  {
   static datetime open_time=0;
   static double predict;
//--- check the current bar opening time
   datetime time=iTime(_Symbol,_Period,0);
   if(time==0)
     {
      PrintFormat("Failed to get Time(0), error %d", GetLastError());
      return;
     }
//--- if the opening time has not changed, exit until the next OnTick call
   if(time==open_time)
      return;
//--- get the Close prices of the last two completed bars
   double close[];
   int recieved=CopyClose(_Symbol,_Period,1,2,close);
   if(recieved!=2)
     {
      PrintFormat("CopyClose(2 bars) failed, error %d",GetLastError());
      return;
     }
   double delta_predict=predict-close[0]; // predicted price change
   double delta_actual=close[1]-close[0]; // actual price change
   if((delta_predict>0 && delta_actual>0) || (delta_predict<0 && delta_actual<0))
      confirmed++;
```

© 2000-2025, MetaQuotes Ltd.

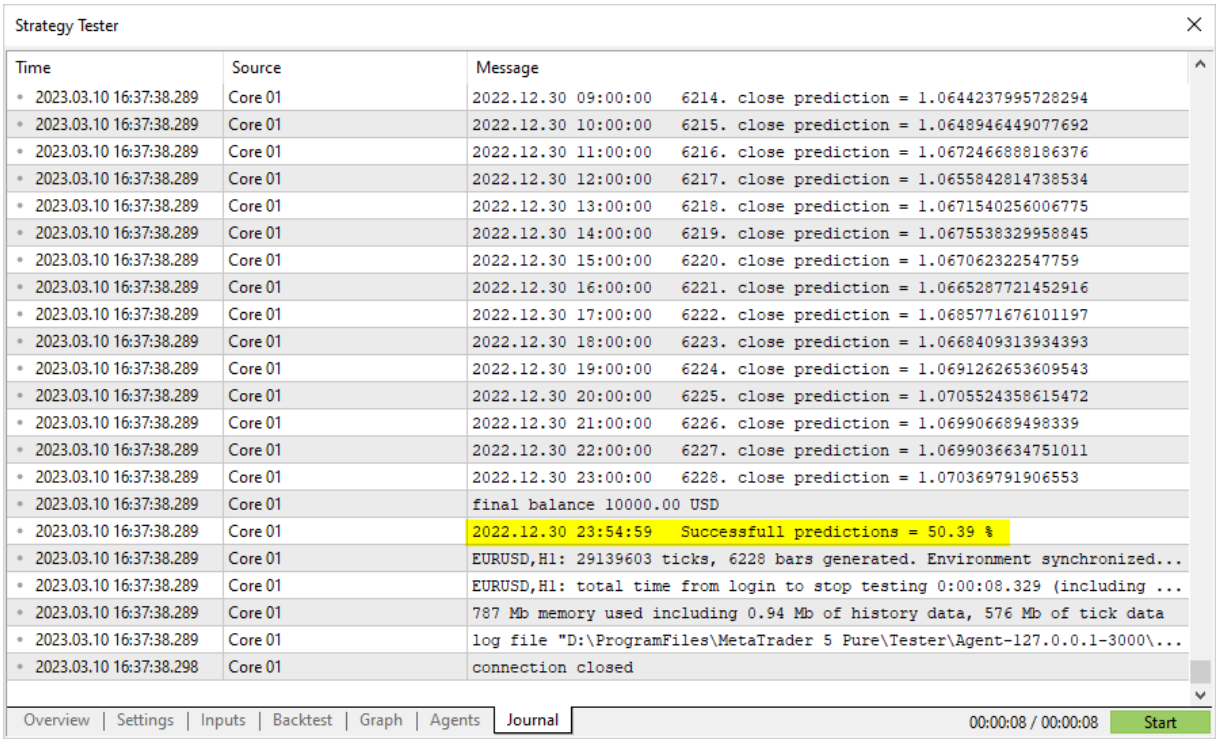
```
//--- calculate the Close price on the new bar to validate the price on the next bar
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,1,10))
      return;
//--- input a set of OHLC vectors
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
   x_norm-=mm;
   x_norm/=ms;
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
     }
//--- do reverse transformation to get the predicted price and to validate it on a new
   predict=y_norm[0]*s[3]+m[3];
   predictions++;  // increase predictions counter
   Print(predictions,". close prediction = ",predict);
//--- save the bar opening time to check on the next tick
   open_time=time;
  }
```

Compile the Expert Advisor and run testing in the period of year 2022. Specify EURUSD with the H1 timeframe, which is the data on which the model was trained. The tick modeling mode can be ignores, since the code checks the emergence of a new bar.

© 2000-2025, MetaQuotes Ltd.



Run and check the result in the testing journal. It shows that a little more than 50% of ppredictions were correct in 2022.



If the preliminary model testing has generated satisfactory results, you can start writing a full-fledged trading strategy based on this model.

© 2000-2025, MetaQuotes Ltd.

OnnxCreate

Create an ONNX session, loading a model from an *.onnx file.

```
long  OnnxCreate(
   string  filename,  // file path
   uint    flags      // flags to create the model
   );
```

Parameters

filename

[in] Path to the *.onnx file of the model relative to the \MQL5\Files\ folder.

flags

[in] Flags from ENUM_ONNX_FLAGS, describing the model creation mode: ONNX_COMMON_FOLDER and ONNX_DEBUG_LOGS.

Return Value

The handle of the created session or INVALID_HANDLE if error occurs. To obtain the error code, call the GetLastError function.

Note

If the specified file is not found on disk, the system retries to open the file, appending the '.onnx' extension to the name.

© 2000-2025, MetaQuotes Ltd.

OnnxCreateFromBuffer

Create an ONNX session, loading a model from a data array.

```
long  OnnxCreateFromBuffer(
   const uchar&  buffer[],   // array reference
   ulong         flags       // model creation flags
   );
```

Parameters

buffer

[in] Array with ONNX model data.

flags

[in] Flags from ENUM_ONNX_FLAGS, describing the model creation mode: ONNX_COMMON_FOLDER and ONNX_DEBUG_LOGS.

Return Value

The handle of the created session or INVALID_HANDLE if error occurs. To obtain the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxRelease

Close an ONNX session.

```
bool  OnnxRelease(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxRun

Run an ONNX model.

```
bool  OnnxRun(
   long    onnx_handle,  // ONNX session handle
   ulong   flags,        // flags describing the run mode
   ...                   // model's inputs and outputs
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

flags

[in] Flags from ENUM_ONNX_FLAGS describing the run mode: ONNX_DEBUG_LOGS and ONNX_NO_CONVERSION.

...

[in] [out] Model inputs and outputs.

Returns true on success or false otherwise. To obtain the error code, call the GetLastError function.

ENUM_ONNX_FLAGS

ID	Description
ONNX_DEBUG_LOGS	Output debug logs
ONNX_NO_CONVERSION	Disable auto conversion, use user data as is
ONNX_COMMON_FOLDER	Load a model file from the Common\Files folder; the value is equal to the FILE_COMMON flag

Example:

```
const long                              ExtOutputShape[] = {1,1};     // model output sh
const long                              ExtInputShape [] = {1,10,4}; // model input for
#resource "Python/model.onnx" as uchar ExtModel[]                    // model as resour
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
int OnStart(void)
  {
   matrix rates;
//--- get 10 bars
   if(!rates.CopyRates("EURUSD",PERIOD_H1,COPY_RATES_OHLC,2,10))
      return(-1);
//--- input a set of OHLC vectors
```

© 2000-2025, MetaQuotes Ltd.

```
   matrix x_norm=rates.Transpose();
   vector m=x_norm.Mean(0);
   vector s=x_norm.Std(0);
   matrix mm(10,4);
   matrix ms(10,4);
//--- fill in the normalization matrices
   for(int i=0; i<10; i++)
     {
      mm.Row(m,i);
      ms.Row(s,i);
     }
//--- normalize the input data
   x_norm-=mm;
   x_norm/=ms;
//--- create the model
   long handle=OnnxCreateFromBuffer(ExtModel,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("OnnxSetInputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("OnnxSetOutputShape failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- convert normalized input data to float type
   matrixf x_normf;
   x_normf.Assign(x_norm);
//--- get the output data of the model here, i.e. the price prediction
   vectorf y_norm(1);
//--- run the model
   if(!OnnxRun(handle,ONNX_DEBUG_LOGS | ONNX_NO_CONVERSION,x_normf,y_norm))
     {
      Print("OnnxRun failed, error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- print the output value of the model to the log
   Print(y_norm);
//--- do the reverse transformation to get the predicted price
   double y_pred=y_norm[0]*s[3]+m[3];
   Print("price predicted:",y_pred);
//--- completed operation
   OnnxRelease(handle);
```

© 2000-2025, MetaQuotes Ltd.

```
   return(0);
  };
```

OnnxGetInputCount

Get the number of inputs in an ONNX model.

```
long  OnnxGetInputCount(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns the number of input parameters on success; otherwise returns -1. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxGetOutputCount

Get the number of outputs in an ONNX model.

```
long  OnnxGetOutputCount(
   long   onnx_handle  // ONNX session handle
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

Return Value

Returns the number of output parameters on success; otherwise returns -1. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxGetInputName

Get the name of a model's input by index.

```
string  OnnxGetInputName(
   long   onnx_handle,  // ONNX session handle
   long   index         // parameter index
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the input parameter, starting with 0.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxGetOutputName

Get the name of a model's output by index.

```
string  OnnxGetOutputName(
   long   onnx_handle,  // ONNX session handle
   long   index         // parameter index
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the output parameter, starting with 0.

Return Value

Returns the name of the output parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxGetInputTypeInfo

Get the description of the input type from the model.

```
bool  OnnxGetInputTypeInfo(
   long           onnx_handle,  // ONNX session handle
   long           index,        // parameter index
   OnnxTypeInfo&  typeinfo      // parameter type description
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the input parameter, starting with 0.

typeinfo

[out] The OnnxTypeInfo structure that describes the type of the input parameter.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxGetOutputTypeInfo

Get the description of the output type from the model.

```
bool  OnnxGetOutputTypeInfo(
   long           onnx_handle,  // ONNX session handle
   long           index,        // parameter index
   OnnxTypeInfo&  typeinfo      // parameter type description
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

index

[in] Index of the output parameter, starting with 0.

typeinfo

[out] The OnnxTypeInfo structure that describes the type of the output parameter.

Return Value

Returns true on success; otherwise returns false. To get the error code, call the GetLastError function.

© 2000-2025, MetaQuotes Ltd.

OnnxSetInputShape

Set the shape of a model's input data by index.

```
bool  OnnxSetInputShape(
   long           onnx_handle,   // ONNX session handle
   long           input_index,   // input parameter index
   const ulong&   shape[]        // array describing input data shape
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

input_index

[in] Index of the input parameter, starting from 0.

shape

[in] Array describing model's input data shape.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

Example:

```
//---- describe the shapes of the model's input and output data
   const long  ExtOutputShape[] = {1,1};
   const long  ExtInputShape [] = {1,10,4};
//--- create the model
   long handle=OnnxCreateFromBuffer(model,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("failed, OnnxSetInputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("failed, OnnxSetOutputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

See also

OnnxSetOutputShape

© 2000-2025, MetaQuotes Ltd.

OnnxSetOutputShape

Set the shape of a model's output data by index.

```
bool  OnnxSetOutputShape(
   long           onnx_handle,    // ONNX session handle
   long           output_index,   // output parameter index
   const ulong&   shape[]         // array describing output data shape
   );
```

Parameters

onnx_handle

[in] ONNX session object handle created via OnnxCreate or OnnxCreateFromBuffer.

output_index

[in] Index of the output parameter, starting from 0.

shape

[in] Array describing model's output data shape.

Return Value

Returns the name of the input parameter on success; otherwise returns NULL. To get the error code, call the GetLastError function.

Example:

```
//---- describe the shapes of the model's input and output data
   const long  ExtOutputShape[] = {1,1};
   const long  ExtInputShape [] = {1,10,4};
//--- create the model
   long handle=OnnxCreateFromBuffer(model,ONNX_DEBUG_LOGS);
//--- specify the shape of the input data
   if(!OnnxSetInputShape(handle,0,ExtInputShape))
     {
      Print("failed, OnnxSetInputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
//--- specify the shape of the output data
   if(!OnnxSetOutputShape(handle,0,ExtOutputShape))
     {
      Print("failed, OnnxSetOutputShape error ",GetLastError());
      OnnxRelease(handle);
      return(-1);
     }
```

Data structures

The following data structures are used for operations with ONNX models:

OnnxTypeInfo

The structure describes the type of an input or output parameter of an ONNX model

```
struct OnnxTypeInfo
 {
  ENUM_ONNX_TYPE         type;          // parameter type
  OnnxTensorTypeInfo     tensor;        // tensor description
  OnnxMapTypeInfo        map;           // map description
  OnnxSequenceTypeInfo   sequence;      // sequence description
 };
```

Only tensor (ONNX_TYPE_TENSOR) can be used as an input. In this case, only the OnnxTypeInfo::tensor field is filled with values, while other fields (map and sequence) are not defined.

Only one of the three OnnxTypeInfo types (ONNX_TYPE_TENSOR, ONNX_TYPE_MAP or ONNX_TYPE_SEQUENCE) can be used as an input. The corresponding substructure (OnnxTypeInfo::tensor, OnnxTypeInfo::map or OnnxTypeInfo::sequence) is filled depending on the type.

OnnxTensorTypeInfo

The structure describes the tensor in the input or output parameter of an ONNX model

```
struct OnnxTensorTypeInfo
 {
  const ENUM_ONNX_DATA_TYPE   data_type;      // data type in the tensor
  const long                  dimensions[];   // number of elements in the tensor
 };
```

OnnxMapTypeInfo

The structure describes the map obtained in the output parameter of an ONNX model

```
struct OnnxMapTypeInfo
 {
  const ENUM_ONNX_DATA_TYPE   key_type;       // key type
  const OnnxTypeInfo &        value_type;     // value type
 };
```

OnnxSequenceTypeInfo

The structure describes the sequence obtained in the output parameter of an ONNX model

```
struct OnnxSequenceTypeInfo
```

© 2000-2025, MetaQuotes Ltd.

```
{
 const OnnxTypeInfo&        value_type;      // data type in the sequence
};
```

ENUM_ONNX_TYPE

The **ENUM_ONNX_TYPE** enumeration describes the type of a model parameter

ID	Description
ONNX_TYPE_UNKNOWN	Unknown
ONNX_TYPE_TENSOR	Tensor
ONNX_TYPE_SEQUENCE	Sequence
ONNX_TYPE_MAP	Map
ONNX_TYPE_OPAQUE	Abstract (opaque)
ONNX_TYPE_SPARSETENSOR	Sparse tensor

ENUM_ONNX_DATA_TYPE

The **ENUM_ONNX_DATA_TYPE** enumeration describes the type of data used

ID	Description
ONNX_DATA_TYPE_UNDEFINED	Undefined
ONNX_DATA_TYPE_FLOAT	float
ONNX_DATA_TYPE_INT8	8-bit int
ONNX_DATA_TYPE_UINT16	16-bit uint
ONNX_DATA_TYPE_INT16	16-bit int
ONNX_DATA_TYPE_INT32	32-bit int
ONNX_DATA_TYPE_INT64	64-bit int
ONNX_DATA_TYPE_STRING	string
ONNX_DATA_TYPE_BOOL	bool
ONNX_DATA_TYPE_FLOAT16	16-bit float
ONNX_DATA_TYPE_DOUBLE	double
ONNX_DATA_TYPE_UINT32	32-bit uint
ONNX_DATA_TYPE_UINT64	64-bit uint

© 2000-2025, MetaQuotes Ltd.

ID	Description
ONNX_DATA_TYPE_COMPLEX64	64-bit complex number
ONNX_DATA_TYPE_COMPLEX128	128-bit complex number
ONNX_DATA_TYPE_BFLOAT16	16-bit bfloat (Brain Floating Point)

ENUM_ONNX_FLAGS

The **ENUM_ONNX_FLAGS** enumeration describes the model run mode

ID	Description
ONNX_DEBUG_LOGS	Output debug logs
ONNX_NO_CONVERSION	Disable auto conversion, use user data as is
ONNX_COMMON_FOLDER	Load a model file from the Common\Files folder; the value is equal to the FILE_COMMON flag

Array conversion when working with ONNX models

Machine learning tasks do not always require greater computational accuracy. To speed up calculations, some models use lower-precision data types such as Float16 and even Float8. To allow users to input the relevant data into models, MQL5 provides four special functions which convert standard MQL5 types into special FP16 and FP8 types.

Function	Action
ArrayToFP16	Copies an array of type float or double into an array of type ushort with the given format
ArrayToFP8	Copies an array of type float or double into an array of type uchar with the given format
ArrayFromFP16	Copies an array of type ushort into an array of float or double type with the given format
ArrayFromFP8	Copies an array of type uchar into an array of float or double type with the given format

These array conversion functions use special formats specified in the below enumerations.

ENUM_FLOAT16_FORMAT

The **ENUM_FLOAT16_FORMAT** enumeration describes two FP16 type formats.

ID	Description
FLOAT_FP16	Standard 16-bit format, also known as half
FLOAT_BFP16	Special brain float point format

© 2000-2025, MetaQuotes Ltd.

Each of these formats has its advantages and limitations. FLOAT16 provides higher accuracy but requires more storage and computation resources. BFLOAT16, on the other hand, provides higher performance and efficiency in data processing, but may be less accurate.

ENUM_FLOAT8_FORMAT

The **ENUM_FLOAT8_FORMAT** enumeration describes four FP8 type formats.

FP8 (8-bit floating point) is one of the data types used to represent floating point numbers. In FP8, each number is represented by 8 data bits, typically divided into three components: sign, exponent and mantissa. This format offers a balance between accuracy and storage efficiency, making it attractive for applications that require memory and computational efficiency.

ID	Description
FLOAT_FP8_E4M3FN	8-bit floating point number, 4 bits for the exponent and 3 bits for the mantissa. Typically used as coefficients.
FLOAT_FP8_E4M3FNUZ	8-bit floating point number, 4 bits for the exponent and 3 bits for the mantissa. Supports NaN, does not support negative zero and Inf. Typically used as coefficients.
FLOAT_FP8_E5M2FN	8-bit floating point number, 5 bits for the exponent and 2 bits for the mantissa. Supports NaN and Inf. Typically used for gradients.
FLOAT_FP8_E5M2FNUZ	8-bit floating point number, 5 bits for the exponent and 2 bits for the mantissa. Supports NaN, does not support negative zero and Inf. Also used for gradients.

One of the key advantages of FP8 is its efficiency in processing large datasets. By employing compact number representation, FP8 reduces memory requirements and accelerates calculations. This is especially important in machine learning and artificial intelligence applications which often process large datasets.

Standard Library

This group of chapters contains the technical details of the MQL5 Standard Library and descriptions of all its key components.

MQL5 Standard Library is written in MQL5 and is designed to facilitate writing programs (indicators, scripts, experts) for end users. Library provides convenient access to the most of the internal MQL5 functions.

MQL5 Standard Library is placed in the working directory of the terminal in the 'Include' folder.

Section	Location
Mathematics	Include\Math\

Mathematics

Multiple libraries are provided to perform calculations in various areas of mathematics:

- Statistics – functions for working with various distributions of the Probability theory
- Fuzzy logic – library that implements Mamdani and Sugeno fuzzy inference systems
- ALGLIB – data analysis (clustering, decision trees, linear regression, neural networks), solving differential equations, Fourier transform, numerical integration, optimization problems, statistical analysis, and more.

© 2000-2025, MetaQuotes Ltd.

Statistics

The Statistical Library provides a convenient way of working with the basic statistical distributions.

The library provides 5 functions for each distribution:

1. Calculation of probability density - functions of the form MathProbabilityDensityX()
2. Calculation of probabilities - functions of the form MathCumulativeDistributionX()
3. Calculation of distribution quantiles - functions of the form MathQuantileX()
4. Generation of random numbers with the specified distribution - functions of the form MathRandomX()
5. Calculation of the theoretical moments of the distributions - functions of the form MathMomentsX()

In addition to calculation of values for the individual random variables, the library also provides overloads for the functions, which perform the same calculations for arrays.

- Statistical Characteristics
- Normal Distribution
- Log-normal distribution
- Beta distribution
- Noncentral beta distribution
- Gamma distribution
- Chi-squared distribution
- Noncentral chi-squared distribution
- Exponential distribution
- F-distribution
- Noncentral F-distribution
- t-distribution
- Noncentral t-distribution
- Logistic distribution
- Cauchy distribution
- Uniform distribution
- Weibull distribution
- Binomial distribution
- Negative binomial distribution
- Geometric distribution
- Hypergeometric distribution
- Poisson distribution
- Subfunctions

Statistical Characteristics

This group of functions calculates the Statistical Characteristics of the array elements:

- mean,
- variance,
- skewness,
- kurtosis,
- median,
- root-mean-square and
- standard deviation.

Function	Description
MathMean	Calculates the mean (first moment) of array elements
MathVariance	Calculates the variance (second moment) of array elements
MathSkewness	Calculates the skewness (third moment) of array elements
MathKurtosis	Calculates the kurtosis (fourth moment) of array elements
MathMoments	Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements
MathMedian	Calculates the median value of array elements
MathStandardDeviation	Calculates the standard deviation of array elements
MathAverageDeviation	Calculates the average absolute deviation of array elements

© 2000-2025, MetaQuotes Ltd.

MathMean

Calculates the mean (first moment) of array elements. Analog of the mean() in R.

```
double  MathMean(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation of the mean.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The mean of array elements. In case of error it returns NaN (not a number).

© 2000-2025, MetaQuotes Ltd.

MathVariance

Calculates the variance (second moment) of array elements. Analog of the var() in R.

```
double  MathVariance(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Variance of array elements. In case of error it returns NaN (not a number).

© 2000-2025, MetaQuotes Ltd.

MathSkewness

Calculates the skewness (third moment) of array elements. Analog of the skewness() in R (e1071 library).

```
double  MathSkewness(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Skewness of array elements. In case of error it returns NaN (not a number).

© 2000-2025, MetaQuotes Ltd.

MathKurtosis

Calculates the kurtosis (fourth moment) of array elements. Analog of the kurtosis() in R (e1071 library).

```
double  MathKurtosis(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Kurtosis of array elements. In case of error it returns NaN (not a number).

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

© 2000-2025, MetaQuotes Ltd.

MathMoments

Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements.

```
double  MathMoments(
   const double&  array[],              // array with data
   double&        mean,                 // mean (1st moment)
   double&        variance,             // variance (2nd moment)
   double&        skewness,             // skewness (3rd moment)
   double&        kurtosis,             // kurtosis (4th moment)
   const int      start=0,              // initial index
   const int      count=WHOLE_ARRAY     // the number of elements
   );
```

Parameters

array

[in] Array with data for calculation.

mean

[out] Variable for the mean (1st moment)

variance

[out] Variable for the variance (2nd moment)

skewness

[out] Variable for the skewness (3rd moment)

kurtosis

[out] Variable for the kurtosis (4th moment)

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

© 2000-2025, MetaQuotes Ltd.

MathMedian

Calculates the median value of array elements. Analog of the median() in R.

```
double  MathMedian(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The median value of array elements. In case of error it returns NaN (not a number).

© 2000-2025, MetaQuotes Ltd.

MathStandardDeviation

Calculates the standard deviation of array elements. Analog of the sd() in R.

```
double  MathStandardDeviation(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The standard deviation of array elements. In case of error it returns NaN (not a number).

© 2000-2025, MetaQuotes Ltd.

MathAverageDeviation

Calculates the average absolute deviation of array elements. Analog of the aad() in R.

```
double  MathAverageDeviation(
   const double&  array[]                // array with data
   );
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The average absolute deviation of array elements. In case of error it returns NaN (not a number).

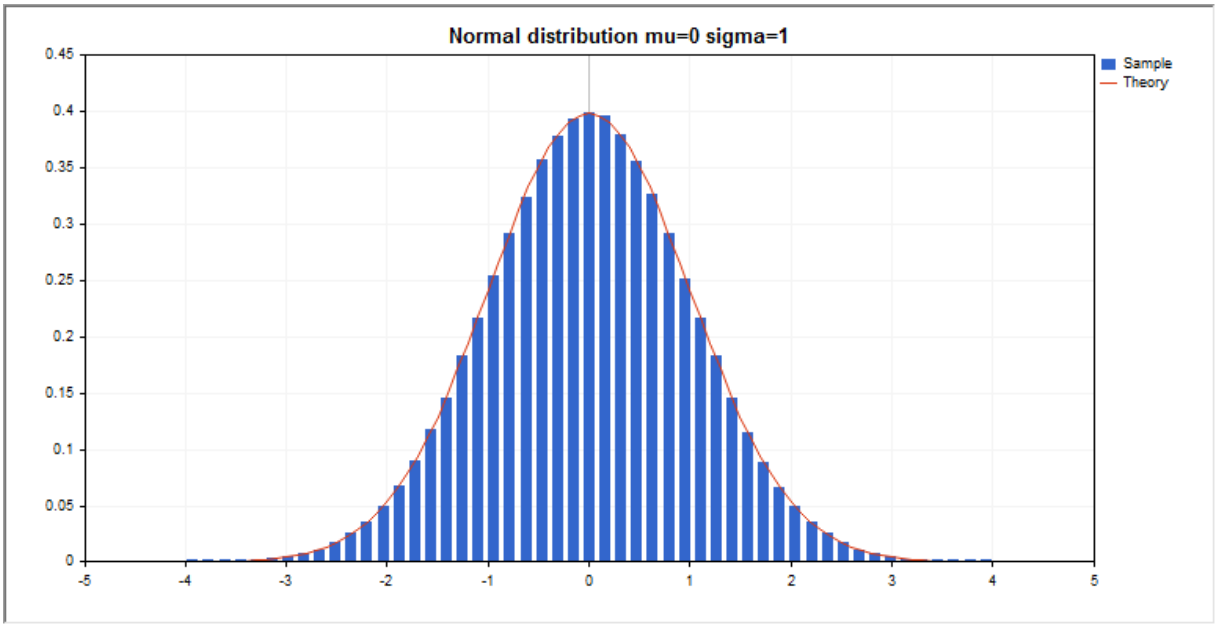
Normal Distribution

This section contains functions for working with normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the normal law. The distribution is defined by the following formula:

$$f_{Normal}(x|\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where:

- x — value of the random variable
- μ — expected value
- σ — root-mean-square deviation



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNormal	Calculates the probability density function of the normal distribution
MathCumulativeDistributionNormal	Calculates the value of the normal probability distribution function
MathQuantileNormal	Calculates the value of the inverse normal distribution function for the specified probability
MathRandomNormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the normal law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsNormal	Calculates the theoretical numerical values of the first 4 moments of the normal distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Normal.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mean_value=0;  // expected value (mean)
input double std_dev=1;     // root-mean-square deviation (standard deviation)
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=51;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals
   double y[];          // the number of values from the sample falling within the int
   double data[];       // sample of random values
   double max,min;      // the maximum and minimum values in the sample
//--- obtain a sample from the normal distribution
   MathRandomNormal(mean_value,std_dev,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);

MathProbabilityDensityNormal

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNormal(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution (expected value
   const double  sigma,          // sigma parameter of the distribution (root-mean-squ
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNormal(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution (expected value
   const double  sigma,          // sigma parameter of the distribution (root-mean-squ
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dnorm() in R.

```
bool  MathProbabilityDensityNormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // mean parameter of the distribution (expected valu
   const double   sigma,         // sigma parameter of the distribution (root-mean-sq
   const bool     log_mode,      // calculate the logarithm of the value
   double&        result[]       // array for values of the probability density funct
   );
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // mean parameter of the distribution (expected valu
   const double   sigma,         // sigma parameter of the distribution (root-mean-sq
   double&        result[]       // array for values of the probability density funct
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNormal

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNormal(
   const double  x,              // value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNormal(
   const double  x,              // value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dnorm() in R.

```
bool  MathCumulativeDistributionNormal(
   const double& x[],            // array with the values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNormal(
   const double& x[],            // array with the values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If tail=true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileNormal

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNormal(
   const double  probability,    // probability value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNormal(
   const double  probability,    // probability value of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the qnorm() in R.

```
bool  MathQuantileNormal(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   const bool    tail,           // flag for calculation of tail
   const bool    log_mode,       // calculate the logarithm of the value
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool  MathQuantileNormal(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // expected value
   const double  sigma,          // root-mean-square deviation
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If false, then calculation is performed for 1.0 - probability.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNormal

Generates a pseudorandom variable distributed according to the normal law with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathRandomNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the normal law with the mu and sigma parameters. In case of error it returns false. Analog of the rnorm() in R.

```
bool  MathRandomNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   const int     data_count,      // amount of required data
   double&       result[]         // array to obtain the pseudorandom variables
   );
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNormal

Calculates the theoretical numerical values of the first 4 moments of the normal distribution.

```
double  MathMomentsNormal(
   const double  mu,              // expected value
   const double  sigma,           // root-mean-square deviation
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable to store the error code
   );
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

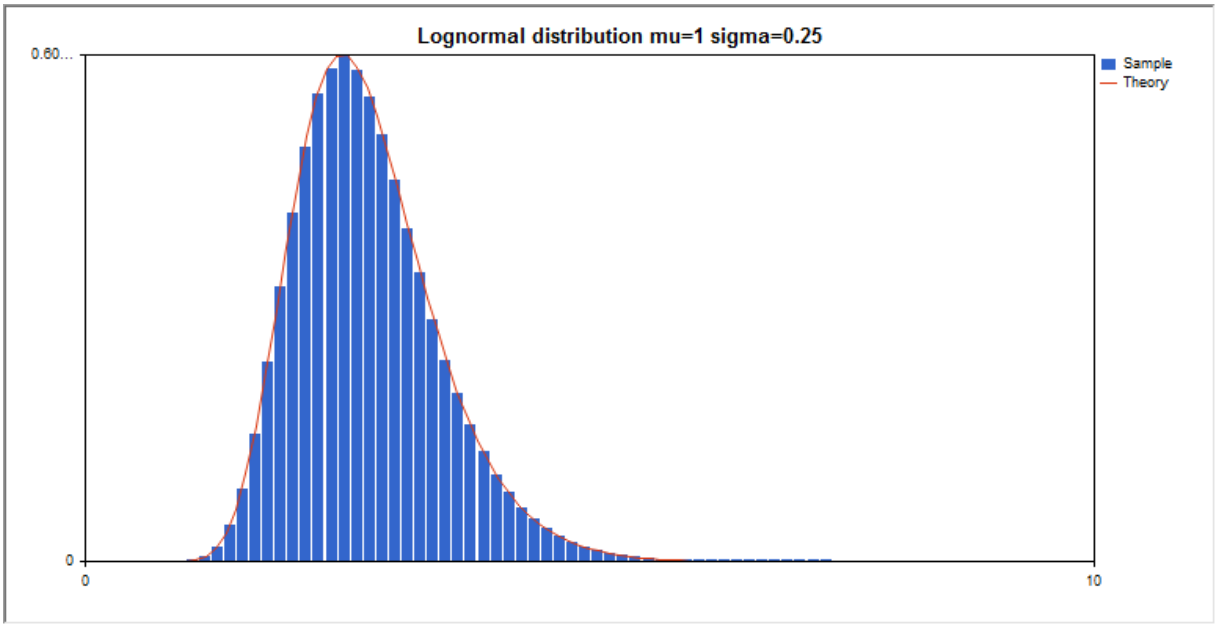
Log-normal distribution

This section contains functions for working with log-normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the log-normal law. The log-normal distribution is defined by the following formula:

$$f_{Lognormal}(x|\mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}$$

where:

- x — value of the random variable
- μ — logarithm of the expected value
- σ — logarithm of the root-mean-square deviation



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityLognormal	Calculates the probability density function of the log-normal distribution
MathCumulativeDistributionLognormal	Calculates the value of the log-normal probability distribution function
MathQuantileLognormal	Calculates the value of the inverse log-normal distribution function for the specified probability
MathRandomLognormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the log-normal law
MathMomentsLognormal	Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution

MathProbabilityDensityLognormal

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns NaN. Analog of the dlnorm() in R.

```
bool  MathProbabilityDensityLognormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // logarithm of the expected value (log mean)
   const double   sigma,         // logarithm of the root-mean-square deviation (log
   const bool     log_mode,      // calculate the logarithm of the value, if log_mode
   double&        result[]       // array for values of the probability density funct
   );
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityLognormal(
   const double&  x[],           // array with the values of random variable
   const double   mu,            // logarithm of the expected value (log mean)
   const double   sigma,         // logarithm of the root-mean-square deviation (log
   double&        result[]       // array for values of the probability density funct
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionLognormal

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=
   int&          error_code      // variable to store the error code
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLognormal(
   const double  x,              // value of random variable
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the plnorm() in R.

```
bool  MathCumulativeDistributionLognormal(
   const double&  x[],            // array with the values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   const bool     tail,           // flag of calculation, if true, then the probabili
   const bool     log_mode,       // flag to calculate the logarithm of the value, if
   double&        result[]        // array for values of the probability function
   );
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionLognormal(
   const double&  x[],            // array with the values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   double&        result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileLognormal

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLognormal(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatior
   int&          error_code      // variable to store the error code
   );
```

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLognormal(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // logarithm of the expected value (log mean)
   const double  sigma,          // logarithm of the root-mean-square deviation (log s
   int&          error_code      // variable to store the error code
   );
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the qlnorm() in R.

```
bool  MathQuantileLognormal(
   const double&  probability[],  // array with probability values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   const bool     tail,           // flag of calculation, if false, then calculation i
   const bool     log_mode,       // flag of calculation, if log_mode=true, calculatio
   double&        result[]        // array with values of quantiles
   );
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool  MathQuantileLognormal(
   const double&  probability[],  // array with probability values of random variable
   const double   mu,             // logarithm of the expected value (log mean)
   const double   sigma,          // logarithm of the root-mean-square deviation (log
   double&        result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable occurrence.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomLognormal

Generates a pseudorandom variable distributed according to the log-normal law with the mu sigma parameters. In case of error it returns NaN.

```
double  MathRandomLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the log-normal law with the mu sigma parameters. In case of error it returns false. Analog of the rlnorm() in R.

```
double  MathRandomLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

data_count

[in] Amount of required data.

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsLognormal

Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution. Returns true if calculation of the moments has been successful, otherwise false.

```
double  MathMomentsLognormal(
   const double  mu,              // logarithm of the expected value (log mean)
   const double  sigma,           // logarithm of the root-mean-square deviation (log s
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable to store the error code
   );
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

mean

[in] Variable for the mean.

variance

[out] Variable for the variance.

skewness

[out] Variable for the skewness.

kurtosis

[out] Variable for the kurtosis.

error code

[out] Variable to store the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

© 2000-2025, MetaQuotes Ltd.

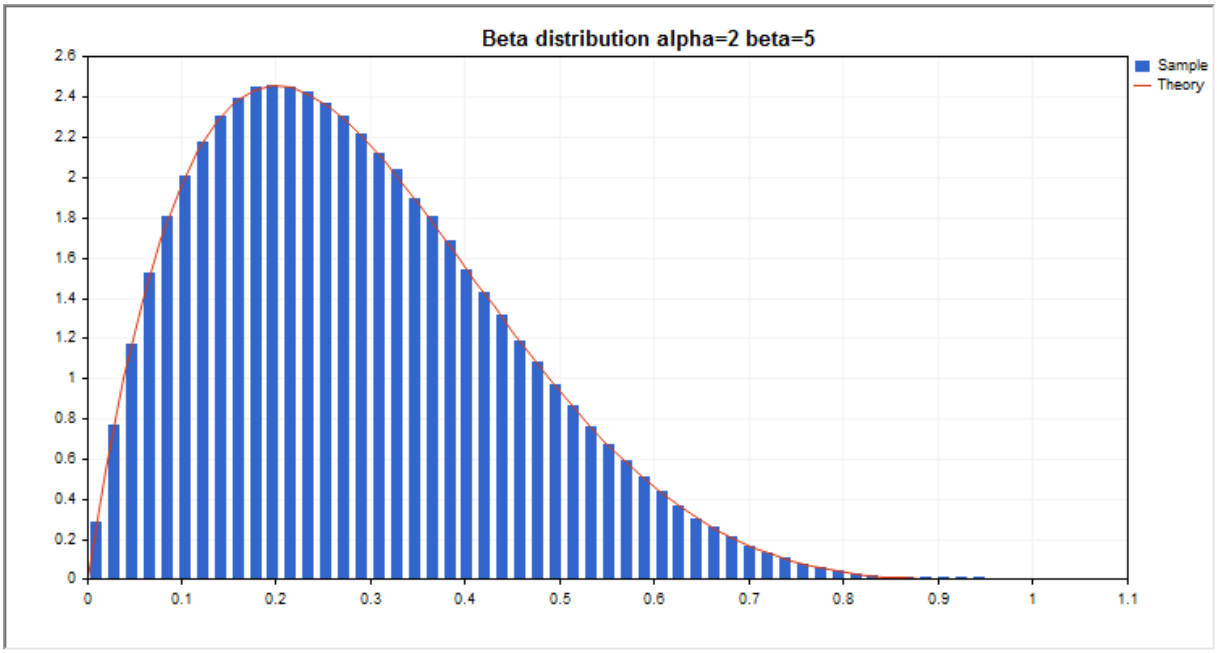
Beta distribution

This section contains functions for working with beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The beta distribution is defined by the following formula:

$$f_{Beta}(x \mid a,b) = \frac{1}{B(a,b)} x^{a-1}(1-x)^{b-1}$$

where:

- x — value of the random variable
- a — the first parameter of beta distribution
- b — the second parameter of beta distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityBeta	Calculates the probability density function of the beta distribution
MathCumulativeDistributionBeta	Calculates the value of the beta probability distribution function
MathQuantileBeta	Calculates the value of the inverse beta distribution function for the specified probability
MathRandomBeta	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the beta distribution law
MathMomentsBeta	Calculates the theoretical numerical values of the first 4 moments of the beta distribution

MathProbabilityDensityBeta

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dbeta() in R.

```
bool  MathProbabilityDensityBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if 1
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionBeta

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the pbeta() in R.

```
bool  MathCumulativeDistributionBeta(
   const double& x[],             // array with the values of random variable
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   const bool    tail,            // flag of calculation, if true, then the probability
   const bool    log_mode,        // flag to calculate the logarithm of the value, if
   double&       result[]         // array for values of the probability function
   );
```

<t0>Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionBeta(
   const double& x[],             // array with the values of random variable
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   double&       result[]         // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileBeta

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false. Analog of the qbeta() in R.

```
double  MathQuantileBeta(
   const double&  probability[], // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileBeta(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

tail

[in] Flag of calculation, if lower_tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomBeta

Generates a pseudorandom variable distributed according to the law of beta distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of beta distribution with the a and b parameters. In case of error it returns false. Analog of the rbeta() in R.

```
bool  MathRandomBeta(
   const double  a,               // the first parameter of beta distribution (shape1)
   const double  b,               // the second parameter of beta distribution (shape2)
   const int     data_count,      // amount of required data
   double&       result[]         // array to obtain the pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsBeta

Calculates the theoretical numerical values of the first 4 moments of the beta distribution.

```
double  MathMomentsBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

© 2000-2025, MetaQuotes Ltd.

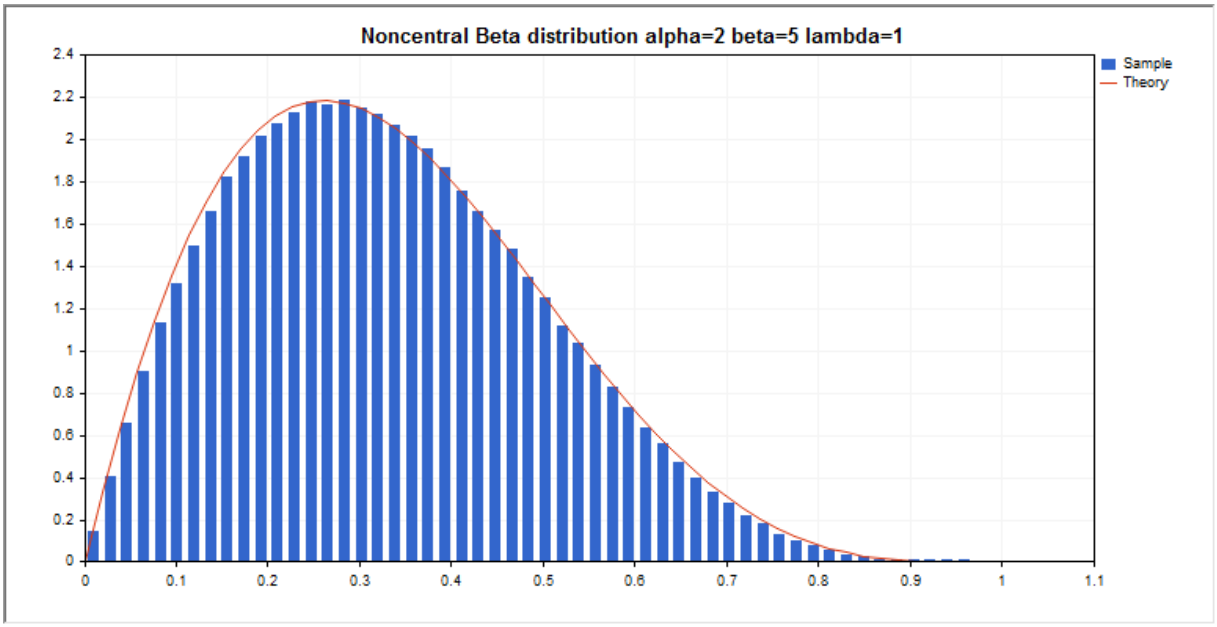
Noncentral beta distribution

This section contains functions for working with noncentral beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral beta distribution is defined by the following formula:

$$f_{NoncentralBeta}(x|a,b,\lambda)=\sum_{r=0}^{\infty}e^{-\frac{\lambda}{2}}\frac{\left(\frac{\lambda}{2}\right)^{r}}{r!}\frac{x^{a+r-1}(1-x)^{b-1}}{B(a+r,b)}$$

where:

- x — value of the random variable
- a — the first parameter of beta distribution
- b — the second parameter of beta distribution
- λ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralBeta	Calculates the probability density function of the noncentral beta distribution
MathCumulativeDistributionNoncentralBeta	Calculates the value of the noncentral beta probability distribution function
MathQuantileNoncentralBeta	Calculates the value of the inverse noncentral beta distribution function for the specified probability
MathRandomNoncentralBeta	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral beta distribution law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsNoncentralBeta	Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution

Example:

```
#include <Graphics\Graphic.mqh>

MathProbabilityDensityNoncentralBeta

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the dbeta() in R.

```
bool  MathProbabilityDensityNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

© 2000-2025, MetaQuotes Ltd.

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNoncentralBeta

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralBeta(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the pbeta() in R.

```
bool  MathCumulativeDistributionNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if t
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralBeta(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       result[]        // array for values of the probability function
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileNoncentralBeta

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters for the occurrence probability of a random variable *probability*. In case of error it returns NaN.

```
double  MathQuantileNoncentralBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters for the occurrence probability of a random variable *probability*. In case of error it returns NaN.

```
double  MathQuantileNoncentralBeta(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified probability[] array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters. In case of error it returns false. Analog of the qbeta() in R.

```
double  MathQuantileNoncentralBeta(
   const double&  probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified probability[] array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the a, b and lambda parameters. In case of error it returns false.

```
bool  MathQuantileNoncentralBeta(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
```

© 2000-2025, MetaQuotes Ltd.

```
   const double   lambda,          // noncentrality parameter
   double&        result[]         // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNoncentralBeta

Generates a pseudorandom variable distributed according to the law of noncentral beta distribution the a, b and lambda parameters. In case of error it returns NaN.

```
double  MathRandomNoncentralBeta(
   const double  a,             // the first parameter of beta distribution (shape1)
   const double  b,             // the second parameter of beta distribution (shape2)
   const double  lambda,        // noncentrality parameter
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of noncentral beta distribution the a, b and lambda parameters. In case of error it returns false. Analog of the rbeta() in R.

```
bool  MathRandomNoncentralBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   const int     data_count,     // amount of required data
   double&       result[]        // array to obtain the pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNoncentralBeta

Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution with the a, b and lambda parameters.

```
double  MathMomentsNoncentralBeta(
   const double  a,              // the first parameter of beta distribution (shape1)
   const double  b,              // the second parameter of beta distribution (shape2)
   const double  lambda,         // noncentrality parameter
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

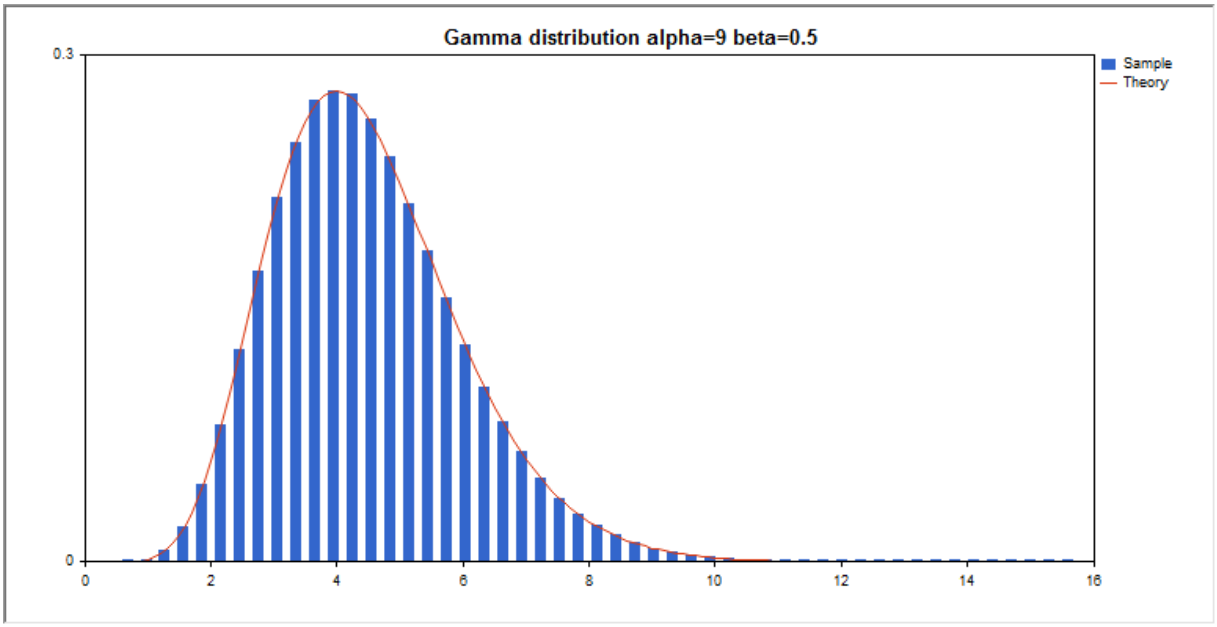
Gamma distribution

This section contains functions for working with gamma distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The gamma distribution is defined by the following formula:

$$f_{Gamma}(x|a,b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where:

- x — value of the random variable
- a — the first parameter of distribution
- b — the second parameter of distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityGamma	Calculates the probability density function of the gamma distribution
MathCumulativeDistributionGamma	Calculates the value of the gamma probability distribution function
MathQuantileGamma	Calculates the value of the inverse gamma distribution function for the specified probability
MathRandomGamma	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the gamma distribution law
MathMomentsGamma	Calculates the theoretical numerical values of the first 4 moments of the gamma distribution

MathProbabilityDensityGamma

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dgamma() in R.

```
bool  MathProbabilityDensityGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if 1
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionGamma

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGamma(
   const double  x,              // value of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the pgamma() in R.

```
bool  MathCumulativeDistributionGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionGamma(
   const double& x[],            // array with the values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale)

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileGamma

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileGamma(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileGamma(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false. Analog of the qgamma() in R.

```
double  MathQuantileGamma(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileGamma(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomGamma

Generates a pseudorandom variable distributed according to the law of gamma distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomGamma(
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of gamma distribution with the a and b parameters. In case of error it returns false. Analog of the rgamma() in R.

```
bool  MathRandomGamma(
   const double  a,               // the first parameter of the distribution (shape)
   const double  b,               // the second parameter of the distribution (scale)
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsGamma

Calculates the theoretical numerical values of the first 4 moments of the gamma distribution with the a and b parameters.

```
double  MathMomentsGamma(
   const double  a,              // the first parameter of the distribution (shape)
   const double  b,              // the second parameter of the distribution (scale)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

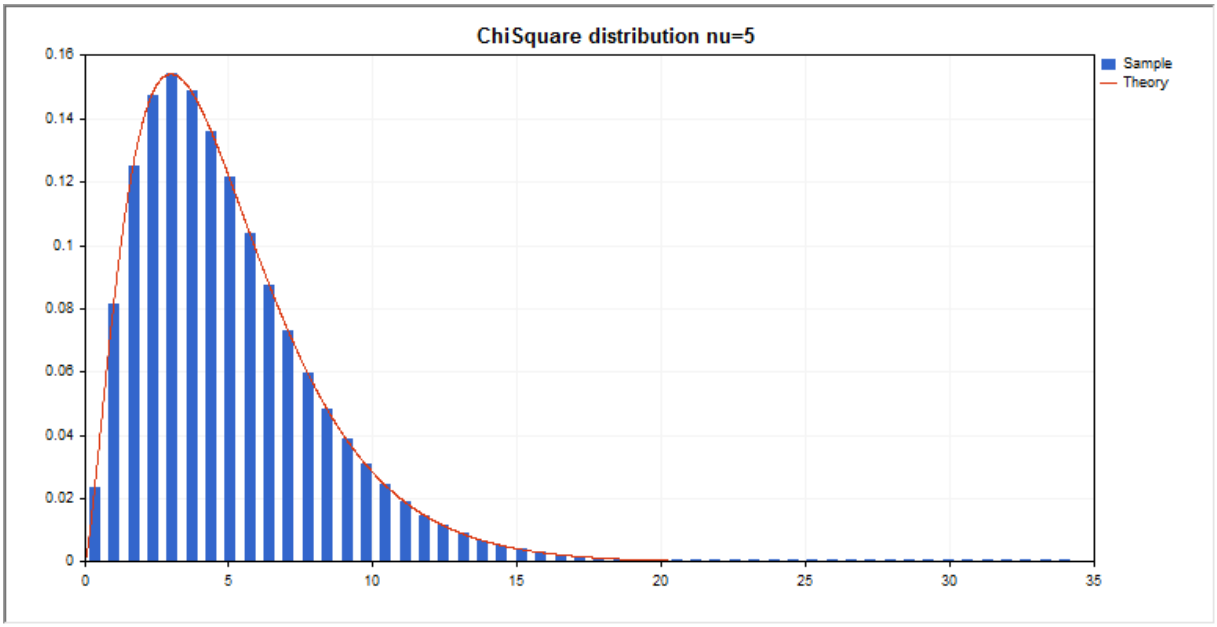
Chi-squared distribution

This section contains functions for working with chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The chi-squared distribution is defined by the following formula:

$$f_{Chi-Square}(x|\nu) = \frac{x^{\frac{(\nu-2)}{2}} e^{-\frac{x}{2}}}{2^{\frac{\nu}{2}}\Gamma\left(\frac{\nu}{2}\right)}$$

where:

- x — value of the random variable
- ν — number of degrees of freedom



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityChiSquare	Calculates the probability density function of the chi-squared distribution
MathCumulativeDistributionChiSquare	Calculates the value of the chi-squared probability distribution function
MathQuantileChiSquare	Calculates the value of the inverse chi-squared distribution function for the specified probability
MathRandomChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the chi-squared distribution law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsChiSquare	Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\ChiSquare.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=5;     // the number of degrees of freedom
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;        // the number of values in the sample
   int ncells=51;        // the number of intervals in the histogram
   double x[];           // centers of the histogram intervals
   double y[];           // the number of values from the sample falling within the int
   double data[];        // sample of random values
   double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the chi-squared distribution
   MathRandomChiSquare(nu_par,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityChiSquare(x2,nu_par,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
   for(int i=0; i<ncells; i++)
```

MathProbabilityDensityChiSquare

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the dchisq() in R.

```
bool  MathProbabilityDensityChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom)

log_mode

© 2000-2025, MetaQuotes Ltd.

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionChiSquare

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns NaN

```
double  MathCumulativeDistributionChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the pchisq() in R.

```
bool  MathCumulativeDistributionChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileChiSquare

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns NaN.

```
double  MathQuantileChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns NaN.

```
double  MathQuantileChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false. Analog of the qchisq() in R.

```
double  MathQuantileChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false.

```
bool  MathQuantileChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomChiSquare

Generates a pseudorandom variable distributed according to the law of chi-squared distribution with the nu parameter. In case of error it returns NaN.

```
double  MathRandomChiSquare(
   const double  nu,            // parameter of distribution (number of degrees of fre
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of chi-squared distribution with the nu parameter. In case of error it returns false. Analog of the rchisq() in R.

```
bool  MathRandomChiSquare(
   const double  nu,             // parameter of distribution (number of degrees of fi
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsChiSquare

Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution with the nu parameter.

```
double  MathMomentsChiSquare(
   const double  nu,              // parameter of distribution (number of degrees of fi
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

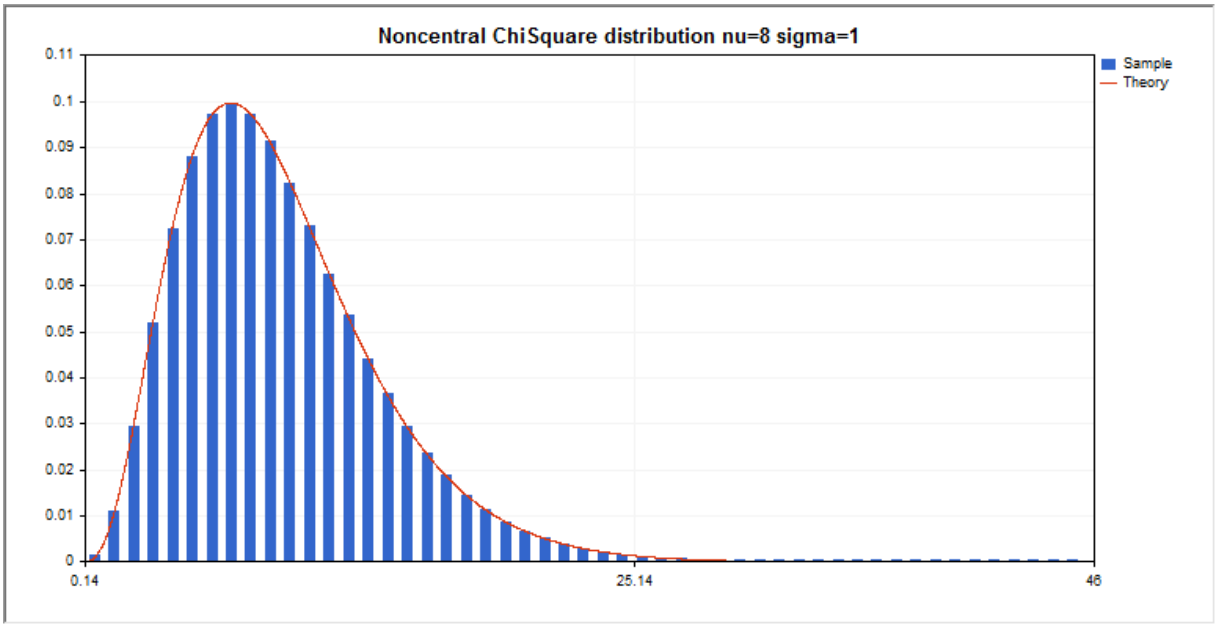
Noncentral chi-squared distribution

This section contains functions for working with noncentral chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral chi-squared distribution is defined by the following formula:

$$f_{NoncentralChiSquare}(x|\nu,\sigma)=\frac{1}{2^{\frac{\nu}{2}}\Gamma\left(\frac{1}{2}\right)}x^{\frac{\nu}{2}-1}e^{-\frac{(x+\sigma)}{2}}\sum_{r=0}^{\infty}\frac{(\lambda x)^r}{(2r)!}\frac{\Gamma\left(\frac{1}{2}+r\right)}{\Gamma\left(\frac{\nu}{2}+r\right)}$$

where:

- x — value of the random variable
- ν — number of degrees of freedom
- σ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralChiSquare	Calculates the probability density function of the noncentral chi-squared distribution
MathCumulativeDistributionNoncentralChiSquare	Calculates the value of the noncentral chi-squared probability distribution function
MathQuantileNoncentralChiSquare	Calculates the value of the inverse noncentral chi-squared distribution function for the specified probability
MathRandomNoncentralChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral chi-squared distribution law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsNoncentralChiSquare	Calculates the theoretical numerical values of the first 4 moments of the noncentral chi-squared distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralChiSquare.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=8;     // the number of degrees of freedom
input double si_par=1;     // noncentrality parameter
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;        // the number of values in the sample
   int ncells=51;        // the number of intervals in the histogram
   double x[];           // centers of the histogram intervals
   double y[];           // the number of values from the sample falling within the int
   double data[];        // sample of random values

MathProbabilityDensityNoncentralChiSquare

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dchisq() in R.

```
bool  MathProbabilityDensityNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNoncentralChiSquare

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=true, then the p
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralChiSquare(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the pchisq() in R.

```
bool  MathCumulativeDistributionNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=true, then the
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralChiSquare(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

© 2000-2025, MetaQuotes Ltd.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileNoncentralChiSquare

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralChiSquare(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function with the nu and sigma parameters. In case of error it returns false. Analog of the qchisq() in R.

```
double  MathQuantileNoncentralChiSquare(
   const double&  probability[],  // array with probability values of random variable
   const double  nu,              // parameter of distribution (number of degrees of f
   const double  sigma,           // noncentrality parameter
   const bool    tail,            // flag of calculation, if false, then calculation i
   const bool    log_mode,        // flag of calculation, if log_mode=true, calculatio
   double&       result[]         // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function. In case of error it returns false.

```
bool  MathQuantileNoncentralChiSquare(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNoncentralChiSquare

Generates a pseudorandom variable distributed according to the law of noncentral chi-squared distribution with the nu and sigma parameters. In case of error it returns NaN.

```
double  MathRandomNoncentralChiSquare(
   const double  nu,            // parameter of distribution (number of degrees of fre
   const double  sigma,         // noncentrality parameter
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of noncentral chi-squared distribution with the nu and sigma parameters. In case of error it returns false. Analog of the rchisq() in R.

```
bool  MathRandomNoncentralChiSquare(
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNoncentralChiSquare

Calculates the theoretical numerical values of the first 4 moments of the noncentral chi-squared distribution with the nu and sigma parameters.

```
double  MathMomentsNoncentralChiSquare(
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  sigma,          // noncentrality parameter
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

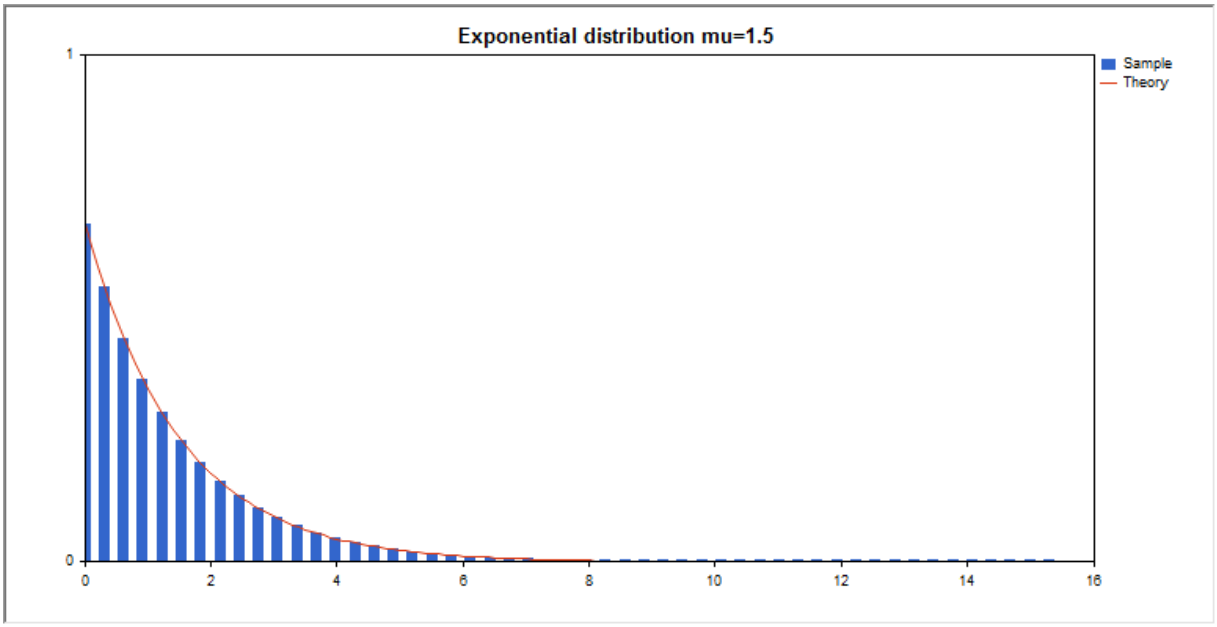
Exponential

This section contains functions for working with exponential distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of exponential distribution. The exponential distribution is defined by the following formula:

$$f_{Exponential}(x \mid \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

where:

- x — value of the random variable
- μ — expected value



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityExponential	Calculates the probability density function of the exponential distribution
MathCumulativeDistributionExponential	Calculates the value of the exponential probability distribution function
MathQuantileExponential	Calculates the value of the inverse exponential distribution function for the specified probability
MathRandomExponential	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the law of exponential distribution
MathMomentsExponential	Calculates the theoretical numerical values of the first 4 moments of the exponential distribution

Example:

MathProbabilityDensityExponential

Calculates the value of the probability density function of exponential distribution with the mu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityExponential(
   const double  x,              // value of random variable
   const double  mu,             // parameter of the distribution (expected value)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of exponential distribution with the mu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityExponential(
   const double  x,              // value of random variable
   const double  mu,             // parameter of the distribution (expected value)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of exponential distribution with the mu parameter for an array of random variables x[]. In case of error it returns false. Analog of the dexp() in R.

```
bool  MathProbabilityDensityExponential(
   const double& x[],            // array with the values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of exponential distribution with the mu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityExponential(
   const double& x[],            // array with the values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Parameter of the distribution (expected value)

log_mode

© 2000-2025, MetaQuotes Ltd.

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionExponential

Calculates the exponential distribution function of probabilities with the mu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionExponential(
   const double  x,              // value of random variable
   const double  mu,             // parameter of the distribution (expected value)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the exponential distribution function of probabilities with the mu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionExponential(
   const double  x,              // value of random variable
   const double  mu,             // parameter of the distribution (expected value)
   int&          error_code      // variable to store the error code
   );
```

Calculates the exponential distribution function of probabilities with the mu parameter for an array of random variables x[]. In case of error it returns false. Analog of the pexp() in R.

```
bool  MathCumulativeDistributionExponential(
   const double& x[],            // array with the values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   const bool    tail,           // flag of calculation, if true, then the probabilit
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the exponential distribution function of probabilities with the mu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionExponential(
   const double& x[],            // array with the values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Parameter of the distribution (expected value).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileExponential

For the specified *probability*, the function calculates the value of inverse exponential distribution function with the mu parameter. In case of error it returns NaN.

```
double  MathQuantileExponential(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // parameter of the distribution (expected value)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse exponential distribution function with the mu parameter. In case of error it returns NaN.

```
double  MathQuantileExponential(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // parameter of the distribution (expected value)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse exponential distribution function with the mu parameter. In case of error it returns false. Analog of the qexp() in R.

```
double  MathQuantileExponential(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse exponential distribution function with the mu parameter. In case of error it returns false.

```
bool  MathQuantileExponential(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // parameter of the distribution (expected value)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

mu

© 2000-2025, MetaQuotes Ltd.

[in] Parameter of the distribution (expected value).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomExponential

Generates a pseudorandom variable distributed according to the law of exponential distribution with the mu parameter. In case of error it returns NaN.

```
double  MathRandomExponential(
   const double  mu,            // parameter of the distribution (expected value)
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of exponential distribution with the mu parameter. In case of error it returns false. Analog of the rexp() in R.

```
bool  MathRandomExponential(
   const double  mu,             // parameter of the distribution (expected value)
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

mu

[in] Parameter of the distribution (expected value).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsExponential

Calculates the theoretical numerical values of the first 4 moments of the exponential distribution with the mu parameter.

```
double  MathMomentsExponential(
   const double  mu,              // parameter of the distribution (expected value)
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

mu

[in] Parameter of the distribution (expected value).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

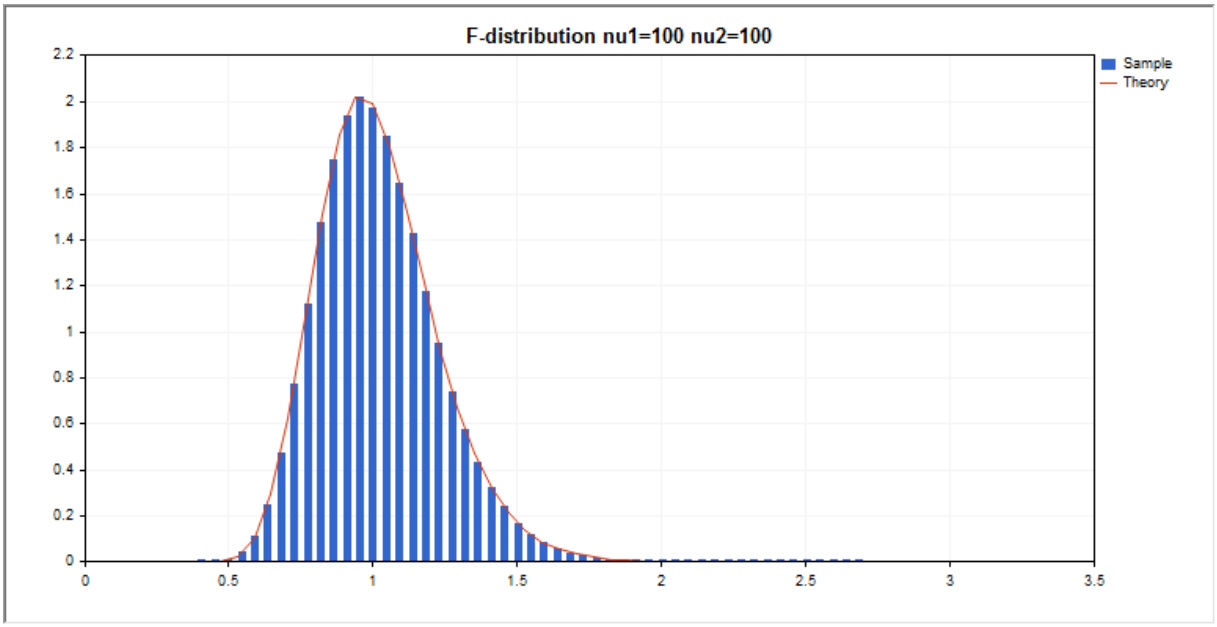
F-distribution

This section contains functions for working with F-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of Fisher's F-distribution. The F-distribution is defined by the following formula:

$$f_F(x \mid \nu_1, \nu_2) = \frac{\Gamma\left(\frac{\nu_1+\nu_2}{2}\right)}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)}\left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{x^{\frac{\nu_1-2}{2}}}{\left(1+\left(\frac{\nu_1}{\nu_2}\right)x\right)^{\frac{\nu_1+\nu_2}{2}}}$$

where:

- x — value of the random variable
- ν1 — the first parameter of distribution (number of degrees of freedom)
- ν2 — the second parameter of distribution (number of degrees of freedom)



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityF	Calculates the probability density function of the F-distribution
MathCumulativeDistributionF	Calculates the value of the F-distribution function
MathQuantileF	Calculates the value of the inverse F-distribution function for the specified probability
MathRandomF	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Fisher's law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsF	Calculates the theoretical numerical values of the first 4 moments of the Fisher's F-distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\F.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_1=100;     // the first number of degrees of freedom
input double nu_2=100;     // the second number of degrees of freedom
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);

MathProbabilityDensityF

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false. Analog of the df() in R.

```
bool  MathProbabilityDensityF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionF

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false. Analog of the pf() in R.

```
bool  MathCumulativeDistributionF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

© 2000-2025, MetaQuotes Ltd.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileF

For the specified *probability*, the function calculates the value of inverse Fisher's F-distribution function with the nu1 and nu2 parameters. In case of error it returns NaN.

```
double  MathQuantileF(
   const double  probability,    // probability value of random variable occurrence
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse Fisher's F-distribution function with the nu1 and nu2 parameters. In case of error it returns NaN.

```
double  MathQuantileF(
   const double  probability,    // probability value of random variable occurrence
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Fisher's F-distribution function with the nu1 and nu2 parameters. In case of error it returns false. Analog of the qf() in R.

```
double  MathQuantileF(
   const double& probability[],  // array with probability values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Fisher's F-distribution function with the nu1 and nu2 parameters. In case of error it returns false.

```
bool  MathQuantileF(
   const double& probability[],  // array with probability values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if lower_tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomF

Generates a pseudorandom variable distributed according to the law of Fisher's F-distribution with the nu1 and nu2 parameters. In case of error it returns NaN.

```
double  MathRandomF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   int&          error_code     // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of Fisher's F-distribution with the nu1 and nu2 parameters. In case of error it returns false. Analog of the rf() in R.

```
bool  MathRandomF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsF

Calculates the theoretical numerical values of the first 4 moments of the Fisher's F-distribution with the nu1 and nu2 parameters.

```
double  MathMomentsF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

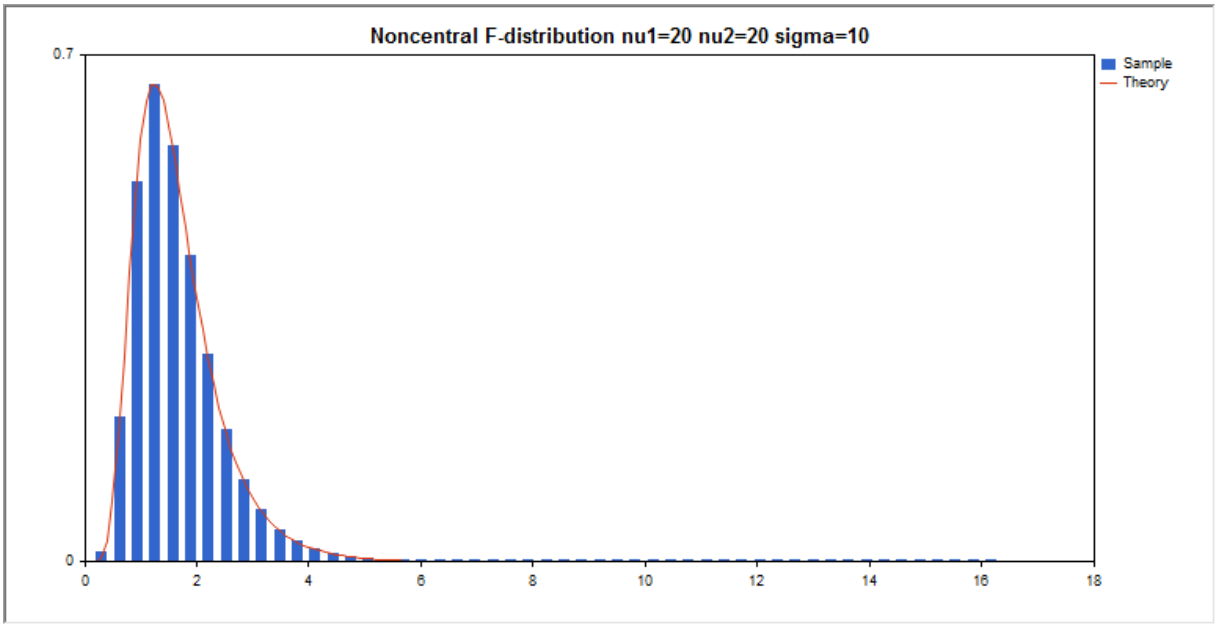
Noncentral F-distribution

This section contains functions for working with noncentral F-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of noncentral Fisher's F-distribution. The noncentral F-distribution is defined by the following formula:

$$f_{NoncentralF}(x|\nu_1,\nu_2,\sigma) = e^{-\frac{\sigma}{2}} \sum_{r=0}^{\infty} \frac{1}{r!}\left(\frac{\sigma}{2}\right)^r \frac{\Gamma\left(\frac{\nu_1+\nu_2}{2}+r\right)}{\Gamma\left(\frac{\nu_2}{2}+r\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_2}{2}+r} \frac{x^{\frac{\nu_2}{2}-1+r}}{\left(1+\frac{\nu_1}{\nu_2}x\right)^{\frac{\nu_1+\nu_2}{2}+r}}$$

where:

- x — value of the random variable
- ν1 — the first parameter of distribution (number of degrees of freedom)
- ν2 — the second parameter of distribution (number of degrees of freedom)
- σ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralF	Calculates the probability density function of the noncentral F-distribution
MathCumulativeDistributionNoncentralF	Calculates the value of the noncentral F-distribution function
MathQuantileNoncentralF	Calculates the value of the inverse noncentral F-distribution function for the specified probability

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathRandomNoncentralF	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral Fisher's distribution law
MathMomentsNoncentralF	Calculates the theoretical numerical values of the first 4 moments of the noncentral Fisher's F-distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralF.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_1=20;     // the first number of degrees of freedom
input double nu_2=20;     // the second number of degrees of freedom
input double sig=10;      // noncentrality parameter
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+

MathProbabilityDensityNoncentralF

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the df() in R.

```
bool  MathProbabilityDensityNoncentralF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

© 2000-2025, MetaQuotes Ltd.

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNoncentralF

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralF(
   const double  x,              // value of random variable
   const double  nu1,            // the first parameter of distribution (number of degr
   const double  nu2,            // the second parameter of distribution (number of deg
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the pf() in R.

```
bool  MathCumulativeDistributionNoncentralF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralF(
   const double& x[],            // array with the values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   double&       result[]        // array for values of the probability function
```

© 2000-2025, MetaQuotes Ltd.

```
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileF

For the specified *probability*, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileF(
   const double  probability,    // probability value of random variable occurrence
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileF(
   const double  probability,    // probability value of random variable occurrence
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns false. Analog of the qf() in R.

```
double  MathQuantileF(
   const double& probability[],  // array with probability values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns false.

```
bool  MathQuantileF(
   const double& probability[],  // array with probability values of random variable
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   double&       result[]        // array with values of quantiles
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNoncentralF

Generates a pseudorandom variable distributed according to the law of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters. In case of error it returns NaN.

```
double  MathRandomNoncentralF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters. In case of error it returns false. Analog of the rf() in R.

```
bool  MathRandomNoncentralF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNoncentralF

Calculates the theoretical numerical values of the first 4 moments of the noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters.

```
double  MathMomentsNoncentralF(
   const double  nu1,            // the first parameter of distribution (number of deg
   const double  nu2,            // the second parameter of distribution (number of de
   const double  sigma,          // noncentrality parameter
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

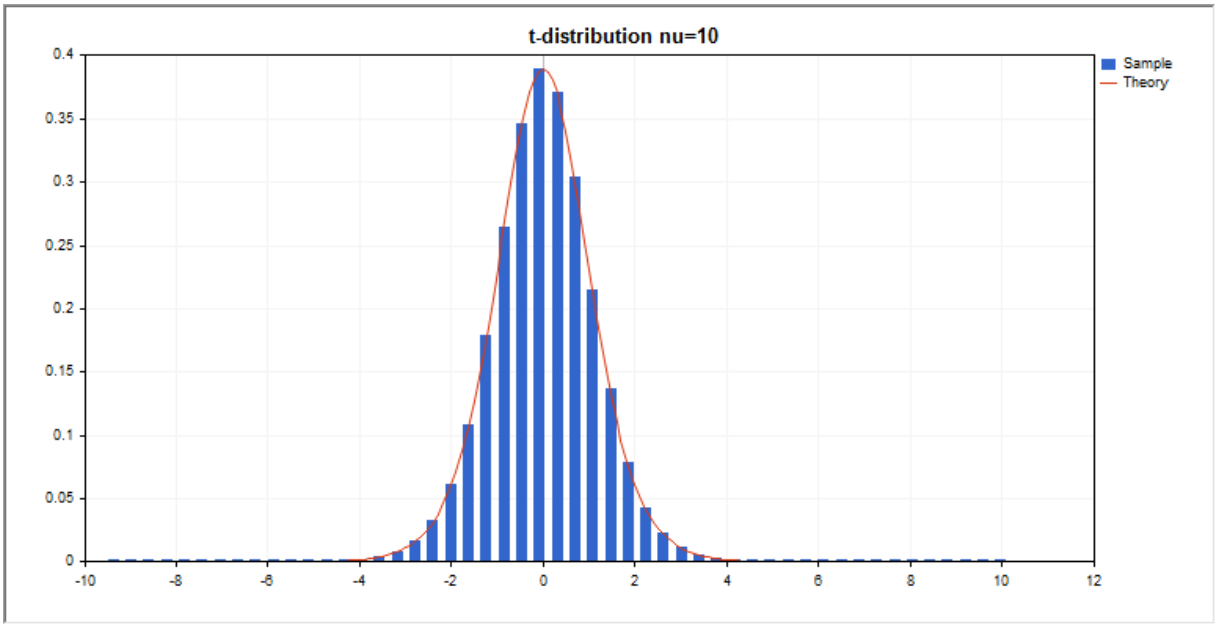
t-distribution

This section contains functions for working with Student's t-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Student's law. The t-distribution is defined by the following formula:

$$f_T(x|\nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\pi\nu}} \frac{1}{\left(1+\frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where:

- x — value of the random variable
- ν — parameter of distribution (number of degrees of freedom)



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityT	Calculates the probability density function of the t-distribution
MathCumulativeDistributionT	Calculates the value of the t-distribution function
MathQuantileT	Calculates the value of the inverse t-distribution function for the specified probability
MathRandomT	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the law of Student's t-distribution

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsT	Calculates the theoretical numerical values of the first 4 moments of the Student's t-distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\T.mqh>
#include <Math\Stat\Math.mqh>

MathProbabilityDensityT

Calculates the value of the probability density function of Student's t-distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Student's t-distribution with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Student's t-distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the dt() in R.

```
bool  MathProbabilityDensityT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of Student's t-distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

log_mode

© 2000-2025, MetaQuotes Ltd.

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionT

Calculates the value of the Student's t-distribution function with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Student's t-distribution function with the nu parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Student's t-distribution function with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the pt() in R.

```
bool  MathCumulativeDistributionT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the Student's t-distribution function with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileT

For the specified *probability*, the function calculates the value of inverse Student's t-distribution function with the nu parameter. In case of error it returns NaN.

```
double  MathQuantileT(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse Student's t-distribution function with the nu parameter. In case of error it returns NaN.

```
double  MathQuantileT(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Student's t-distribution function with the nu parameter. In case of error it returns false. Analog of the qt() in R.

```
double  MathQuantileT(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Student's t-distribution function with the nu parameter. In case of error it returns false.

```
bool  MathQuantileT(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

© 2000-2025, MetaQuotes Ltd.

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomT

Generates a pseudorandom variable distributed according to the law of Student's t-distribution with the nu parameter. In case of error it returns NaN.

```
double  MathRandomT(
   const double  nu,              // parameter of distribution (number of degrees of fi
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of Student's t-distribution with the nu parameter. In case of error it returns false. Analog of the rt() in R.

```
bool  MathRandomT(
   const double  nu,              // parameter of distribution (number of degrees of fi
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsT

Calculates the theoretical numerical values of the first 4 moments of the Student's t-distribution with the nu parameter.

```
double  MathMomentsT(
   const double  nu,              // parameter of distribution (number of degrees of fi
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

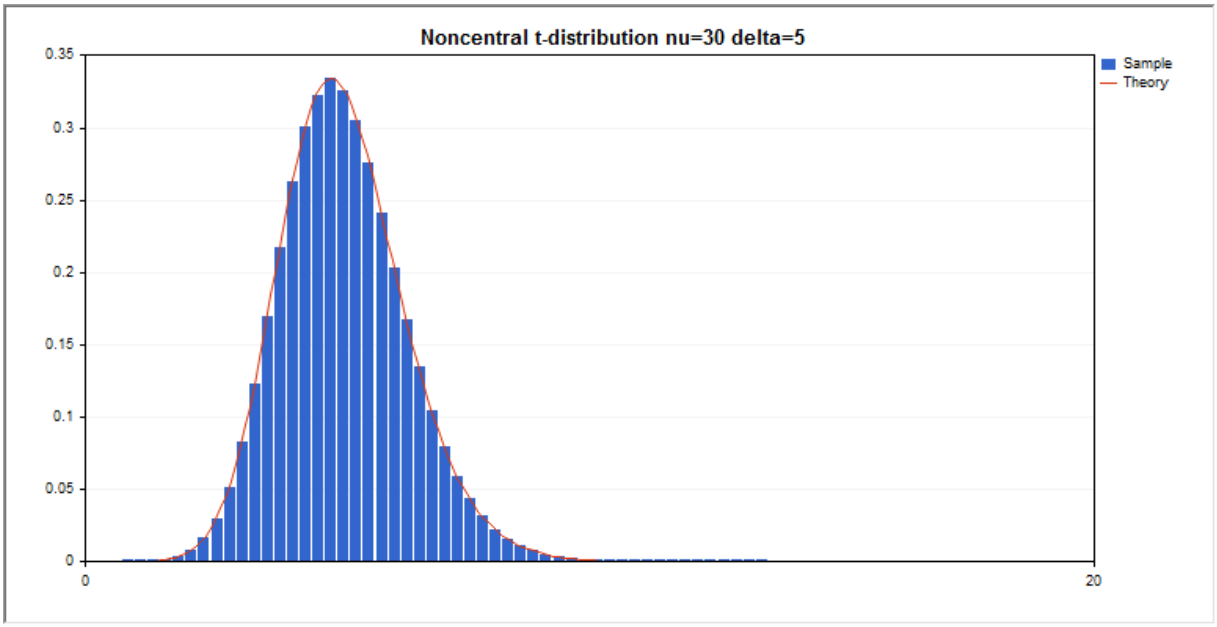
t-distribution

This section contains functions for working with noncentral Student's t-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of noncentral t-distribution. The noncentral t-distribution is defined by the following formula:

$$f_{NoncentralT}(x \mid \nu, \delta) = \frac{\nu^{\frac{\nu}{2}} e^{-\frac{\sigma^2}{2}}}{\Gamma\left(\frac{\nu}{2}\right)\sqrt{\pi}\left(\nu+x^2\right)^{\frac{\nu+1}{2}}} \sum_{r=0}^{\infty} \frac{(x\delta)^r}{r!}\left(\frac{2}{\nu+x^2}\right)^{\frac{r}{2}} \Gamma\left(\frac{\nu+r+1}{2}\right)$$

where:

- x — value of the random variable
- ν — parameter of distribution (number of degrees of freedom)
- σ — noncentrality parameter



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralT	Calculates the probability density function of the noncentral t-distribution
MathCumulativeDistributionNoncentralT	Calculates the value of the noncentral t-distribution function
MathQuantileNoncentralT	Calculates the value of the inverse noncentral t-distribution function for the specified probability
MathRandomNoncentralT	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral Student's t-distribution law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsNoncentralT	Calculates the theoretical numerical values of the first 4 moments of the noncentral Student's t-distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralT.mqh>
#include <Math\Stat\Math.mqh>

MathProbabilityDensityNoncentralT

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  delta,          // noncentrality parameter
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable for the error code
   );
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNoncentralT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  delta,          // noncentrality parameter
   int&          error_code      // variable for the error code
   );
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false. Analog of the dt() in R.

```
bool  MathProbabilityDensityNoncentralT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  delta,          // noncentrality parameter
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNoncentralT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  delta,          // noncentrality parameter
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNoncentralT

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  delta,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNoncentralT(
   const double  x,              // value of random variable
   const double  nu,             // parameter of distribution (number of degrees of fre
   const double  delta,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false. Analog of the pt() in R.

```
bool  MathCumulativeDistributionNoncentralT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  delta,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNoncentralT(
   const double& x[],            // array with the values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  delta,          // noncentrality parameter
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

© 2000-2025, MetaQuotes Ltd.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralT

For the specified *probability*, the function calculates the value of inverse noncentral Student's t-distribution function with the nu and delta parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralT(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  delta,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=false, then cal
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatior
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse noncentral Student's t-distribution function with the nu and delta parameters. In case of error it returns NaN.

```
double  MathQuantileNoncentralT(
   const double  probability,    // probability value of random variable occurrence
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  delta,          // noncentrality parameter
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Student's t-distribution function with the nu and delta parameters. In case of error it returns false. Analog of the qt() in R.

```
double  MathQuantileNoncentralT(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  delta,          // noncentrality parameter
   const bool    tail,           // flag of calculation, if lower_tail=false, then cal
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatior
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Student's t-distribution function with the nu and delta parameters. In case of error it returns false.

```
bool  MathQuantileNoncentralT(
   const double& probability[],  // array with probability values of random variable
   const double  nu,             // parameter of distribution (number of degrees of fr
   const double  delta,          // noncentrality parameter
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

© 2000-2025, MetaQuotes Ltd.

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNoncentralT

Generates a pseudorandom variable distributed according to the law of noncentral Student's t-distribution with the nu and delta parameters. In case of error it returns NaN.

```
double  MathRandomNoncentralT(
   const double  nu,              // parameter of distribution (number of degrees of fi
   const double  delta,           // noncentrality parameter
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of noncentral Student's t-distribution with the nu and delta parameters. In case of error it returns false. Analog of the rt() in R.

```
bool  MathRandomNoncentralT(
   const double  nu,              // parameter of distribution (number of degrees of fi
   const double  delta,           // noncentrality parameter
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNoncentralT

Calculates the theoretical numerical values of the first 4 moments of the noncentral Student's t-distribution with the nu and delta parameters.

```
double  MathMomentsNoncentralT(
   const double  nu,             // parameter of distribution (number of degrees of fi
   const double  delta,          // noncentrality parameter
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

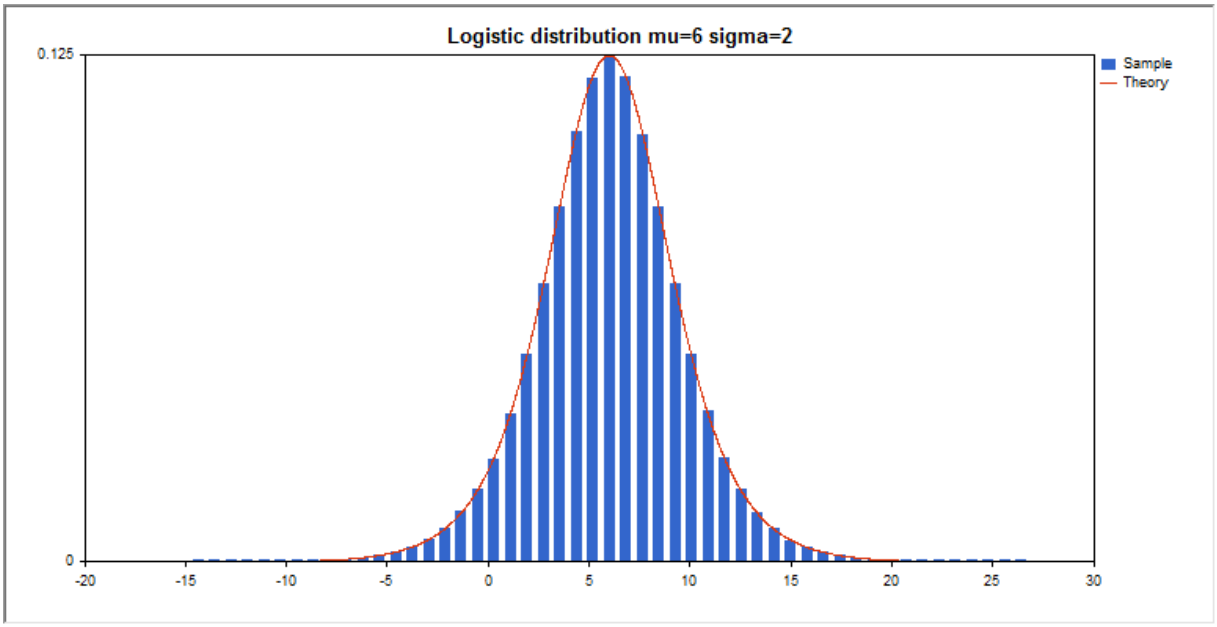
Logistic distribution

This section contains functions for working with logistic distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the logistic law. The logistic distribution is defined by the following formula:

$$f_{Logistic}(x|\mu,\sigma) = \frac{e^{\frac{x-\mu}{\sigma}}}{\sigma\left(1+e^{\frac{x-\mu}{\sigma}}\right)^2}$$

where:

- x — value of the random variable
- μ — mean parameter of the distribution
- σ — scale parameter of the distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityLogistic	Calculates the probability density function of the logistic distribution
MathCumulativeDistributionLogistic	Calculates the value of the logistic probability distribution function
MathQuantileLogistic	Calculates the value of the inverse logistic distribution function for the specified probability
MathRandomLogistic	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the logistic law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsLogistic	Calculates the theoretical numerical values of the first 4 moments of the logistic distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Logistic.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mu_par=6;         // mean parameter of the distribution
input double sigma_par=2;      // scale parameter of the distribution
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;        // the number of values in the sample
   int ncells=51;        // the number of intervals in the histogram
   double x[];           // centers of the histogram intervals
   double y[];           // the number of values from the sample falling within the int
   double data[];        // sample of random values
   double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the logistic distribution
   MathRandomLogistic(mu_par,sigma_par,n,data);
//--- calculate the data to plot the histogram
   CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
   double step;
   GetMaxMinStepValues(max,min,step);
   step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
   double x2[];
   double y2[];
   MathSequence(min,max,step,x2);
   MathProbabilityDensityLogistic(x2,mu_par,sigma_par,false,y2);
//--- set the scale
   double theor_max=y2[ArrayMaximum(y2)];
   double sample_max=y[ArrayMaximum(y)];
   double k=sample_max/theor_max;
```

MathProbabilityDensityLogistic

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLogistic(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityLogistic(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the dlogis() in R.

```
bool  MathProbabilityDensityLogistic(
   const double& x[],            // array with the values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityLogistic(
   const double& x[],            // array with the values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionLogistic

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLogistic(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionLogistic(
   const double  x,              // value of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionLogistic(
   const double& x[],            // array with the values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the plogis() in R.

```
bool  MathCumulativeDistributionLogistic(
   const double& x[],            // array with the values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileLogistic

For the specified *probability*, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLogistic(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathQuantileLogistic(
   const double  probability,    // probability value of random variable occurrence
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the qlogis() in R.

```
double  MathQuantileLogistic(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool  MathQuantileLogistic(
   const double& probability[],  // array with probability values of random variable
   const double  mu,             // mean parameter of the distribution
   const double  sigma,          // scale parameter of the distribution
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomLogistic

Generates a pseudorandom variable distributed according to the law of logistic distribution with the mu and sigma parameters. In case of error it returns NaN.

```
double  MathRandomLogistic(
   const double  mu,              // mean parameter of the distribution
   const double  sigma,           // scale parameter of the distribution
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of logistic distribution with the mu and sigma parameters. In case of error it returns false. Analog of the rlogis() in R.

```
bool  MathRandomLogistic(
   const double  mu,              // mean parameter of the distribution
   const double  sigma,           // scale parameter of the distribution
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsLogistic

Calculates the theoretical numerical values of the first 4 moments of the logistic distribution with the mu and sigma parameters.

```
double  MathMomentsLogistic(
   const double  mu,              // mean parameter of the distribution
   const double  sigma,           // scale parameter of the distribution
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

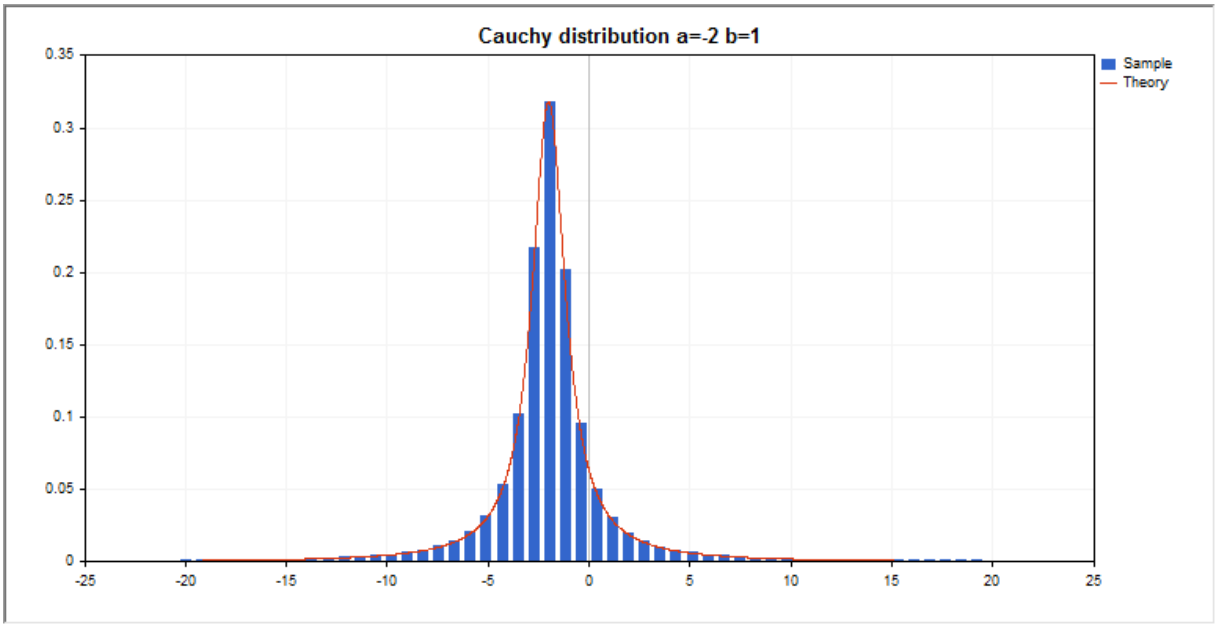
Cauchy distribution

This section contains functions for working with Cauchy distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Cauchy law. The Cauchy distribution is defined by the following formula:

$$f_{Cauchy}(x|a,b) = \frac{1}{\pi}\frac{b}{\left(b^2+(x-a)^2\right)}$$

where:

- x — value of the random variable
- a — mean parameter of the distribution
- b — scale parameter of the distribution



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityCauchy	Calculates the probability density function of the Cauchy distribution
MathCumulativeDistributionCauchy	Calculates the value of the Cauchy probability distribution function
MathQuantileCauchy	Calculates the value of the inverse Cauchy distribution function for the specified probability
MathRandomCauchy	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Cauchy law
MathMomentsCauchy	Calculates the theoretical numerical values of the first 4 moments of the Cauchy distribution

© 2000-2025, MetaQuotes Ltd.

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Cauchy.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters

MathProbabilityDensityCauchy

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityCauchy(
   const double  x,              // value of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityCauchy(
   const double  x,              // value of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dcauchy() in R.

```
bool  MathProbabilityDensityCauchy(
   const double& x[],            // array with the values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityCauchy(
   const double& x[],            // array with the values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionCauchy

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionCauchy(
   const double  x,              // value of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionCauchy(
   const double  x,              // value of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionCauchy(
   const double& x[],            // array with the values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the plogis() in R.

```
bool  MathCumulativeDistributionCauchy(
   const double& x[],            // array with the values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileCauchy

For the specified *probability*, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileCauchy(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileCauchy(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns false. Analog of the qcauschy() in R.

```
double  MathQuantileCauchy(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileCauchy(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomCauchy

Generates a pseudorandom variable distributed according to the law of Cauchy distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomCauchy(
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of Cauchy distribution with the a and b parameters. In case of error it returns false. Analog of the rcauchy() in R.

```
bool  MathRandomCauchy(
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsCauchy

Calculates the theoretical numerical values of the first 4 moments of the Cauchy distribution with the a and b parameters.

```
double  MathMomentsCauchy(
   const double  a,              // mean parameter of the distribution
   const double  b,              // scale parameter of the distribution
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

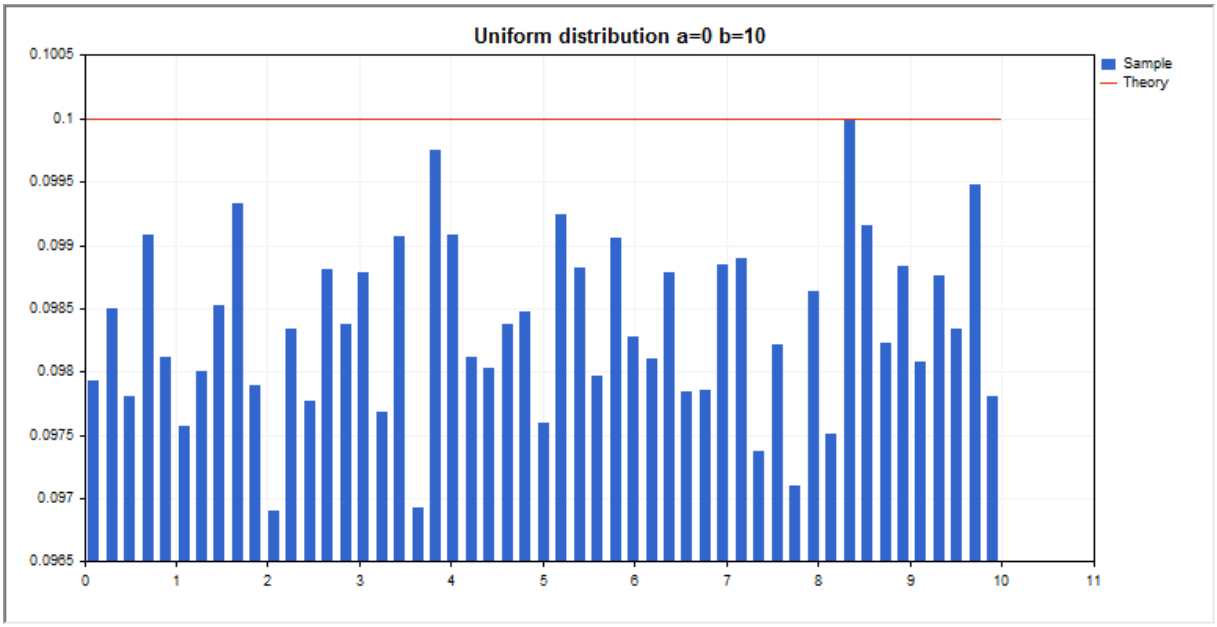
Uniform distribution

This section contains functions for working with uniform distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the uniform law. The uniform distribution is defined by the following formula:

$$f_{Uniform}(x|\,a,b) = \frac{1}{b-a}$$

where:

- x — value of the random variable
- a — parameter of the distribution (lower bound)
- b — parameter of the distribution (upper bound)



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityUniform	Calculates the probability density function of the uniform distribution
MathCumulativeDistributionUniform	Calculates the value of the uniform probability distribution function
MathQuantileUniform	Calculates the value of the inverse uniform distribution function for the specified probability
MathRandomUniform	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the uniform law
MathMomentsUniform	Calculates the theoretical numerical values of the first 4 moments of the uniform distribution

MathProbabilityDensityUniform

Calculates the value of the probability density function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityUniform(
   const double  x,              // value of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityUniform(
   const double  x,              // value of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dunif() in R.

```
bool  MathProbabilityDensityUniform(
   const double& x[],            // array with the values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityUniform(
   const double& x[],            // array with the values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionUniform

Calculates the probability distribution function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionUniform(
   const double  x,              // value of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionUniform(
   const double  x,              // value of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   int&          error_code      // variable to store the error code
   );
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionUniform(
   const double& x[],            // array with the values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the punif() in R.

```
bool  MathCumulativeDistributionUniform(
   const double& x[],            // array with the values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileUniform

For the specified *probability*, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileUniform(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileUniform(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns false. Analog of the qcauschy() in R.

```
double  MathQuantileUniform(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileUniform(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomUniform

Generates a pseudorandom variable distributed according to the law of uniform distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomUniform(
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of uniform distribution with the a and b parameters. In case of error it returns false. Analog of the runif() in R.

```
bool  MathRandomUniform(
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsUniform

Calculates the theoretical numerical values of the first 4 moments of the uniform distribution with the a and b parameters.

```
double  MathMomentsUniform(
   const double  a,              // distribution parameter a (lower bound)
   const double  b,              // distribution parameter b (upper bound)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

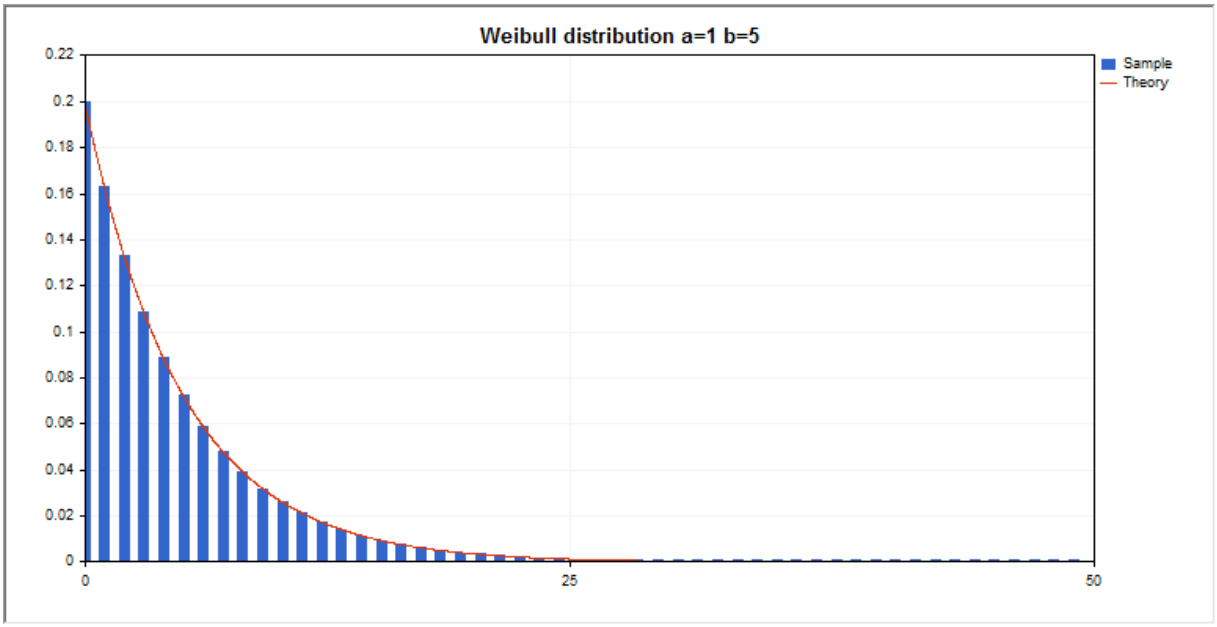
Weibull distribution

This section contains functions for working with Weibull distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Weibull law. The Weibull distribution is defined by the following formula:

$$f_{Weibull}(x|a,b) = \frac{a}{b}\left(\frac{x}{b}\right)^{a-1} e^{-\left(\frac{x}{b}\right)^{a}}$$

where:

- x — value of the random variable
- a — parameter of the distribution (shape)
- b — parameter of the distribution (scale)



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityWeibull	Calculates the probability density function of the Weibull distribution
MathCumulativeDistributionWeibull	Calculates the value of the Weibull probability distribution function
MathQuantileWeibull	Calculates the value of the inverse Weibull distribution function for the specified probability
MathRandomWeibull	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Weibull law
MathMomentsWeibull	Calculates the theoretical numerical values of the first 4 moments of the Weibull distribution

© 2000-2025, MetaQuotes Ltd.

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Weibull.mqh>
#include <Math\Stat\Math.mqh>

MathProbabilityDensityWeibull

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityWeibull(
   const double  x,              // value of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityWeibull(
   const double  x,              // value of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the dweibull() in R.

```
bool  MathProbabilityDensityWeibull(
   const double& x[],            // array with the values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if 1
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityWeibull(
   const double& x[],            // array with the values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionWeibull

Calculates the value of the Weibull distribution function with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionWeibull(
   const double  x,              // value of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Weibull distribution function with the a and b parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionWeibull(
   const double  x,              // value of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Weibull distribution function with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the pweibull() in R.

```
bool  MathCumulativeDistributionWeibull(
   const double& x[],            // array with the values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the Weibull distribution function with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionWeibull(
   const double& x[],            // array with the values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileWeibull

For the specified *probability*, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileWeibull(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns NaN.

```
double  MathQuantileWeibull(
   const double  probability,    // probability value of random variable occurrence
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns false. Analog of the qweibull() in R.

```
double  MathQuantileWeibull(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns false.

```
bool  MathQuantileWeibull(
   const double& probability[],  // array with probability values of random variable
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomWeibull

Generates a pseudorandom variable distributed according to the law of Weibull distribution with the a and b parameters. In case of error it returns NaN.

```
double  MathRandomWeibull(
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of Weibull distribution with the a and b parameters. In case of error it returns false. Analog of the rweibull() in R.

```
bool  MathRandomWeibull(
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsWeibull

Calculates the theoretical numerical values of the first 4 moments of the Weibull distribution with the a and b parameters.

```
double  MathMomentsWeibull(
   const double  a,              // parameter of the distribution (shape)
   const double  b,              // parameter of the distribution (scale)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

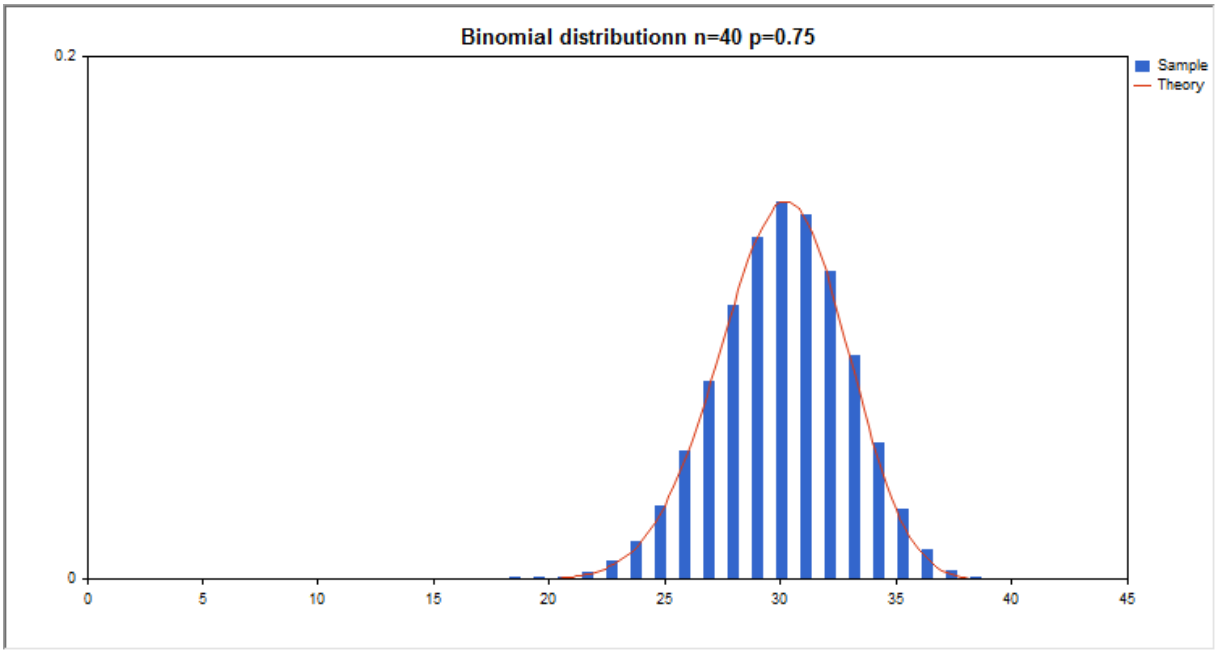
Binomial distribution

This section contains functions for working with binomial distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the binomial law. The binomial distribution is defined by the following formula:

$$f_{Binomial}(x \mid n, p) = \binom{n}{x} p^x (1-p)^{n-x}$$

where:

- x — value of the random variable
- n — number of tests
- p — probability of success for each test



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityBinomial	Calculates the probability density function of the binomial distribution
MathCumulativeDistributionBinomial	Calculates the value of the binomial probability distribution function
MathQuantileBinomial	Calculates the value of the inverse binomial distribution function for the specified probability
MathRandomBinomial	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the binomial law
MathMomentsBinomial	Calculates the theoretical numerical values of the first 4 moments of the binomial distribution

© 2000-2025, MetaQuotes Ltd.

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Binomial.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double n_par=40;        // the number of tests
input double p_par=0.75;      // probability of success for each test
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()

MathProbabilityDensityBinomial

Calculates the value of the probability mass function of binomial distribution with the n and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBinomial(
   const double  x,              // value of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of event
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of binomial distribution with the n and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityBinomial(
   const double  x,              // value of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of event
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of binomial distribution with the n and p parameters for an array of random variables x[]. In case of error it returns false. Analog of the dbinom() in R.

```
bool  MathProbabilityDensityBinomial(
   const double& x[],            // array with the values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability mass function of binomial distribution with the n and p parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityBinomial(
   const double& x[],            // array with the values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionBinomial

Calculates the value of the probability distribution function for binomial law with the n and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBinomial(
   const double  x,              // value of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of event
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionBinomial(
   const double  x,              // value of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of event
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for an array of random variables x[]. In case of error it returns false. Analog of the pweibull() in R.

```
bool  MathCumulativeDistributionBinomial(
   const double& x[],            // array with the values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionBinomial(
   const double& x[],            // array with the values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

© 2000-2025, MetaQuotes Ltd.

x[]

[in] Array with the values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileBinomial

For the specified *probability*, the function calculates the inverse value of distribution function for binomial law with the n and p parameters. In case of error it returns NaN.

```
double  MathQuantileBinomial(
   const double  probability,    // probability value of random variable occurrence
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatio
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the inverse value of distribution function for binomial law with the n and p parameters. In case of error it returns NaN.

```
double  MathQuantileBinomial(
   const double  probability,    // probability value of random variable occurrence
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for binomial law with the n and p parameters. In case of error it returns false. Analog of the qbinom() in R.

```
double  MathQuantileBinomial(
   const double& probability[],  // array with probability values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatio
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for binomial law with the n and p parameters. In case of error it returns false.

```
bool  MathQuantileBinomial(
   const double& probability[],  // array with probability values of random variable
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

© 2000-2025, MetaQuotes Ltd.

probability[]

[in] Array with probability values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomBinomial

Generates a pseudorandom variable distributed according to the law of binomial distribution with the n and p parameters. In case of error it returns NaN.

```
double  MathRandomBinomial(
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of binomial distribution with the n and p parameters. In case of error it returns false. Analog of the rweibull() in R.

```
bool  MathRandomBinomial(
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsBinomial

Calculates the theoretical numerical values of the first 4 moments of the binomial distribution with the n and p parameters.

```
double  MathMomentsBinomial(
   const double  n,              // parameter of the distribution (number of tests)
   const double  p,              // parameter of the distribution (probability of ever
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

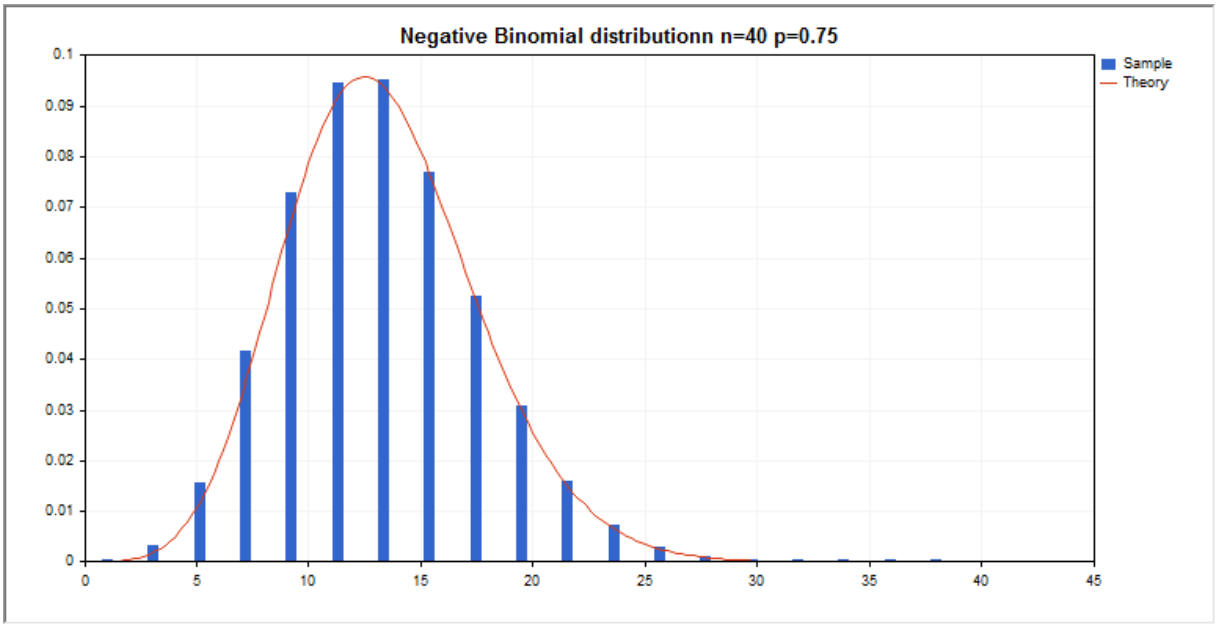
Negative binomial distribution

This section contains functions for working with negative binomial distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the negative binomial law. The negative binomial distribution is defined by the following formula:

$$f_{NegativeBinomial}(x \mid r, p) = \frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)} p^r (1-p)^x$$

where:

- x — value of the random variable
- r — number of successful tests
- p — probability of success



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNegativeBinomial	Calculates the probability density function of the negative binomial distribution
MathCumulativeDistributionNegativeBinomial	Calculates the value of the negative binomial probability distribution function
MathQuantileNegativeBinomial	Calculates the value of the inverse negative binomial distribution function for the specified probability
MathRandomNegativeBinomial	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the negative binomial law
MathMomentsNegativeBinomial	Calculates the theoretical numerical values of the first 4 moments of the negative binomial distribution

MathProbabilityDensityNegativeBinomial

Calculates the value of the probability mass function of negative binomial distribution with the r and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNegativeBinomial(
   const double  x,              // value of random variable (integer)
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of negative binomial distribution with the r and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityNegativeBinomial(
   const double  x,              // value of random variable (integer)
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of negative binomial distribution with the r and p parameters for an array of random variables x[]. In case of error it returns false. Analog of the dnbinom() in R.

```
bool  MathProbabilityDensityNegativeBinomial(
   const double& x[],            // array with the values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability mass function of negative binomial distribution with the r and p parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityNegativeBinomial(
   const double& x[],            // array with the values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

© 2000-2025, MetaQuotes Ltd.

[in] Array with the values of random variable.

r

[in] Number of successful tests

p

[in] Probability of success.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionNegativeBinomial

Calculates the value of the probability distribution function for negative binomial law with the r and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNegativeBinomial(
   const double  x,              // value of random variable (integer)
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for negative binomial law with the r and p parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionNegativeBinomial(
   const double  x,              // value of random variable (integer)
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for negative binomial law with the r and p parameters for an array of random variables x[]. In case of error it returns false. Analog of the pweibull() in R.

```
bool  MathCumulativeDistributionNegativeBinomial(
   const double& x[],            // array with the values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the probability distribution function for negative binomial law with the r and p parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionNegativeBinomial(
   const double& x[],            // array with the values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

© 2000-2025, MetaQuotes Ltd.

x[]

[in] Array with the values of random variable.

r

[in] Number of successful tests.

p

[in] Probability of success.

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileNegativeBinomial

For the specified *probability*, the function calculates the inverse value of distribution function for negative binomial law with the r and p parameters. In case of error it returns NaN.

```
double  MathQuantileNegativeBinomial(
   const double  probability,    // probability value of random variable occurrence
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the inverse value of distribution function for negative binomial law with the r and p parameters. In case of error it returns NaN.

```
double  MathQuantileNegativeBinomial(
   const double  probability,    // probability value of random variable occurrence
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for negative binomial law with the r and p parameters. In case of error it returns false. Analog of the qnbinom() in R.

```
double  MathQuantileNegativeBinomial(
   const double& probability[],  // array with probability values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for negative binomial law with the r and p parameters. In case of error it returns false.

```
bool  MathQuantileNegativeBinomial(
   const double& probability[],  // array with probability values of random variable
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

© 2000-2025, MetaQuotes Ltd.

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

r

[in] Number of successful tests.

p

[in] Probability of success.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomNegativeBinomial

Generates a pseudorandom variable distributed according to the law of negative binomial distribution with the r and p parameters. In case of error it returns NaN.

```
double  MathRandomNegativeBinomial(
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of negative binomial distribution with the r and p parameters. In case of error it returns false. Analog of the rweibull() in R.

```
bool  MathRandomNegativeBinomial(
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

r

[in] Number of successful tests.

p

[in] Probability of success.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsNegativeBinomial

Calculates the theoretical numerical values of the first 4 moments of the negative binomial distribution with the r and p parameters.

```
double  MathMomentsNegativeBinomial(
   const double  r,              // number of successful tests
   const double  p,              // probability of success
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

r

[in] Number of successful tests.

p

[in] Probability of success.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

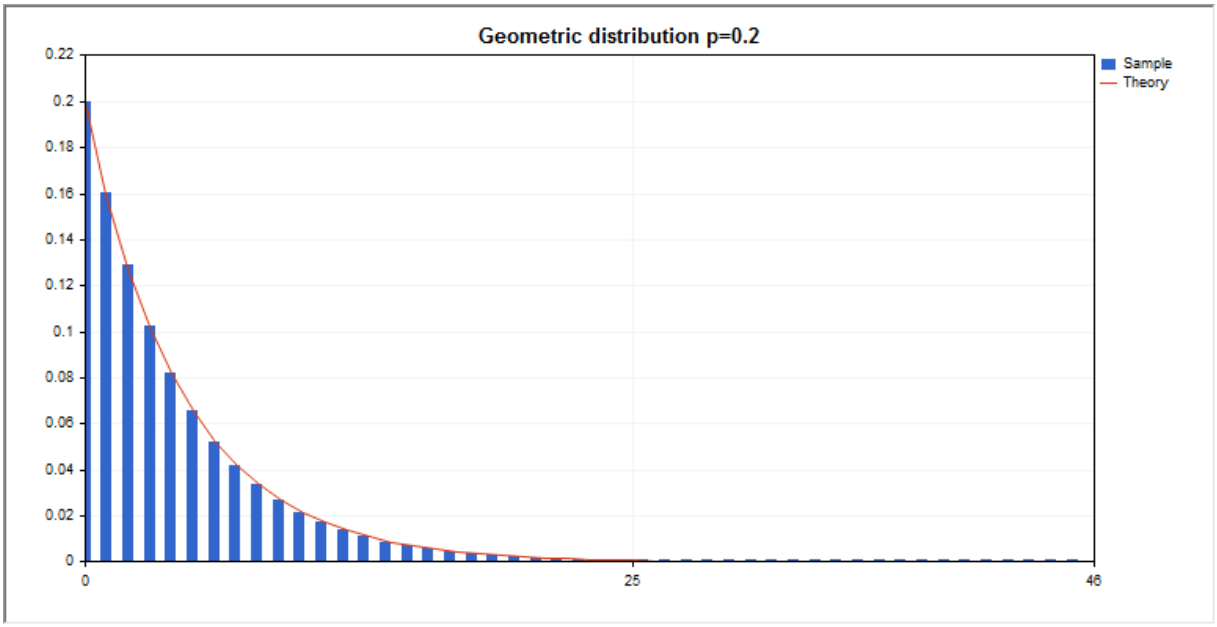
Geometric distribution

This section contains functions for working with geometric distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the geometric law. The geometric distribution is defined by the following formula:

$$f_{Geometric}(x|p) = p(1-p)^x$$

where:

- x — value of the random variable (integer)
- p — probability of event occurrence in one test



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityGeometric	Calculates the probability density function of the geometric distribution
MathCumulativeDistributionGeometric	Calculates the value of the geometric probability distribution function
MathQuantileGeometric	Calculates the value of the inverse geometric distribution function for the specified probability
MathRandomGeometric	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the geometric law
MathMomentsGeometric	Calculates the theoretical numerical values of the first 4 moments of the geometric distribution

Example:

MathProbabilityDensityGeometric

Calculates the value of the probability mass function of geometric distribution with the p parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGeometric(
   const double  x,              // value of random variable (integer)
   const double  p,              // parameter of the distribution (probability of event
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityGeometric(
   const double  x,              // value of random variable (integer)
   const double  p,              // parameter of the distribution (probability of event
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for an array of random variables x[]. In case of error it returns false. Analog of the dgeom() in R.

```
bool  MathProbabilityDensityGeometric(
   const double& x[],            // array with the values of random variable
   const double  p,              // parameter of the distribution (probability of ever
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityGeometric(
   const double& x[],            // array with the values of random variable
   const double  p,              // parameter of the distribution (probability of ever
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

p

[in] Parameter of the distribution (probability of event occurrence in one test).

log_mode

© 2000-2025, MetaQuotes Ltd.

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionGeometric

Calculates the value of the probability distribution function for geometric law with the p parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGeometric(
   const double  x,              // value of random variable (integer)
   const double  p,              // parameter of the distribution (probability of event
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for geometric law with the p parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionGeometric(
   const double  x,              // value of random variable (integer)
   const double  p,              // parameter of the distribution (probability of event
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for geometric law with the p parameter for an array of random variables x[]. In case of error it returns false. Analog of the pgeom() in R.

```
bool  MathCumulativeDistributionGeometric(
   const double& x[],            // array with the values of random variable
   const double  p,              // parameter of the distribution (probability of even
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability function
   );
```

Calculates the value of the probability distribution function for geometric law with the p parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionGeometric(
   const double& x[],            // array with the values of random variable
   const double  p,              // parameter of the distribution (probability of even
   double&       result[]        // array for values of the probability function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

p

[in] Parameter of the distribution (probability of event occurrence in one test).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation, if tail=true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileGeometric

For the specified *probability*, the function calculates the inverse value of distribution function for geometric law with the p parameter. In case of error it returns NaN.

```
double  MathQuantileGeometric(
   const double  probability,    // probability value of random variable occurrence
   const double  p,              // parameter of the distribution (probability of ever
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatio
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the inverse value of distribution function for geometric law with the p parameter. In case of error it returns NaN.

```
double  MathQuantileGeometric(
   const double  probability,    // probability value of random variable occurrence
   const double  p,              // parameter of the distribution (probability of ever
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for geometric law with the p parameter. In case of error it returns false. Analog of the qgeom() in R.

```
double  MathQuantileGeometric(
   const double& probability[],  // array with probability values of random variable
   const double  p,              // parameter of the distribution (probability of ever
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculatio
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for geometric law with the p parameter. In case of error it returns false.

```
bool  MathQuantileGeometric(
   const double& probability[],  // array with probability values of random variable
   const double  p,              // parameter of the distribution (probability of ever
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

p

© 2000-2025, MetaQuotes Ltd.

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomGeometric

Generates a pseudorandom variable distributed according to the law of geometric distribution with the p parameter. In case of error it returns NaN.

```
double  MathRandomGeometric(
   const double  p,              // parameter of the distribution (probability of ever
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of geometric distribution with the p parameter. In case of error it returns false. Analog of the rgeom() in R.

```
bool  MathRandomGeometric(
   const double  p,              // parameter of the distribution (probability of ever
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

p

[in] Parameter of the distribution (probability of event occurrence in one test).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsGeometric

Calculates the theoretical numerical values of the first 4 moments of the geometric distribution with the p parameter.

```
double  MathMomentsGeometric(
   const double  p,              // parameter of the distribution (probability of ever
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

p

[in] Parameter of the distribution (probability of event occurrence in one test).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

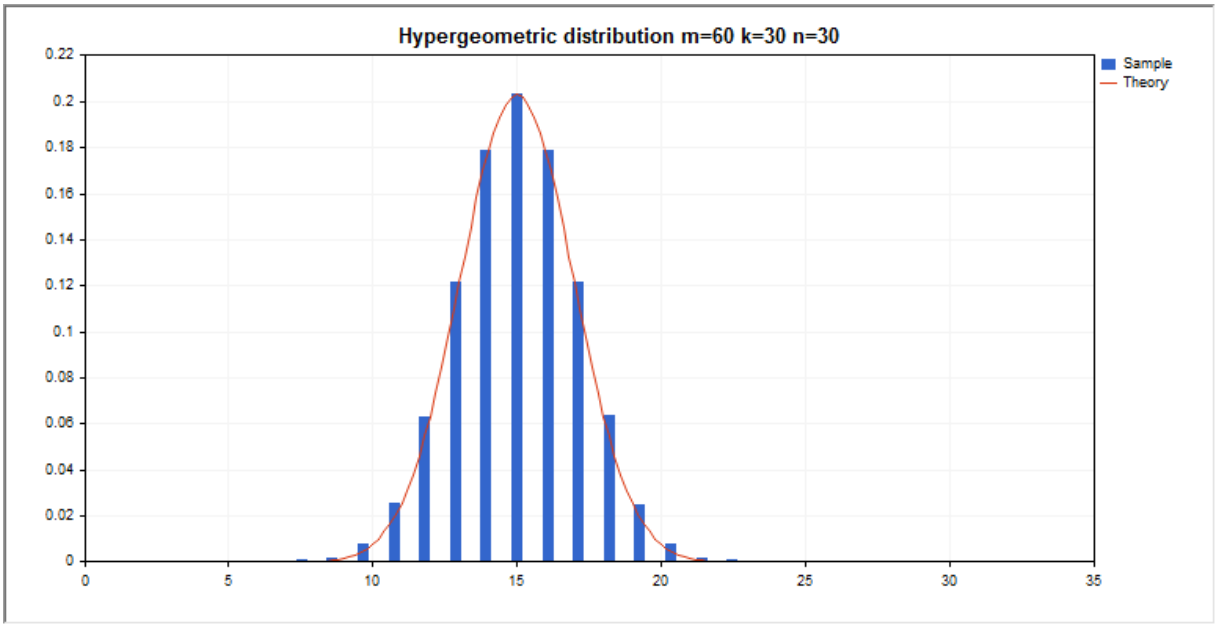
Hypergeometric distribution

This section contains functions for working with hypergeometric distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the hypergeometric law. The hypergeometric distribution is defined by the following formula:

$$f_{Hypergeometric}(x \mid m,k,n) = \frac{\binom{k}{x}\binom{m-k}{n-x}}{\binom{m}{n}}$$

where:

- x — value of the random variable (integer)
- m — total number of objects
- k — number of objects with the desired characteristic
- n — number of object draws



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityHypergeometric	Calculates the probability density function of the hypergeometric distribution
MathCumulativeDistributionHypergeometric	Calculates the value of the hypergeometric probability distribution function
MathQuantileHypergeometric	Calculates the value of the inverse hypergeometric distribution function for the specified probability
MathRandomHypergeometric	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the hypergeometric law

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathMomentsHypergeometric	Calculates the theoretical numerical values of the first 4 moments of the hypergeometric distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Hypergeometric.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double m_par=60;      // the total number of objects
input double k_par=30;      // the number of objects with the desired characteristic
input double n_par=30;      // the number of object draws
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
  {
//--- hide the price chart
   ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
   MathSrand(GetTickCount());
//--- generate a sample of the random variable
   long chart=0;
   string name="GraphicNormal";
   int n=1000000;       // the number of values in the sample
   int ncells=15;       // the number of intervals in the histogram
   double x[];          // centers of the histogram intervals

MathProbabilityDensityHypergeometric

Calculates the value of the probability mass function of hypergeometric distribution with the m, k and n parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityHypergeometric(
   const double  x,              // value of random variable (integer)
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of hypergeometric distribution with the m, k and n parameters for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityHypergeometric(
   const double  x,              // value of random variable (integer)
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of hypergeometric distribution with the m, k and n parameters for an array of random variables x[]. In case of error it returns false. Analog of the dhyper() in R.

```
bool  MathProbabilityDensityHypergeometric(
   const double& x[],            // array with the values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability mass function of hypergeometric distribution with the m, k and n parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityHypergeometric(
   const double& x[],            // array with the values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

© 2000-2025, MetaQuotes Ltd.

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionHypergeometric

Calculates the value of the probability distribution function for hypergeometric law with the m, k and n parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionHypergeometric(
   const double  x,              // value of random variable (integer)
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for hypergeometric law with the m, k and n parameters for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionHypergeometric(
   const double  x,              // value of random variable (integer)
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability distribution function for hypergeometric law with the m, k and n parameters for an array of random variables x[]. In case of error it returns false. Analog of the dhyper() in R.

```
bool  MathCumulativeDistributionHypergeometric(
   const double& x[],            // array with the values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if
   double&       result[]        // array for values of the distribution function
   );
```

Calculates the value of the probability distribution function for hypergeometric law with the m, k and n parameters for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionHypergeometric(
   const double& x[],            // array with the values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   double&       result[]        // array for values of the distribution function
   );
```

© 2000-2025, MetaQuotes Ltd.

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the distribution function.

© 2000-2025, MetaQuotes Ltd.

MathQuantileHypergeometric

For the specified *probability*, the function calculates the inverse value of distribution function for hypergeometric law with the m, k and n parameters. In case of error it returns NaN.

```
double  MathQuantileHypergeometric(
   const double  probability,    // probability value of random variable occurrence
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the inverse value of distribution function for hypergeometric law with the m, k and n parameters. In case of error it returns NaN.

```
double  MathQuantileHypergeometric(
   const double  probability,    // probability value of random variable occurrence
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for hypergeometric law with the m, k and n parameters. In case of error it returns false. Analog of the qhyper() in R.

```
double  MathQuantileHypergeometric(
   const double& probability[],  // array with probability values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for hypergeometric law with the m, k and n parameters. In case of error it returns false.

```
bool  MathQuantileHypergeometric(
   const double& probability[],  // array with probability values of random variable
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   double&       result[]        // array with values of quantiles
```

© 2000-2025, MetaQuotes Ltd.

```
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

tail

[in] Flag of calculation, if tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomHypergeometric

Generates a pseudorandom variable distributed according to the law of hypergeometric distribution with the m, n and k parameters. In case of error it returns NaN.

```
double  MathRandomHypergeometric(
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   int&          error_code      // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of hypergeometric distribution with the m, n and k parameters. In case of error it returns false. Analog of the rgeom() in R.

```
bool  MathRandomHypergeometric(
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   const int     data_count,     // amount of required data
   double&       result[]        // array with values of pseudorandom variables
   );
```

Parameters

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsHypergeometric

Calculates the theoretical numerical values of the first 4 moments of the hypergeometric distribution with the m, n and k parameters.

```
double  MathMomentsHypergeometric(
   const double  m,              // total number of objects (integer)
   const double  k,              // number of objects with the desired characteristic
   const double  n,              // number of object draws (integer)
   double&       mean,           // variable for the mean
   double&       variance,       // variable for the variance
   double&       skewness,       // variable for the skewness
   double&       kurtosis,       // variable for the kurtosis
   int&          error_code      // variable for the error code
   );
```

Parameters

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

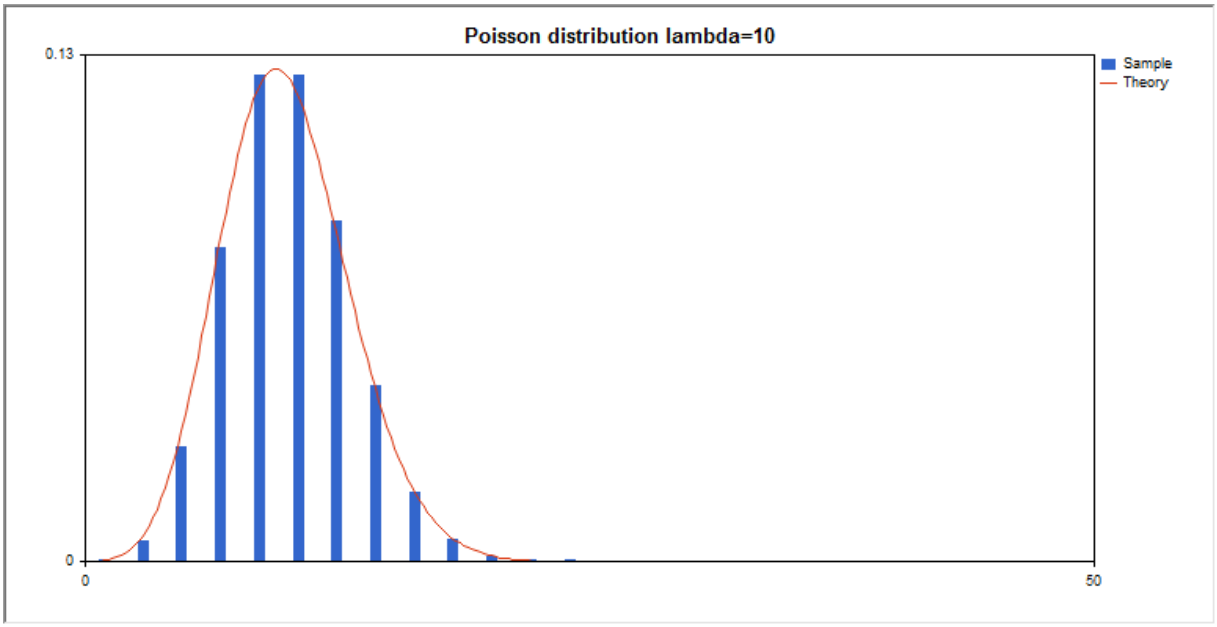
Poisson distribution

This section contains functions for working with Poisson distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Poisson law. The Poisson distribution is defined by the following formula:

$$f_{Poisson}(x|\lambda) = \frac{\lambda^x}{x!}e^{-\lambda}$$

where:

- x — value of the random variable
- λ — parameter of the distribution (mean)



In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityPoisson	Calculates the probability density function of the Poisson distribution
MathCumulativeDistributionPoisson	Calculates the value of the Poisson probability distribution function
MathQuantilePoisson	Calculates the value of the inverse Poisson distribution function for the specified probability
MathRandomPoisson	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Poisson law
MathMomentsPoisson	Calculates the theoretical numerical values of the first 4 moments of the Poisson distribution

Example:

MathProbabilityDensityPoisson

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityPoisson(
   const double  x,              // value of random variable (integer)
   const double  lambda,         // parameter of the distribution (mean)
   const bool    log_mode,       // calculate the logarithm of the value, if log_mode=t
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for a random variable x. In case of error it returns NaN.

```
double  MathProbabilityDensityPoisson(
   const double  x,              // value of random variable (integer)
   const double  lambda,         // parameter of the distribution (mean)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for an array of random variables x[]. In case of error it returns false. Analog of the dhyper() in R.

```
bool  MathProbabilityDensityPoisson(
   const double& x[],            // array with the values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the probability density functi
   );
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathProbabilityDensityPoisson(
   const double& x[],            // array with the values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   double&       result[]        // array for values of the probability density functi
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

lambda

[in] Parameter of the distribution (mean).

log_mode

© 2000-2025, MetaQuotes Ltd.

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionPoisson

Calculates the value of the Poisson distribution function with the lambda parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionPoisson(
   const double  x,              // value of random variable (integer)
   const double  lambda,         // parameter of the distribution (mean)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if lo
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Poisson distribution function with the lambda parameter for a random variable x. In case of error it returns NaN.

```
double  MathCumulativeDistributionPoisson(
   const double  x,              // value of random variable (integer)
   const double  lambda,         // parameter of the distribution (mean)
   int&          error_code      // variable to store the error code
   );
```

Calculates the value of the Poisson distribution function with the lambda parameter for an array of random variables x[]. In case of error it returns false. Analog of the dhyper() in R.

```
bool  MathCumulativeDistributionPoisson(
   const double& x[],            // array with the values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   const bool    tail,           // flag of calculation, if true, then the probability
   const bool    log_mode,       // flag to calculate the logarithm of the value, if l
   double&       result[]        // array for values of the distribution function
   );
```

Calculates the value of the Poisson distribution function with the lambda parameter for an array of random variables x[]. In case of error it returns false.

```
bool  MathCumulativeDistributionPoisson(
   const double& x[],            // array with the values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   double&       result[]        // array for values of the distribution function
   );
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

lambda

[in] Parameter of the distribution (mean).

© 2000-2025, MetaQuotes Ltd.

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the distribution function.

© 2000-2025, MetaQuotes Ltd.

MathQuantilePoisson

For the specified *probability*, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns NaN.

```
double  MathQuantilePoisson(
   const double  probability,    // probability value of random variable occurrence
   const double  lambda,         // parameter of the distribution (mean)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability*, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns NaN.

```
double  MathQuantilePoisson(
   const double  probability,    // probability value of random variable occurrence
   const double  lambda,         // parameter of the distribution (mean)
   int&          error_code      // variable to store the error code
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns false. Analog of the qhyper() in R.

```
double  MathQuantilePoisson(
   const double& probability[],  // array with probability values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   const bool    tail,           // flag of calculation, if false, then calculation is
   const bool    log_mode,       // flag of calculation, if log_mode=true, calculation
   double&       result[]        // array with values of quantiles
   );
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns false.

```
bool  MathQuantilePoisson(
   const double& probability[],  // array with probability values of random variable
   const double  lambda,         // parameter of the distribution (mean)
   double&       result[]        // array with values of quantiles
   );
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

lambda

© 2000-2025, MetaQuotes Ltd.

[in] Parameter of the distribution (mean).

tail

[in] Flag of calculation, if tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

© 2000-2025, MetaQuotes Ltd.

MathRandomPoisson

Generates a pseudorandom variable distributed according to the law of Poisson distribution with the lambda parameter. In case of error it returns NaN.

```
double  MathRandomPoisson(
   const double  lambda,          // parameter of the distribution (mean)
   int&          error_code       // variable to store the error code
   );
```

Generates pseudorandom variables distributed according to the law of Poisson distribution with the lambda parameter. In case of error it returns false. Analog of the rgeom() in R.

```
bool  MathRandomPoisson(
   const double  lambda,          // parameter of the distribution (mean)
   const int     data_count,      // amount of required data
   double&       result[]         // array with values of pseudorandom variables
   );
```

Parameters

lambda

[in] Parameter of the distribution (mean).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

© 2000-2025, MetaQuotes Ltd.

MathMomentsPoisson

Calculates the theoretical numerical values of the first 4 moments of the Poisson distribution with the lambda parameter.

```
double  MathMomentsPoisson(
   const double  lambda,          // parameter of the distribution (mean)
   double&       mean,            // variable for the mean
   double&       variance,        // variable for the variance
   double&       skewness,        // variable for the skewness
   double&       kurtosis,        // variable for the kurtosis
   int&          error_code       // variable for the error code
   );
```

Parameters

lambda

[in] Parameter of the distribution (mean).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

Subfunctions

Group of functions that perform basic mathematical operations: calculation of the gamma function, beta function, factorial, exponential, logarithms with different bases, square root, etc.

They provide the ability to process both individual numeric values (real and integer) and arrays of such values (with output of the results to a separate or the original array).

Function	Description
MathRandomNonZero	Returns a random number with a floating point in the range from 0.0 to 1.0.
MathMoments	Calculates the first 4 moments of array elements: mean, variance, skewness, kurtosis.
MathPowInt	Raises a number to the specified integer power.
MathFactorial	Calculates the factorial of the specified integer.
MathTrunc	Calculates the integer part of the specified number or array elements.
MathRound	Rounds a number or an array of numbers to the specified number of decimal places.
MathArctan2	Calculates the angle, the tangent of which is equal to the ratio of the two specified numbers in the range of [-pi, pi].
MathGamma	Calculates the value of the gamma function.
MathGammaLog	Calculates the logarithm of the gamma function.
MathBeta	Calculates the value of the beta function.
MathBetaLog	Calculates the logarithm of the beta function.
MathBetaIncomplete	Calculates the value of the incomplete beta function.
MathGammaIncomplete	Calculates the value of the incomplete gamma function.
MathBinomialCoefficient	Calculates the binomial coefficient.
MathBinomialCoefficientLog	Calculates the logarithm of the binomial coefficient.
MathHypergeometric2F2	Calculates the value of the hypergeometric function.

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathSequence	Generates a sequence based on values: the first element, the last element, the step of the sequence.
MathSequenceByCount	Generates a sequence based on values: the first element, the last element, the number of elements in the sequence.
MathReplicate	Generates a repeating sequence of values.
MathReverse	Generates an array of values with reverse order of elements.
MathIdentical	Compares two arrays of values and returns true if all elements match.
MathUnique	Generates an array with unique values only.
MathQuickSortAscending	Function for sorting in ascending order.
MathQuickSortDescending	Function for sorting in descending order.
MathQuickSort	Function for sorting.
MathOrder	Generates an array with permutation according to order of the array elements after sorting.
MathBitwiseNot	Calculates the result of bitwise NOT operation for array elements.
MathBitwiseAnd	Calculates the result of bitwise AND operation for elements of arrays.
MathBitwiseOr	Calculates the result of bitwise OR operation for elements of arrays.
MathBitwiseXor	Calculates the result of bitwise XOR operation for elements of arrays.
MathBitwiseShiftL	Calculates the result of bitwise SHL operation for array elements.
MathBitwiseShiftR	Calculates the result of bitwise SHR operation for array elements.
MathCumulativeSum	Generates an array with the cumulative sums.
MathCumulativeProduct	Generates an array with the cumulative products.
MathCumulativeMin	Generates an array with the cumulative minima.
MathCumulativeMax	Generates an array with the cumulative maxima.

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathSin	Calculates the values of the sin(x) function for array elements.
MathCos	Calculates the values of the cos(x) function for array elements.
MathTan	Calculates the values of the tan(x) function for array elements.
MathArcsin	Calculates the values of the arcsin(x) function for array elements.
MathArccos	Calculates the values of the arccos(x) function for array elements.
MathArctan	Calculates the values of the arctan(x) function for array elements.
MathSinPi	Calculates the values of the sin(pi*x) function for array elements.
MathCosPi	Calculates the values of the cos(pi*x) function for array elements.
MathTanPi	Calculates the values of the tan(pi*x) function for array elements.
MathAbs	Calculates the absolute values of array elements.
MathCeil	Returns the nearest larger integers for array elements.
MathFloor	Returns the nearest smaller integers for array elements.
MathSqrt	Calculates the square roots of array elements.
MathExp	Calculates the values of the exp(x) function for array elements.
MathPow	Calculates the values of the pow(x, power) function for array elements.
MathLog	Calculates the values of the log(x) function for array elements.
MathLog2	Calculates the logarithm to the base 2 for the array elements.
MathLog10	Calculates the logarithm to the base 10 for the array elements.
MathDifference	Generates an array with element differences of y[i]=x[i+lag]-x[i].

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathSample	Generates a random sample from the array elements.
MathTukeySummary	Calculates the Tukey's five-number summary for the array elements.
MathRange	Calculates the minima and maxima of array elements.
MathMin	Returns the minimum value of all array elements.
MathMax	Returns the maximum value of all array elements.
MathSum	Returns the sum of array elements.
MathProduct	Returns the product of array elements.
MathStandardDeviation	Calculates the standard deviation of array elements.
MathAverageDeviation	Calculates the average absolute deviation of array elements.
MathMedian	Calculates the median value of array elements.
MathMean	Calculates the mean values of array elements.
MathVariance	Calculates the variance of the array elements.
MathSkewness	Calculates the skewness of the array elements.
MathKurtosis	Calculates the kurtosis of the array elements.
MathLog1p	Calculates the values of the log(1+x) function for array elements.
MathExpm1	Calculates the values of the exp(x)-1 function for array elements.
MathSinh	Calculates the values of the sinh(x) function for array elements.
MathCosh	Calculates the values of the cosh(x) function for array elements.
MathTanh	Calculates the values of the tanh(x) function for array elements.
MathArcsinh	Calculates the values of the arcsinh(x) function for array elements.

© 2000-2025, MetaQuotes Ltd.

Function	Description
MathArccosh	Calculates the values of the arccosh(x) function for array elements.
MathArctanh	Calculates the values of the arctanh(x) function for array elements.
MathSignif	Rounds a value to the specified number of digits in the mantissa.
MathRank	Calculates the ranks of array elements.
MathCorrelationPearson	Calculates the Pearson's correlation coefficient.
MathCorrelationSpearman	Calculates the Spearman's correlation coefficient.
MathCorrelationKendall	Calculates the Kendall's correlation coefficient.
MathQuantile	Calculates sample quantiles corresponding to the specified probabilities.
MathProbabilityDensityEmpirical	Calculates the empirical probability density function for random values.
MathCumulativeDistributionEmpirical	Calculates the empirical cumulative distribution function for random values.

© 2000-2025, MetaQuotes Ltd.

MathRandomNonZero

Returns a random number with a floating point in the range from 0.0 to 1.0.

```
double  MathRandomNonZero()
```

Return Value

Random number with a floating point in the range from 0.0 to 1.0.

© 2000-2025, MetaQuotes Ltd.

MathMoments

Calculates the first 4 moments of array elements: mean, variance, skewness, kurtosis.

```
bool  MathMoments(
   const double&  array[],            // array of values
   double&        mean,               // variable for the mean
   double&        variance,           // variable for the variance
   double&        skewness,           // variable for the skewness
   double&        kurtosis,           // variable for the kurtosis
   const int      start=0,            // initial index
   const int      count=WHOLE_ARRAY   // the number of elements
   )
```

Parameters

array[]

[in] Array of values.

mean

[out] Variable for the mean (1st moment).

variance

[out] Variable for the variance (2nd moment).

skewness

[out] Variable for the skewness (3rd moment).

kurtosis

[out] Variable for the kurtosis (4th moment).

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathPowInt

Raises a number to the specified integer power.

```
double  MathPowInt(
   const double  x,      // value of the number
   const int     power   // power to raise to
   )
```

Parameters

x

[in] Double-precision floating-point number to be raised to the power.

power

[in] Integer specifying the power.

Return Value

The number x, raised to the specified power.

© 2000-2025, MetaQuotes Ltd.

MathFactorial

Calculates the factorial of the specified integer.

```
double  MathFactorial(
   const int  n   // value of the number
   )
```

Parameters

n

[in] Integer number, the factorial of which is to be calculated.

Return Value

The factorial of the number.

© 2000-2025, MetaQuotes Ltd.

MathTrunc

Calculates the integer part of the specified number or array elements.

Version for working with a double-precision floating-point number:

```
double  MathTrunc(
   const double   x          // value of the number
   )
```

Return Value

The integer part of the specified number.

Version for working with an array of double-precision floating-point numbers. The results are output to a new array:

```
bool  MathTrunc(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Return Value

Returns true if successful, otherwise false.

Version for working with an array of double-precision floating-point numbers. The results are output to the original array:

```
bool  MathTrunc(
   double&        array[]    // array of values
   )
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Double-precision floating-point number, the integer part of which is to be obtained.

array[]

[in] Array of double-precision floating-point numbers, the integer parts of which are to be obtained.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

© 2000-2025, MetaQuotes Ltd.

MathRound

Rounds a double-precision floating-point number or an array of such numbers to the specified number of decimal places.

Version for rounding a double-precision floating-point number to the specified number of decimal places:

```
double  MathRound(
   const double   x,          // value of the number
   const int      digits      // the number of decimal places
   )
```

Return Value

A number nearest to the x parameter, with the number of decimal places equal to digits.

Version for rounding an array of double-precision floating-point numbers to the specified number of decimal places. The results are output to a new array.

```
bool  MathRound(
   const double&  array[],    // array of values
   int            digits,     // the number of decimal places
   double&        result[]    // array of results
   )
```

Return Value

Returns true if successful, otherwise false.

Version for rounding an array of double-precision floating-point numbers to the specified number of decimal places. The results are output to the original array.

```
bool  MathRound(
   double&        array[],    // array of values
   int            digits      // the number of decimal places
   )
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Double-precision floating-point number to be rounded.

digits

[in] The number of decimal places in the returned value.

array[]

[in] Array of double-precision floating-point numbers to be rounded.

array[]

© 2000-2025, MetaQuotes Ltd.

[out] Array of output values.

result[]

[out] Array of output values.

© 2000-2025, MetaQuotes Ltd.

MathArctan2

Returns the arctangent of the quotient of two arguments (x, y).

Version for working with the ratio of the two specified numbers (x, y):

```
double  MathArctan2(
   const double       y,          // Y coordinate
   const double       x           // X coordinate
   )
```

Return Value

Angle θ, measured in radians, so that -π≤θ≤π and tan (θ) = y or x, where (x, y) is a point in a Cartesian coordinate system.

Version for working with the ratio of the element pairs from the x and y arrays:

```
bool  MathArctan2(
   const double&      x[],        // array of x values
   const double&      y[],        // array of y values
   double&            result[]    // array of results
   )
```

Return Value

Returns true if successful, otherwise false.

Parameters

y

[in] The Y coordinate of the point.

x

[in] The X coordinate of the point.

x[]

[in] Array of X coordinates of the points.

y[]

[in] Array of Y coordinates of the points.

result[]

[out] Array to output the results

Notes

Please note the following.

- For (x, y) in the quadrant 1, the return value will be: 0 < θ < π/2.
- For (x, y) in the quadrant 2, the return value will be: π/2 < θ≤π.
- For (x, y) in the quadrant 3, the return value will be: -π < θ <-π/2.
- For (x, y) in the quadrant 4, the return value will be: -π/2 < θ < 0.

© 2000-2025, MetaQuotes Ltd.

The return value for the points outside these quadrants is indicated below.

- If y is 0 and x is not negative, then θ = 0.
- If y is 0 and x is negative, then θ = π.
- If y is a positive number, and x is 0, then θ = π/2.
- If y is negative and x is 0, then θ = -π/2.
- If y is 0 and x is 0, then θ = -π/2.

If the value of the x or y parameter is NaN, or if the values of the x and y parameters are equal to the value PositiveInfinity or NegativeInfinity, the method returns the NaN value.

© 2000-2025, MetaQuotes Ltd.

MathGamma

Calculates the value of the gamma function for the real argument *x*.

```
double  MathGamma(
   const double  x       // argument of the function
   )
```

Parameters

x

[in] The real argument of the function.

Return Value

The value of the gamma function.

© 2000-2025, MetaQuotes Ltd.

MathGammaLog

Calculates the logarithm of the gamma function for the real argument x.

```
double  MathGammaLog(
   const double  x      // argument of the function
   )
```

Parameters

x

[in] The real argument of the function.

Return Value

Logarithm of the function.

© 2000-2025, MetaQuotes Ltd.

MathBeta

Calculates the value of the beta function for the real arguments a and b.

```
double  MathBeta(
   const double  a,      // the first argument of the function
   const double  b       // the second argument of the function
   )
```

Parameters

a

[in] The a argument of the function.

b

[in] The b argument of the function.

Return Value

Value of the function.

© 2000-2025, MetaQuotes Ltd.

MathBetaLog

Calculates the logarithm of the beta function for the real arguments a and b.

```
double  MathBetaLog(
   const double  a,      // the first argument of the function
   const double  b       // the second argument of the function
   )
```

Parameters

a

[in] The a argument of the function.

b

[in] The b argument of the function.

Return Value

Logarithm of the function.

© 2000-2025, MetaQuotes Ltd.

MathBetaIncomplete

Calculates the value of the incomplete beta function.

```
double  MathBetaIncomplete(
   const double  x,      // argument of the function
   const double  p,      // the first parameter of the function
   const double  q       // the second parameter of the function
   )
```

Parameters

x

[in] The argument of the function.

p

[in] The first parameter of the beta function, must be >0.0.

q

[in] The second parameter of the beta function, must be >0.0.

Return Value

Value of the function.

© 2000-2025, MetaQuotes Ltd.

MathGammaIncomplete

Calculates the value of the incomplete gamma function.

```
double  MathGammaIncomplete(
   double  x,           // argument of the function
   double  alpha        // parameter of the function
   )
```

Parameters

x

[in] The argument of the function.

alpha

[in] The parameter of the incomplete gamma function.

Return Value

Value of the function.

© 2000-2025, MetaQuotes Ltd.

MathBinomialCoefficient

Calculates the binomial coefficient: C(n,k)=n!/(k!*(n-k)!).

```
long  MathBinomialCoefficient(
   const int  n,      // the total number of elements
   const int  k       // the number of elements in combination
   )
```

Parameters

n

[in] The number of elements.

k

[in] The number of elements for each combination.

Return Value

The number of combinations of N choose K.

© 2000-2025, MetaQuotes Ltd.

MathBinomialCoefficientLog

Calculates the logarithm of the binomial coefficient: Log(C(n,k))=Log(n!/(k!*(n-k)!))

Version for integer arguments:

```
double  MathBinomialCoefficientLog(
   const int      n,       // the total number of elements
   const int      k        // the number of elements in combination
   )
```

Version for real arguments:

```
double  MathBinomialCoefficientLog(
   const double   n,       // the total number of elements
   const double   k        // the number of elements in combination
   )
```

Parameters

n

[in] The number of elements.

k

[in] The number of elements for each combination.

Return Value

The logarithm of C(n,k).

© 2000-2025, MetaQuotes Ltd.

MathHypergeometric2F2

Calculates the value of the Hypergeometric_2F2 (a, b, c, d, z) function using the Taylor's method.

```
double  MathHypergeometric2F2(
   const double  a,      // the first parameter of the function
   const double  b,      // the second parameter of the function
   const double  c,      // the third parameter of the function
   const double  d,      // the fourth parameter of the function
   const double  z       // the fifth parameter of the function
   )
```

Parameters

a

[in] The first parameter of the function.

b

[in] The second parameter of the function.

c

[in] The third parameter of the function.

d

[in] The fourth parameter of the function.

z

[in] The fifth parameter of the function.

Return Value

Value of the function.

© 2000-2025, MetaQuotes Ltd.

MathSequence

Generates a sequence of values based on the following values: the first element, the last element, the step of the sequence.

Version for working with real values:

```
bool  MathSequence(
   const double  from,        // initial value
   const double  to,          // final value
   const double  step,        // step
   double&       result[]     // array of results
   )
```

Version for working with integer values:

```
bool  MathSequence(
   const int     from,        // initial value
   const int     to,          // final value
   const int     step,        // step
   int&          result[]     // array of results
   )
```

Parameters

from

[in] The first value of the sequence

to

[in] The last value of the sequence

step

[in] The step of the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSequenceByCount

Generates a sequence of values based on the following values: the first element, the last element, the number of elements in the sequence.

Version for working with real values:

```
bool  MathSequenceByCount(
   const double  from,        // initial value
   const double  to,          // final value
   const int     count,       // count
   double&       result[]     // array of results
   )
```

Version for working with integer values:

```
bool  MathSequenceByCount(
   const int     from,        // initial value
   const int     to,          // final value
   const int     count,       // count
   int&          result[]     // array of results
   )
```

Parameters

from

[in] The first value of the sequence.

to

[in] The last value of the sequence.

count

[in] The number of elements in the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathReplicate

Generates a repeating sequence of values.

Version for working with real values:

```
bool  MathReplicate(
   const double&  array[],    // array of values
   const int      count,      // number of repetitions
   double&        result[]    // array of results
   )
```

Version for working with integer values:

```
bool  MathReplicate(
   const int&     array[],    // array of values
   const int      count,      // number of repetitions
   int&           result[]    // array of results
   )
```

Parameters

array[]

[in] Array for generating a sequence.

count

[in] The number of the array repetitions in the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathReverse

Generates an array of values with reverse order of elements.

Version for working with real values and with output of the results to a new array:

```
bool  MathReverse(
   const double&  array[],      // array of values
   double&        result[]      // array of results
   )
```

Version for working with integer values and with output of the results to a new array:

```
bool  MathReverse(
   const int&     array[],      // array of values
   int&           result[]      // array of results
   )
```

Version for working with real values and with output of the results to the original array.

```
bool  MathReverse(
   double&        array[]       // array of values
   )
```

Version for working with integer values and with output of the results to the original array:

```
bool  MathReverse(
   int&           array[]       // array of values
   )
```

Parameters

array[]

[in] Array of values.

array[]

[out] Output array with the reverse order of values.

result[]

[out] Output array with the reverse order of values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathIdentical

Compares two arrays of values and returns true if all elements match.

Version for working with arrays of real values:

```
bool  MathIdentical(
   const double&  array1[],      // the first array of values
   const double&  array2[]       // the second array of values
   )
```

Version for working with arrays of integer values:

```
bool  MathIdentical(
   const int&     array1[],      // the first array of values
   const int&     array2[]       // the second array of values
   )
```

Parameters

array1[]

[in] The first array to compare.

array2[]

[in] The second array to compare.

Return Value

Returns true if the arrays are equal, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathUnique

Generates an array with unique values only.

Version for working with real values:

```
bool  MathUnique(
   const double&   array[],   // array of values
   double&         result[]   // array of results
   )
```

Version for working with integer values:

```
bool  MathUnique(
   const int&     array[],      // array of values
   int&           result[]      // array of results
   )
```

Parameters

array[]

[in] The source array.

result[]

[out] Array to output the unique values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathQuickSortAscending

The function for the simultaneous ascending sorting of the array[] and indices[] arrays using the QuickSort algorithm.

```
void  MathQuickSortAscending(
   double&  array[],      // array of values
   int&     indices[],    // array of indexes
   int      first,        // initial value
   int      last          // final value
   )
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

© 2000-2025, MetaQuotes Ltd.

MathQuickSortDescending

The function for the simultaneous descending sorting of the array[] and indices[] arrays using the QuickSort algorithm.

```
void  MathQuickSortDescending(
   double&  array[],     // array of values
   int&     indices[],   // array of indexes
   int      first,       // initial value
   int      last         // final value
   )
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

© 2000-2025, MetaQuotes Ltd.

MathQuickSort

The function for the simultaneous sorting of the array[] and indices[] arrays using the QuickSort algorithm.

```
void  MathQuickSort(
   double&  array[],      // array of values
   int&     indices[],    // array of indexes
   int      first,        // initial value
   int      last,         // final value
   int      mode          // direction
   )
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

mode

[in] Direction of sorting (>0 ascending; otherwise, descending).

© 2000-2025, MetaQuotes Ltd.

MathOrder

Generates an integer array with permutation according to order of the array elements after sorting.

Version for working with an array of real values:

```
bool  MathOrder(
   const double&  array[],   // array of values
   int&           result[]   // array of results
   )
```

Version for working with an array of integer values:

```
bool  MathOrder(
   const int&     array[],   // array of values
   int&           result[]   // array of results
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array to output the sorted indexes.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseNot

Calculates the result of bitwise NOT operation for array elements.

Version with output of the results to a new array:

```
bool  MathBitwiseNot(
   const int&  array[],   // array of values
   int&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathBitwiseNot(
   int&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseAnd

Calculates the result of bitwise AND operation for specified arrays.

```
bool  MathBitwiseAnd(
   const int&  array1[],  // the first array of values
   const int&  array2[],  // the second array of values
   int&        result[]   // array of results
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseOr

Calculates the result of bitwise OR operation for specified arrays.

```
bool  MathBitwiseOr(
   const int&  array1[],  // the first array of values
   const int&  array2[],  // the second array of values
   int&        result[]   // array of results
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseXor

Calculates the result of bitwise XOR operation for specified arrays.

```
bool  MathBitwiseXor(
   const int&  array1[],  // the first array of values
   const int&  array2[],  // the second array of values
   int&        result[]   // array of results
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseShiftL

Calculates the result of bitwise SHL (bitwise shift left) operation for array elements.

Version with output of the results to a new array:

```
bool  MathBitwiseShiftL(
   const int&  array[],    // array of values
   const int   n,          // shift value
   int&        result[]    // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathBitwiseShiftL(
   int&        array[],    // array of values
   const int   n           // shift value
   )
```

Parameters

array[]

[in] Array of values.

n

[in] The number of bits to shift.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathBitwiseShiftR

Calculates the result of bitwise SHR (bitwise shift right) operation for array elements.

Version with output of the results to a new array:

```
bool  MathBitwiseShiftR(
   const int&  array[],    // array of values
   const int   n,          // shift value
   int&        result[]    // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathBitwiseShiftR(
   int&        array[],    // array of values
   const int   n           // shift value
   )
```

Parameters

array[]

[in] Array of values.

n

[in] The number of bits to shift.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeSum

Generates an array with the cumulative sums.

Version with output of the results to a new array:

```
bool  MathCumulativeSum(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCumulativeSum(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeProduct

Generates an array with the cumulative products.

Version with output of the results to a new array:

```
bool  MathCumulativeProduct(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCumulativeProduct(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeMin

Generates an array with the cumulative minima.

Version with output of the results to a new array:

```
bool  MathCumulativeMin(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCumulativeMin(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeMax

Generates an array with the cumulative maxima.

Version with output of the results to a new array:

```
bool  MathCumulativeMax(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCumulativeMax(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSin

Calculates the values of the sin(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathSin(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathSin(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCos

Calculates the values of the cos(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathCos(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCos(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathTan

Calculates the values of the tan(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathTan(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathTan(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArcsin

Calculates the values of the arcsin(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArcsin(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArcsin(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArccos

Calculates the values of the arccos(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArccos(
   const double&   array[],    // array of values
   double&         result[]    // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArccos(
   double&         array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArctan

Calculates the values of the arctan(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArctan(
   const double&   array[],   // array of values
   double&         result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArctan(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSinPi

Calculates the values of the sin(pi*x) function for array elements.

Version with output of the results to a new array:

```
bool  MathSinPi(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathSinPi(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCosPi

Calculates the values of the cos(pi*x) function for array elements.

Version with output of the results to a new array:

```
bool  MathCosPi(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCosPi(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathTanPi

Calculates the values of the tan(pi*x) function for array elements.

Version with output of the result to a new array:

```
bool  MathTanPi(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the result to the original array:

```
bool  MathTanPi(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathAbs

Calculates the absolute values of array elements.

Version with output of the results to a new array:

```
bool  MathAbs(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathAbs(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCeil

Returns the nearest larger integers for array elements.

Version with output of the results to a new array:

```
bool  MathCeil(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCeil(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathFloor

Returns the nearest smaller integers for array elements.

Version with output of the results to a new array:

```
bool  MathFloor(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathFloor(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSqrt

Calculates the square roots of array elements.

Version with output of the results to a new array:

```
bool  MathSqrt(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathSqrt(
   double&         array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathExp

Calculates the values of the exp(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathExp(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathExp(
   double&       array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathPow

Calculates the values of the pow(x, power) function for array elements.

Version with output of the results to a new array:

```
bool  MathPow(
   const double&  array[],    // array of values
   const double   power,      // power
   double&        result[]    // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathPow(
   double&        array[],    // array of values
   const double   power       // power
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathLog

Calculates the values of the log(x) function for array elements.

Version for calculating the natural logarithm with output of the results to a new array.

```
bool  MathLog(
   const double&  array[],      // array of values
   double&        result[]      // array of results
   )
```

Version for calculating the natural logarithm with output of the results to the original array.

```
bool  MathLog(
   double&        array[]       // array of values
   )
```

Version for calculating the logarithm to a specified base with output of the results to a new array.

```
bool  MathLog(
   const double&   array[],     // array of values
   const double    base,        // base of the logarithm
   double&         result[]     // array of results
   )
```

Version for calculating the logarithm to a specified base with output of the results to the original array.

```
bool  MathLog(
   double&         array[],     // array of values
   const double    base         // base of the logarithm
   )
```

Parameters

array[]

[in] Array of values.

base

[in] The base of the logarithm.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathLog2

Calculates the logarithm to the base 2 for the array elements.

Version with output of the results to a new array:

```
bool  MathLog2(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathLog2(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathLog10

Calculates the logarithm to the base 10 for the array elements.

Version with output of the results to a new array:

```
bool  MathLog10(
   const double&   array[],   // array of values
   double&         result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathLog10(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathLog1p

Calculates the values of the log(1+x) function for array elements.

Version with output of the results to a new array:

```
bool  MathLog1p(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathLog1p(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathDifference

Generates an array with element differences of y[i]=x[i+lag]-x[i].

Version for a single generation of an array of real values:

```
bool  MathDifference(
   const double  &array[],     // array of values
   const int     lag,          // lag
   double        &result[]     // array of results
   )
```

Version for a single generation of an array of integer values:

```
bool  MathDifference(
   const int     &array[],     // array of values
   const int     lag,          // lag
   int           &result[]     // array of results
   )
```

Version for iterated generation of an array of real values (the number of iterations is set in the input parameters):

```
bool  MathDifference(
   const double  &array[],     // array of values
   const int     lag,          // lag
   const int     differences,  // number of iterations
   double        &result[]     // array of results
   )
```

Version for iterated generation of an array of integer values (the number of iterations is set in the input parameters):

```
bool  MathDifference(
   const int&    array[],      // array of values
   const int     lag,          // lag
   const int     differences,  // number of iterations
   int&          result[]      // array of results
   )
```

Parameters

array[]

[in] Array of values.

lag

[in] Lag parameter.

differences

[in] The number of iterations.

result[]

© 2000-2025, MetaQuotes Ltd.

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSample

Generates a random sample from the array elements.

Version for working with an array of real values:

```
bool  MathSample(
   const double&  array[],          // array of values
   const int      count,            // count
   double&        result[]          // array of results
   )
```

Version for working with an array of integer values:

```
bool  MathSample(
   const int&     array[],          // array of values
   const int      count,            // count
   int&           result[]          // array of results
   )
```

Version for working with an array of real values. It is possible to obtain a sample with replacement:

```
bool  MathSample(
   const double&  array[],          // array of values
   const int      count,            // count
   const bool     replace,          // flag
   double&        result[],         // array of results
   )
```

Version for working with an array of integer values. It is possible to obtain a sample with replacement:

```
bool  MathSample(
   const int&     array[],          // array of values
   const int      count,            // count
   const bool     replace,          // flag
   int&           result[]          // array of results
   )
```

Version for working with an array of real values, for which the probabilities of sampling are defined.

```
bool  MathSample(
   const double&  array[],          // array of values
   double&        probabilities[],  // array of probabilities
   const int      count,            // count
   double&        result[]          // array of results
   )
```

Version for working with an array of integer values, for which the probabilities of sampling are defined.

© 2000-2025, MetaQuotes Ltd.

```
bool  MathSample(
   const int&      array[],           // array of values
   double&         probabilities[],   // array of probabilities
   const int       count,             // count
   int&            result[]           // array of results
   )
```

Version for working with an array of real values, for which the probabilities of sampling are defined. It is possible to obtain a sample with replacement:

```
bool  MathSample(
   const double&   array[],           // array of values
   double&         probabilities[],   // array of probabilities
   const int       count,             // count
   const bool      replace,           // flag
   double&         result[]           // array of results
   )
```

Version for working with an array of integer values, for which the probabilities of sampling are defined. It is possible to obtain a sample with replacement:

```
bool  MathSample(
   const int&      array[],           // array of values
   double&         probabilities[],   // array of probabilities
   const int       count,             // count
   const bool      replace,           // flag
   int&            result[]           // array of results
   )
```

Parameters

array[]

[in] Array of integer values.

probabilities[]

[in] Array of probabilities for sampling the elements.

count

[in] The number of elements.

replace

[in] Parameter that allows sampling with replacement.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

Note

© 2000-2025, MetaQuotes Ltd.

The replace=true argument allows performing random sampling of the elements with replacement back to the original sequence.

© 2000-2025, MetaQuotes Ltd.

MathTukeySummary

Calculates the Tukey's five-number summary (minimum, lower quartile, median, upper quartile, maximum) for the array elements.

```
bool  MathTukeySummary(
   const double&  array[],       // array of values
   const bool     removeNAN,     // flag
   double&        minimum,       // minimum value
   double&        lower_hinge,   // lower quartile
   double&        median,        // median value
   double&        upper_hinge,   // upper quartile
   double&        maximum        // maximum value
   )
```

Parameters

array[]

[in] Array of real values.

removeNAN

[in] Flag that indicates if non-numeric values are to be removed.

minimum

[out] Variable to store the minimum value.

lower_hinge

[out] Variable to store the lower quartile.

median

[out] Variable to store the median value.

upper_hinge

[out] Variable to store the upper quartile.

maximum

[out] Variable to store the maximum value.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathRange

Calculates the minima and maxima of array elements.

```
bool  MathRange(
   const double&  array[],  // array of values
   double&        min,      // minimum value
   double&        max       // maximum value
   )
```

Parameters

array[]

[in] Array of values.

min

[out] Variable to store the minimum value.

max

[out] Variable to store the maximum value.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathMin

Returns the minimum value of all array elements.

```
double  MathMin(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The minimum value.

© 2000-2025, MetaQuotes Ltd.

MathMax

Returns the maximum value of all array elements.

```
double  MathMax(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The maximum value.

© 2000-2025, MetaQuotes Ltd.

MathSum

Returns the sum of array elements.

```
double  MathSum(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The sum of the elements.

© 2000-2025, MetaQuotes Ltd.

MathProduct

Returns the product of array elements.

```
double  MathProduct(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The product of the elements.

© 2000-2025, MetaQuotes Ltd.

MathStandardDeviation

Calculates the standard deviation of array elements.

```
double  MathStandardDeviation(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

Standard deviation.

© 2000-2025, MetaQuotes Ltd.

MathAverageDeviation

The function calculates the average absolute deviation of array elements.

```
double  MathAverageDeviation(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The average absolute deviation of array elements.

© 2000-2025, MetaQuotes Ltd.

MathMedian

Calculates the median value of array elements.

```
double  MathMedian(
   double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The median value.

© 2000-2025, MetaQuotes Ltd.

MathMean

Calculates the mean values of array elements.

```
double  MathMean(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

The mean value.

© 2000-2025, MetaQuotes Ltd.

MathVariance

The function calculates the variance (second moment) of array elements.

```
double  MathVariance(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

Value of the variance.

© 2000-2025, MetaQuotes Ltd.

MathSkewness

The function calculates the skewness (third moment) of array elements.

```
double  MathSkewness(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

Skewness.

© 2000-2025, MetaQuotes Ltd.

MathKurtosis

The function calculates the kurtosis (fourth moment) of array elements.

```
double  MathKurtosis(
   const double&  array[]   // array of values
   )
```

Parameters

array[]

[in] Array of values.

Return Value

Kurtosis.

© 2000-2025, MetaQuotes Ltd.

MathExpm1

Calculates the values of the exp(x)-1 function for array elements.

Version with output of the results to a new array:

```
bool  MathExpm1(
   const double&   array[],   // array of values
   double&         result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathExpm1(
   double&         array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSinh

Calculates the values of the sinh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathSinh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathSinh(
   double&       array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCosh

Calculates the values of the cosh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathCosh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathCosh(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathTanh

Calculates the values of the tanh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathTanh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathTanh(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArcsinh

Calculates the values of the arcsinh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArcsinh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArcsinh(
   double&         array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArccosh

Calculates the values of the arccosh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArccosh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArccosh(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathArctanh

Calculates the values of the arctanh(x) function for array elements.

Version with output of the results to a new array:

```
bool  MathArctanh(
   const double&  array[],   // array of values
   double&        result[]   // array of results
   )
```

Version with output of the results to the original array:

```
bool  MathArctanh(
   double&        array[]    // array of values
   )
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathSignif

Rounds a value to the specified number of digits in the mantissa.

Version for working with a real value:

```
double  MathSignif(
   const double   x,          // value
   const int      digits      // number of decimal places
   )
```

Return Value

The rounded value.

Version for working with an array of real values and with output of the results to a separate array:

```
bool  MathSignif(
   const double&  array[],   // array of values
   int            digits,    // number of decimal places
   double         result[]   // array of results
   )
```

Return Value

Returns true if successful, otherwise false.

Version for working with an array of real values and with output of the results to the original array:

```
bool  MathSignif(
   double&        array[],   // array of values
   int            digits     // number of decimal places
   )
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Real value to be rounded.

digits

[in] Number of decimal places.

array[]

[in] Array of real values.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

© 2000-2025, MetaQuotes Ltd.

© 2000-2025, MetaQuotes Ltd.

MathRank

Calculates the ranks of array elements.

Version for working with an array of real values:

```
bool  MathRank(
   const double&  array[],  // array of values
   double&        rank[]    // array of ranks
   )
```

Version for working with an array of integer values:

```
bool  MathRank(
   const int&     array[],  // array of values
   double&        rank[]    // array of ranks
   )
```

Parameters

array[]

[in] Array of values.

rank[]

[out] Array to output the ranks.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCorrelationPearson

Calculates the Pearson's correlation coefficient.

Version for working with arrays of real values:

```
bool  MathCorrelationPearson(
   const double&  array1[],  // the first array of values
   const double&  array2[],  // the second array of values
   double&        r          // correlation coefficient
   )
```

Version for working with arrays of integer values:

```
bool  MathCorrelationPearson(
   const int&     array1[],  // the first array of values
   const int&     array2[],  // the second array of values
   double&        r          // correlation coefficient
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

r

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCorrelationSpearman

Calculates the Spearman's correlation coefficient.

Version for working with arrays of real values:

```
bool  MathCorrelationSpearman(
   const double&  array1[],  // the first array of values
   const double&  array2[],  // the second array of values
   double&        r          // correlation coefficient
   )
```

Version for working with arrays of integer values:

```
bool  MathCorrelationSpearman(
   const int&     array1[],   // the first array of values
   const int&     array2[],   // the second array of values
   double&        r           // correlation coefficient
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

r

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCorrelationKendall

Calculates the Kendall's correlation coefficient.

Version for working with arrays of real values:

```
bool  MathCorrelationKendall(
   const double&  array1[],  // the first array of values
   const double&  array2[],  // the second array of values
   double&        tau        // correlation coefficient
   )
```

Version for working with arrays of integer values:

```
bool  MathCorrelationKendall(
   const int&     array1[],  // the first array of values
   const int&     array2[],  // the second array of values
   double&        tau        // correlation coefficient
   )
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

tau

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathQuantile

Calculates sample quantiles corresponding to the specified probabilities: Q[i](p) = (1 - gamma) *x[j] + gamma*x[j+1]

```
bool  MathQuantile(
   const double&  array[],     // array of values
   const double&  probs[],     // array of probabilities
   double&        quantile[]   // array to output the quantiles
   )
```

Parameters

array[]

[in] Array of values.

probs[]

[in] Array of probabilities.

quantile[]

[out] Array to output the quantiles.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathProbabilityDensityEmpirical

The function calculates the empirical probability density function (pdf) for random values from an array.

```
bool  MathProbabilityDensityEmpirical(
   const double&  array[],   // array of random values
   const int      count,     // the number of pairs
   double&        x[],       // array of x values
   double&        pdf[]      // array of pdf values
   )
```

Parameters

array[]

[in] Array of random values.

count

[in] The number of (x, pdf(x)) pairs.

x[]

[out] Array to output the x values.

pdf[]

[out] Array to output the pdf(x) values.

Return Value

Returns true if successful, otherwise false.

© 2000-2025, MetaQuotes Ltd.

MathCumulativeDistributionEmpirical

The function calculates the empirical cumulative distribution function (cdf) for random values from an array.

```
bool  MathCumulativeDistributionEmpirical(
   const double&  array[],   // array of random values
   const int      count,     // the number of pairs
   double&        x[],       // array of x values
   double&        cdf[]      // array of cdf values
   )
```

Parameters

array[]

[in] Array of random values.

count

[in] The number of (x, cdf(x)) pairs.

x[]

[out] Array to output the x values.

cdf[]

[out] Array to output the cdf(x) values.

Return Value

Returns true if successful, otherwise false.

Fuzzy is a library for working with fuzzy logic

Fuzzy logic is a synthesis of the traditional Aristotelian logic when truth is marked as a linguistic variable. Fuzzy logic, equivalent to classical logic, has its own fuzzy logic operations on fuzzy sets defined. There are the same operations for fuzzy sets as well as for ordinary sets, only their calculation is by far more difficult. We should also note that the composition of fuzzy sets constitutes as a fuzzy set.

The main principles of fuzzy logic, setting it apart from classical logic, are the maximum proximity to the reflection of reality and a high level of subjectivity, which can lead to significant errors in calculations.

Fuzzy model (or system) is a mathematical model whose calculation is based on fuzzy logic. Construction of such models is applicable when the subject of study has a weak formalization and its exact mathematical description is too complex or unknown. The quality of these models' output values (error model) directly depends only on the Expert Advisor, which set up this model. The best option to minimize errors is to draw the most complete and comprehensive model and subsequently adjust it with machine learning on a large training set.

The progress of a model construction can be divided into three main stages:

1. Definition of input and output characteristics of a model.
2. Building a knowledge base.
3. Selecting one of the methods of fuzzy inference (Mamdani or Sugeno).

The first stage directly effects the consequent two and determines the future operation of the model. A knowledge base or, as sometimes called, rule base is a set of fuzzy rules type: "if, then" that define the relationship between inputs and outputs of the examined object. The number of rules in the system is not limited and is also determined by the Expert Advisor. The generalized format of fuzzy rules is as follows:

If rule condition, then rule conclusion.

Rule condition describes the current state of the object, and rule conclusion — how this condition affects the object. General view of conditions and conclusions cannot be selected because they are determined by a fuzzy inference.

Each rule in the system has its weight — this characteristic defines the importance of a rule in the model. Weighting factors are assigned to a rule within range [0, 1]. In many examples with fuzzy models, which can be found in the relevant literature, weight data is not specified, but it does not mean that it is not present. In fact, in such case for each rule from the database, the weight is fixed and equals unity. There can be two types of terms and conclusions for each rule:

1. simple — includes one fuzzy variable;
2. complex — includes several fuzzy variables.

Depending on the created knowledge base, the system of fuzzy inference is determined for a model. Fuzzy logical inference is a receipt of conclusion in form of a fuzzy set corresponding to the current value of the inputs with use of knowledge base and fuzzy operations. The two main types of fuzzy inference are Mamdani and Sugeno.

Membership functions

A **membership function** is a function that allows to calculate the membership degree of a random element of the universal set to a fuzzy set. Consequently, the domain of a membership function should be within the range [0, 1].

In most cases, the membership function is continuous and monotonic.

Classes of membership functions	Description
CConstantMembershipFunction	Class for implementing a membership function as a straight line in parallel with the coordinate axis
CCompositeMembershipFunction	Class for implementing a composition of membership functions
CDifferencTwoSigmoidalMembershipFunction	Class for implementing the membership function in the form of a difference between two sigmoid functions with the A1, A2, C1 and C2 parameters
CGeneralizedBellShapedMembershipFunction	Class for implementing a generalized bell-shaped membership function with A, B and C parameters
CNormalCombinationMembershipFunction	Class for implementing a two-sided Gaussian membership function with the B1, B2, Sigma1 and Sigma2 parameters
CNormalMembershipFunction	Class for implementing a symmetrical Gaussian membership function with the B and Sigma parameters
CP_ShapedMembershipFunction	Class for implementing a pi-shaped membership function with the A, B, C and D parameters
CProductTwoSigmoidalMembershipFunction	Class for implementing the membership function in the form of a product of two sigmoid functions with the A1, A2, C1 and C2 parameters
CS_ShapedMembershipFunction	Class for implementing an S-like membership function with the A and B parameters
CTrapezoidMembershipFunction	Class for implementing a trapezoidal membership function with the X1, X2, X3 and X4 parameters
CTriangularMembershipFunction	Class for implementing a triangle membership function with the X1, X2 and X3 parameters
CSigmoidalMembershipFunction	Class for implementing a sigmoid membership function with the A and C parameters

© 2000-2025, MetaQuotes Ltd.

Classes of membership functions	Description
CZ_ShapedMembershipFunction	Class for implementing a z-like membership function with the A and B parameters.
IMembershipFunction	Basic class for all membership function classes.

© 2000-2025, MetaQuotes Ltd.

CConstantMembershipFunction

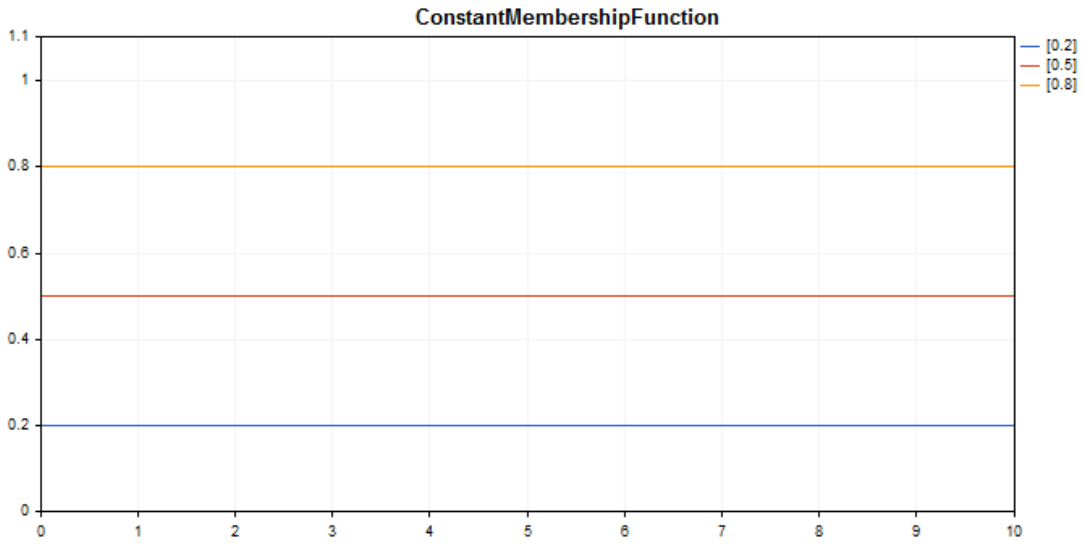
Class for implementing a membership function as a straight line in parallel with the coordinate axis.

Description

The function is described by the equation:

y(x)=c

Therefore, the membership degree for the function is the same along the entire numerical axis and is equal to the parameter specified in the constructor.



A sample code for plotting a chart is displayed below.

Declaration

```
class CConstantMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

```
   graphic.CurvePlotAll();
   graphic.Update();
  }
```

CompositionType

Sets the composition operator.

```
void  CompositionType(
   MfCompositionType  value      // operator type
   )
```

Parameters

value

[in] Composition operator type.

Note

The following operator types are available:

- MinMF (minimum of functions)
- MaxMF (maximum of functions)
- ProdMF (product of functions)
- SumMF (sum of functions)

MembershipFunctions

Gets the list of membership functions included into a composition.

```
CList*  MembershipFunctions(
   void        // list of membership functions
   )
```

Return Value

List of membership functions.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

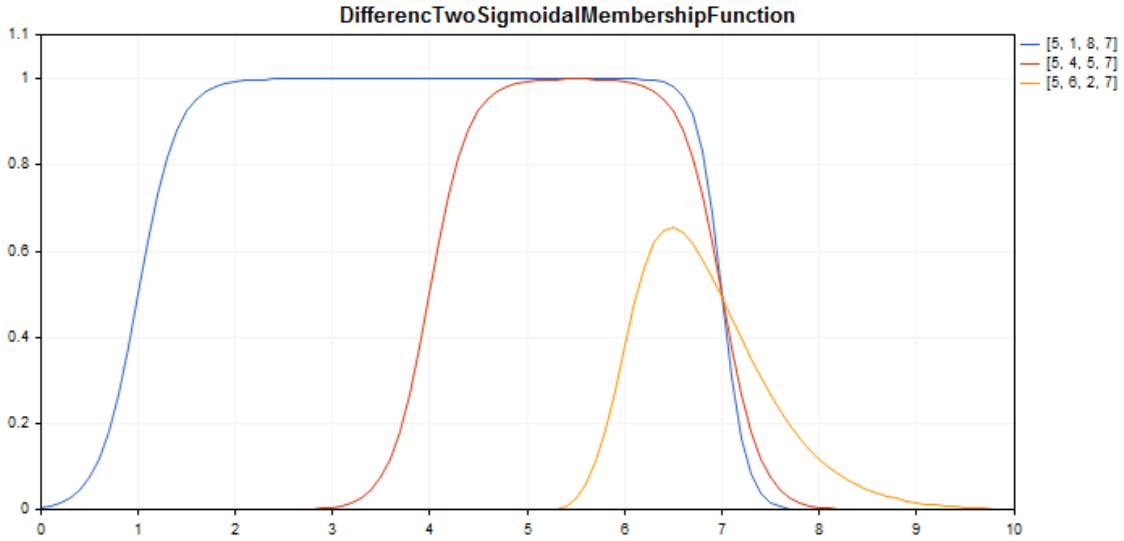
© 2000-2025, MetaQuotes Ltd.

CDifferencTwoSigmoidalMembershipFunction

Class for implementing the membership function in the form of a difference between two sigmoid functions with the A1, A2, C1 and C2 parameters.

Description

The function is based on a sigmoid curve. It allows creating membership functions with the values equal to 1 beginning with an argument value. Such functions are suitable if you need to set such linguistic terms as "short" or "long".



A sample code for plotting a chart is displayed below.

Declaration

```
class CDifferencTwoSigmoidalMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

   graphic.YAxis().DefaultStep(0.2);
//--- plot
   graphic.CurvePlotAll();
   graphic.Update();
  }
```

A1 (Get method)

Gets the first membership function slope ratio.

```
double  A1()
```

Return Value

Slope ratio value.

A1 (Set method)

Sets the first membership function slope ratio.

```
void  A1(
   const double  a1      // slope ratio value
   )
```

Parameters

a1

[in] Slope ratio value.

A2 (Get method)

Gets the second membership function slope ratio.

```
double  A2()
```

Return Value

Slope ratio value.

A2 (Set method)

© 2000-2025, MetaQuotes Ltd.

Sets the second membership function slope ratio.

```
void  A2(
   const double  a2      // slope ratio value
   )
```

Parameters

a2

[in] Slope ratio value.

C1 (Get method)

Gets the first membership function inflection coordinate parameter.

```
double  C1()
```

Return Value

Inflection coordinate value.

C1 (Set method)

Sets the first membership function inflection coordinate parameter.

```
void  C1(
   const double  c1      // inflection coordinate value
   )
```

Parameters

c1

[in] Inflection coordinate value.

C2 (Get method)

Gets the second membership function inflection coordinate parameter.

```
double  C2()
```

Return Value

Inflection coordinate value.

C2 (Set method)

Sets the second membership function inflection coordinate parameter.

```
void  C2(
   const double  c2      // inflection coordinate value
   )
```

© 2000-2025, MetaQuotes Ltd.

Parameters

c2

[in] Inflection coordinate value.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const double  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

```

A (Get method)

Gets the membership function concentration ratio.

```
double  A()
```

Return Value

Concentration ratio value.

A (Set method)

Sets the membership function concentration ratio.

```
void  A(
   const double  a      // concentration ratio value
   )
```

Parameters

a

[in] Membership function concentration ratio.

B (Get method)

Gets the membership function slope ratio.

```
double  B()
```

Return Value

Slope ratio value.

B (Set method)

Sets the membership function slope ratio.

© 2000-2025, MetaQuotes Ltd.

```
void  B(
   const double  b      // slope ratio value
   )
```

Parameters

b

[in] Membership function slope ratio.

C (Get method)

Gets the membership function maximum coordinate.

```
double  C()
```

Return Value

Membership function maximum coordinate.

C (Set method)

Sets the membership function maximum coordinate.

```
void  C(
   const double  c      // maximum coordinate value
   )
```

Parameters

c

[in] Membership function maximum coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

   graphic.CurvePlotAll();
   graphic.Update();
  }
```

B1 (Get method)

Gets the value of the first membership function center.

```
double  B1()
```

Return Value

Value of the first membership function center.

B1 (Set method)

Sets the value of the first membership function center.

```
void  B1(
   const double  b1      // first center value
   )
```

Parameters

b

[in] Value of the first membership function center.

B2 (Get method)

Gets the value of the second membership function center.

```
double  B2()
```

Return Value

The value of the second membership function center.

© 2000-2025, MetaQuotes Ltd.

B2 (Set method)

Sets the value of the second membership function center.

```
void  B2(
   const double  b2      // second center value
   )
```

Parameters

b2

[in] Value of the second membership function center.

Sigma1 (Get method)

Gets the first parameter of the membership function curvature.

```
double  Sigma1()
```

Return Value

The value of the first parameter of the membership function curvature.

Sigma1 (Set method)

Sets the value of the first parameter of the membership function curvature.

```
void  Sigma1(
   const double  sigma1      // first curvature parameter value
   )
```

Parameters

sigma1

[in] The first parameter of the membership function curvature.

Sigma2 (Get method)

Gets the second parameter of the membership function curvature.

```
double  Sigma2()
```

Return Value

The value of the second parameter of the membership function curvature.

Sigma2 (Set method)

© 2000-2025, MetaQuotes Ltd.

Sets the value of the second parameter of the membership function curvature.

```
void  Sigma2(
   const double  sigma2      // second curvature parameter value
   )
```

Parameters

sigma2

[in] The second curvature parameter of the membership function.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

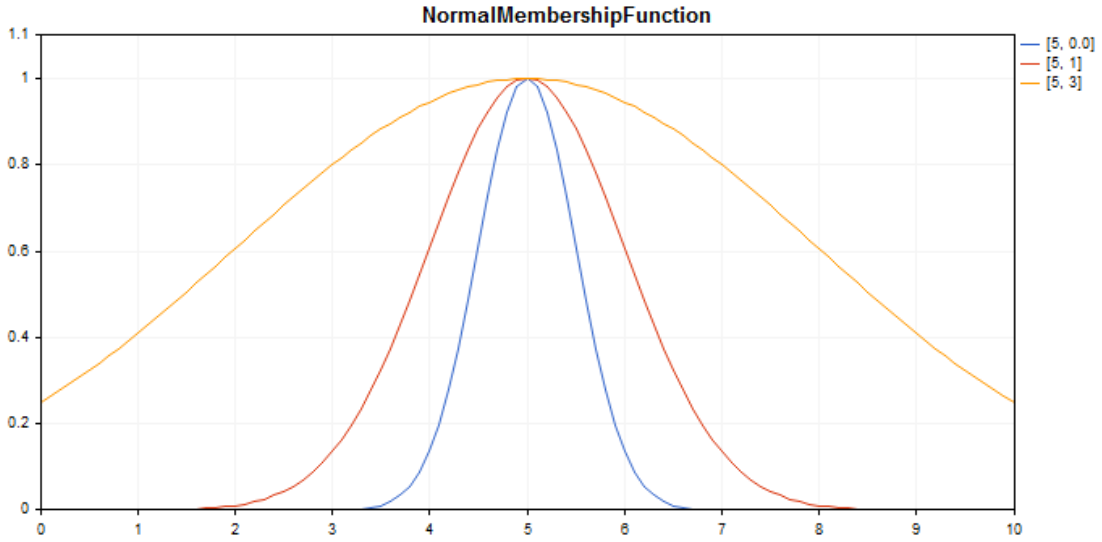
CNormalMembershipFunction

Class for implementing a symmetrical Gaussian membership function with the B and Sigma parameters.

Description

The symmetrical Gaussian membership function is formed using Gaussian distribution. The function is smooth and takes non-zero values along the entire definition area.



A sample code for plotting a chart is displayed below.

Declaration

```
class CNormalMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

CObject
  IMembershipFunction
    CNormalMembershipFunction

```

Return Value

Parameter of the fuzzy set beginning.

A (Set method)

Sets the parameter of the fuzzy set beginning.

```
void  A(
   const double  a      // parameter of the fuzzy set beginning
   )
```

Parameters

a

[in] Parameter of the fuzzy set beginning.

B (Get method)

Gets the first parameter of the fuzzy set core.

```
double  B()
```

Return Value

The first parameter of the fuzzy set core.

B (Set method)

Sets the first parameter of the fuzzy set core.

```
void  B(
   const double  b      // value of the fuzzy set core first parameter
   )
```

© 2000-2025, MetaQuotes Ltd.

Parameters

b

[in] The first parameter of the fuzzy set core.

C (Get method)

Gets the second parameter of the fuzzy set core.

```
double  C()
```

Return Value

The second parameter of the fuzzy set core.

C (Set method)

Sets the second parameter of the fuzzy set core.

```
void  C(
   const double  c      // value of the fuzzy set core second parameter
   )
```

Parameters

c

[in] The second parameter of the fuzzy set core.

D (Get method)

Gets the parameter of the fuzzy set end.

```
double  D()
```

Return Value

Value of the fuzzy set end parameter.

D (Set method)

Sets the parameter of the fuzzy set end.

```
void  D(
   const double  d      // value of the fuzzy set end parameter
   )
```

Parameters

d

[in] Value of the fuzzy set end parameter.

GetValue

© 2000-2025, MetaQuotes Ltd.

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const double  x
   )
```

Parameters

x

[in] membership function argument

Return Value

membership function value

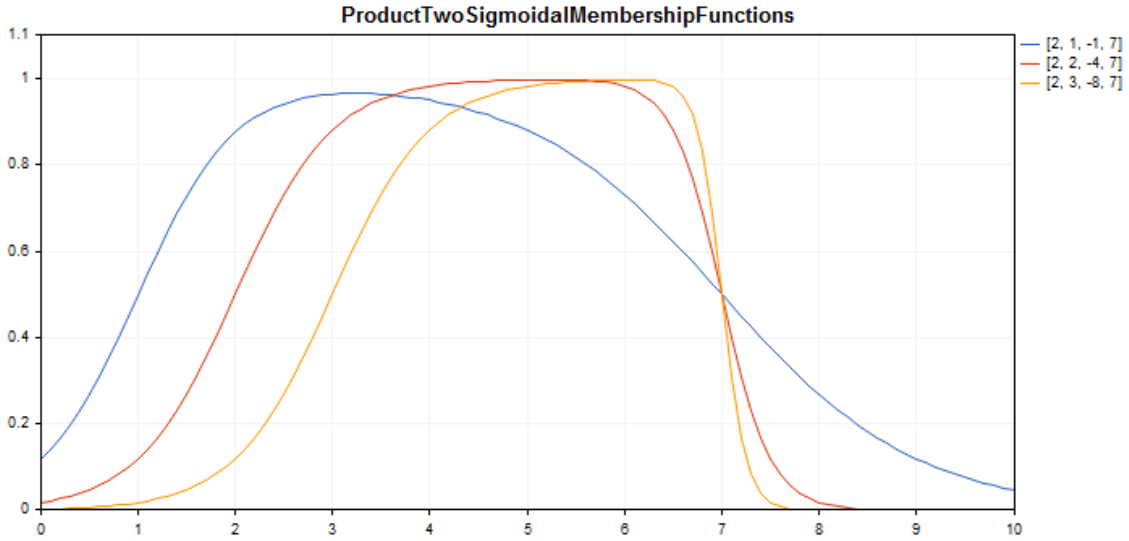
© 2000-2025, MetaQuotes Ltd.

CProductTwoSigmoidalMembershipFunction

Class for implementing the membership function in the form of a product of two sigmoid functions with the A1, A2, C1 and C2 parameters.

Description

A product of two sigmoid membership functions is applied for setting smooth asymmetric functions. It allows creating membership functions with the values equal to 1 beginning with an argument value. Such functions are suitable if you need to set such linguistic terms as "short" or "long".



A sample code for plotting a chart is displayed below.

Declaration

```
class CProductTwoSigmoidalMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

  }
```

A1 (Get method)

Gets the first membership function slope ratio.

```
double  A1()
```

Return Value

The first membership function slope ratio.

A1 (Set method)

Sets the first membership function slope ratio.

```
void  A1(
   const double  a1      // the first membership function slope ratio
   )
```

Parameters

a1

[in] The first membership function slope ratio.

A2 (Get method)

Gets the second membership function slope ratio.

```
double  A2()
```

Return Value

The second membership function slope ratio.

© 2000-2025, MetaQuotes Ltd.

A2 (Set method)

Sets the second membership function slope ratio.

```
void  A2(
   const double  a2      // the second membership function slope ratio
   )
```

Parameters

a2

[in] The second membership function slope ratio.

C1 (Get method)

Gets the first membership function inflection coordinate parameter.

```
double  C1()
```

Return Value

The first membership function inflection coordinate.

C1 (Set method)

Sets the first membership function inflection coordinate.

```
void  C1(
   const double  c1      // the first membership function inflection coordinate
   )
```

Parameters

c1

[in] The first membership function inflection coordinate.

C2 (Get method)

Gets the second membership function inflection coordinate parameter.

```
double  C2()
```

Return Value

The second membership function inflection coordinate.

C2 (Set method)

Sets the second membership function inflection coordinate.

```
void  C2(
   const double  c2      // the second membership function inflection coordinate
   )
```

© 2000-2025, MetaQuotes Ltd.

Parameters

c2

[in] The second membership function inflection coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

© 2000-2025, MetaQuotes Ltd.

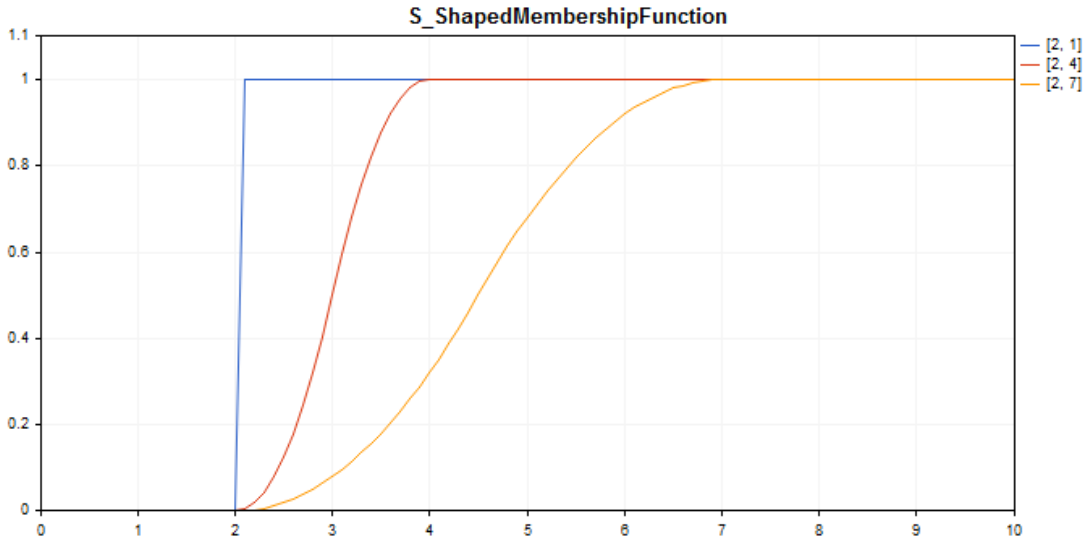
CS_ShapedMembershipFunction

Class for implementing an S-like membership function with the A and B parameters.

Description

The function sets an S-like two-parameter membership function. This is a non-decreasing function that takes values from 0 to 1. The A and B parameters define the interval, within which the function increases in non-linear trajectory from 0 to 1.

The function represents fuzzy sets of "very high" type (i.e. non-decreasing membership functions with saturation are set).



A sample code for plotting a chart is displayed below.

Declaration

```
class CS_ShapedMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

  }
```

A (Get method)

Gets the membership function slope ratio.

```
double  A()
```

Return Value

The membership function slope ratio.

A (Set method)

Sets the membership function slope ratio.

```
void  A(
   const double  a      // the first membership function slope ratio
   )
```

Parameters

a

[in] Membership function slope ratio.

C (Get method)

Gets the membership function inflection coordinate parameter.

```
double  C()
```

Return Value

Membership function inflection coordinate.

C (Set method)

Sets the membership function inflection coordinate.

```
void  C(
   const double  c      // membership function inflection coordinate
   )
```

Parameters

c

© 2000-2025, MetaQuotes Ltd.

[in] The membership function inflection coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

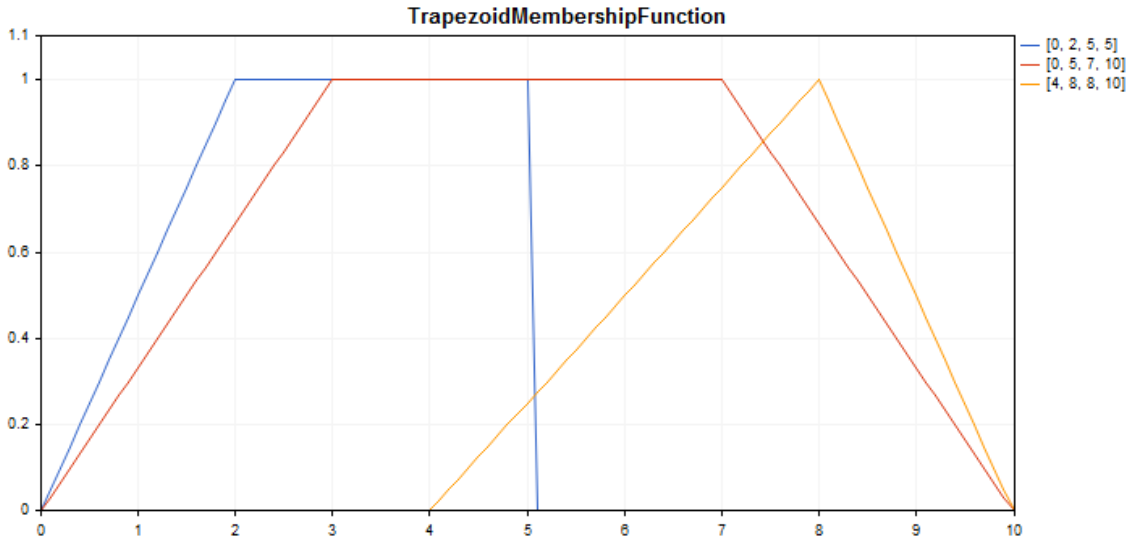
CTrapezoidMembershipFunction

Class for implementing a trapezoidal membership function with the X1, X2, X3 and X4 parameters.

Description

The function is formed using piecewise linear approximation. This is a generalization of the triangular function allowing you to assign a fuzzy set core as an interval. Such a membership function makes it possible to conveniently interpret optimistic/pessimistic assessments.

The function is used to set asymmetric membership functions of the variables with their most critical values defined within a certain interval.



A sample code for plotting a chart is displayed below.

Declaration

```
class CTrapezoidMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

CObject

IMembershipFunction

CTrapezoidMembershipFunction

Class methods

Class method	Description
X1	Gets and sets the value of the first point on the X axis.

© 2000-2025, MetaQuotes Ltd.

Class method	Description
X2	Gets and sets the value of the second point on the X axis.
X3	Gets and sets the value of the third point on the X axis.
X4	Gets and sets the value of the fourth point on the X axis.
GetValue	Calculates the value of the membership function by a specified argument.

```

X1 (Get method)

Gets the value of the first point on the X axis.

```
double  X1()
```

Return Value

The value of the first point on the X axis.

X1 (Set method)

Sets the value of the first point on the X axis.

```
void  X1(
   const double  x1      // value of the first point on the X axis
   )
```

Parameters

x1

[in] The value of the first point on the X axis.

X2 (Get method)

Gets the value of the second point on the X axis.

```
double  X2()
```

Return Value

The value of the second point on the X axis.

X2 (Set method)

© 2000-2025, MetaQuotes Ltd.

Sets the value of the second point on the X axis.

```
void  X2(
   const double  x2      // value of the second point on the X axis
   )
```

Parameters

x2

[in] The value of the second point on the X axis.

X3 (Get method)

Gets the value of the third point on the X axis.

```
double  X3()
```

Return Value

The value of the third point on the X axis.

X3 (Set method)

Sets the value of the third point on the X axis.

```
void  X3(
   const double  x3      // value of the third point on the X axis
   )
```

Parameters

x3

[in] The value of the third point on the X axis.

X4 (Get method)

Gets the value of the fourth point on the X axis.

```
double  X4()
```

Return Value

The value of the fourth point on the X axis.

X4 (Set method)

Sets the value of the fourth point on the X axis.

```
void  X4(
   const double  x4      // value of the fourth point on the X axis
   )
```

Parameters

x4

© 2000-2025, MetaQuotes Ltd.

[in] The value of the fourth point on the X axis.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

   const double  x1      // value of the first point on the X axis
   )
```

Parameters

x1

[in] The value of the first point on the X axis.

X2 (Get method)

Gets the value of the second point on the X axis.

```
double  X2()
```

Return Value

The value of the second point on the X axis.

X2 (Set method)

Sets the value of the second point on the X axis.

```
void  X2(
```

© 2000-2025, MetaQuotes Ltd.

```
   const double  x2      // value of the second point on the X axis
   )
```

Parameters

x2

[in] The value of the second point on the X axis.

X3 (Get method)

Gets the value of the third point on the X axis.

```
double  X3()
```

Return Value

The value of the third point on the X axis.

X3 (Set method)

Sets the value of the third point on the X axis.

```
void  X3(
   const double  x3      // value of the third point on the X axis
   )
```

Parameters

x3

[in] The value of the third point on the X axis.

ToNormalMF

Converts a triangle membership function into a Gaussian one.

```
CNormalMembershipFunction*  ToNormalMF()
```

Return Value

The pointer to a Gaussian membership function.

GetValue

Calculates the value of the membership function by a specified argument.

```
double  GetValue(
   const  x      // membership function argument
   )
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

© 2000-2025, MetaQuotes Ltd.

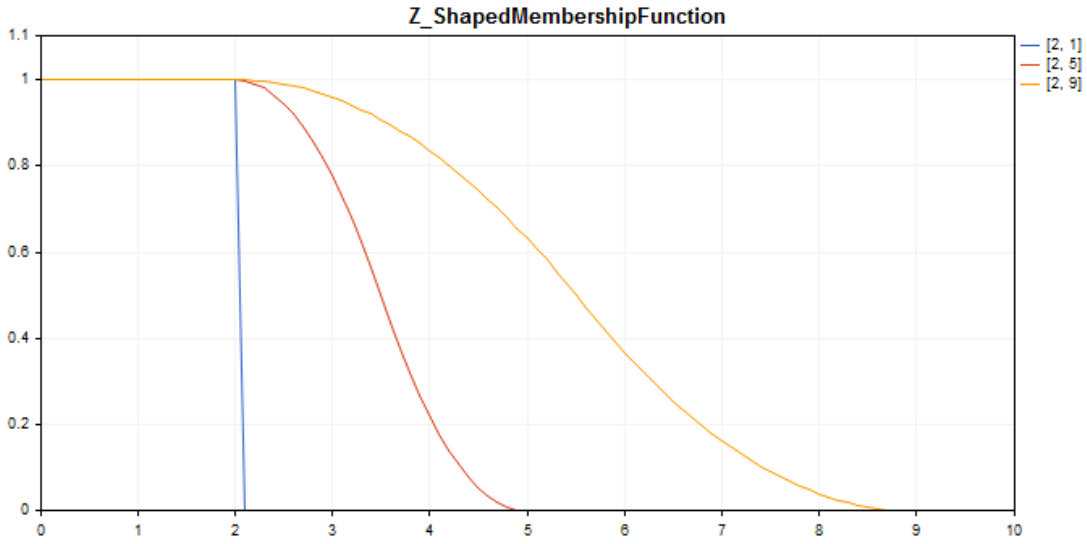
CZ_ShapedMembershipFunction

Class for implementing a z-like membership function with the A and B parameters.

Description

The function sets a z-like two-parameter membership function. This is a non-increasing membership function that takes values from 1 to 0. The function parameters define an interval, within which the function decreases in non-linear trajectory from 1 to 0.

The function represents fuzzy sets of "very low" type. In other words, it sets non-increasing membership functions with saturation.



A sample code for plotting a chart is displayed below.

Declaration

```
class CZ_ShapedMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

CObject

IMembershipFunction

CZ_ShapedMembershipFunction

Class methods

Class method	Description
A	Gets and sets the parameter of the decreasing interval start.

© 2000-2025, MetaQuotes Ltd.

Class method	Description
B	Gets and sets the parameter of the decreasing interval end.
GetValue	Calculates the value of the membership function by a specified argument.

Fuzzy systems rules

A **fuzzy system** (fuzzy logical inference system) is a receipt of conclusion in the form of a fuzzy set corresponding to the current values of the inputs with the use of a set of **fuzzy rules** and fuzzy operations.

The **fuzzy rules** determine the relationship between inputs and outputs of an examined object. Amount of rules in the system is unlimited. The generalized format of fuzzy rules is as follows:

if *rule condition*, **then** *rule conclusion*.

Rule condition describes the current state of the object. *Rule conclusion* describes how the condition affects the object.

Class of rules for fuzzy systems	Description
CMamdaniFuzzyRule	Class for implementing a fuzzy logic rule for the Mamdani algorithm
CSugenoFuzzyRule	Class for implementing a fuzzy logic rule for the Sugeno algorithm
CSingleCondition	The class sets a fuzzy condition expressed by "Fuzzy variable — Fuzzy term" pair.
CConditions	Class defines a set of fuzzy conditions connected to each other by an operator.
CGenericFuzzyRule	Base class for implementing the both types of fuzzy rules.

© 2000-2025, MetaQuotes Ltd.

CMamdaniFuzzyRule

Mamdani-type fuzzy inference — one of the two basic types of fuzzy systems. Output variable values are set using fuzzy terms.

Description

Fuzzy logic rule for the Mamdani algorithm can be described as follows:

$$if(X_1\ is\ a_1) \wedge (X_2\ is\ a_2) \wedge \ldots \wedge (X_n\ is\ a_n)\ then\ (Y\ is\ d)(W)$$

where:

- X = (X1, X2, X3 ... Xn) — vector of input variables;
- Y — output variable;
- a = (a1, a2, a3 ... an) — vector of input variable values;
- d — output variable value;
- W — rule weight.

Declaration

```
class CMamdaniFuzzyRule : public CGenericFuzzyRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Inheritance hierarchy

CObject
  IParsableRule
    CGenericFuzzyRule
      CMamdaniFuzzyRule

Class methods

Class method	Description
Conclusion	Gets and sets the Mamdani fuzzy rule conclusion
Weight	Gets and sets the Mamdani fuzzy rule weight

Methods inherited from class CObject

Conclusion (Get method)

© 2000-2025, MetaQuotes Ltd.

Gets the Mamdani fuzzy rule conclusion

```
CSingleConditon*  Conclusion()
```

Return Value

Conclusion of a Mamdani fuzzy rule.

Conclusion (Set method)

Sets the Mamdani fuzzy rule conclusion.

```
void  Conclusion(
   CSingleConditon*  value      // conclusion of a Mamdani fuzzy rule
   )
```

Parameters

value

[in] Conclusion of a Mamdani fuzzy rule.

Weight (Get method)

Gets the Mamdani fuzzy rule weight.

```
double  Weight()
```

Return Value

Mamdani fuzzy rule weight.

Weight (Set method)

Sets the Mamdani fuzzy rule weight.

```
void  Weight(
   const double  value      // weight of a Mamdani fuzzy rule
   )
```

Parameters

value

[in] Weight of a Mamdani fuzzy rule.

© 2000-2025, MetaQuotes Ltd.

CSugenoFuzzyRule

Sugeno-type fuzzy inference — one of the two basic types of fuzzy systems. Output variable values are set as a linear combination of input variables.

Description

Unlike the Mamdani rule, an input variable value is set by a linear function from input parameters rather than by a fuzzy term. Fuzzy logic rule for the Sugeno algorithm can be described as follows:

$$if(X_1\ is\ a_1)\wedge(X_2\ is\ a_2)\wedge\ldots\wedge(X_n\ is\ a_n)\ then\ (Y=b_0+b_1\cdot X_1+b_2\cdot X_2+\ldots+b_n\cdot X_n)(W)$$

where:

- X = (X1, X2, X3 ... Xn) — vector of input variables;
- Y — output variable;
- a = (a1, a2, a3 ... an) — vector of input variable values;
- b = (b1, b2, b3 ... bn) — free term ratio in the linear function for an output value
- W — rule weight.

Declaration

```
class CSugenoFuzzyRule : public CGenericFuzzyRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Conclusion (Get method)

© 2000-2025, MetaQuotes Ltd.

Gets the Sugeno fuzzy rule conclusion.

```
CSingleConditon*  Conclusion()
```

Return Value

Sugeno fuzzy rule conclusion.

Conclusion (Set method)

Sets the Sugeno fuzzy rule conclusion.

```
void  Conclusion(
   CSingleCondition*  value      // conclusion of a Sugeno fuzzy rule
   )
```

Parameters

value

[in] Conclusion of a Sugeno fuzzy rule.

© 2000-2025, MetaQuotes Ltd.

CSingleCondition

The class sets a fuzzy condition expressed by "Fuzzy variable — Fuzzy term" pair.

Description

According to a fuzzy condition, one variable corresponds to one term. A fuzzy condition can be described by the following expression: *X is a*,

where:

- X is a fuzzy variable;
- a is a fuzzy variable value (fuzzy term).

Declaration

```
class CSingleCondition : public ICondition

The flag value.

Not (Set method)

Sets the flag indicating whether it is necessary to apply negation to this condition.

```
void  Not(
   bool  not      // flag value
   )
```

Parameters

not

[in] Flag value.

Term (Get method)

Gets a fuzzy term for the given condition.

```
INamedValue* Term()
```

Return Value

A fuzzy term for the given condition.

Term (Set method)

Sets a fuzzy term for the given condition.

```
void  Term(
   INamedValue*&  value      // fuzzy term for the given condition
   )
```

Parameters

value

[in] A fuzzy term for the given condition.

Var (Get method)

Gets a fuzzy variable for the given condition.

```
INamedVariable* Var()
```

Return Value

A fuzzy variable for the given condition.

Var (Set method)

Sets a fuzzy variable for the given condition

```
void  Var(
   INamedVariable*&  value      // a fuzzy variable for the given condition
```

© 2000-2025, MetaQuotes Ltd.

```
)
```

Parameters

value

[in] fuzzy variable.

© 2000-2025, MetaQuotes Ltd.

CConditions

Class defines a set of fuzzy conditions connected to each other by an operator.

Description

A set of fuzzy conditions connected to each other by an operator may be described as follows:

$$(X_1\ is\ a_1)\wedge(X_2\ is\ a_2)\wedge\ldots\wedge(X_n\ is\ a_n)$$

where:

- X = (X1, X2, X3 ... Xn) — vector of input variables;
- a = (a1, a2, a3 ... an) — vector of input variable values.

In this example, the *and* operator is used. Besides, the *or* operator is available in this class.

Declaration

```
class CConditions : public ICondition
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Inheritance hierarchy

CObject
  ICondition
    CConditions

Class methods

Class method	Description
ConditionsList	Gets the list of all conditions
Not	Gets and sets the flag indicating whether it is necessary to apply negation to these conditions
Op	Gets and sets a type of the conditions bundle operator.

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

ConditionsList

Gets the list of all conditions.

```
CList*  ConditionsList()
```

Return Value

© 2000-2025, MetaQuotes Ltd.

List of all conditions.

Not (Get method)

Gets the flag indicating whether it is necessary to apply negation to these conditions.

```
bool Not()
```

Return Value

The flag value.

Not (Set method)

Sets the flag indicating whether it is necessary to apply negation to these conditions

```
void  Not(
   bool  not      // flag value
   )
```

Parameters

not

[in] Flag value.

Op (Get method)

Gets a type of the conditions bundle operator. The *and* and *or* operators are available.

```
OperatorType Op()
```

Return Value

Type of the conditions bundle operator.

Op (Set method)

Set the conditions bundle operator. The *and* and *or* operators are available.

```
void  Op(
   OperatorType  op     // type of the conditions bundle operator
   )
```

Parameters

op

[in] Type of the conditions bundle operator.

© 2000-2025, MetaQuotes Ltd.

CGenericFuzzyRule

Base class for both types of fuzzy rules.

Declaration

```
class CGenericFuzzyRule : public IParsableRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Inheritance hierarchy

CObject

IParsableRule

CGenericFuzzyRule

Direct descendants

CMamdaniFuzzyRule, CSugenoFuzzyRule

Class methods

Class method	Description
Conclusion	Gets and sets the fuzzy rule conclusion
Condition	Gets and sets the 'if' condition (set of conditions) for a fuzzy rule
CreateCondition	Creates a condition for a fuzzy rule by specified parameters

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Conclusion (Get method)

Gets the conclusion of a fuzzy rule.

```
CSingleConditon*  Conclusion()
```

Return Value

Conclusion of a fuzzy rule.

Conclusion (Set method)

Sets the fuzzy rule conclusion.

```
virtual void  Conclusion(
   CSingleConditon*  value      // conclusion of a fuzzy rule
```

© 2000-2025, MetaQuotes Ltd.

```
   )
```

Parameters

value

[in] Conclusion of a fuzzy rule.

Condition (Get method)

Gets the 'if' condition (set of conditions) for a fuzzy rule.

```
CConditons*  Condition()
```

Return Value

Fuzzy condition (set of conditions).

Condition (Set method)

Sets the 'if' condition (set of conditions) for a fuzzy rule.

```
void  Condition(
   CConditons*  value      // 'if' condition (set of conditions) for a fuzzy rule
   )
```

Parameters

value

[in] Fuzzy condition (set of conditions).

CreateCondition

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition*  CreateCondition(
   CFuzzyVariable*  var,       // fuzzy variable
   CFuzzyTerm*      term,      // fuzzy term
   )
```

Parameters

var

[in] Fuzzy variable.

term

[in] Fuzzy term.

Return Value

Fuzzy rule status.

CreateCondition

© 2000-2025, MetaQuotes Ltd.

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition*  CreateCondition(
   CFuzzyVariable*  var,      // fuzzy variable
   CFuzzyTerm*      term,     // fuzzy term
   bool             not,      // flag indicating whether it is necessary to apply nega
   )
```

Parameters

var

[in] Fuzzy variable.

term

[in] Fuzzy term.

not

[in] Flag indicating whether it is necessary to apply negation to a condition.

Return Value

Fuzzy rule status.

CreateCondition

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition*  CreateCondition(
   CFuzzyVariable* var,      // fuzzy variable
   CFuzzyTerm*     term,     // fuzzy term
   bool            not,      // flag indicating whether it is necessary to apply negat
   HedgeType       hedge     // condition bundle type
   )
```

Parameters

var

[in] Fuzzy variable.

term

[in] Fuzzy term.

not

[in] Flag indicating whether it is necessary to apply negation to a condition.

hedge

[in] Condition bundle type.

Return Value

Fuzzy rule status.

Fuzzy systems variables

Fuzzy (linguistic) variables **are applied in fuzzy systems**. These are the variables whose values are words or word combinations in a natural or artificial language.

Linguistic variables comprise fuzzy sets. The nature and number of fuzzy variables change for each certain task when defining fuzzy sets.

Class	Description
CFuzzyVariable	Class for creating general fuzzy variables.
CSugenoVariable	Class for creating fuzzy Sugeno-type variables.

© 2000-2025, MetaQuotes Ltd.

CFuzzyVariable

Class for creating general fuzzy variables.

Description

Here, a fuzzy variable is created with the following parameters:

- maximum variable value;
- minimum variable value;
- fuzzy variable name;
- term set (set of all possible values, which a linguistic variable is capable of receiving).

Declaration

```
class CFuzzyVariable : public CNamedVariableImpl
```

Title

```
#include <Math\Fuzzy\fuzzyvariable.mqh>
```

Inheritance hierarchy

CObject
  INamedValue
    INamedVariable
      CNamedVariableImpl
        CFuzzyVariable

Class methods

Class method	Description
AddTerm	Adds a single fuzzy term to a fuzzy variable.
GetTermByName	Gets a fuzzy term by a specified name.
Max	Gets and sets a maximum value for a fuzzy variable.
Min	Gets and sets a minimum value for a fuzzy variable.
Terms	Gets and sets a list of fuzzy terms for the given fuzzy variable.
Values	Gets and sets a list of fuzzy terms for the given fuzzy variable.

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CNamedVariableImpl

Name, Name

© 2000-2025, MetaQuotes Ltd.

AddTerm

Adds a single fuzzy term to a fuzzy variable.

```
void  AddTerm(
   CFuzzyTerm*&  term      // fuzzy term
   )
```

Parameters

term

[in] Fuzzy term.

GetTermByName

Gets a fuzzy term by a specified name.

```
CFuzzyTerm*  GetTermByName(
   const string  name      // fuzzy term name
   )
```

Parameters

name

[in] Fuzzy term name.

Return Value

Fuzzy term with a specified name.

Max (Get method)

Gets the maximum value for a fuzzy variable.

```
double  Max()
```

Return Value

Maximum value for a fuzzy variable.

Max (Set method)

Sets the maximum value for a fuzzy variable.

```
void  Max(
   const double  max      // maximum value for a fuzzy variable
   )
```

Parameters

max

[in] Maximum value for a fuzzy variable.

© 2000-2025, MetaQuotes Ltd.

Min (Get method)

Gets the minimum value for a fuzzy variable.

```
double  Min()
```

Return Value

Minimum value for a fuzzy variable.

Max (Set method)

Sets the minimum value for a fuzzy variable.

```
void  Min(
   const double  min      // minimum value for a fuzzy variable
   )
```

Parameters

min

[in] Minimum value for a fuzzy variable.

Terms (Get method)

Gets a list of fuzzy terms for the given fuzzy variable.

```
CList*  Terms()
```

Return Value

List of fuzzy terms for the given fuzzy variable.

Terms (Set method)

Sets a list of fuzzy terms for the given fuzzy variable.

```
void  Terms(
   CList*&  terms      // list of fuzzy terms for the given variable
   )
```

Parameters

terms

[in] list of fuzzy terms for the given fuzzy variable.

Values

Gets a list of fuzzy terms for the given fuzzy variable.

```
CList*  Values()
```

Return Value

© 2000-2025, MetaQuotes Ltd.

List of fuzzy terms for the given variable.

© 2000-2025, MetaQuotes Ltd.

CSugenoVariable

Class for creating fuzzy Sugeno-type variables.

Description

Fuzzy Sugeno-type variable is different from the general linguistic variable since it is not set by a term set but by a set of linear functions.

Declaration

```
class CSugenoVariable : public CNamedVariableImpl
```

Title

```
#include <Math\Fuzzy\sugenovariable.mqh>
```

Inheritance hierarchy

CObject
  INamedValue
    INamedVariable
      CNamedVariableImpl
        CSugenoVariable

Class methods

Class method	Description
Functions	Gets the list of linear functions of the fuzzy Sugeno variable.
GetFuncByName	Gets the linear function by a specified name.
Values	Gets the list of linear functions of the fuzzy Sugeno variable.

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CNamedVariableImpl

Name, Name

Functions

Gets the list of linear functions of the fuzzy Sugeno variable.

```
CList*  Functions()
```

Return Value

© 2000-2025, MetaQuotes Ltd.

List of linear functions.

GetFuncByName

Gets the linear function by a specified name.

```
ISugenoFunction*  GetFuncByName(
   const string  name      // linear function name
   )
```

Parameters

name

[in] Linear function name.

Return Value

Linear function with a specified name.

Values

Gets the list of linear functions of the fuzzy Sugeno variable.

```
CList*  Values()
```

Return Value

List of linear functions of the fuzzy Sugeno variable.

© 2000-2025, MetaQuotes Ltd.

CFuzzyTerm (fuzzy terms)

Class for implementing fuzzy terms.

Description

A term is any element of a term set. A term is defined by two components:

- fuzzy term name;
- membership function.

Declaration

```
class CFuzzyTerm : public CNamedValueImpl
```

Title

```
#include <Math\Fuzzy\fuzzyterm.mqh>
```

Inheritance hierarchy

CObject
  INamedValue
    CNamedValueImpl
      CFuzzyTerm

Class methods

Class method	Description
MembershipFunction	Gets a membership function for the fuzzy term.

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CNamedValueImpl

Name, Name

© 2000-2025, MetaQuotes Ltd.

MembershipFunction

Gets a membership function for the fuzzy term.

```
IMembershipFunction*  MembershipFunction()
```

Return Value

Membership function

© 2000-2025, MetaQuotes Ltd.

Fuzzy systems

Fuzzy system (or *fuzzy model*) is a mathematical model whose calculation is based on fuzzy logic. Construction of such models is applicable when the subject of study has a weak formalization and its exact mathematical description is too complex or unknown.

The progress of a model construction can be divided into three main stages:

1. Definition of input and output characteristics of a model.
2. Building a knowledge base.
3. Selecting one of the methods of fuzzy inference (Mamdani and Sugeno).

The first stage directly effects the consequent two and determines the future operation of the model.

A knowledge base (*rule base*) is a set of fuzzy rules of "if, then" type that define the relationship between inputs and outputs of the examined object.

Rule condition describes the current state of the object, and **rule conclusion** — how this condition affects the object.

There can be two types of terms and conclusions for each rule:

1. simple (link to Csinglcond) — includes one fuzzy variable;
2. complex (link to Cconditions) — includes several fuzzy variables.

Each rule in the system has its **weight** — importance of a rule in the model. Weighting factors are assigned to a rule within range [0, 1].

Depending on the created knowledge base, the system of fuzzy inference is determined for a model. **Fuzzy logical inference** is a receipt of conclusion in form of a fuzzy set corresponding to the current value of the inputs with use of knowledge base and fuzzy operations. The two main types of fuzzy inference are Mamdani and Sugeno.

© 2000-2025, MetaQuotes Ltd.

Mamdani system

Output variable values in the Mamdani system are set using fuzzy terms.

Description

Fuzzy logic rule for the Mamdani algorithm can be described as follows:

$$if(X_1\ is\ a_1) \wedge (X_2\ is\ a_2) \wedge \ldots \wedge (X_n\ is\ a_n)\ then\ (Y\ is\ d)(W)$$

where:

- X = (X1, X2, X3 ... Xn) — vector of input variables;
- Y — output variable;
- a = (a1, a2, a3 ... an) — vector of input variable values;
- d — output variable value;
- W — rule weight.

Class methods

Class method	Description
AggregationMethod	Sets the type of conditions aggregation
Calculate	Calculates a fuzzy inference for the system
DefuzzificationMethod	Sets defuzzification method type
EmptyRule	Creates an empty fuzzy Mamdani rule based on the current system
ImplicationMethod	Sets a type of the system implication operator
Output	Gets the list of fuzzy Mamdani output variables.
OutputByName	Gets a fuzzy Mamdani output variable by a specified name.
ParseRule	Creates a fuzzy Mamdani rule based on a specified line.
Rules	Returns the list of fuzzy Mamdani rules.

Methods inherited from class CGenericFuzzySystem

Input, AndMethod, AndMethod, OrMethod, OrMethod, InputByName, Fuzzify

AggregationMethod

Sets the type of conditions aggregation method.

```
void  AggregationMethod(
   AggregationMethod  value      // aggregation method type
```

© 2000-2025, MetaQuotes Ltd.

```
   )
```

Parameters

value

[in] Type of conditions aggregation method.

Calculate

Calculates a fuzzy inference for the system

```
CList*  Calculate(
   CList*  inputValues      // input data
   )
```

Parameters

inputValues

[in] Input data for calculation.

Return Value

Calculation result.

DefuzzificationMethod

Sets defuzzification method type.

```
void  DefuzzificationMethod(
   DefuzzificationMethod  value      // defuzzification method type.
   )
```

Parameters

value

[in] Defuzzification method type.

EmptyRule

Creates an empty fuzzy Mamdani rule based on the current system

```
CMamdaniFuzzyRule*  EmptyRule()
```

Return Value

Fuzzy Mamdani rule.

ImplicationMethod

Sets a type of the conditions implication operator.

```
void  ImplicationMethod(
   ImplicationMethod  value      // implication operator type
```

© 2000-2025, MetaQuotes Ltd.

```
   )
```

Parameters

value

[in] Type of the conditions implication operator.

Output

Gets the list of fuzzy Mamdani output variables.

```
CList*  Output()
```

Return Value

List of fuzzy variables.

OutputByName

Gets a fuzzy Mamdani output variable by a specified name.

```
CFuzzyVariable*  OutputByName(
   const string  name      // fuzzy variable name
   )
```

Parameters

name

[in] Fuzzy variable name.

Return Value

Fuzzy Mamdani variable with a specified name.

ParseRule

Creates a fuzzy Mamdani rule based on a specified line.

```
CMamdaniFuzzyRule*  ParseRule(
   const string  rule      // string representation of a fuzzy rule
   )
```

Parameters

rule

[in] String representation of a fuzzy Mamdani rule.

Return Value

Fuzzy Mamdani rule.

Rules

© 2000-2025, MetaQuotes Ltd.

Returns the list of fuzzy Mamdani rules.

```
CList*  Rules()
```

Return Value

List of fuzzy Mamdani rules.

© 2000-2025, MetaQuotes Ltd.

Sugeno system

Sugeno fuzzy logic system is one of the two basic types of fuzzy systems. Output variable values are set as a linear combination of input variables.

Description

Unlike the Mamdani rule, an input variable value is set by a linear function from entries rather than by a fuzzy term. Fuzzy logic rule for the Sugeno algorithm can be described as follows:

$$if(X_1\ is\ a_1)\wedge(X_2\ is\ a_2)\wedge\ldots\wedge(X_n\ is\ a_n)\ then\ (Y=b_0+b_1\cdot X_1+b_2\cdot X_2+\ldots+b_n\cdot X_n)(W)$$

where:

- X = (X1, X2, X3 ... Xn) — vector of input variables;
- Y — output variable;
- a = (a1, a2, a3 ... an) — vector of input variable values;
- b = (b1, b2, b3 ... bn) — free term ratio in the linear function for an output value
- W — rule weight.

Class methods

Class method	Description
Calculate	Calculates a fuzzy inference for the system
CreateSugenoFunction	Creates a linear Sugeno function for the system.
EmptyRule	Creates an empty fuzzy Sugeno rule based on the current system.
Output	Gets the list of fuzzy Sugeno output variables.
OutputByName	Gets a fuzzy Sugeno output variable by a specified name.
ParseRule	Creates a fuzzy Sugeno rule based on a specified line.
Rules	Returns the list of fuzzy rules.

Methods inherited from class CGenericFuzzySystem

Input, AndMethod, AndMethod, OrMethod, OrMethod, InputByName, Fuzzify

Calculate

Calculates a fuzzy inference for the system

```
CList*  Calculate(
   CList*&  inputValues      // input data
   )
```

Parameters

© 2000-2025, MetaQuotes Ltd.

inputValues

[in] Input data for calculation.

Return Value

Calculation result.

CreateSugenoFunction

Creates a linear Sugeno function for the system.

```
CLinearSugenoFunction*  CreateSugenoFunction(
   const string  name,          // function name
   const double& coeffs[]       // function ratios
   )
```

Parameters

name

[in] Function name.

coeffs[]

[in] Function ratios.

Return Value

Linear Sugeno function.

Note

The size of the ratio array may be equal to a number of inputs or exceed that number by one. In the first case, the free term of the Sugeno linear function is equal to zero, while in the second case, it is equal to the last ratio.

CreateSugenoFunction

Creates a linear Sugeno function for the system.

```
CLinearSugenoFunction*  CreateSugenoFunction(
   const string  name,          // function name
   CList*&       coeffs,        // list of pairs fuzzy variable - its ratio
   const double  constValue     // function free term ratio
   )
```

Parameters

name

[in] Function name.

coeffs[]

[in] Function ratios.

Return Value

© 2000-2025, MetaQuotes Ltd.

Linear Sugeno function.

EmptyRule

Creates an empty fuzzy Sugeno rule based on the current system.

```
CSugenoFuzzyRule*  EmptyRule()
```

Return Value

Fuzzy Sugeno rule.

Output

Gets the list of fuzzy Sugeno output variables.

```
CList*  Output()
```

Return Value

List of fuzzy variables.

OutputByName

Gets a fuzzy Sugeno output variable by a specified name.

```
CSugenoVariable*  OutputByName(
   const string  name      // fuzzy variable name
   )
```

Parameters

name

Fuzzy variable name.

Return Value

Fuzzy Sugeno variable with a specified name.

ParseRule

Creates a fuzzy Sugeno rule based on a specified line.

```
CSugenoFuzzyRule*  ParseRule(
   const string  rule      // string representation of a fuzzy Sugeno rule
   )
```

Parameters

rule

[in] String representation of a fuzzy Sugeno rule.

Return Value

© 2000-2025, MetaQuotes Ltd.

Fuzzy Sugeno rule.

Rules

Returns the list of fuzzy rules.

```
CList*  Rules()
```

Return Value

List of fuzzy rules.

© 2000-2025, MetaQuotes Ltd.

Class for working with OpenCL programs

The COpenCL class is a wrapper to facilitate working with the OpenCL functions. In some cases, use of the GPU allows to substantially increase the speed of computations.

Examples of class use for calculations based on float and double values can be found in the corresponding subdirectories of the MQL5\Scripts\Examples\OpenCL\ folder. The source codes of the OpenCL programs are located in MQL5\Scripts\Examples\OpenCL\Double\Kernels and MQL5\Scripts\Examples\OpenCL\Float\Kernels subdirectories.

- MatrixMult.mq5 - example of matrix multiplication using global and local memory
- BitonicSort.mq5 - example of parallel sorting of array elements in GPU
- FFT.mq5 - example of fast Fourier transform calculation
- Wavelet.mq5 - example of wavelet transform of data using the Morlet wavelet.

It is recommended to write the source code for OpenCL in separate CL files, which can later be included in the MQL5 program using the resource variables.

Declaration

```
class COpenCL
```

Title

```
#include <OpenCL\OpenCL.mqh>
```

Class methods

Name	Description
BufferCreate	Creates an OpenCL buffer at the specified index
BufferFree	Deletes buffer at the specified index
BufferFromArray	Creates a buffer at the specified index from an array of values
BufferRead	Reads an OpenCL buffer at the specified index into an array
BufferWrite	Writes an array of values into buffer at the specified index
Execute	Executes the OpenCL kernel with the specified index
GetContext	Returns handle of the OpenCL context
GetKernel	Returns handle of the kernel object at the specified index
GetKernelName	Returns name of the kernel object at the specified index
GetProgram	Returns handle of the OpenCL program
Initialize	Initializes the OpenCL program
KernelCreate	Creates an entry point into the OpenCL program at the specified index
KernelFree	Removes an OpenCL start function at the specified index

© 2000-2025, MetaQuotes Ltd.

Name	Description
SetArgument	Sets a parameter for the OpenCL function at the specified index
SetArgumentBuffer	Sets an OpenCL buffer as a parameter of the OpenCL function at the specified index
SetArgumentLocalMemory	Sets a parameter in local memory for the OpenCL function at the specified index
SetBuffersCount	Sets the number of buffers
SetKernelsCount	Sets the number of kernel objects
Shutdown	Unloads the OpenCL program
SupportDouble	Checks if floating point data types are supported on the device

© 2000-2025, MetaQuotes Ltd.

BufferCreate

Creates an OpenCL buffer at the specified index.

```
bool  BufferCreate(
   const int   buffer_index,      // buffer index
   const uint  size_in_bytes,     // buffer size in bytes
   const uint  flags              // combination of flags that define the buffer prope
   );
```

Parameters

buffer_index

[in] Index buffer.

size_in_bytes

[in] Buffer size in bytes.

flags

[in] Buffer properties that are set using a combination of flags.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

BufferFree

Deletes buffer at the specified index.

```
bool  BufferFree(
   const int  buffer_index      // buffer index
   );
```

Parameters

buffer_index

[in] Index buffer.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

BufferFromArray

Creates a buffer at the specified index from an array of values.

```
template<typename T>
bool  BufferFromArray(
   const int   buffer_index,          // buffer index
   T           &data[],               // array of values
   const uint  data_array_offset,     // offset in the array of values, in bytes
   const uint  data_array_count,      // number of values from the array to write
   const uint  flags                  // combination of flags that define the buffer p
   );
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] An array of values to be written into the OpenCL buffer.

data_array_offset

[in] Offset in the array of values in bytes, from which writing of values begins.

data_array_count

[in] The number of values to be written.

flags

[in] Buffer properties that are set using a combination of flags.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

BufferRead

Reads an OpenCL buffer at the specified index into an array.

```
template<typename T>
bool  BufferRead(
   const int   buffer_index,          // buffer index
   T           &data[],               // array of values
   const uint  cl_buffer_offset,      // offset in the OpenCL buffer, in bytes
   const uint  data_array_offset,     // shift in the array elements
   const uint  data_array_count       // number of values from the buffer to read
   );
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] Array to obtain the values of the OpenCL buffer.

cl_buffer_offset

[in] Offset in the OpenCL buffer in bytes, from which to start reading values.

data_array_offset

[in] Index of the first element of the array to write values of the OpenCL buffer.

data_array_count

[in] The number of values to be read.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

BufferWrite

Writes an array of values into buffer at the specified index.

```
template<typename T>
bool  BufferWrite(
   const int   buffer_index,          // buffer index
   T           &data[],               // array of values
   const uint  cl_buffer_offset,      // offset in the OpenCL buffer, in bytes
   const uint  data_array_offset,     // shift in the array elements
   const uint  data_array_count       // number of values from the array to write
   );
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] An array of values to be written into the OpenCL buffer.

cl_buffer_offset

[in] Offset in the OpenCL buffer in bytes, from which to start writing values.

data_array_offset

[in] Index of the first element of the array, starting from which the array values are written to the OpenCL buffer.

data_array_count

[in] The number of values to be written.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

Execute

Executes the OpenCL program at the specified index.

```
bool  Execute(
   const int   kernel_index,           // index of the kernel
   const int   work_dim,               // dimension of the tasks space
   const uint  &work_offset[],         // initial offset in the tasks space
   const uint  &work_size[]            // total number of tasks
   );
```

Executes the OpenCL kernel with the specified index and number of tasks in the local group.

```
bool  Execute(
   const int   kernel_index,           // index of the kernel
   const int   work_dim,               // dimension of the tasks space
   const uint  &work_offset[],         // initial offset in the tasks space
   const uint  &work_size[],           // total number of tasks
   const uint  &local_work_size[]      // number of tasks in the local group
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

work_dim

[in] Dimension of the tasks space.

&work_offset[]

[in][out] Initial offset in the tasks space. Passed by reference.

&work_size[]

[in][out] The size of the tasks subset. Passed by reference.

&local_work_size[]

[in][out] The size of the local tasks subset in the group. Passed by reference.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

GetContext

Returns handle of the OpenCL context.

```
int  GetContext();
```

Return Value

Handle of the OpenCL context.

© 2000-2025, MetaQuotes Ltd.

GetKernel

Returns handle of the kernel object at the specified index.

```
int  GetKernel(
   const int  kernel_index      // index of the kernel
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

Handle of the kernel object.

© 2000-2025, MetaQuotes Ltd.

GetKernelName

Returns name of the kernel object at the specified index.

```
string  GetKernelName(
   const int  kernel_index      // index of the kernel
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

Name of the kernel object.

© 2000-2025, MetaQuotes Ltd.

GetProgram

Returns handle of the OpenCL program.

```
int  GetProgram();
```

Return Value

Handle of the OpenCL program.

© 2000-2025, MetaQuotes Ltd.

Initialize

Initializes the OpenCL program.

```
bool  Initialize(
   const string  program,           // handle of the OpenCL program
   const bool    show_log=true      // keep a log
   );
```

Parameters

program

[in] Handle of the OpenCL program.

show_log=true

[in] Enable logging messages.

Return Value

Returns true, if the initialization succeeded. Otherwise, it returns false.

© 2000-2025, MetaQuotes Ltd.

KernelCreate

Creates an entry point into the OpenCL program at the specified index.

```
bool  KernelCreate(
   const int     kernel_index,     // index of the kernel
   const string  kernel_name       // name of the kernel
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

kernel_name

[in] Name of the kernel object.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

KernelFree

Removes an OpenCL start function at the specified index.

```
bool  KernelFree(
   const int  kernel_index      // index of the kernel
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

SetArgument

Sets a parameter for the OpenCL function at the specified index.

```
template<typename T>
bool  SetArgument(
   const int  kernel_index,     // index of the kernel
   const int  arg_index,        // index of the function argument
   T          value             // source code
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

value

[in] The value of the function argument.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

SetArgumentBuffer

Sets an OpenCL buffer as a parameter of the OpenCL function at the specified index.

```
bool  SetArgumentBuffer(
   const int  kernel_index,     // index of the kernel
   const int  arg_index,        // index of the function argument
   const int  buffer_index      // buffer index
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

buffer_index

[in] Index buffer.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

SetArgumentLocalMemory

Sets a parameter in local memory for the OpenCL function at the specified index.

```
bool  SetArgumentLocalMemory(
   const int  kernel_index,          // index of the kernel
   const int  arg_index,             // index of the function argument
   const int  local_memory_size      // size of the local memory
   );
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

local_memory_size

[in] Size of the local memory.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

SetBuffersCount

Sets the number of buffers.

```
bool  SetBuffersCount(
   const int  total_buffers      // number of buffers
   );
```

Parameters

total_buffers

[in] The total number of buffers.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

SetKernelsCount

Sets the number of kernel objects.

```
bool  SetKernelsCount(
   const int  total_kernels      // number of kernels
   );
```

Parameters

total_kernels

[in] The total number of kernels.

Return Value

In case of successful execution, returns true, otherwise - false.

© 2000-2025, MetaQuotes Ltd.

Shutdown

Unloads the OpenCL program.

```
void  Shutdown();
```

Return Value

No return value.

© 2000-2025, MetaQuotes Ltd.

SupportDouble

Checks if floating point data types are supported on the device.

```
bool  SupportDouble();
```

Return Value

Returns true, if the device supports floating point data types.

© 2000-2025, MetaQuotes Ltd.

Basic Class CObject

Class CObject is the base class for constructing a MQL5 Standard Library.

Description

Class CObject allows all its descendants to be part of a linked list. Also, a number of virtual methods for further implementation in descendant classes are identified.

Declaration

```
class CObject
```

Title

```
#include <Object.mqh>
```

Inheritance hierarchy

CObject

Direct descendants

CAccountInfo, CArray, CChart, CChartObject, CCurve, CDealInfo, CDictionary_Obj_Double, CDictionary_Obj_Obj, CDictionary_String_Obj, CExpertBase, CFile, CHistoryOrderInfo, CList, COrderInfo, CPositionInfo, CString, CSymbolInfo, CTerminalInfo, CTrade, CTreeNode, CWnd, ICondition, IExpression, IMembershipFunction, INamedValue, IParsableRule

Class Methods by Groups

Attributes	
Prev	Gets the value of the previous item
Prev	Sets the value of the previous item
Next	Gets the value of the subsequent element
Next	Sets the next element
Compare methods	
virtual Compare	Returns the result of comparison with another object
Input/output	
virtual Save	Writes object to a file
virtual Load	Reads the object from the file
virtual Type	Returns the type of object

© 2000-2025, MetaQuotes Ltd.

Prev

Gets a pointer to the previous element in the list.

```
CObject*  Prev()
```

Return Value

Pointer to the previous element in the list. If an item is listed first, then return NULL.

Example:

```
//--- example for CObject::Prev()
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object_first,*object_second;
   //---
   object_first=new CObject;
   if(object_first==NULL)
     {
      printf("Object create error");
      return;
     }
   object_second=new CObject;
   if(object_second==NULL)
     {
      printf("Object create error");
      delete object_first;
      return;
     }
   //--- set interconnect
   object_first.Next(object_second);
   object_second.Prev(object_first);
   //--- use prev object
   CObject *object=object_second.Prev();
   //--- delete objects
   delete object_first;
   delete object_second;
  }
```

© 2000-2025, MetaQuotes Ltd.

Prev

Sets the pointer to the previous element in the list.

```
void  Prev(
   CObject*  object      // Pointer to the previous element in the list
   )
```

Parameters

object

[in] New value of the pointer to the previous element in the list.

Example:

```
//--- example for CObject::Prev(CObject*)
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object_first,*object_second;
   //---
   object_first=new CObject;
   if(object_first==NULL)
     {
      printf("Object create error");
      return;
     }
   object_second=new CObject;
   if(object_second==NULL)
     {
      printf("Object create error");
      delete object_first;
      return;
     }
   //--- set interconnect
   object_first.Next(object_second);
   object_second.Prev(object_first);
   //--- use objects
   //--- ...
   //--- delete objects
   delete object_first;
   delete object_second;
  }
```

© 2000-2025, MetaQuotes Ltd.

Next

Gets a pointer to the next element in the list.

```
CObject*  Next()
```

Return Value

Pointer to the next element in the list. If this is the last element in the list, return NULL.

Example:

```
//--- example for CObject::Next()
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object_first,*object_second;
   //---
   object_first=new CObject;
   if(object_first==NULL)
     {
      printf("Object create error");
      return;
     }
   object_second=new CObject;
   if(object_second==NULL)
     {
      printf("Object create error");
      delete object_first;
      return;
     }
   //--- set interconnect
   object_first.Next(object_second);
   object_second.Prev(object_first);
   //--- use next object
   CObject *object=object_first.Next();
   //--- delete objects
   delete object_first;
   delete object_second;
  }
```

© 2000-2025, MetaQuotes Ltd.

Next

Sets the pointer to the next element in the list.

```
void  Next(
   CObject*  object      // Pointer to the next element in the list
   )
```

Parameters

object

[in] New value of the pointer to the next element in the list.

Example:

```
//--- example for CObject::Next(CObject*)
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object_first,*object_second;
   //---
   object_first=new CObject;
   if(object_first==NULL)
     {
      printf("Object create error");
      return;
     }
   object_second=new CObject;
   if(object_second==NULL)
     {
      printf("Object create error");
      delete object_first;
      return;
     }
   //--- set interconnect
   object_first.Next(object_second);
   object_second.Prev(object_first);
   //--- use objects
   //--- ...
   //--- delete objects
   delete object_first;
   delete object_second;
  }
```

© 2000-2025, MetaQuotes Ltd.

Compare

Compares the data on a list element with data on another list element.

```
virtual int  Compare(
   const CObject*  node,      // element
   const int       mode=0     // variant
   ) const
```

Parameters

node

[in] Pointer to a list element to compare

mode=0

[in] Comparison variant

Return Value

0 - in case the list elements are equal, -1 - if the list element is less than the element used for comparison (node), 1 - if the list element is greater than the element used for comparison (node).

Note

Compare() method in CObject class always returns 0 and does not perform any action. If you want to compare data in derived class, the Compare(...) method should be implemented. The 'mode' parameter should be used when implementing multivariate comparison.

Example:

```
//--- example for CObject::Compare(...)
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object_first,*object_second;
   //---
   object_first=new CObject;
   if(object_first==NULL)
     {
      printf("Object create error");
      return;
     }
   object_second=new CObject;
   if(object_second==NULL)
     {
      printf("Object create error");
      delete object_first;
      return;
     }
   //--- set interconnect
   object_first.Next(object_second);
```

© 2000-2025, MetaQuotes Ltd.

```
   object_second.Prev(object_first);
   //--- compare objects
   int result=object_first.Compare(object_second);
   //--- delete objects
   delete object_first;
   delete object_second;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves list element data in a file.

```
virtual bool  Save(
   int  file_handle      // File handle
   )
```

Parameters

file_handle

[in] Handle of the binary file opened earlier using the FileOpen () function

Return Value

true - successfully completed, false - error.

Note

Save(int) method in CObject class always returns 'true' and does not perform any action. If you want to save the data of a derived class in a file, the Save(int) method should be implemented.

Example:

```
//--- example for CObject::Save(int)
#include <Object.mqh>
//---
void OnStart()
  {
   int    file_handle;
   CObject *object=new CObject;
   //---
   if(object!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- set objects data
   //--- . . .
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!object.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete object;
         FileClose(file_handle);
         //---
         return;
        }
```

© 2000-2025, MetaQuotes Ltd.

```
      FileClose(file_handle);
     }
   delete object;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads list element data from a file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file opened earlier using the FileOpen() function.

Return Value

true - successfully completed, false - error.

Note

Load(int) method in the CObject class always returns 'true' and does not perform any action. If you want to load the data of a derived class from a file, the Load(int) method should be implemented.

Example:

```
//--- example for CObject::Load(int)
#include <Object.mqh>
//---
void OnStart()
  {
   int    file_handle;
   CObject *object=new CObject;
   //---
   if(object!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!object.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete object;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use object
   //--- . . .
   delete object;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the type identifier.

```
virtual int  Type() const
```

Return Value

Type identifier (for CObject - 0).

Example:

```
//--- example for CObject::Type()
#include <Object.mqh>
//---
void OnStart()
  {
   CObject *object=new CObject;
   //---
   object=new CObject;
   if(object ==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get objects type
   int type=object.Type();
   //--- delete object
   delete object;
  }
```

Data Structures

This section contains the technical details on working with various data structures (arrays, linked lists, etc.) and description of the relevant components of the MQL5 Standard Library.

Using classes of data structures will save time when creating custom data stores of various formats (including composite data structures).

MQL5 Standard Library (in terms of data sets) is placed in the working directory of the terminal in the Include\Arrays folder.

Data Arrays

Use of classes of dynamic data arrays will save time when creating a custom data stores of various formats (including multidimensional arrays).

MQL5 Standard Library (in terms of arrays of data) is located in the working directory of the terminal in the Include\Arrays folder.

Class	Description
CArray	Base class of dynamic data array
CArrayChar	Dynamic array of char or uchar variables
CArrayShort	Dynamic array of short or ushort variables
CArrayInt	Dynamic array of int or uint variables
CArrayLong	Dynamic array of long or ulong variables
CArrayFloat	Dynamic array of float variables
CArrayDouble	Dynamic array of double variables
CArrayString	Dynamic array of string variables
CArrayObj	Dynamic array of CObject pointers
CList	Provides the ability to work with a list of instances of CObject class and its descendants
CTreeNode	Provides the ability to work with nodes of the CTree binary tree
CTree	Provides the ability to work with the binary tree of the CTreeNode class instances and its descendants

© 2000-2025, MetaQuotes Ltd.

CArray

CArray class is the base class of a dynamic array of variables.

Description

Class CArray is intended to operate on dynamic arrays of variables: memory allocation, sorting, and working with files.

Declaration

```
class CArray : public CObject
```

Title

```
#include <Arrays\Array.mqh>
```

Inheritance hierarchy

CObject

CArray

Direct descendants

CArrayChar, CArrayDouble, CArrayFloat, CArrayInt, CArrayLong, CArrayObj, CArrayShort, CArrayString

Class Methods by Groups

Attributes	
Step	Gets the increment size of the array
Step	Sets the increment size of the array
Total	Gets the number of elements in the array
Available	Gets the number of free elements of the array that are available without additional memory allocation
Max	Gets the maximum possible size of the array without memory reallocation
IsSorted	Gets the flag of array being sorted using specified sorting mode
SortMode	Gets the sorting mode for an array
Clear methods	
Clear	Deletes all of the array elements without memory release
Sort methods	
Sort	Sorts an array to the specified option
Input/output	

© 2000-2025, MetaQuotes Ltd.

Attributes	
virtual Save	Saves data array in a file
virtual Load	Loads data array from a file

Methods inherited from class CObject

Prev, Prev, Next, Next, Type, Compare

© 2000-2025, MetaQuotes Ltd.

Step

Gets the increment size of the array.

```
int  Step() const
```

Return Value

Increment size of the array.

Example:

```
//--- example for CArray::Step()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get resize step
   int step=array.Step();
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Step

Sets the increment size of the array.

```
bool  Step(
   int  step      // step
   )
```

Parameters

step

[in] The new value of the increment size of the array.

Return Value

true - successful, false - there was an attempt to establish a step less than or equal to zero.

Example:

```
//--- example for CArray::Step(int)
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- set resize step
   bool result=array.Step(1024);
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Total

Gets the number of elements in the array.

```
int  Total() const;
```

Return Value

Number of elements in the array.

Example:

```
//--- example for CArray::Total()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check total
   int total=array.Total();
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Available

Gets the number of free elements of the array that are available without additional memory allocation.

```
int  Available() const
```

Return Value

Number of free elements of the array available without additional memory allocation.

Example:

```
//--- example for CArray::Available()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check available
   int available=array.Available();
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Max

Gets the maximum possible size of the array without memory reallocation.

```
int  Max() const
```

Return Value

The maximum possible size of the array without memory reallocation.

Example:

```
//--- example for CArray::Max()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check maximum size
   int max=array.Max();
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

IsSorted

Gets the flag of array being sorted using the specified sorting mode.

```
bool  IsSorted(
   int  mode=0      // sorting mode
   ) const
```

Parameters

mode=0

[in] Tested sorting mode.

Return Value

Flag of the sorted list. If the list is sorted using the specified mode - true, otherwise - false.

Note

The sort flag cannot be changed directly. It is set by the Sort() method and reset by any add/insert method except for the InserSort(...).

Example:

```
//--- example for CArray::IsSorted()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check sorted
   if(array.IsSorted())
     {
      //--- use methods for sorted array
      //--- ...
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SortMode

Gets the sorting mode for an array.

```
int  SortMode() const;
```

Return Value

Sorting mode.

Example:

```
//--- example for CArray::SortMode()
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check sort mode
   int sort_mode=array.SortMode();
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Clear

Deletes all of the array elements without memory release.

```
void  Clear()
```

Return Value

None.

Example:

```
//--- example for CArray::Clear()
#include <Arrays\Array.mqh>
//---
void OnStart()
 {
 CArray *array=new CArray;
 //---
 if(array==NULL)
 {
 printf("Object create error");
 return;
 }
 //--- use array
 //--- ...
 //--- clear array
 array.Clear();
 //--- delete array
 delete array;
 }
```

© 2000-2025, MetaQuotes Ltd.

Sort

Sorts an array using the specified option.

```
void  Sort(
   int  mode=0       // sorting mode
   )
```

Parameters

mode=0

[in] Mode of array sorting.

Return Value

No.

Note

Sorting an array is always ascending. For arrays of primitive data types (CArrayChar, CArrayShort, etc.), the 'mode' parameter is not used. For the CArrayObj array, multivariate sorting should be implemented in the Sort(int) method of derived classes.

Example:

```
//--- example for CArray::Sort(int)
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   CArray *array=new CArray;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- sorting by mode 0
   array.Sort(0);
   //--- use array
   //--- ...
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of a binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArray::Save(int)
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   int     file_handle;
   CArray *array=new CArray;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from a file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of a binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArray::Load(...)
#include <Arrays\Array.mqh>
//---
void OnStart()
  {
   int     file_handle;
   CArray *array=new CArray;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- delete array
   delete array;
  }
```

CArrayChar

CArrayChar is a class of dynamic array of char or uchar variables.

Description

CArrayChar class provides the ability to work with a dynamic array of char or uchar variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayChar : public CArray
```

Title

```
#include <Arrays\ArrayChar.mqh>
```

Inheritance hierarchy

CObject
  CArray
    CArrayChar

Class Methods

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Modify methods	
Update	Changes the element at the specified array position

© 2000-2025, MetaQuotes Ltd.

Memory control	
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array methods	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the array type identifier

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

Methods inherited from class CArray

Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is increased by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayChar::Reserve(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayChar::Resize(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayChar::Shutdown()
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   char  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayChar::Add(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const char&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayChar::AddArray(const char &[])
#include <Arrays\ArrayChar.mqh>
//---
char src[];
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayChar*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayChar class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayChar::AddArray(const CArrayChar*)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayChar *src=new CArrayChar;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   char  element,     // element to insert
   int   pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayChar::Insert(char,int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const char&  src[],     // source array
   int           pos       // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayChar::InsertArray(const char &[],int)
#include <Arrays\ArrayChar.mqh>
//---
char src[];
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayChar*  src,      // pointer to the source
   int           pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayChar::InsertArray(const CArrayChar*,int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayChar *src=new CArrayChar;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const char&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayChar::AssignArray(const char &[])
#include <Arrays\ArrayChar.mqh>
//---
char src[];
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayChar*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayChar::AssignArray(const CArrayChar*)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayChar *src  =new CArrayChar;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays are identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int   pos,          // position
   char  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayChar::Update(int,char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,'A'))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // value
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayChar::Shift(int,int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayChar::Delete(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of the last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayChar::DeleteRange(int,int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
char  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, CHAR_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, CHAR_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayChar::At(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      char result=array.At(i);
      if(result==CHAR_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- error of reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const char&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayChar::CompareArray(const char &[])
#include <Arrays\ArrayChar.mqh>
//---
char src[];
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const CArrayChar*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayChar::CompareArray(const CArrayChar*)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayChar *src=new CArrayChar;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   char  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayChar::InsertSort(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort('A'))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::Search(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search('A')!=-1) printf("Element found");
   else                      printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element, if successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchGreat(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat('A')!=-1) printf("Element found");
   else                           printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLess(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess('A')!=-1) printf("Element found");
   else                          printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchGreatOrEqual(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual('A')!=-1) printf("Element found");
   else                                  printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLessOrEqual(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual('A')!=-1) printf("Element found");
   else                                 printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchFirst(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst('A')!=-1) printf("Element found");
   else                           printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLast(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast('A')!=-1) printf("Element found");
   else                          printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   char  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayChar::SearchLinear(char)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear('A')!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayChar::Save(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   int          file_handle;
   CArrayChar *array=new CArrayChar;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayChar::Load(int)
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   int          file_handle;
   CArrayChar *array=new CArrayChar;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = '%c'",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayChar - 77).

Example:

```
//--- example for CArrayChar::Type()
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
  {
   CArrayChar *array=new CArrayChar;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayShort

CArrayShort is a class of dynamic array of short or ushort variables.

Description

Class CArrayShort provides the ability to work with a dynamic array of short or ushort variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayShort : public CArray
```

Title

```
#include <Arrays\ArrayShort.mqh>
```

Inheritance hierarchy

CObject
  CArray
    CArrayShort

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	

© 2000-2025, MetaQuotes Ltd.

Memory control	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayShort::Reserve(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayShort::Resize(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayShort::Shutdown()
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   short  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayShort::Add(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const short&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayShort::AddArray(const short &[])
#include <Arrays\ArrayShort.mqh>
//---
short src[];
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayShort*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayShort class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayShort::AddArray(const CArrayShort*)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayShort *src=new CArrayShort;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   short  element,     // element to insert
   int    pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayShort::Insert(short,int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const short&  src[],     // source array
   int            pos        // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayShort::InsertArray(const short &[],int)
#include <Arrays\ArrayShort.mqh>
//---
short src[];
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayShort*  src,      // pointer to the source
   int            pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements to insert.

pos

[in] Position in the array to insert.

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayShort::InsertArray(const CArrayShort*,int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayShort *src=new CArrayShort;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const short&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayShort::AssignArray(const short &[])
#include <Arrays\ArrayShort.mqh>
//---
short src[];
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayShort*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayShort::AssignArray(const CArrayShort*)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayShort *src  =new CArrayShort;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int    pos,          // position
   short  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayShort::Update(int,short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,100))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // positions
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayShort::Shift(int,int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayShort::Delete(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of the last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayShort::DeleteRange(int,int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
short  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, SHORT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, SHORT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayShort::At(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      short result=array.At(i);
      if(result==SHORT_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- error of reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const short&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayShort::CompareArray(const short &[])
#include <Arrays\ArrayShort.mqh>
//---
short src[];
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const CArrayShort*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayShort::CompareArray(const CArrayShort*)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayShort *src=new CArrayShort;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   short  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayShort::InsertSort(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(100))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::Search(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search(100)!=-1) printf("Element found");
   else                      printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - element not found.

Example:

```
//--- example for CArrayShort::SearchGreat(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat(100)!=-1) printf("Element found");
   else                           printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchLess(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess(100)!=-1) printf("Element found");
   else                          printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchGreatOrEqual(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual(100)!=-1) printf("Element found");
   else                                  printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchLessOrEqual(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual(100)!=-1) printf("Element found");
   else                                 printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchFirst(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst(100)!=-1) printf("Element found");
   else                           printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchLast(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast(100)!=-1) printf("Element found");
   else                          printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   short  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayShort::SearchLinear(short)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear(100)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayShort::Save(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayShort *array=new CArrayShort;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(i);
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayShort::Load(int)
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayShort *array=new CArrayShort;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = %d",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayShort - 82).

Example:

```
//--- example for CArrayShort::Type()
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
  {
   CArrayShort *array=new CArrayShort;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayInt

CArrayInt is a class of dynamic array of int or uint variables.

Description

The class CArrayInt provides the ability to work with a dynamic array of int or uint variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayInt : public CArray
```

Title

```
#include <Arrays\ArrayInt.mqh>
```

Inheritance hierarchy

CObject

CArray

CArrayInt

Direct descendants

CSpreadBuffer

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

© 2000-2025, MetaQuotes Ltd.

Memory control	
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayInt::Reserve(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // number
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayInt::Resize(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayInt::Shutdown()
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   int  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayInt::Add(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const int&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayInt::AddArray(const int &[])
#include <Arrays\ArrayInt.mqh>
//---
int src[];
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayInt*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayInt class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayInt::AddArray(const CArrayInt*)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayInt *src=new CArrayInt;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   int  element,     // element to insert
   int  pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayInt::Insert(int,int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const int&  src[],     // source array
   int          pos        // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayInt::InsertArray(const int &[],int)
#include <Arrays\ArrayInt.mqh>
//---
int src[];
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayInt*  src,     // pointer to the source
   int          pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements to insert.

pos

[in] Position in the array to insert.

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayInt::InsertArray(const CArrayInt*,int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayInt *src=new CArrayInt;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const int&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayInt::AssignArray(const int &[])
#include <Arrays\ArrayInt.mqh>
//---
int src[];
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayInt*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayInt::AssignArray(const CArrayInt*)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayInt *src  =new CArrayInt;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- arrays is identical
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int  pos,          // position
   int  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change.

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayInt::Update(int,int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,10000))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayInt::Shift(int,int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayInt::Delete(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of the last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayInt::DeleteRange(int,int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
int  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, INT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, INT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayInt::At(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      int result=array.At(i);
      if(result==INT_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- error of reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const int&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayInt::CompareArray(const int &[])
#include <Arrays\ArrayInt.mqh>
//---
int src[];
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const CArrayInt*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayInt::CompareArray(const CArrayInt*)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayInt *src=new CArrayInt;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   int  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayInt::InsertSort(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(10000))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::Search(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search(10000)!=-1) printf("Element found");
   else                        printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchGreat(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat(10000)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLess(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess(10000)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchGreatOrEqual(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual(10000)!=-1) printf("Element found");
   else                                    printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLessOrEqual(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual(10000)!=-1) printf("Element found");
   else                                   printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt:: SearchFirst(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst(10000)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLast(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast(10000)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   int  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayInt::SearchLinear(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear(10000)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayInt::Save(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   int         file_handle;
   CArrayInt *array=new CArrayInt;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(i);
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayInt::Load(int)
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   int         file_handle;
   CArrayInt *array=new CArrayInt;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = %d",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayInt - 82).

Example:

```
//--- example for CArrayInt::Type()
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
  {
   CArrayInt *array=new CArrayInt;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayLong

CArrayLong class is a class of dynamic array of long or ulong variables.

Description

The CArrayLong class provides the ability to work with a dynamic array of long or ulong variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayLong : public CArray
```

Title

```
#include <Arrays\ArrayLong.mqh>
```

Inheritance hierarchy

CObject

CArray

CArrayLong

Direct descendants

CRealVolumeBuffer, CTickVolumeBuffer, CTimeBuffer

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

© 2000-2025, MetaQuotes Ltd.

Memory control	
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

Methods inherited from class CArray

Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayLong::Reserve(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayLong::Resize(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayLong::Shutdown()
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   long  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayLong::Add(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const long&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayLong::AddArray(const long &[])
#include <Arrays\ArrayLong.mqh>
//---
long src[];
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayLong*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayLong class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayLong::AddArray(const CArrayLong*)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayLong *src=new CArrayLong;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   long  element,     // element to insert
   int   pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayLong::Insert(long,int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const long&  src[],     // source array
   int           pos        // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayLong::InsertArray(const long &[],int)
#include <Arrays\ArrayLong.mqh>
//---
long src[];
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayLong*  src,      // pointer to the source
   int           pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayLong::InsertArray(const CArrayLong*,int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayLong *src=new CArrayLong;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const long&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayLong::AssignArray(const long &[])
#include <Arrays\ArrayLong.mqh>
//---
long src[];
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayLong*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayLong::AssignArray(const CArrayLong*)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayLong *src  =new CArrayLong;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int   pos,          // position
   long  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayLong::Update(int,long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,1000000))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayLong::Shift(int,int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayLong::Delete(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of the last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayLong::DeleteRange(int,int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
long  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, LONG_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, LONG_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayLong::At(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      long result=array.At(i);
      if(result==LONG_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- Error reading from the array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const long&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayLong::CompareArray(const long &[])
#include <Arrays\ArrayLong.mqh>
//---
long src[];
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArrayconst

Compares the array with another one.

```
bool  CompareArrayconst(
   const CArrayLong*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayLong::CompareArray(const CArrayLong*)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayLong *src=new CArrayLong;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   long  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayLong::InsertSort(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(1000000))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::Search(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search(1000000)!=-1) printf("Element found");
   else                          printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchGreat(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat(1000000)!=-1) printf("Element found");
   else                               printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLess(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess(1000000)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchGreatOrEqual(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual(1000000)!=-1) printf("Element found");
   else                                      printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLessOrEqual(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual(1000000)!=-1) printf("Element found");
   else                                     printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchFirst(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst(1000000)!=-1) printf("Element found");
   else                               printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLast(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast(1000000)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   long  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayLong::SearchLinear(long)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear(1000000)!=-1) printf("Element found");
   else                                printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayLong::Save(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   int          file_handle;
   CArrayLong *array=new CArrayLong;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(i);
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayLong::Load(int)
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   int          file_handle;
   CArrayLong *array=new CArrayLong;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = %I64",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayLong - 84).

Example:

```
//--- example for CArrayLong::Type()
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
  {
   CArrayLong *array=new CArrayLong;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayFloat

CArrayFloat class is a class of dynamic array of float variables.

Description

The CArrayFloat class provides the ability to work with a dynamic array of float variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayFloat : public CArray
```

Title

```
#include <Arrays\ArrayFloat.mqh>
```

Inheritance hierarchy

CObject
  CArray
    CArrayFloat

Class Methods by Groups

Attributes	
Delta	Sets the comparison tolerance
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

© 2000-2025, MetaQuotes Ltd.

Attributes	
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

© 2000-2025, MetaQuotes Ltd.

Delta

Sets the comparison tolerance.

```
void  Delta(
   float  delta      // tolerance
   )
```

Parameters

delta

[in] The new value of the comparison tolerance.

Return Value

None

Note

Comparison tolerance is used in the search. Values are considered equal if their difference is less than or equal to tolerance. The default tolerance is 0.0.

Example:

```
//--- example for CArrayFloat::Delta(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- set compare variation
   array.Delta(0.001);
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayFloat::Reserve(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayFloat::Resize(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayFloat::Shutdown()
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   float  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayFloat::Add(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const float&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayFloat::AddArray(const float &[])
#include <Arrays\ArrayFloat.mqh>
//---
float src[];
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayFloat*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayFloat class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayFloat::AddArray(const CArrayFloat*)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayFloat *src=new CArrayFloat;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   float  element,     // element to insert
   int    pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayFloat::Insert(float,int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const float&  src[],     // source array
   int            pos        // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayFloat::InsertArray(const float &[],int)
#include <Arrays\ArrayFloat.mqh>
//---
float src[];
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayFloat*  src,      // pointer to the source
   int            pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayFloat::InsertArray(const CArrayFloat*,int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayFloat *src=new CArrayFloat;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const float&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayFloat::AssignArray(const float &[])
#include <Arrays\ArrayFloat.mqh>
//---
float src[];
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayFloat*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayFloat::AssignArray(const CArrayFloat*)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayFloat *src  =new CArrayFloat;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int    pos,          // position
   float  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayFloat::Update(int,float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,100.0))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayFloat::Shift(int,int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayFloat::Delete(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayFloat::DeleteRange(int,int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
float  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, FLT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, FLT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayFloat::At(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      float result=array.At(i);
      if(result==FLT_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- error reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const float&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayFloat::CompareArray(const float &[])
#include <Arrays\ArrayFloat.mqh>
//---
float src[];
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArrayconst

Compares the array with another one.

```
bool  AssignArrayconst(
   const CArrayFloat*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayFloat::CompareArray(const CArrayFloat*)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayFloat *src=new CArrayFloat;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   float  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayFloat::InsertSort(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(100.0))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::Search(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search(100.0)!=-1) printf("Element found");
   else                        printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchGreat(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat(100.0)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat:: SearchLess(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess(100.0)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchGreatOrEqual(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual(100.0)!=-1) printf("Element found");
   else                                    printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchLessOrEqual(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual(100.0)!=-1) printf("Element found");
   else                                   printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchFirst(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst(100.0)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchLast(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast(100.0)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   float  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayFloat::SearchLinear(float)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear(100.0)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayFloat::Save(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(i);
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayFloat::Load(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = %f",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayFloat - 87).

Example:

```
//--- example for CArrayFloat::Type()
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
  {
   CArrayFloat *array=new CArrayFloat;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayDouble

CArrayDouble class is a class of dynamic array of double variables.

Description

The CArrayDouble class provides the ability to work with a dynamic array of double variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayDouble : public CArray
```

Title

```
#include <Arrays\ArrayDouble.mqh>
```

Inheritance hierarchy

CObject

CArray

CArrayDouble

Direct descendants

CDoubleBuffer

Class Methods by Groups

Attributes	
Delta	Set the comparison tolerance
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position

© 2000-2025, MetaQuotes Ltd.

Attributes	
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Search for min/max	
Minimum	Gets the lowest value index in the specified range
Maximum	Gets the highest value index in the specified range
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array

© 2000-2025, MetaQuotes Ltd.

Attributes	
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CArray

Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

© 2000-2025, MetaQuotes Ltd.

Delta

Sets the comparison tolerance.

```
void  Delta(
   double  delta      // tolerance
   )
```

Parameters

delta

[in] The new value of the comparison tolerance.

Return Value

No

Note

Comparison tolerance is used in the search. Values are considered equal if their difference is less than or equal to tolerance. The default tolerance is 0.0.

Example:

```
//--- example for CArrayDouble::Delta(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- set compare variation
   array.Delta(0.001);
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayDouble::Reserve(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayDouble::Resize(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayDouble::Shutdown()
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   double  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayDouble::Add(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(i))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const double&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayDouble::AddArray(const double &[])
#include <Arrays\ArrayDouble.mqh>
//---
double src[];
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayDouble*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayDouble class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayDouble::AddArray(const CArrayDouble*)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayDouble *src=new CArrayDouble;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   double  element,     // element to insert
   int     pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayDouble::Insert(double,int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(i,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const double&  src[],      // source array
   int            pos         // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayDouble::InsertArray(const double &[],int)
#include <Arrays\ArrayDouble.mqh>
//---
double src[];
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayDouble*  src,     // pointer to the source
   int            pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayDouble::InsertArray(const CArrayDouble*,int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayDouble *src=new CArrayDouble;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const double&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayDouble::AssignArray(const double &[])
#include <Arrays\ArrayDouble.mqh>
//---
double src[];
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayDouble*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayDouble::AssignArray(const CArrayDouble*)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayDouble *src  =new CArrayDouble;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int     pos,          // position
   double  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element.

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayDouble::Update(int,double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,100.0))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayDouble::Shift(int,int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayDouble::Delete(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of the last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayDouble::DeleteRange(int,int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
double  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, DBL_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, DBL_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayDouble::At(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      double result=array.At(i);
      if(result==DBL_MAX && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //---  Error reading from the array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const double&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayDouble::CompareArray(const double &[])
#include <Arrays\ArrayDouble.mqh>
//---
double src[];
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const CArrayDouble*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayDouble::CompareArray(const CArrayDouble*)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayDouble *src=new CArrayDouble;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Minimum

Gets index of the lowest element of the array in the specified range.

```
int  Minimum(
   int  start,      // starting index
   int  count       // number of elements
   ) const
```

Parameters

start

[in] Starting index of the search range.

count

[in] Search range size (number of elements).

Return Value

Index of the lowest element in the specified range.

© 2000-2025, MetaQuotes Ltd.

Maximum

Gets index of the highest element of the array in the specified range.

```
int  Maximum(
   int  start,      // starting index
   int  count       // number of elements
   ) const
```

Parameters

start

[in] Starting index of the search range.

count

[in] Search range size (number of elements).

Return Value

Index of the highest element in the specified range.

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   double  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayDouble::InsertSort(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(100.0))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::Search(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search(100.0)!=-1) printf("Element found");
   else                        printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchGreat(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat(100.0)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble:: SearchLess(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess(100.0)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchGreatOrEqual(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual(100.0)!=-1) printf("Element found");
   else                                    printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchLessOrEqual(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual(100.0)!=-1) printf("Element found");
   else                                   printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchFirst(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst(100.0)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchLast(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast(100.0)!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   double  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayDouble::SearchLinear(double)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear(100.0)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayDouble::Save(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(i);
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayDouble::Load(int)
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = %f",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayDouble - 87).

Example:

```
//--- example for CArrayDouble::Type()
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
  {
   CArrayDouble *array=new CArrayDouble;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayString

CArrayString class is a class of dynamic array of string variables.

Description

The CArrayString class provides the ability to work with a dynamic array of string variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayString : public CArray
```

Title

```
#include <Arrays\ArrayString.mqh>
```

Inheritance hierarchy

CObject
  CArray
    CArrayString

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	

© 2000-2025, MetaQuotes Ltd.

Memory control	
Update	Changes the element at the specified position array
Shift	Moves an item from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array opetations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayString::Reserve(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reserve memory
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayString::Resize(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with a full memory release.

```
bool  Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayString::Shutdown()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   string  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
//--- example for CArrayString::Add(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(IntegerToString(i)))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const string&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayString::AddArray(const string &[])
#include <Arrays\ArrayString.mqh>
//---
string src[];
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements of one array to the end of another.

```
bool  AddArray(
   const CArrayString*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of CArrayString class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayString::AddArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayString *src=new CArrayString;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- add another array
   if(!array.AddArray(src))
     {
      printf("Array addition error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array
   delete src;
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   string  element,     // element to insert
   int     pos          // position
   )
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayString::Insert(string,int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(IntegerToString(i),0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const string&  src[],     // source array
   int             pos        // position
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayString::InsertArray(const string &[],int)
#include <Arrays\ArrayString.mqh>
//---
string src[];
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   CArrayString*  src,     // pointer to the source
   int             pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayString::InsertArray(const CArrayString*,int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayString *src=new CArrayString;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- insert another array
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
   //--- delete source array
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const string&  src[]      // source array
   )
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayString::AssignArray(const string &[])
#include <Arrays\ArrayString.mqh>
//---
string src[];
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Copies the elements of one array to another.

```
bool  AssignArray(
   const CArrayString*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayString::AssignArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayString *src  =new CArrayString;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int     pos,          // position
   string  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayString::Update(int, string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,"ABC"))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayString::Shift(int,int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayString::Delete(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete element
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayString::DeleteRange(int,int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
string  At(
   int  pos      // position
   ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, ""- there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, "" may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
//--- example for CArrayString::At(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      string result=array.At(i);
      if(result=="" && GetLastError()==ERR_OUT_OF_RANGE)
        {
         //--- Error reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const string&  src[]      // source array
   ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayString::CompareArray(const string &[])
#include <Arrays\ArrayString.mqh>
//---
string src[];
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArrays(
   const CArrayString*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayString::CompareArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayString *src=new CArrayString;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- add source arrays elements
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   string  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayString::InsertSort(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort("ABC"))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString::Search(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.Search("ABC")!=-1) printf("Element found");
   else                        printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString::SearchGreat(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreat("ABC")!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchLess(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLess("ABC")!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchGreatOrEqual(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchGreatOrEqual("ABC")!=-1) printf("Element found");
   else                                    printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchLessOrEqual(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLessOrEqual("ABC")!=-1) printf("Element found");
   else                                   printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchFirst(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchFirst("ABC")!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchLast(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- search element
   if(array.SearchLast("ABC")!=-1) printf("Element found");
   else                            printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLinear

Searches for the element equal to the sample in the array.

```
int  SearchLinear(
   string  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayString::SearchLinear(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- search element
   if(array.SearchLinear("ABC")!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayString::Save(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayString *array=new CArrayString;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      array.Add(IntegerToString(i));
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayString::Load(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CArrayString *array=new CArrayString;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use arrays elements
   for(int i=0;i<array.Total();i++)
     {
      printf("Element[%d] = '%s'",i,array.At(i));
```

© 2000-2025, MetaQuotes Ltd.

```
      }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayString - 89).

Example:

```
//--- example for CArrayString::Type()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
  {
   CArrayString *array=new CArrayString;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CArrayObj

CArrayObj class is a class of dynamic array of pointers to instances of CObject and its derived classes.

Description

Class CArrayObj provides the ability to work with a dynamic array of pointers to instances of CObject and its derived classes. This allows working both with multidimensional dynamic arrays of primitive data types and with data structures that have more complex organization of data.

The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are certain subtleties of the class CArrayObj.

Declaration

```
class CArrayObj : public CArray
```

Title

```
#include <Arrays\ArrayObj.mqh>
```

Inheritance hierarchy

CObject

CArray

CArrayObj

Class Methods by Groups

Attributes	
FreeMode	Gets the flag of memory management
FreeMode	Sets the flag of memory management
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with full deallocation of its memory (but not its elements).
Creating a new element	
virtual CreateElement	Creates a new array element in the specified position

© 2000-2025, MetaQuotes Ltd.

Attributes	
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds an element to the end of the array
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified position array
Shift	Moves an item from a given position in the array to the specified offset
Delete methods	
Detach	Gets the element from the specified position and removes it from the array
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Clear	Removes all elements of the array without the release of the array memory
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array

© 2000-2025, MetaQuotes Ltd.

Attributes	
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
Input/output	
Save	Saves data array in the file
Load	Loads data array from the file
Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

Methods inherited from class CArray

Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

Arrays of the CObject class have practical application (including all classes of the Standard Library).

For example, consider the options for two-dimensional array:

```
#include <Arrays\ArrayDouble.mqh>
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   int i,j;
   int first_size=10;
   int second_size=100;
//--- create array
   CArrayObj    *array=new CArrayObj;
   CArrayDouble *sub_array;
//---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
//--- create subarrays
   for(i=0;i<first_size;i++)
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       sub_array=new CArrayDouble;
       if(sub_array==NULL)
         {
          delete array;
          printf("Object create error");
          return;
         }
       //--- fill array
       for(j=0;j<second_size;j++)
         {
          sub_array.Add(i*j);
         }
       array.Add(sub_array);
      }
//--- create array OK
   for(i=0;i<first_size;i++)
     {
      sub_array=array.At(i);
      for(j=0;j<second_size;j++)
        {
         double element=sub_array.At(j);
         //--- use array element
        }
     }
   delete array;
  }
```

Subtleties

The class has a mechanism to control dynamic memory, so be careful when working with elements of the array.

Mechanism of memory management can be switched on/off using the method FreeMode (bool). By default, the mechanism is enabled.

Accordingly, there are two options for dealing with the CArrayObj class:

1. Mechanism of memory management is enabled. (default)

In this case, CArrayObj takes responsibility for releasing the memory used for the elements after their removal from the array. A custom program should not release the array elements.

Example:

```
   int i;
//--- create an array
   CArrayObj *array=new CArrayObj;
//--- fill array elements
   for(i=0;i<10;i++) array.Add(new CObject);
```

© 2000-2025, MetaQuotes Ltd.

```
//--- do something
   for(i=0;i<array.Total();i++)
     {
      CObject *object=array.At(i);
      //--- actions performed with the element
      . . .
     }
//--- remove the array with the elements
   delete array;
```

2. Mechanism of memory management is disabled.

In this case, CArrayObj is not responsible for deallocating of the elements' memory after their removal from the array. Besides, the user program must deallocate the array elements.

Example:

```
   int i;
//--- create an array
   CArrayObj *array=new CArrayObj;
//--- disable the mechanism of memory management
   array.FreeMode(false);
//--- fill array with elements
   for(i=0;i<10;i++) array.Add(new CObject);
//--- do something
   for(i=0;i<array.Total();i++)
     {
      CObject *object=array.At(i);
      //--- actions performed with the element
      . . .
     }
//--- remove array elements
   while(array.Total()) delete array.Detach();
//--- remove empty array
   delete array;
```

© 2000-2025, MetaQuotes Ltd.

FreeMode

Gets the flag of memory management.

```
bool  FreeMode() const
```

Return Value

Flag of memory management.

Example:

```
//--- example for CArrayObj::FreeMode()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get free mode flag
   bool array_free_mode=array.FreeMode();
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

FreeMode

Sets the flag of memory management.

```
void  FreeMode(
   bool  mode      // new flag
   )
```

Parameters

mode

[in] New value of the memory management flag.

Return Value

None.

Note

Setting the memory management flag is an important part in the CArrayObj class use. Since the array elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the array.

If the flag is set, removing an element from the array, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, the user must understand his responsibility for the removal of the array before the termination of the program. Otherwise the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to crash of your terminal.

If the user does not reset the memory management flag, there is another pitfall. When pointer elements in array are stored somewhere in the local variables, then removing the array will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the array is responsible for freeing the memory elements.

Example:

```
//--- example for CArrayObj::FreeMode(bool)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reset free mode flag
   array.FreeMode(false);
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Reserve

Allocates memory to increase the size of the array.

```
bool  Reserve(
   int  size      // number
   )
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayObj::Reserve(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   if(!array.Reserve(1024))
     {
      printf("Reserve error");
      delete array;
      return;
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(
   int  size      // size
   )
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. The memory of the lost elements is released or not depending on the memory management mode.

To reduce fragmentation of memory, change the size of the array is made with a step previously given through the method of Step (int), or 16 (default).

Example:

```
//--- example for CArrayObj::Resize(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- resize array
   if(!array.Resize(10))
     {
      printf("Resize error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements of the array without the release of the memory array.

```
void  Clear()
```

Return Value

No.

Note

If the memory management flag is enabled, the memory used for the deleted objects is released.

Example:

```
//--- example for CArrayObj::Clear()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- clear array
   array.Clear();
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shutdown

Clears the array with full deallocation of memory for it (but not for its elements).

```
bool  Shutdown()
```

Return Value

true - successful, false - an error occurred.

Note

If memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CArrayObj::Shutdown()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shutdown array
   if(!array.Shutdown())
     {
      printf("Shutdown error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CreateElement

Creates a new array element at the specified position.

```
bool  CreateElement(
   int  index      // position
   )
```

Parameters

index

[in] Position in which you want to create a new element.

Return Value

true - successful, false - cannot create an element.

Note

Method CreateElement (int) in class CArrayObj always returns false and does not perform any action. If necessary, the CreateElement(int) method should be implemented in a derived class.

Example:

```
//--- example for CArrayObj::CreateElement(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   int        size=100;
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- fill array
   array.Reserve(size);
   for(int i=0;i<size;i++)
     {
      if(!array.CreateElement(i))
        {
         printf("Element create error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
}
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the array.

```
bool  Add(
   CObject*  element      // element to add
   )
```

Parameters

element

[in] value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
//--- example for CArrayObj::Add(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 arrays elements
   for(int i=0;i<100;i++)
     {
      if(!array.Add(new CObject))
        {
         printf("Element addition error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AddArray

Adds elements from one array to the end of another.

```
bool  AddArray(
   const CArrayObj *  src      // pointer to the source array
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class - source of elements to add.

Return Value

true - successful, false - cannot add items.

Note

Adding elements from array to array is actually copying the pointers. Therefore, when calling the method, there is a pitfall - there may be a pointer to a dynamic object in more than one variable.

```
//--- example
extern bool       make_error;
extern int        error;
extern CArrayObj *src;
//--- create a new instance CArrayObj
//--- default memory management is turned on
CArrayObj *array=new CArrayObj;
//--- add (copy) the elements from the source array
if(array!=NULL)
   bool result=array.AddArray(src);
if(make_error)
  {
   //--- perform erroneous actions
   switch(error)
     {
      case 0:
         //--- remove the source array without checking its memory management flag
         delete src;
         //--- result:
         //--- it is possible to address an element by invalid pointer in the receive
         break;
      case 1:
         //--- disable the mechanism of memory management in the source array
         if(src.FreeMode()) src.FreeMode(false);
         //--- but do not remove the source array
         //--- result:
         //--- after removing the receiver array, it is possible to address an element
         break;
      case 2:
```

© 2000-2025, MetaQuotes Ltd.

```
         //--- disable the mechanism of memory management in the source array
         src.FreeMode(false);
         //--- disable the mechanism of memory management in the receiver array
         array.FreeMode(false);
         //--- result:
         //--- after the program termination, get a "memory leak"
         break;
      }
   }
else
   {
    //--- disable the mechanism of memory management in the source array
    if(src.FreeMode()) src.FreeMode(false);
    //--- delete the source array
    delete src;
    //--- result:
    //--- addressing the receiver array element will be correct
    //--- deleting the receiver array will lead to deleting its elements
   }
```

Example:

```
//--- example for CArrayObj::AddArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
   {
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
      {
       printf("Object create error");
       return;
      }
    //--- create source array
    CArrayObj *src=new CArrayObj;
    if(src==NULL)
      {
       printf("Object create error");
       delete array;
       return;
      }
    //--- reset free mode flag
    src.FreeMode(false);
    //--- fill source array
    //--- . . .
    //--- add another array
    if(!array.AddArray(src))
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       printf("Array addition error");
       delete src;
       delete array;
       return;
      }
    //--- delete source array without elements
    delete src;
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the array.

```
bool  Insert(
   CObject*  element,      // element to insert
   int       pos           // position
   )
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
//--- example for CArrayObj::Insert(CObject*,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert elements
   for(int i=0;i<100;i++)
     {
      if(!array.Insert(new CObject,0))
        {
         printf("Insert error");
         delete array;
         return;
        }
     }
   //--- use array
   //--- . . .
   //--- delete array
```

© 2000-2025, MetaQuotes Ltd.

```
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(
   const CArrayObj*  src,     // pointer to the source
   int               pos      // position
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Note

See: CArrayObj::AddArray(const CArrayObj*).

Example:

```
//--- example for CArrayObj::InsertArray(const CArrayObj*,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayObj *src=new CArrayObj;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- reset free mode flag
   src.FreeMode(false);
   //--- fill source array
   //--- . . .
   //--- insert another array
```

© 2000-2025, MetaQuotes Ltd.

```
   if(!array.InsertArray(src,0))
     {
      printf("Array inserting error");
      delete src;
      delete array;
      return;
     }
   //--- delete source array without elements
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

AssignArray

Compares the array with another one.

```
bool  AssignArray(
   const CArrayObj*  src      // pointer to the source
   )
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Note

If the receiver array is not empty when calling AssignArray, then all its elements will be removed; and if the memory management flag is set, the memory used for the deleted elements will be released. The receiver array becomes an exact copy of the source one. Additionally, see CArrayObj::AddArray(const CArrayObj*).

Example:

```
//--- example for CArrayObj::AssignArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayObj *src=new CArrayObj;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- reset free mode flag
   src.FreeMode(false);
   //--- fill source array
   //--- . . .
   //--- assign another array
   if(!array.AssignArray(src))
```

© 2000-2025, MetaQuotes Ltd.

```
     {
      printf("Array assigned error");
      delete src;
      delete array;
      return;
     }
   //--- arrays is identical
   //--- delete source array without elements
   delete src;
   //--- use array
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Update

Changes the element at the specified array position.

```
bool  Update(
   int       pos,          // position
   CObject*  element       // value
   )
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Note

The element will not change if an invalid pointer (for example, NULL) is passed as a parameter. If the memory management is enabled, the memory of a replaced element is deallocated.

Example:

```
//--- example for CArrayObj::Update(int,CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- update element
   if(!array.Update(0,new CObject))
     {
      printf("Update error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Shift

Moves an item from a given position in the array to the specified offset.

```
bool  Shift(
   int  pos,        // position
   int  shift       // shift
   )
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayObj::Shift(int,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- shift element
   if(!array.Shift(10,-5))
     {
      printf("Shift error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Detach

Removes an element from a given position in the array.

```
CObject*  Detach(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of a removed item in the array.

Return Value

Pointer to the removed element - success, NULL - cannot remove the element.

Note

When an element is removed from the array, it will not be deleted regardless of the memory management flag. Once the array element pointer is used, it has to be deallocated.

Example:

```
//--- example for CArrayObj::Detach(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   CObject *object=array.Detach(0);
   if(object==NULL)
     {
      printf("Detach error");
      delete array;
      return;
     }
   //--- use element
   //--- . . .
   //--- delete element
   delete object;
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the specified array position.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CArrayObj::Delete(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   if(!array.Delete(0))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteRange

Deletes a group of elements from the specified array position.

```
bool  DeleteRange(
   int  from,     // position of the first element
   int  to        // position of last element
   )
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove elements.

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CArrayObj::DeleteRange(int,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- delete elements
   if(!array.DeleteRange(0,10))
     {
      printf("Delete error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

At

Gets the element from the specified array position.

```
CObject*  At(
   int  pos      // position
   )
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - successful, NULL- there was an attempt to get an element of a non-existent position.

Example:

```
//--- example for CArrayObj::At(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add elements
   //--- . . .
   for(int i=0;i<array.Total();i++)
     {
      CObject *result=array.At(i);
      if(result==NULL)
        {
         //--- Error reading from array
         printf("Get element error");
         delete array;
         return;
        }
      //--- use element
      //--- . . .
     }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareArray

Compares the array with another one.

```
bool  CompareArray(
   const CArrayObj*  src      // pointer to the source
   ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements for comparison.

Return Value

true - the arrays are equal - the arrays are not equal.

Example:

```
//--- example for CArrayObj::CompareArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source array
   CArrayObj *src=new CArrayObj;
   if(src==NULL)
     {
      printf("Object create error");
      delete array;
      return;
     }
   //--- fill source array
   //--- . . .
   //--- compare with another array
   int result=array.CompareArray(src);
   //--- delete arrays
   delete src;
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

InsertSort

Inserts an element in a sorted array.

```
bool  InsertSort(
   CObject*  element      // element to insert
   )
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
//--- example for CArrayObj::InsertSort(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- insert element
   if(!array.InsertSort(new CObject))
     {
      printf("Insert error");
      delete array;
      return;
     }
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted array.

```
int  Search(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::Search(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.Search(sample)!=-1) printf("Element found");
   else                         printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int  SearchGreat(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::SearchGreat(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchGreat(sample)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int  SearchLess(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj:: SearchLess(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchLess(sample)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int  SearchGreatOrEqual(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::SearchGreatOrEqual(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchGreatOrEqual(sample)!=-1) printf("Element found");
   else                                     printf("Element not found");
   //--- delete array
   delete array;
```

© 2000-2025, MetaQuotes Ltd.

```
}
```

© 2000-2025, MetaQuotes Ltd.

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int  SearchLessOrEqual(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj:: SearchLessOrEqual(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchLessOrEqual(sample)!=-1) printf("Element found");
   else                                    printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int  SearchFirst(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::SearchFirst(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchFirst(sample)!=-1) printf("Element found");
   else                              printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int  SearchLast(
   CObject*  element      // sample
   ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj:: SearchLast(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- sort array
   array.Sort();
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete array;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(array.SearchLast(sample)!=-1) printf("Element found");
   else                             printf("Element not found");
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves data array in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayObj::Save(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   int         file_handle;
   CArrayObj *array=new CArrayObj;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add arrays elements
   //--- . . .
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads data array from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Note

When reading array elements from the file, the CArrayObj::CreateElement(int) method is called to create each element.

Example:

```
//--- example for CArrayObj::Load(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   int         file_handle;
   CArrayObj *array=new CArrayObj;
   //---
   if(array!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!array.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete array;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use arrays elements
   //--- . . .
   //--- delete array
   delete array;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the array type identifier.

```
virtual int  Type() const
```

Return Value

Array type identifier (for CArrayObj - 7778).

Example:

```
//--- example for CArrayObj::Type()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
  {
   CArrayObj *array=new CArrayObj;
   //---
   if(array==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get array type
   int type=array.Type();
   //--- delete array
   delete array;
  }
```

CList

CList Class is a class of dynamic list of instances of the CObject class and its derived classes.

Description

Class CList provides the ability to work with a list of instances of CObject and its derived classes. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are some subtleties of working with the CList class. The class has a mechanism to control dynamic memory, so be careful when working with elements of the list.

Subtleties of the mechanism of memory management similar to those described in CArrayObj.

Declaration

```
class CList : public CObject
```

Title

```
#include <Arrays\List.mqh>
```

Inheritance hierarchy

CObject
  CList

Class Methods by Groups

Attributes	
FreeMode	Gets the flag of memory management when deleting list elements
FreeMode	Sets the flag of memory management when deleting list elements
Total	Gets the number of elements in the list
IsSorted	Gets sorted list flag
SortMode	Gets the sorting mode
Create methods	
CreateElement	Creates a new list element
Add methods	
Add	Adds an element to the end of the list
Insert	Inserts an element to the specified position of the list
Delete methods	
DetachCurrent	Removes an element from the current position in the list without deleting it "physically"

© 2000-2025, MetaQuotes Ltd.

Attributes	
DeleteCurrent	Removes the element from the current position in the list
Delete	Removes the element from the specified position in the list
Clear	Removes all list elements
Navigation	
IndexOf	Gets the index of the specified list element
GetNodeAtIndex	Gets an item with the specified index of the list
GetFirstNode	Gets the first element of the list
GetPrevNode	Gets the previous element of the list
GetCurrentNode	Gets the current list element
GetNextNode	Gets the next element in the list
GetLastNode	Gets the last element in the list
Ordering methods	
Sort	Sorts the list
MoveToIndex	Moves the current element in the list to the specified position
Exchange	Swaps two elements in the list
Compare methods	
CompareList	Compares the list with another one
Search methods	
Search	Searches for an element equal to the sample in sorted list
Input/output	
virtual Save	Saves list data in the file
virtual Load	Loads list data from the file
virtual Type	Gets the list type identifier

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

© 2000-2025, MetaQuotes Ltd.

FreeMode

Gets the flag of memory management when deleting list elements.

```
bool  FreeMode() const
```

Return Value

Flag of memory management.

Example:

```
//--- example for CList::FreeMode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get free mode flag
   bool list_free_mode=list.FreeMode();
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

FreeMode

Sets the flag of memory management when deleting list elements.

```
void  FreeMode(
   bool  mode      // new value
   )
```

Parameters

mode

[in] New value of the memory management flag.

Note

Setting the memory management flag is an important part in the CList class use. Since the list elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the list.

If the flag is set, when removing an element from the list, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, users should understand their responsibility for the removal of the list elements before the termination of the program. Otherwise, the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to a terminal crash.

If the user program does not reset the memory management flag, there is another "pitfall". When pointer elements in list are stored somewhere in the local variables, then removing the list will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the list is responsible for releasing the memory elements.

Example:

```
//--- example for CList::FreeMode(bool)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- reset free mode flag
   list.FreeMode(false);
   //--- use list
   //--- . . .
   //--- delete list
```

© 2000-2025, MetaQuotes Ltd.

```
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Total

Gets the number of elements in the list.

```
int  Total() const
```

Return Value

Number of elements in the list.

Example:

```
//--- example for CList::Total()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check total
   int total=list.Total();
   //--- use list
   //--- ...
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

IsSorted

Gets the sorted list flag.

```
bool  IsSorted(
   int  mode=0      // sorting mode
   ) const
```

Parameters

mode=0

[in] Checked sort mode.

Return Value

Flag of the sorted list. Returns true if the list is sorted using the specified mode, otherwise returns false.

Note

Flag of the sorted list cannot be changed directly. The flag is set by Sort(int) and resets by any add/insert methods.

Example:

```
//--- example for CList::IsSorted()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check sorted
   if(list.IsSorted(0))
     {
      //--- use methods for sorted list
      //--- ...
     }
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

SortMode

Gets the version of the sorting.

```
int  SortMode() const
```

Return Value

Sorting mode, or -1 if the list is not sorted.

Example:

```
//--- example for CList::SortMode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- check sort mode
   int sort_mode=list.SortMode();
   //--- use list
   //--- ...
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

CreateElement

Creates a new element of the list.

```
CObject*  CreateElement()
```

Return Value

Pointer to the newly created element - successful, NULL - cannot create an element.

Note

Method CreateElement () in the CList class always returns NULL and does not perform any actions. If necessary, method CreateElement () should be implemented in a derived class.

Example:

```
//--- example for CList::CreateElement(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   int    size=100;
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- fill list
   for(int i=0;i<size;i++)
     {
      CObject *object=list.CreateElement();
      if(object==NULL)
        {
         printf("Element create error");
         delete list;
         return;
        }
      list.Add(object);
     }
   //--- use list
   //--- . . .
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the end of the list.

```
int  Add(
   CObject*  element      // element to add
   )
```

Parameters

element

[in] Value of the element to add to the list.

Return Value

Index of the added element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```
//--- example for CList::Add(Cobject*)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add 100 elements
   for(int i=0;i<100;i++)
     {
      if(list.Add(new CObject)==-1)
        {
         printf("Element addition error");
         delete list;
         return;
        }
     }
   //--- use list
   //--- . . .
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element to the specified position in the list.

```
int  Insert(
   CObject*  element,      // element to insert
   int       pos           // position
   )
```

Parameters

element

[in] value of the element to insert in the list

pos

[in] position in the list to insert

Return Value

index of inserted element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```
//--- example for CList::Insert(CObject*,int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- insert 100 elements
   for(int i=0;i<100;i++)
     {
      if(list.Insert(new CObject,0)==-1)
        {
         printf("Element insert error");
         delete list;
         return;
        }
     }
   //--- use list
   //--- . . .
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

DetachCurrent

Extracts an element from the current position in the list without its "physical" deletion.

```
CObject*  DetachCurrent()
```

Return Value

Pointer to the removed element in case of success, NULL - cannot remove the element.

Note

When removed from the list, the element is not removed in any state of the memory management flag. The pointer to the extracted element should be released after it has been used.

Example:

```
//--- example for CList::DetachCurrent()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.DetachCurrent();
   if(object==NULL)
     {
      printf("Detach error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- delete element
   delete object;
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

DeleteCurrent

Removes the element from the current position in the list.

```
bool  DeleteCurrent()
```

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management is enabled, memory for the removed element is deallocated.

Example:

```
//--- example for CList::DeleteCurrent()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   if(!list.DeleteCurrent())
     {
      printf("Delete error");
      delete list;
      return;
     }
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes the element from the given position in the list.

```
bool  Delete(
   int  pos      // position
   )
```

Parameters

pos

[in] position of element to be removed from the list.

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management flag is enabled, the memory used for the deleted element is released.

Example:

```
//--- example for CList::Delete(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   if(!list.Delete(0))
     {
      printf("Delete error");
      delete list;
      return;
     }
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements of the list.

```
void  Clear()
```

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CList::Clear()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   //--- clear list
   list.Clear();
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

IndexOf

Gets the index of the specified list element.

```
int  IndexOf(
   CObject*  element      // pointer to the element
   )
```

Parameters

element

[in] pointer to the list element.

Return Value

List element index, or -1.

Example:

```
//--- example for CList::IndexOf(CObject*)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   CObject *object=new CObject;
   if(object==NULL)
     {
      printf("Element create error");
      delete list;
      return;
     }
   if(list.Add(object))
     {
      int pos=list.IndexOf(object);
     }
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetNodeAtIndex

Gets an element from the specified position in the list.

```
CObject*  GetNodeAtIndex(
   int  pos      // position
   )
```

Parameters

pos

[in] element position in the list.

Return Value

pointer to the element - success, NULL - cannot receive a pointer.

Example:

```
//--- example for CList::GetNodeAtIndex(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetNodeAtIndex(10);
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetFirstNode

Gets the first element of the list.

```
CObject*  GetFirstNode()
```

Return Value

Pointer to the first element - success, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetFirstNode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetFirstNode();
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetPrevNode

Gets the previous element of the list.

```
CObject*  GetPrevNode()
```

Return Value

Pointer to the previous element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetPrevNode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetPrevNode();
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetCurrentNode

Gets the current list element.

```
CObject*  GetCurrentNode()
```

Return Value

Pointer to the current element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetCurrentNode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetCurrentNode();
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetNextNode

Gets the next element in the list.

```
CObject*  GetNextNode()
```

Return Value

Pointer to the next element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetNextNode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetNextNode();
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

GetLastNode

Gets the last element of the list.

```
CObject*  GetLastNode()
```

Return Value

Pointer to the last element - success, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetLastNode()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add list elements
   //--- . . .
   CObject *object=list.GetLastNode();
   if(object==NULL)
     {
      printf("Get node error");
      delete list;
      return;
     }
   //--- use element
   //--- . . .
   //--- do not delete element
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Sort

Sorts a list.

```
void  Sort(
   int  mode      // sorting mode
   )
```

Parameters

mode

[in] Sorting mode.

Return Value

No.

Note

The list is always sorted in ascending order.

Example:

```
//--- example for CList::Sort(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- sorting by mode 0
   list.Sort(0);
   //--- use list
   //--- ...
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

MoveToIndex

Moves the current element in the list to the specified position.

```
bool  MoveToIndex(
   int  pos      // position
   )
```

Parameters

pos

[in] position in the list to move.

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CList::MoveToIndex(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- move current node to begin
   list.MoveToIndex(0);
   //--- use list
   //--- . . .
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Exchange

Swaps two elements in the list.

```
bool  Exchange(
   CObject*  node1,      // list element
   CObject*  node2       // list element
   )
```

Parameters

node1

[in] list element

node2

[in] list element

Return Value

true - successful, false - cannot swap the elements.

Example:

```
//--- example for CList::Exchange(CObject*,CObject*)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- exchange
   list.Exchange(list.GetFirstNode(),list.GetLastNode());
   //--- use list
   //--- . . .
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

CompareList

Compares the list with another one.

```
bool  CompareList(
   CList*  list      // pointer to the source
   )
```

Parameters

list

[in] a pointer to an instance of the CList class used as a source of elements for comparison.

Return Value

true - the lists are equal, false - the lists are not equal.

Example:

```
//--- example for CList::CompareList(const CList*)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- create source list
   CList *src=new CList;
   if(src==NULL)
     {
      printf("Object create error");
      delete list;
      return;
     }
   //--- fill source list
   //--- . . .
   //--- compare with another list
   bool result=list.CompareList(src);
   //--- delete lists
   delete src;
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Search

Searches for an element equal to the sample in the sorted list.

```
CObject*  Search(
   CObject*  element      // sample
   )
```

Parameters

element

[in] element sample to search for in the list.

Return Value

Pointer to the found element - successful, NULL - the element is not found.

Example:

```
//--- example for CList::Search(CObject*)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add lists elements
   //--- . . .
   //--- sort list
   list.Sort(0);
   //--- create sample
   CObject *sample=new CObject;
   if(sample==NULL)
     {
      printf("Sample create error");
      delete list;
      return;
     }
   //--- set sample attributes
   //--- . . .
   //--- search element
   if(list.Search(sample)!=NULL) printf("Element found");
   else                          printf("Element not found");
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves list data in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CList::Save(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   int    file_handle;
   CList *list=new CList;
   //---
   if(list!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- add lists elements
   //--- . . .
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!list.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         delete list;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- delete list
   delete list;
```

© 2000-2025, MetaQuotes Ltd.

```
}
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads list data from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Note

When reading list elements from the file, the CList::CreateElement(int) method is called to create each element.

Example:

```
//--- example for CLoad::Load(int)
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   int    file_handle;
   CList *list=new CList;
   //---
   if(list!=NULL)
     {
      printf("Object create error");
      return;
     }
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!list.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         delete list;
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
```

© 2000-2025, MetaQuotes Ltd.

```
   //--- use list elements
   //--- . . .
   //--- delete list
   delete list;
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the list type identifier.

```
virtual int  Type()
```

Return Value

List type identifier (for CList - 7779).

Example:

```
//--- example for CList::Type()
#include <Arrays\List.mqh>
//---
void OnStart()
  {
   CList *list=new CList;
   //---
   if(list==NULL)
     {
      printf("Object create error");
      return;
     }
   //--- get list type
   int type=list.Type();
   //--- delete list
   delete list;
  }
```

CTreeNode

CTreeNode is a class of the CTree binary tree node.

Description

CTreeNode provides the ability to work with nodes of the CTree binary tree. Options of navigation through the tree are implemented in the class. Besides, methods of working with the file are implemented.

Declaration

```
class CTreeNode : public CObject
```

Title

```
#include <Arrays\TreeNode.mqh>
```

Inheritance hierarchy

CObject

CTreeNode

Direct descendants

CTree

Class Methods by Groups

Attributes	
Owner	Gets/sets the pointer of the owner node
Left	Gets/sets the pointer of the left node
Right	Gets/sets the pointer of the right node
Balance	Gets the node balance
BalanceL	Gets the balance of the left sub-branch of the node
BalanceR	Gets the balance of the right sub-branch of the node
Creation of a new element	
CreateSample	Creates a new node instance
Comparison	
RefreshBalance	Recalculates the node balance
Search	
GetNext	Gets the pointer of the next node
Input/Output	

© 2000-2025, MetaQuotes Ltd.

Attributes	
SaveNode	Saves the node data to a file
LoadNode	Downloads the node data from a file
virtual Type	Gets the identifier of the node type

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Compare

Trees of CTreeNode class descendants have practical application.

A descendant of CTreeNode class should have predefined methods: CreateSample creates a new instance of the descendant class of CTreeNode, Compare compares values of key fields of the descendant class of CTreeNode, Type (if it is necessary to identify a node), SaveNode and LoadNode (if it is necessary to work with a file).

Let's consider an example of a CTree descendant class.

```

Owner

Gets the pointer of the owner node.

```
CTreeNode*  Owner()
```

Return Value

Pointer of the owner node.

Owner

Sets the pointer of the owner node.

```
void  Owner(
   CTreeNode*  node       // node
   )
```

Parameters

node

[in] New value of the pointer of the owner node.

Return Value

None.

© 2000-2025, MetaQuotes Ltd.

Left

Gets the pointer of the left node.

```
CTreeNode*  Left()
```

Return Value

Pointer of the left node.

Left

Sets the pointer of the left node.

```
void  Left(
   CTreeNode*  node      // node
   )
```

Parameters

node

[in] New value of the pointer of the left node.

Return Value

None.

© 2000-2025, MetaQuotes Ltd.

Right

Gets the pointer of the right node.

```
CTreeNode*  Right()
```

Return Value

The pointer of the right node.

Right

Sets the pointer of the right node.

```
void  Right(
   CTreeNode*  node      // node
   )
```

Parameters

node

[in] New value of the pointer of the right node.

Return Value

None.

© 2000-2025, MetaQuotes Ltd.

Balance

Gets the node balance.

```
int  Balance() const
```

Return Value

Node balance.

© 2000-2025, MetaQuotes Ltd.

BalanceL

Gets the balance of the left sub-branch of the node.

```
int  BalanceL() const
```

Return Value

Balance of the left sub-branch of the node.

© 2000-2025, MetaQuotes Ltd.

BalanceR

Gets the balance of the right sub-branch of the node.

```
int  BalanceR() const
```

Return Value

Balance of the right sub-branch of the node.

© 2000-2025, MetaQuotes Ltd.

CreateSample

Creates a new node sample.

```
virtual CTreeNode*  CreateSample()
```

Return Value

Pointer to the new node sample or NULL.

© 2000-2025, MetaQuotes Ltd.

RefreshBalance

Recalculates the node balance.

```
int  RefreshBalance()
```

Return Value

Node balance.

© 2000-2025, MetaQuotes Ltd.

GetNext

Gets the pointer of the next node.

```
CTreeNode*  GetNext(
   CTreeNode*  node      // node
   )
```

Parameters

node

[in] Node of the search start.

Return Value

Pointer of the next node.

© 2000-2025, MetaQuotes Ltd.

SaveNode

Writes node data to a file.

```
bool  SaveNode(
   int  file_handle      // handle
   )
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for writing.

Return Value

true - success, otherwise false.

© 2000-2025, MetaQuotes Ltd.

LoadNode

Reads node data from a file.

```
bool  LoadNode(
   int          file_handle,      // handle
   CTreeNode*   main              // node
   )
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for reading.

main

[in] Node for data.

Return Value

true - success, otherwise false.

© 2000-2025, MetaQuotes Ltd.

Type

Gets the identifier of the node type.

```
virtual int  Type() const
```

Return Value

Identifier of the node type.

© 2000-2025, MetaQuotes Ltd.

CTree

CTree is a class of the binary tree of the instances of CTreeNode class and its descendants.

Description

CTree class provides the possibility to work with the binary tree of CTreeNode class instances and its descendants. Options of adding/inserting/deleting of tree elements and search in the tree are implemented in the class. Besides that, methods of working with a file are implemented.

Note that mechanism of dynamic memory management is not implemented in class CTree (unlike classes CList and CArrayObj). All tree nodes are deleted with memory deallocation.

Declaration

```
class CTree : public CTreeNode
```

Title

```
#include <Arrays\Tree.mqh>
```

Inheritance hierarchy

CObject
  CTreeNode
    CTree

Class Methods by Groups

Attributes	
Root	Gets the root node of the tree
Creation of a new element	
CreateElement	Creates a new instance of the node
Filling	
Insert	Adds a node to a tree
Deletion	
Detach	Detaches a specified node from a tree
Delete	Deletes a specified node from a tree
Clear	Deletes all nodes of a tree
Search	
Find	Searches for a node in a tree by sample
Input/output	

© 2000-2025, MetaQuotes Ltd.

Attributes	
virtual Save	Saves all the tree data to a file
virtual Load	Downloads tree data from a file
virtual Type	Gets identifier of the tree type

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

Methods inherited from class CTreeNode

Parent, Parent, Left, Left, Right, Right, Balance, BalanceL, BalanceR, RefreshBalance, GetNext, SaveNode, LoadNode

Trees of CTreeNode class descendants - descendants of class CTree - have practical application.

Descendant of CTree class should have a predefined method CreateElement that creates a new instance of the CTreeNode descendant class.

Let's consider an example of the CTree descendant class.

```
//+------------------------------------------------------------------+

      node.SetLong(mode*(long)(-1)*MathRand());
      node.SetDouble(-MathPow(2.02,mode)*MathRand());
     }
   node.SetString(str_array[mode%10]);
```

© 2000-2025, MetaQuotes Ltd.

```
   node.SetDateTime(10000*mode);
  }
```

© 2000-2025, MetaQuotes Ltd.

Root

Gets the root node of the tree.

```
CTreeNode*  Root() const
```

Return Value

Pointer of the root node of the tree.

© 2000-2025, MetaQuotes Ltd.

CreateElement

Creates a new instance of the node.

```
virtual CTreeNode*  CreateElement()
```

Return Value

Pointer of the new instance of the node or NULL.

© 2000-2025, MetaQuotes Ltd.

Insert

Adds a node to a tree.

```
CTreeNode*  Insert(
   CTreeNode*  new_node      // node
   )
```

Parameters

new_node

[in] Pointer of a node to insert to a tree.

Return Value

Pointer of the owner node or NULL.

© 2000-2025, MetaQuotes Ltd.

Detach

Detaches a specified node from a tree.

```
bool  Detach(
   CTreeNode*  node       // node
   )
```

Parameters

node

[in] Node pointer to detach.

Return Value

true - success, otherwise false.

Note

After detachment, the node pointer is not released. The tree is balanced.

© 2000-2025, MetaQuotes Ltd.

Delete

Deletes a specified node from a tree.

```
bool  Delete(
   CTreeNode*  node      // node
   )
```

Parameters

node

[in] Node pointer to delete.

Return Value

true - success, otherwise false.

Note

After deletion, a node pointer is released. The tree is balanced.

© 2000-2025, MetaQuotes Ltd.

Clear

Deletes all nodes of a tree.

```
void  Clear()
```

Return Value

None.

Note

After deletion, node pointers are released.

© 2000-2025, MetaQuotes Ltd.

Find

Searches for a node in a tree by sample.

```
CTreeNode*  Find(
   CTreeNode*  node      // node
   )
```

Parameters

node

[in] Node that contains data used as a search sample.

Return Value

Pointer of the found node or NULL.

© 2000-2025, MetaQuotes Ltd.

Save

Writes tree data to a file.

```
virtual bool  Save(
   int  file_handle      // handle
   )
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for writing.

Return Value

true - success, otherwise false.

© 2000-2025, MetaQuotes Ltd.

Load

Reads tree data from a file.

```
virtual bool  Load(
   int  file_handle      // handle
   )
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for reading.

Return Value

true - success, otherwise false.

© 2000-2025, MetaQuotes Ltd.

Type

Gets identifier of the tree type.

```
virtual int  Type() const
```

Return Value

Identifier of the tree type.

© 2000-2025, MetaQuotes Ltd.

Generic Data Collections

The library provides classes and interfaces that define generic collections, which allow users to create strongly typed collections. These collections provide greater convenience and data handling performance than non-generic typed collections.

The library is available in the Include\Generic folder of the terminal working directory.

Objects:

Object	Description	Type
ICollection	Interface for implementing generic data collections	INTERFACE
IEqualityComparable	Interface for implementing objects that can be compared	INTERFACE
IComparable	Interface for implementing objects that can be compared in terms of "greater than, less than or equal to"	INTERFACE
IComparer	Interface for implementing a generic class that compares two object of the T type, whether one is "greater than, less than or equal to" the other one	INTERFACE
IEqualityComparer	Interface for implementing a generic class that compares two object of the T type for equality	INTERFACE
IList	Interface for implementing generic data lists	INTERFACE
IMap	Interface for implementing generic collections of key/value pairs	INTERFACE
ISet	Interface for implementing generic data sets	INTERFACE
CDefaultComparer	A helper class that implements the IComparer<T> generic interface based on Compare global methods	CLASS
CDefaultEqualityComparer	A helper class that implements the IEqualityComparer<T> generic interface using Equals<T> and GetHashCode global methods	CLASS
CArrayList	A generic class that implements the IList<T> interface	CLASS
CKeyValuePair	The class implements the key/value pair	CLASS

© 2000-2025, MetaQuotes Ltd.

Object	Description	Type
CHashMap	A generic class that implements the IMap<TKey, TValue> interface	CLASS
CHashSet	A generic class that implements the ISet<T> interface	CLASS
CLinkedListNode	A helper class for implementing the CLinkedListNode<T> class	CLASS
CLinkedList	A generic class that implements the ICollection<T> interface	CLASS
CQueue	A generic class that implements the ICollection<T> interface	CLASS
CRedBlackTreeNode	A helper class used in implementing the CRedBlackTree<T> class	CLASS
CRedBlackTree	A generic class that implements the ICollection<T> interface	CLASS
CSortedMap	A generic class that implements the IMap<TKey, TValue> interface	CLASS
CSortedSet	A generic class that implements the ISet<T> interface	CLASS
CStack	A generic class that implements the ICollection<T> interface	CLASS

Global methods:

Method	Description
ArrayBinarySearch	Searches for the specified value in an ascending-sorted one-dimensional array using the IComparable<T> interface to compare elements
ArrayIndexOf	Searches for the first occurrence of a value in a one-dimensional array
ArrayLastIndexOf	Searches for the last occurrence of a value in a one-dimensional array
ArrayReverse	Changes the sequence of elements in a one-dimensional array
Compare	Compares two values, whether one of them is greater than, less than or equal to the other one
Equals	Compares two values for equality
GetHashCode	Calculates the hash code value

© 2000-2025, MetaQuotes Ltd.

ICollection<T>

ICollection<T> is an interface for implementing generic data collections.

Description

The ICollection<T> interface determines basic methods to work with collections, including methods to count elements, to clear a collection, to add or delete elements, and others.

Declaration

```
template<typename T>
interface ICollection
```

Header

```
#include <Generic\Interfaces\ICollection.mqh>
```

Inheritance Hierarchy

ICollection

Direct descendants

CLinkedList, CQueue, CRedBlackTree, CStack, IList, IMap, ISet

Class Methods

Method	Description
Add	Adds an element to a collection
Count	Returns the number of elements in a collection
Contains	Determines whether a collection contains an element with the specified value
CopyTo	Copies all elements of a collection to the specified array starting at the specified index
Clear	Removes all elements from a collection
Remove	Removes the first occurrence of the specified element from a collection

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a collection.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in a collection.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether a collection contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the collection, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a collection to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the collection will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements of a collection.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the specified element from a collection.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IEqualityComparable<T>

IEqualityComparable<T> is an interface for implementing objects that can be compared.

Description

The IEqualityComparable<T> interface defines methods to retrieve the hash code of the current object and to check whether it is equal to another object of the same type.

Declaration

```
template<typename T>
interface IEqualityComparable
```

Header

```
#include <Generic\Interfaces\IEqualityComparable.mqh>
```

Inheritance Hierarchy

IEqualityComparable

Direct descendants

IComparable

Class Methods

Method	Description
Equals	Compares the current object with the specified value
HashCode	Calculates the hash code value for the current object

© 2000-2025, MetaQuotes Ltd.

Equals

Compares the current object with the specified value.

```
bool Equals(
   T  value     // the value to compare
   );
```

Parameters

value

[in] The value to compare the current object with.

Return Value

Returns true if the objects are equal, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

HashCode

Calculates the hash code value for the current object.

```
int HashCode();
```

Return Value

Returns the hash code.

© 2000-2025, MetaQuotes Ltd.

IComparable<T>

IComparable<T> is an interface for implementing objects that can be compared to find out whether one is greater than, less than or equal to the other one

Description

The IComparable<T> interface defines a method to compare the current object to another object of the same type, on the basis of which the collection of these objects can be sorted.

Declaration

```
template<typename T>
interface IComparable : public IEqualityComparable<T>
```

Header

```
#include <Generic\Interfaces\IComparable.mqh>
```

Inheritance Hierarchy

IEqualityComparable

IComparable

Direct descendants

CKeyValuePair

Class Methods

Method	Description
Compare	Compares the current object with the specified value

© 2000-2025, MetaQuotes Ltd.

Compare

Compares the current object with the specified value.

```
int Compare(
   T  value     // the value to compare
   );
```

Parameters

value

[in] The value to compare the current object with.

Return Value

Returns a number that expresses the ratio of the current and passed object:

- if the result is less than zero, the current object is less than the passed one
- if the result is zero, the current object is equal to than the passed one
- if the result is greater than zero, the current object is greater than the passed one

© 2000-2025, MetaQuotes Ltd.

IComparer<T>

IComparer<T> is an interface for implementing a generic class that compares two object of the T type, whether one is greater than, less than or equal to the other one

Description

The IComparer<T> interface determines a method to compare two objects of the T type, on the basis of which a collection of these objects can be sorted.

Declaration

```
template<typename T>
interface IComparer
```

Header

```
#include <Generic\Interfaces\IComparer.mqh>
```

Inheritance Hierarchy

IComparer

Direct descendants

CDefaultComparer

Class Methods

Method	Description
Compare	Compares two values of type T

© 2000-2025, MetaQuotes Ltd.

Compare

Compares two values of type T.

```
int Compare(
   T  x,      // the first value
   T  y       // the second value
   );
```

Parameters

x

[in] The first value to compare.

y

[in] The first value to compare.

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, x is less than y (x<y)
- if the result is equal to zero, x is equal to y (x=y)
- if the result is greater than zero, x is greater than y (x>y)

© 2000-2025, MetaQuotes Ltd.

IEqualityComparer<T>

IEqualityComparer<T> is an interface for implementing a generic class that compares two object of the T type.

Description

The IEqualityComparer<T> interface defines methods to retrieve the hash code of a T type object and to check whether two objects of type T are equal.

Declaration

```
template<typename T>
interface IEqualityComparer
```

Header

```
#include <Generic\Interfaces\IEqualityComparer.mqh>
```

Inheritance Hierarchy

IEqualityComparer

Direct descendants

CDefaultEqualityComparer

Class Methods

Method	Description
Equals	Compares two values of type T
HashCode	Calculates the hash code value based on the T type object

© 2000-2025, MetaQuotes Ltd.

Equals

Compares two values of type T.

```
bool Equals(
   T  x,      // the first value
   T  y       // the second value
   );
```

Parameters

x

[in] The first value to compare.

y

[in] The second value to compare.

Return Value

Returns true if the values are equal, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

HashCode

Calculates the hash code value based on the T type object.

```
int HashCode(
   T  value     // an object for calculation
   );
```

Parameters

value

[in] The object for which you want to get the hash code.

Return Value

Returns the hash code.

© 2000-2025, MetaQuotes Ltd.

IList<T>

IList<T> is an interface for implementing generic data lists.

Description

The IList<T> interface defines basic methods to work with lists, such as to access an element by index, to search and delete elements, sort, and others.

Declaration

```
template<typename T>
interface IList : public ICollection<T>
```

Header

```
#include <Generic\Interfaces\IList.mqh>
```

Inheritance Hierarchy

ICollection

IList

Direct descendants

CArrayList

Class Methods

Method	Description
TryGetValue	Gets a list element at the specified index
TrySetValue	Changes a value from the list at the specified index
Insert	Inserts an element into the list at the specified index
IndexOf	Searches for the first occurrence of a value in a list
LastIndexOf	Searches for the last occurrence of a value in a list
RemoveAt	Removes a list element at the specified index

© 2000-2025, MetaQuotes Ltd.

TryGetValue

Gets a list element at the specified index.

```
bool TryGetValue(
   const int  index,      // element index
   T&         value       // a variable for writing
   );
```

Parameters

index

[in] The index of the element from the list.

&value

[out] The variable to which the specified value of the element from the list will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrySetValue

Changes a value from the list at the specified index.

```
bool TrySetValue(
   const int  index,      // element index
   T          value       // new value
   );
```

Parameters

index

[in] The index of the element from the list.

value

[in] The new value to assign to the specified list element.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element into the list at the specified index.

```
bool Insert(
   const int  index,      // index to insert at
   T          item        // the value to be inserted
   );
```

Parameters

index

[in] The index to insert at.

item

[in] The value to be inserted at the specified index.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IndexOf

Searches for the first occurrence of a value in a list.

```
int IndexOf(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns the index of the first found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

LastIndexOf

Searches for the last occurrence of a value in a list.

```
int LastIndexOf(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

RemoveAt

Removes a list element at the specified index.

```
bool RemoveAt(
   const int  index     // element index
   );
```

Parameters

index

[in] The index of the element that you want to delete.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IMap<TKey, TValue>

IMap<TKey, TValue> is an interface for implementing generic collections of key/value pairs.

Description

The IMap<TKey, TValue> interface defines basic methods to work with collections whose data are stored as key/value pairs.

Declaration

```
template<typename TKey, typename TValue>
interface IMap : public ICollection<TKey>
```

Header

```
#include <Generic\Interfaces\IMap.mqh>
```

Inheritance Hierarchy

ICollection

IMap

Direct descendants

CHashMap, CSortedMap

Class Methods

Method	Description
Add	Adds a key/value pair to a collection
Contains	Determines whether a collection contains the key/value table with the specified key
Remove	Removes the first occurrence of a key/value pair from a collection
TryGetValue	Gets an element with the specified key from a collection
TrySetValue	Changes the value of the key/value pair from a collection at the specified key
CopyTo	Copies all key/value pairs from a collection to specified arrays, starting at the specified index

© 2000-2025, MetaQuotes Ltd.

Add

Adds a key/value pair to a collection.

```
bool Add(
   TKey    key,       // key
   TValue  value      // value
   );
```

Parameters

key

[in] Key.

value

[in] Value.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether a collection contains the key/value table with the specified key.

```
bool Contains(
   TKey    key,       // key
   TValue  value      // value
   );
```

Parameters

key

[in] Key.

value

[in] Value.

Return Value

Returns true, if the collection contains the key/value pair with the specified key and value, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of a key/value pair from a collection.

```
bool Remove(
   TKey  key      // key
   );
```

Parameters

key

[in] Key.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TryGetValue

Gets an element with the specified key from a collection.

```
bool TryGetValue(
   TKey      key,       // key
   TValue&   value      // a variable for writing the value
   );
```

Parameters

key

[in] Key.

&value

[out] The variable to which the specified value of the key/value pair will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrySetValue

Changes the value of the key/value pair from the collection at the specified key.

```
bool TrySetValue(
   TKey    key,       // key
   TValue  value      // new value
   );
```

Parameters

key

[in] Key.

value

[in] The new value to assign to the specified key-value pair.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all key/value pairs from a collection to the specified arrays, starting at the specified index.

```
int CopyTo(
   TKey&       dst_keys[],       // an array for writing keys
   TValue&     dst_values[],     // an array for writing values
   const int   dst_start=0       // the starting index for writing
   );
```

Parameters

&dst_keys[]

[out] An array to which all keys from the collection will be written.

&dst_values[]

[out] An array to which values of corresponding keys from the collection will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied key/value pairs.

© 2000-2025, MetaQuotes Ltd.

ISet<T>

ISet<T> is an interface for implementing generic data sets.

Description

The ISet interface defines basic methods to work with sets, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

Declaration

```
template<typename T>
interface ISet : public ICollection<T>
```

Header

```
#include <Generic\Interfaces\ISet.mqh>
```

Inheritance Hierarchy

ICollection

ISet

Direct descendants

CHashSet, CSortedSet

Class Methods

Method	Description
ExceptWith	Produces the operation of difference between the current collection and a passed collection (array)
IntersectWith	Produces the operation of intersection of the current collection and a passed collection (array)
SymmetricExceptWith	Produces the operation of symmetrical difference between the current collection and a passed collection (array)
UnionWith	Produces the union of the current collection and a passed collection (array)
IsProperSubsetOf	Determines whether the current set is a proper subset of the specified collection or array
IsProperSupersetOf	Determines whether the current set is a proper superset of the specified collection or array
IsSubsetOf	Determines whether the current set is a subset of the specified collection or array
IsSupersetOf	Determines whether the current set is a superset of the specified collection or array

© 2000-2025, MetaQuotes Ltd.

Method	Description
Overlaps	Determines whether the current set overlaps the specified collection or array
SetEquals	Determines whether the current set contains all elements of the specified collection or array

© 2000-2025, MetaQuotes Ltd.

ExceptWith

Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void ExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void ExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to be excepted from the current set.

&collection[]

[in] An array to be excepted from the current set.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void IntersectWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void IntersectWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be intersected.

&collection[]

[in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

SymmetricExceptWith

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection<T> interface.

```
void SymmetricExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void SymmetricExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to produce the symmetrical difference with.

&collection[]

[in] An array to produce the symmetrical difference with.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

UnionWith

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void UnionWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void UnionWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be united.

&collection[]

[in] An array with which the current set will be united.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IsProperSubsetOf

Determines whether the current set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsProperSupersetOf

Determines whether the current set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSubsetOf

Determines whether the current set is a subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSupersetOf

Determines whether the current set is a superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Overlaps

Determines whether the current set overlaps the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool Overlaps(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool Overlaps(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to determine overlapping.

&collection[]

[in] An array to determine overlapping.

Return Value

Returns true if the current set and a collection or an array overlap, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

SetEquals

Determines whether the current set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool SetEquals(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool SetEquals(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to compare elements.

&collection[]

[in] A collection to compare elements.

Return Value

Returns true if the current set contains all elements of the specified collection or array, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CDefaultComparer<T>

CDefaultComparer<T> is a helper class that implements the IComparer<T> generic interface based on Compare global methods.

Description

The CDefaultComparer<T> class is used by default in generic data collections, unless the user implicitly uses another class implementing the IComparer<T> interface.

Declaration

```
template<typename T>
class CDefaultComparer : public IComparer<T>
```

Header

```
#include <Generic\Internal\DefaultComparer.mqh>
```

Inheritance Hierarchy

IComparer

CDefaultComparer

Class Methods

Method	Description
Compare	Compares two values of type T

© 2000-2025, MetaQuotes Ltd.

Compare

Compares two values of type T.

```
int Compare(
   T  x,      // the first value
   T  y       // the second value
   );
```

Parameters

x

[in] The first value to compare.

y

[in] The second value to compare.

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, x is less than y (x<y)
- if the result is equal to zero, x is equal to y (x=y)
- if the result is greater than zero, x is greater than y (x>y)

Note

The x and y values are compared based one one of he overloads of the Compare global method depending on the T type.

© 2000-2025, MetaQuotes Ltd.

CDefaultEqualityComparer<T>

CDefaultEqualityComparer<T> is a helper class that implements the IEqualityComparer<T> generic interface based on Equals<T> and GetHashCode global methods.

Description

The CDefaultEqualityComparer<T> class is used by default in generic data collections, unless the user implicitly uses another class implementing the IEqualityComparer<T> interface.

Declaration

```
template<typename T>
class CDefaultEqualityComparer : public IEqualityComparer<T>
```

Header

```
#include <Generic\Internal\DefaultEqualityComparer.mqh>
```

Inheritance Hierarchy

IEqualityComparer

CDefaultEqualityComparer

Class Methods

Method	Description
Equals	Compares two values of type T
HashCode	Calculates the hash code value based on the T type object

© 2000-2025, MetaQuotes Ltd.

Equals

Compares two values of type T.

```
bool Equals(
   T  x,      // the first value
   T  y       // the second value
   );
```

Parameters

x

[in] The first value to compare.

y

[in] The second value to compare.

Return Value

Returns true if the values are equal, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

HashCode

Calculates the hash code value based on the T type object.

```
int HashCode(
   T  value     // an object for calculation
   );
```

Parameters

value

[in] The object for which you want to get the hash code.

Return Value

Returns the hash code.

© 2000-2025, MetaQuotes Ltd.

CRedBlackTreeNode<T>

CRedBlackTreeNode<T> is a helper class used in implementing the CRedBlackTree<T> class.

Description

The CRedBlackTreeNode<T> class is a node of the CRedBlackTree<T>. Tree navigation methods are implemented in the class.

Declaration

```
template<typename T>
class CRedBlackTreeNode
```

Header

```
#include <Generic\RedBlackTree.mqh>
```

Class Methods

Method	Description
Value	Returns and sets a node value
Parent	Returns and sets a pointer to the parent node
Left	Returns and sets a pointer to the left node
Right	Returns and sets a pointer to the right node
Color	Returns and sets a node color
IsLeaf	Determines whether the specified node is a leaf
CreateEmptyNode	Creates a new black node with no parent and children, and returns a pointer to it

© 2000-2025, MetaQuotes Ltd.

Value (the Get method)

Returns the node value.

```
T Value();
```

Return Value

Returns the node value.

Value (the Set method)

Sets the node value

```
void Value(
   T  value     // node value
   );
```

Parameters

value

[in] Node value.

© 2000-2025, MetaQuotes Ltd.

Parent (the Get method)

Returns a pointer to the parent node.

```
CRedBlackTreeNode<T>* Parent();
```

Return Value

Returns a pointer to the parent node.

Parent (the Set method)

Sets a pointer to the parent node.

```
void Parent(
   CRedBlackTreeNode<T>*  node     // a pointer to the parent node
   );
```

Parameters

node

[in] A pointer to the parent node.

© 2000-2025, MetaQuotes Ltd.

Left (the Get method)

Returns a pointer to the left node.

```
CRedBlackTreeNode<T>* Left();
```

Return Value

Returns a pointer to the left node.

Left (the Set method)

Sets a pointer to the left node.

```
void Left(
   CRedBlackTreeNode<T>*  node     // a pointer to the left node
   );
```

Parameters

node

[in] A pointer to the left node.

© 2000-2025, MetaQuotes Ltd.

Right (the Get method)

Returns a pointer to the right node.

```
CRedBlackTreeNode<T>* Right();
```

Return Value

Returns a pointer to the right node.

Right (the Set method)

Sets a pointer to the right node.

```
void Right(
   CRedBlackTreeNode<T>*  node     // a pointer to the right node
   );
```

Parameters

node

[in] A pointer to the right node.

© 2000-2025, MetaQuotes Ltd.

Color (Get method)

Returns a node color.

```
ENUM_RED_BLACK_TREE_NODE_TYPE Color();
```

Return Value

Returns a node color.

Color (Set method)

Sets the node color.

```
void Color(
   ENUM_RED_BLACK_TREE_NODE_TYPE  clr     // node color
   );
```

Parameters

clr

[in] Node color.

Note

The color of the node is set using a value from ENUM_RED_BLACK_TREE_NODE_TYPE. It can be of two types:

- RED_BLACK_TREE_NODE_RED — the red color of the node;
- RED_BLACK_TREE_NODE_BLACK — the black color of the node.

© 2000-2025, MetaQuotes Ltd.

IsLeaf

Determines whether the specified node is a leaf.

```
bool IsLeaf();
```

Return Value

Returns true if the node is a leaf, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CreateEmptyNode

Creates a new black node with no parent and children, and returns a pointer to it.

```
static CRedBlackTreeNode<T>* CreateEmptyNode();
```

Return Value

Returns a pointer to the new node.

© 2000-2025, MetaQuotes Ltd.

CLinkedListNode<T>

CLinkedListNode<T> is a helper class used in implementing the CLinkedListNode<T> class.

Description

The CLinkedListNode<T> class is a node of the doubly linked list CLinkedListNode<T>. List navigation methods are implemented in the class.

Declaration

```
template<typename T>
class CLinkedListNode
```

Header

```
#include <Generic\LinkedList.mqh>
```

Class Methods

Method	Description
List	Returns and sets a pointer to the CLinkedList<T>
Next	Returns and sets a pointer to the next node
Previous	Returns and sets a pointer to the previous node
Value	Returns and sets the node value

© 2000-2025, MetaQuotes Ltd.

List (the Get method)

Returns a pointer to the CLinkedList<T>.

```
CLinkedList<T>* List();
```

Return Value

Returns a pointer to the CLinkedList<T> linked list.

List (the Set method)

Sets a pointer to the CLinkedList<T>.

```
void List(
   CLinkedList<T>*  value     // a pointer to the list
   );
```

Parameters

value

[in] A pointer to the linked list CLinkedList<T>.

© 2000-2025, MetaQuotes Ltd.

Next (the Get method)

Returns a pointer to the next node.

```
CLinkedListNode<T>* Next();
```

Return Value

Returns a pointer to the next node.

Next (the Set method)

Sets a pointer to the next node

```
void Next(
   CLinkedListNode<T>*  value     // a pointer to the next node
   );
```

Parameters

value

[in] A pointer to the next node.

© 2000-2025, MetaQuotes Ltd.

Previous (the Get method)

Returns a pointer to the previous node.

```
CLinkedListNode<T>* Previous();
```

Return Value

Returns a pointer to the previous node.

Previous (the Set method)

Sets a pointer to the previous node.

```
void Previous(
   CLinkedListNode<T>*  value     // a pointer to the previous node
   );
```

Parameters

value

[in] A pointer to the previous node.

© 2000-2025, MetaQuotes Ltd.

Value (the Get method)

Returns the node value.

```
T Value();
```

Return Value

Returns the node value.

Value (the Set method)

Sets the node value

```
void Value(
   T  value     // Node value
   );
```

Parameters

value

[in] Node value.

© 2000-2025, MetaQuotes Ltd.

CKeyValuePair<TKey,TValue>

The CKeyValuePair<TKey,TValue> class implements a key/value pair.

Description

The CKeyValuePair<TKey,TValue> class implements methods for working with the key and the value of the key/value pair.

Declaration

```
template<typename TKey, typename TValue>
class CKeyValuePair : public IComparable<CKeyValuePair<TKey,TValue>*>
```

Header

```
#include <Generic\HashMap.mqh>
```

Inheritance Hierarchy

IEqualityComparable

IComparable

CKeyValuePair

Class Methods

Method	Description
Key	Gets and sets the key in the key/value pair
Value	Gets and sets the value in the key/value pair
Clone	Creates a new key/value pair whose key and value are equal to the current ones
Compare	Compares the current key/value pair to the specified one
Equals	Checks whether the current key/value pair and the specified one are equal
HashCode	Calculates the hash value based on the key/value pair

© 2000-2025, MetaQuotes Ltd.

Key (the Get method)

Gets the key in the key/value pair.

```
TKey Key();
```

Return Value

Returns the key.

Key (the Set method)

Sets the key in the key/value pair.

```
void Key(
   TKey  key      // key
   );
```

Parameters

key

[in] Key.

© 2000-2025, MetaQuotes Ltd.

Value (the Get method)

Gets the value in the key/value pair.

```
TValue Value();
```

Return Value

Returns the value.

Value (the Set method)

Sets the value in the key/value pair.

```
void Value(
   TValue  value     // value
   );
```

Parameters

value

[in] Value

© 2000-2025, MetaQuotes Ltd.

Clone

Creates a new key/value pair whose key and value are equal to the current ones.

```
TValue>* Clone();
```

Return Value

Returns a new key/value pair

© 2000-2025, MetaQuotes Ltd.

Compare

Compares the current key/value pair to the specified one.

```
int Compare(
   CKeyValuePair<TKeyTValue>*  pair     // the pair to compare
   );
```

Parameters

pair

[in] The pair to compare.

Return Value

Returns a number that expresses the ratio of the current and passed key-value pairs:

- if the result is less than zero, the current key/value pair is less than the passed one
- if the result is zero, the current key/value pair is equal to than the passed one
- if the result is greater than zero, the current key/value pair is greater than the passed one

Note

Key/value pairs are compared based on their keys.

© 2000-2025, MetaQuotes Ltd.

Equals

Checks whether the current key/value pair and the specified one are equal.

```
bool Equals(
   CKeyValuePair<TKeyTValue>*  pair     // the pair to compare
   );
```

Parameters

pair

[in] The pair to compare

Return Value

Returns true if the key/value pairs are equal, or false otherwise.

Note

Key/value pairs are compared based on their keys.

© 2000-2025, MetaQuotes Ltd.

HashCode

Calculates the hash value based on the key/value pair.

```
int HashCode();
```

Return Value

Returns the hash code.

Note

The hash code of the key/value pair is equal to the key hash code.

© 2000-2025, MetaQuotes Ltd.

CArrayList<T>

CArrayList<T> is a generic class that implements the IList<T> interface.

Description

The CArrayList<T> class is an implementation of the dynamic data list of the T type. This class provides the basic methods to work with the list, such as to access an element by index, to search and delete elements, sort, and others.

Declaration

```
template<typename T>
class CArrayList : public IList<T>
```

Header

```
#include <Generic\ArrayList.mqh>
```

Inheritance Hierarchy

ICollection
  IList
    CArrayList

Class Methods

Method	Description
Capacity	Gets and sets the current capacity of a list
Count	Returns the number of elements in the list
Contains	Determines whether a list contains an element with the specified value
TrimExcess	Sets the capacity of a list to the actual number of elements
TryGetValue	Gets an element of the list at the specified index
TrySetValue	Sets the value of the list element at the specified index
Add	Adds an element to the list
AddRange	Adds a collection or an array of elements to the list
Insert	Inserts an element into the list at the specified index
InsertRange	Inserts a collection or an array of elements into the list at the specified index
CopyTo	Copies all elements of a list to the specified array starting at the specified index
BinarySearch	Searches for the specified value in an ascending-sorted list
IndexOf	Searches for the first occurrence of a value in a list

© 2000-2025, MetaQuotes Ltd.

Method	Description
LastIndexOf	Searches for the last occurrence of a value in a list
Clear	Removes all elements from a collection
Remove	Removes the first occurrence of the specified element from the list
RemoveAt	Removes an element at the specified index of the list
RemoveRange	Removes a range of elements from the list
Reverse	Reverses the order of elements in the list
Sort	Sorts elements in the list

© 2000-2025, MetaQuotes Ltd.

Capacity (the Get method)

Returns the current list capacity.

```
int Capacity();
```

Return Value

Returns the current list capacity.

Capacity (the Set method)

Sets the current capacity of a list.

```
void Capacity(
   const int  capacity     // capacity value
   );
```

Parameters

capacity

[in] A new value of capacity.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the list.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the list contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the list, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrimExcess

Sets the capacity of a list to the actual number of elements, and thus frees up unused memory.

```
void TrimExcess();
```

© 2000-2025, MetaQuotes Ltd.

TryGetValue

Gets an element of the list at the specified index.

```
bool TryGetValue(
   const int  index,      // index
   T&         value       // a variable to write
   );
```

Parameters

index

[in] The index of the list element the value of which you want to get.

&value

[out] The variable to write the element value to.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrySetValue

Sets the value of the list element at the specified index.

```
bool TrySetValue(
   const int  index,      // index
   T          value       // element value
   );
```

Parameters

index

[in] The index of the list element the value of which you want to set.

value

[in] Sets the value of the list element.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the list.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

AddRange

Adds a collection or an array of elements to the list.

The version that adds an array.

```
bool AddRange(
   const T&  array[]               // an array to be added
   );
```

The version that adds a collection.

```
bool AddRange(
   ICollection<T>*  collection     // a collection to be added
   );
```

Parameters

&array[]

[in] An array to be added.

**collection*

[in] A collection to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts an element into the list at the specified index.

```
bool Insert(
   const int  index,      // index to insert at
   T          item        // the value to be inserted
   );
```

Parameters

index

[in] The index to insert at.

item

[in] The value to be inserted at the specified index.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

InsertRange

Inserts a collection or an array of elements into the list at the specified index.

The version that inserts an array.

```
bool InsertRange(
   const int  index,               // index to insert at
   const T&   array[]              // an array to be inserted
   );
```

The version that inserts a collection.

```
bool InsertRange(
   const int        index,         // index to insert at
   ICollection<T>*  collection     // a collection to be inserted
   );
```

Parameters

index

[in] The index to insert at.

&array[]

[in] An array to be inserted at the specified index.

**collection*

[in] A collection to be inserted at the specified index.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a list to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the list will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

BinarySearch

Searches for the specified value in an ascending-sorted list.

The version that searches in the specified range of values using the class that implements the IComparable<T> interface for comparing elements.

```
int BinarySearch(
   const int       index,        // the starting index
   const int       count,        // the search range
   T               item,         // the search value
   IComparer<T>*   comparer      // interface to compare
   );
```

The version that searches using the class that implements the IComparable<T> interface for comparing elements.

```
int BinarySearch(
   T               item,         // the search value
   IComparer<T>*   comparer      // interface to compare
   );
```

The version that searches using the ::Compare global method for comparing elements.

```
int BinarySearch(
   T  item                       // the search value
   );
```

Parameters

index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

item

[in] The searched value.

**comparer*

[in] An interface for comparing elements.

Return Value

Returns the index of the found element. If the search value is not found, it returns the index of the smallest element, which is closest in value.

© 2000-2025, MetaQuotes Ltd.

IndexOf

Searches for the first occurrence of a value in a list.

Version that searches in the entire list.

```
int IndexOf(
   T  item                    // the search value
   );
```

Version that searches from the specified position and to the end of the list.

```
int IndexOf(
   T           item,          // the search value
   const int   start_index    // the starting index
   );
```

Version that searches from the specified position in the specified range.

```
int IndexOf(
   T           item,          // the search value
   const int   start_index,   // the starting index
   const int   count          // the search range
   );
```

Parameters

item

[in] The searched value.

start_index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

Return Value

Returns the index of the first found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

LastIndexOf

Searches for the last occurrence of a value in a list.

Version that searches in the entire list.

```
int LastIndexOf(
   T  item                    // the search value
   );
```

Version that searches from the specified position and to the end of the list.

```
int LastIndexOf(
   T          item,           // the search value
   const int  start_index     // the starting index
   );
```

Version that searches from the specified position in the specified range.

```
int LastIndexOf(
   T          item,           // the search value
   const int  start_index,    // the starting index
   const int  count           // the search range
   );
```

Parameters

item

[in] The searched value.

start_index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements of a collection.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the specified element from the list.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveAt

Removes an element at the specified index of the list.

```
bool RemoveAt(
   const int  index     // index
   );
```

Parameters

index

[in] The index of the element to remove.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveRange

Removes a range of elements from the list.

```
bool RemoveRange(
   const int  start_index,     // the starting index
   const int  count            // the number of elements
   );
```

Parameters

start_index

[in] The starting index from which the deletion begins.

count

[in] The number of elements to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Reverse

Reverses the order of elements in the list.

The version for working with the entire list.

```
bool Reverse();
```

The version for working with the specified range of list elements.

```
bool Reverse(
   const int  start_index,     // the starting index
   const int  count            // the number of elements
   );
```

Parameters

start_index

[in] The starting index.

count

[in] The number of list elements participating in the operation.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Sort

Sorts elements in the list.

The version that sorts all elements in the list.

```
bool Sort();
```

The version that sorts all elements in the list using the class that implements the IComparable<T> interface for comparing elements.

```
bool Sort(
   IComparer<T>*  comparer         // interface for comparing
   );
```

The version that sorts the specified range of elements in the list using the class that implements the IComparable<T> interface for comparing elements.

```
bool Sort(
   const int  start_index,     // the starting index
   const int  count            // the number of elements
   IComparer<T>*  comparer     // interface to compare
   );
```

Parameters

comparer

[in] An interface for comparing elements.

start_index

[in] The starting index from which sorting begins.

count

[in] The length of the sorting range.

Return Value

Returns true on successful, or false otherwise.

CHashMap<TKey, TValue>

CHashMap<TKey, TValue> is a generic class that implements the IMap<TKey, TValue> interface.

Description

The CHashMap<TKey, TValue> class is an implementation of the dynamic hash table, the data of which are stored in the form of unordered key/value pairs taking into account the key uniqueness requirement. This class provides basic methods to work with a hash table, such as to access a value by key, to search and delete a key/value pair, and others.

Declaration

```
template<typename TKey, typename TValue>
class CHashMap : public IMap<TKey, TValue>
```

Header

```
#include <Generic\HashMap.mqh>
```

Inheritance Hierarchy

ICollection
  IMap
    CHashMap

Class Methods

Method	Description
Add	Adds a key/value pair to the hash table
Count	Returns the number of elements in the hash table
Comparer	Returns a pointer to the IEqualityComparer<T> interface, used to organize a hash table
Contains	Determines whether the hash table contains the specified key/value pair
ContainsKey	Determines whether the hash table contains the key/value pair with the specified key
ContainsValue	CHashMap<TKey, TValue> is a generic class that implements the IMap<TKey, TValue> interface
CopyTo	Copies all key/value pairs from the hash table to the specified arrays, starting at the specified index
Clear	Removes all elements from the hash table
Remove	Removes the first occurrence of the key/value pair from the hash table
TryGetValue	Gets an element with the specified key from the hash table

© 2000-2025, MetaQuotes Ltd.

Method	Description
TrySetValue	Changes the value of a key/value pair from the hash table at the specified key

© 2000-2025, MetaQuotes Ltd.

Add

Adds a key/value pair to the hash table.

A version that adds a generated key/value pair.

```
bool Add(
   CKeyValuePair<TKeyTValue>*  pair     // the key/value pair
   );
```

A version that adds a new key/value pair with the specified key and value.

```
bool Add(
   TKey    key,                         // key
   TValue  value                        // value
   );
```

Parameters

**pair*

[in] The key/value pair.

key

[in] Key.

value

[in] Value.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the hash table.

```
int Count();
```

© 2000-2025, MetaQuotes Ltd.

Comparer

Returns a pointer to the IEqualityComparer<T> interface, used to organize a hash table.

```
IEqualityComparer<TKey>* Comparer() const;
```

Return Value

Returns a pointer to the IEqualityComparer<T> interface.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the hash table contains the specified key/value pair.

The version for working with a generated key/value pair.

```
bool Contains(
   CKeyValuePair<TKeyTValue>*  item     // the key/value pair
   );
```

The version for working with a key/value pair in the form of a separately set key and value.

```
bool Contains(
   TKey   key,                          // key
   TValue value                         // value
   );
```

Parameters

**item*

[in] The key/value pair.

key

[in] Key.

value

[in] Value.

Return Value

Returns true, if the hash table contains the key/value pair with the specified key and value, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ContainsKey

Determines whether the hash table contains the key/value pair with the specified key.

```
bool ContainsKey(
   TKey  key     // key
   );
```

Parameters

key

[in] Key.

Return Value

Returns true if the hash table contains a key/value pair with the specified key, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ContainsValue

Determines whether the hash table contains the key/value pair with the specified value.

```
bool ContainsValue(
   TValue  value     // value
   );
```

Parameters

value

[in] Value.

Return Value

Returns true if the hash table contains a key/value pair with the specified value, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all key/value pairs from the hash table to the specified arrays, starting at the specified index.

The version that copies a hash table to the array of key/value pairs.

```
int CopyTo(
   CKeyValuePair<TKeyTValue>*&  dst_array[],     // an array for writing key/value pai
   const int                    dst_start=0      // the starting index for writing
   );
```

The version that copies a hash table to separate arrays for keys and values.

```
int CopyTo(
   TKey&       dst_keys[],                      // an array for writing keys
   TValue&     dst_values[],                    // an array for writing values
   const int   dst_start=0                      // starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which all pairs from the hash table will be written.

&dst_keys[]

[out] An array to which all keys from the hash table will be written.

&dst_values[]

[out] An array to which all values from the hash table will be written.

dst_start=0

[in] The array index from which copying starts.

Return Value

Returns the number of copied key/value pairs.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from the hash table.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the key/value pair from the hash table.

The version that removes a key-value pair based on the generated key-value pair.

```
bool Remove(
   CKeyValuePair<TKeyTValue>*  item     // the key/value pair"
   );
```

The version that removes a key-value pair based on the key.

```
bool Remove(
   TKey  key                           // key
   );
```

Parameters

**item*

[in] The key/value pair.

key

[in] Key.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TryGetValue

Gets an element with the specified key from the hash table.

```
bool TryGetValue(
   TKey      key,       // key
   TValue&   value      // a variable for writing the value
   );
```

Parameters

key

[in] Key.

&value

[out] The variable to which the specified value of the key/value pair will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrySetValue

Changes the value of a key/value pair from the hash table at the specified key.

```
bool TrySetValue(
   TKey    key,       // key
   TValue  value      // new value
   );
```

Parameters

key

[in] Key.

value

[in] The new value to assign to the specified key-value pair.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CHashSet<T>

CHashSet<T> is a generic class that implements the ISet<T> interface.

Description

The CHashSet<T> class is an implementation of the unordered dynamic data set of type T, with the required uniqueness of each value. This class provides basic methods to work with sets and related operations, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

Declaration

```
template<typename T>
class CHashSet : public ISet<T>
```

Header

```
#include <Generic\HashSet.mqh>
```

Inheritance Hierarchy

ICollection
  ISet
    CHashSet

Class Methods

Method	Description
Add	Adds an element to a set
Count	Returns the number of elements in a set
Comparer	Determines whether a set contains an element with the specified value
Contains	Returns a pointer to the IEqualityComparer<T> interface, used to organize a set
TrimExcess	Sets the capacity of a set to the actual number of elements, and thus frees up unused memory
CopyTo	Copies all elements of a set to the specified array starting at the specified index
Clear	Removes all elements from a set
Remove	Removes the specified element from a set
ExceptWith	Produces the operation of difference between the current collection and a passed collection (array)
IntersectWith	Produces the operation of intersection of the current collection and a passed collection (array)

© 2000-2025, MetaQuotes Ltd.

Method	Description
SymmetricExceptWith	Produces the operation of symmetrical difference between the current collection and a passed collection (array)
UnionWith	Produces the union of the current collection and a passed collection (array)
IsProperSubsetOf	Determines whether the current set is a proper subset of the specified collection or array
IsProperSupersetOf	Determines whether the current set is a proper superset of the specified collection or array
IsSubsetOf	Determines whether the current set is a subset of the specified collection or array
IsSupersetOf	Determines whether the current set is a superset of the specified collection or array
Overlaps	Determines whether the current set overlaps the specified collection or array
SetEquals	Determines whether the current set contains all elements of the specified collection or array

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a set.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in a set.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether a set contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the set, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Comparer

Returns a pointer to the IEqualityComparer<T> interface, used to organize a set.

```
IEqualityComparer<T>* Comparer() const;
```

Return Value

Returns a pointer to the IEqualityComparer<T> interface.

© 2000-2025, MetaQuotes Ltd.

TrimExcess

Sets the capacity of a set to the actual number of elements, and thus frees up unused memory.

```
void TrimExcess();
```

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a set to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the set will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from a set.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the specified element from a set.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ExceptWith

Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void ExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void ExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to be excepted from the current set.

&collection[]

[in] An array to be excepted from the current set.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void IntersectWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void IntersectWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be intersected.

&collection[]

[in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

SymmetricExceptWith

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection<T> interface.

```
void SymmetricExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void SymmetricExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to produce the symmetrical difference with.

&collection[]

[in] An array to produce the symmetrical difference with.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

UnionWith

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void UnionWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void UnionWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be united.

&collection[]

[in] An array with which the current set will be united.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IsProperSubsetOf

Determines whether the current set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsProperSupersetOf

Determines whether the current set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSubsetOf

Determines whether the current set is a subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSupersetOf

Determines whether the current set is a superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Overlaps

Determines whether the current set overlaps the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool Overlaps(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool Overlaps(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to determine overlapping.

&collection[]

[in] An array to determine overlapping.

Return Value

Returns true if the current set and a collection or an array overlap, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

SetEquals

Determines whether the current set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool SetEquals(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool SetEquals(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to compare elements.

&collection[]

[in] An array to compare elements.

Return Value

Returns true if the current set contains all elements of the specified collection or array, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CLinkedList<T>

CLinkedList<T> is a generic class that implements the ICollection<T> interface.

Description

The CLinkedList<T> class is an implementation of the dynamic doubly linked data list of the T type. This class provides basic methods to work with doubly linked lists, such as to add, delete, search elements, and others.

Declaration

```
template<typename T>
class CLinkedList : public ICollection<T>
```

Header

```
#include <Generic\LinkedList.mqh>
```

Inheritance Hierarchy

ICollection

CLinkedList

Class Methods

Method	Description
Add	Adds an element to a linked list
AddAfter	Adds an element after the specified node in the linked list
AddBefore	Adds an element before the specified node in the linked list
AddFirst	Adds an element at the beginning of the linked list
AddLast	Adds an element at the end of the linked list
Count	Returns the number of elements in the linked list
Head	Returns a pointer to the first node of the linked list
First	Returns a pointer to the first node of the linked list
Last	Returns a pointer to the last node of the linked list
Contains	Determines whether the linked list contains an element with the specified value
CopyTo	Copies all elements of the linked list to the specified array starting at the specified index
Clear	Removes all elements from a linked list
Remove	Removes the first occurrence of the specified element from the linked list

© 2000-2025, MetaQuotes Ltd.

Method	Description
RemoveFirst	Removes the first element of the linked list
RemoveLast	Removes the last element of the linked list
Find	Searches for the first occurrence of the specified value in the linked list
FindLast	Searches for the last occurrence of the specified value in the linked list

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a linked list.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

AddAfter

Adds an element after the specified node in the linked list.

The version that adds an element by value.

```
CLinkedListNode<T>* AddAfter(
   CLinkedListNode<T>*   node,         // the node after which the element should be add
   T                     value         // the element to add
   );
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```
bool AddAfter(
   CLinkedListNode<T>*   node,         // the node after which the element should be add
   CLinkedListNode<T>*   new_node      // the node to be added
   );
```

Parameters

node

[in] The node of the linked list, after which a new element will be added.

value

[in] An element to be added.

new_node

[in] A node to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

AddBefore

Adds an element before the specified node in the linked list.

The version that adds an element by value.

```
CLinkedListNode<T>* AddBefore(
   CLinkedListNode<T>*  node,         // the node before which the element should be ad
   T                    value         // the element to add
   );
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```
bool AddBefore(
   CLinkedListNode<T>*  node,         // the node before which the element should be ad
   CLinkedListNode<T>*  new_node      // the node to be added
   );
```

Parameters

node

[in] The node of the linked list, before which a new element will be added.

value

[in] An element to be added.

new_node

[in] A node to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

AddFirst

Adds an element at the beginning of the linked list.

The version that adds an element by value.

```
CLinkedListNode<T>* AddFirst(
   T   value                     // an element to add
   );
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```
bool AddFirst(
   CLinkedListNode<T>*  node     // the node to add
   );
```

Parameters

value

[in] An element to be added.

**node*

[in] A node to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

AddLast

Adds an element at the end of the linked list

The version that adds an element by value.

```
CLinkedListNode<T>* AddLast(
   T  value                        // an element to add
   );
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```
bool AddLast(
   CLinkedListNode<T>*  node      // the node to add
   );
```

Parameters

value

[in] An element to be added.

**node*

[in] A node to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the linked list.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Head

Returns a pointer to the first node of the linked list.

```
CLinkedListNode<T>* Head();
```

Return Value

Returns a pointer to the first node.

© 2000-2025, MetaQuotes Ltd.

First

Returns a pointer to the first node of the linked list.

```
CLinkedListNode<T>* First();
```

Return Value

Returns a pointer to the first node.

© 2000-2025, MetaQuotes Ltd.

Last

Returns a pointer to the last node of the linked list.

```
CLinkedListNode<T>* Last();
```

Return Value

Returns a pointer to the last node.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the linked list contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the linked list, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of the linked list to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],      // an array for writing
   const int   dst_start=0       // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the linked list will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements of a collection.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the specified element from the linked list.

The version that removes an element by value.

```
bool Remove(
   T  item                        // the element value
   );
```

The version that removes an element by a pointer to a node.

```
bool Remove(
   CLinkedListNode<T>*  node      // the element node
   );
```

Parameters

item

[in] The value of the element to be deleted.

**node*

[in] The node of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveFirst

Removes the first element of the linked list.

```
bool RemoveFirst();
```

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveLast

Removes the last element of the linked list.

```
bool RemoveLast();
```

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Find

Searches for the first occurrence of the specified value in the linked list.

```
CLinkedListNode<T>* Find(
   T  value     // the search value
   );
```

Parameters

value

[in] The searched value.

Return Value

Returns a pointer to the first found node containing the search value on success, or NULL otherwise.

© 2000-2025, MetaQuotes Ltd.

FindLast

Searches for the last occurrence of the specified value in the linked list.

```
CLinkedListNode<T>* FindLast(
   T  value     // the search value
   );
```

Parameters

value

[in] The searched value.

Return Value

Returns a pointer to the last found node containing the search value on success, or NULL otherwise.

© 2000-2025, MetaQuotes Ltd.

CQueue<T>

CQueue<T> is a generic class that implements the ICollection<T> interface.

Description

The CQueue<T> class is a dynamic collection of T type data, which is organized as a queue that operates on the FIFO (first in, first out) principle.

Declaration

```
template<typename T>
class CQueue : public ICollection<T>
```

Header

```
#include <Generic\Queue.mqh>
```

Inheritance Hierarchy

ICollection

CQueue

Class Methods

Method	Description
Add	Adds an element to a queue
Enqueue	Adds an element to a queue
Count	Returns the number of elements in the queue
Contains	Determines whether the queue contains an element with the specified value
TrimExcess	Sets the capacity of a queue to the actual number of elements, and thus frees up unused memory
CopyTo	Copies all elements of a queue to the specified array starting at the specified index
Clear	Removes all elements from a queue
Remove	Removes the first occurrence of the specified element from the queue
Dequeue	Returns the starting element and removes it from the queue
Peek	Returns the starting element without removing it from the queue

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a queue.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Enqueue

Adds an element to a queue.

```
bool Enqueue(
   T  value     // element to add
   );
```

Parameters

value

[in] An element to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the queue.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the queue contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the queue, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrimExcess

Sets the capacity of a queue to the actual number of elements, and thus frees up unused memory.

```
void TrimExcess();
```

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a queue to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the queue will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from a queue.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the specified element from the queue.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Dequeue

Returns the first element and removes it from the queue.

```
T Dequeue();
```

Return Value

Returns the starting element.

© 2000-2025, MetaQuotes Ltd.

Peek

Returns the first element not removing it from the queue.

```
T Peek();
```

Return Value

Returns the starting element.

© 2000-2025, MetaQuotes Ltd.

CRedBlackTree<T>

CRedBlackTree<T> is a generic class that implements the ICollection<T> interface.

Description

The CRedBlackTree<T> class is an implementation of a dynamic red-black tree whose nodes store T type data. The class provides basic methods to work with red-black trees, such as to add, delete, search for the maximum and minimum value, and more.

Declaration

```
template<typename T>
class CRedBlackTree : public ICollection<T>
```

Header

```
#include <Generic\RedBlackTree.mqh>
```

Inheritance Hierarchy

ICollection

CRedBlackTree

Class Methods

Method	Description
Add	Adds an element to a red-black tree
Root	Returns a pointer to the root of the red-black tree
Count	Returns the number of elements in the red-black tree
Contains	Determines whether the red-black tree contains an element with the specified value
Comparer	Returns a pointer to the IComparer<T> interface used to organize a red-black tree
TryGetMin	Gets the minimum element of a red-black tree
TryGetMax	Gets the maximum element of a red-black tree
CopyTo	Copies all elements of a red-black tree to the specified array starting at the specified index
Clear	Removes all elements from a red-black tree
Remove	Removes the occurrence of the specified element from a red-black tree
RemoveMin	Removes an element with the minimum value from a red-black tree
RemoveMax	Removes an element with the maximum value from a red-black tree
Find	Searches for the occurrence of a specified value in a red-black tree

© 2000-2025, MetaQuotes Ltd.

Method	Description
FindMax	Searches for an element with the maximum value in a red-black tree
FindMin	Searches for an element with the minimum value in a red-black tree

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a red-black tree.

```
bool Add(
   T  value     // element to add
   );
```

Parameters

value

[in] An element to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the red-black tree.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Root

Returns a pointer to the root of the red-black tree.

```
CRedBlackTreeNode<T>* Root();
```

Return Value

Returns a pointer to the root.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the red-black tree contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the red-black tree, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Comparer

Returns a pointer to the IComparer<T> interface used to organize a red-black tree.

```
IComparer<T>* Comparer() const;
```

Return Value

Returns a pointer to the IComparer<T> interface.

© 2000-2025, MetaQuotes Ltd.

TryGetMin

Gets the minimum element of a red-black tree.

```
bool TryGetMin(
   T&  min     // a variable for writing the value
   );
```

Parameters

&min

[out] The variable to which the minimum value will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TryGetMax

Gets the maximum element of a red-black tree.

```
bool TryGetMax(
   T&  max     // a variable for writing the value
   );
```

Parameters

&max

[out] The variable to which the maximum value will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a red-black tree to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the red-black tree will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from a red-black tree.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the occurrence of the specified element from a red-black tree.

The version that removes an element with the specified value.

```
bool Remove(
   T  value                         // the element value
   );
```

The version that removes an element by a pointer to a node.

```
bool Remove(
   CRedBlackTreeNode<T>*  node      // the element node
   );
```

Parameters

item

[in] The value of the element to be deleted.

**node*

[in] The node of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveMin

Removes an element with the minimum value from a red-black tree.

```
bool RemoveMin();
```

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

RemoveMax

Removes an element with the maximum value from a red-black tree.

```
bool RemoveMax();
```

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Find

Searches for the occurrence of a specified value in a red-black tree.

```
CRedBlackTreeNode<T>* Find(
   T  value     // the search value
   );
```

Parameters

value

[in] The searched value.

Return Value

Returns a pointer to the found node containing the search value on success, or NULL otherwise.

© 2000-2025, MetaQuotes Ltd.

FindMin

Searches for an element with the minimum value in a red-black tree.

```
CRedBlackTreeNode<T>* FindMin();
```

Return Value

Returns a pointer to the node containing the minimum value on success, or NULL otherwise.

© 2000-2025, MetaQuotes Ltd.

FindMax

Searches for an element with the maximum value in a red-black tree.

```
CRedBlackTreeNode<T>* FindMax();
```

Return Value

Returns a pointer to the node containing the maximum value on success, or NULL otherwise.

© 2000-2025, MetaQuotes Ltd.

CSortedMap<TKey,TValue>

CSortedMap<TKey,TValue> is a generic class that implements the IMap<TKey,TValue> interface.

Description

The CSortedMap<TKey,TValue> class is an implementation of a dynamic hash table whose data are stored as key/value pairs sorted by key and taking into account the key uniqueness requirement. This class provides basic methods to work with a hash table, such as to access a value by key, to search and delete a key/value pair, and others.

Declaration

```
template<typename TKey, typename TValue>
class CSortedMap : public IMap<TKey, TValue>
```

Header

```
#include <Generic\SortedMap.mqh>
```

Inheritance Hierarchy

ICollection
  IMap
    CSortedMap

Class Methods

Method	Description
Add	Adds a key/value pair to the hash table
Count	Returns the number of elements in the sorted hash table
Contains	Determines whether the sorted hash table contains the specified key/value table
ContainsKey	Determines whether the sorted hash table contains the key/value table with the specified key
ContainsValue	Determines whether the sorted hash table contains the key/value table with the specified value
Comparer	Returns a pointer to the IComparer<T> interface, used to organize a sorted hash table
CopyTo	Copies all key/value pairs from the sorted hash table to the specified arrays, starting at the specified index
Clear	Removes all elements from the sorted hash table
Remove	Removes the first occurrence of the key/value pair from the sorted hash table

© 2000-2025, MetaQuotes Ltd.

Method	Description
TryGetValue	Gets an element with the specified key from the sorted hash table
TrySetValue	Changes a key/value pair with the specified key from the sorted hash table

© 2000-2025, MetaQuotes Ltd.

Add

Adds a key/value pair to the hash table.

A version that adds a generated key/value pair.

```
bool Add(
   CKeyValuePair<TKeyTValue>*  pair     // the key/value pair
   );
```

A version that adds a new key/value pair with the specified key and value.

```
bool Add(
   TKey    key,                         // key
   TValue  value                        // value
   );
```

Parameters

**pair*

[in] The key/value pair.

key

[in] Key.

value

[in] Value.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the sorted hash table.

```
int Count();
```

© 2000-2025, MetaQuotes Ltd.

Comparer

Returns a pointer to the IComparer<T> interface, used to organize a sorted hash table.

```
IComparer<TKey>* Comparer() const;
```

Return Value

Returns a pointer to the IComparer<T> interface.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the sorted hash table contains the specified key/value table.

The version for working with a generated key/value pair.

```
bool Contains(
   CKeyValuePair<TKeyTValue>*  item     // the key/value pair
   );
```

The version for working with a key/value pair in the form of a separately set key and value.

```
bool Contains(
   TKey    key,                         // key
   TValue  value                        // value
   );
```

Parameters

**item*

[in] The key/value pair.

key

[in] Key.

value

[in] Value.

Return Value

Returns true, if the sorted hash table contains the key/value pair with the specified key and value, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ContainsKey

Determines whether the sorted hash table contains the key/value table with the specified key.

```
bool ContainsKey(
   TKey  key     // key
   );
```

Parameters

key

[in] Key.

Return Value

Returns true, if the sorted hash table contains the key/value pair with the specified key, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ContainsValue

Determines whether the sorted hash table contains the key/value table with the specified value.

```
bool ContainsValue(
   TValue  value     // value
   );
```

Parameters

value

[in] Value.

Return Value

Returns true, if the sorted hash table contains the key/value pair with the specified value, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all key/value pairs from the sorted hash table to the specified arrays, starting at the specified index.

The version that copies a hash table to the array of key/value pairs.

```
int CopyTo(
   CKeyValuePair<TKeyTValue>*&  dst_array[],     // an array for writing key/value pa
   const int                    dst_start=0      // the starting index for writing
   );
```

The version that copies a hash table to separate arrays for keys and values.

```
int CopyTo(
   TKey&       dst_keys[],                       // an array for writing keys
   TValue&     dst_values[],                     // an array for writing values
   const int   dst_start=0                       // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which all pairs from the hash table will be written.

&dst_keys[]

[out] An array to which all keys from the hash table will be written.

&dst_values[]

[out] An array to which all values from the hash table will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied key/value pairs.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from the sorted hash table.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the key/value pair from the sorted hash table.

The version that removes a key-value pair based on the generated key-value pair.

```
bool Remove(
   CKeyValuePair<TKeyTValue>*  item     // the key/value pair
   );
```

The version that removes a key-value pair based on the key.

```
bool Remove(
   TKey  key                           // key
   );
```

Parameters

**item*

[in] The key/value pair.

key

[in] Key.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TryGetValue

Gets an element with the specified key from the sorted hash table.

```
bool TryGetValue(
   TKey     key,       // key
   TValue&  value      // a variable for writing the value
   );
```

Parameters

key

[in] Key.

&value

[out] The variable to which the specified value of the key/value pair will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrySetValue

Changes the value of the key/value pair from the sorted hash table at the specified key.

```
bool TrySetValue(
   TKey    key,       // key
   TValue  value      // new value
   );
```

Parameters

key

[in] Key.

value

[in] The new value to assign to the specified key-value pair.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CSortedSet<T>

CSortedSet<T> is a generic class that implements the ISet<T> interface.

Description

The CSortedSet<T> class is an implementation of the sorted dynamic data set of type T, with the required uniqueness of each value. This class provides basic methods to work with sets and related operations, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

Declaration

```
template<typename T>
class CSortedSet : public ISet<T>
```

Header

```
#include <Generic\SortedSet.mqh>
```

Inheritance Hierarchy

ICollection
  ISet
    CSortedSet

Class Methods

Method	Description
Add	Adds an element to a sorted set
Count	Returns the number of elements in a sorted set
Contains	Determines whether a sorted set contains an element with the specified value
Comparer	Returns a pointer to the IComparer<T> interface, used to organize a sorted set
TryGetMin	Gets the minimum element from a sorted set
TryGetMax	Gets the maximum element from a sorted set
CopyTo	Copies all elements of a sorted set to the specified array starting at the specified index
Clear	Removes all elements from a sorted set
Remove	Removes the occurrence of the specified element from a sorted set
ExceptWith	Produces the operation of difference between the current collection and a passed collection (array)

© 2000-2025, MetaQuotes Ltd.

Method	Description
IntersectWith	Produces the operation of intersection of the current collection and a passed collection (array)
SymmetricExceptWith	Produces the operation of symmetrical difference between the current collection and a passed collection (array)
UnionWith	Produces the union of the current collection and a passed collection (array)
IsProperSubsetOf	Determines whether the current sorted set is a proper subset of the specified collection or array
IsProperSupersetOf	Determines whether the current sorted set is a proper superset of the specified collection or array
IsSubsetOf	Determines whether the current sorted set is a subset of the specified collection or array
IsSupersetOf	Determines whether the current sorted set is a superset of the specified collection or array
Overlaps	Determines whether the current sorted set overlaps the specified collection or array
SetEquals	Determines whether the current sorted set contains all elements of the specified collection or array
GetViewBetween	Gets from the current sorted set a subset specified by the minimum and maximum values
GetReverse	Gets a copy of the current sorted set, in which all the elements are arranged in a reverse order

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to a sorted set.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the sorted set.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether the sorted set contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the set, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Comparer

Returns a pointer to the IComparer<T> interface, used to organize a sorted set.

```
IComparer<T>* Comparer() const;
```

Return Value

Returns a pointer to the IComparer<T> interface.

© 2000-2025, MetaQuotes Ltd.

TryGetMin

Gets the minimum element from the sorted set.

```
bool TryGetMin(
   T&  min     // a variable for writing the value
   );
```

Parameters

&min

[out] The variable to which the minimum value will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TryGetMax

Gets the maximum element from the sorted set.

```
bool TryGetMax(
   T&  max     // a variable for writing the value
   );
```

Parameters

&max

[out] The variable to which the maximum value will be written.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a sorted set to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],     // an array for writing
   const int   dst_start=0      // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the set will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from a sorted set.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the occurrence of the specified element from the sorted set.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

ExceptWith

Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void ExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void ExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to be excepted from the current sorted set.

&collection[]

[in] An array to be excepted from the current sorted set.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void IntersectWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void IntersectWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be intersected.

&collection[]

[in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

SymmetricExceptWith

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection<T> interface.

```
void SymmetricExceptWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void SymmetricExceptWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection to produce the symmetrical difference with.

&collection[]

[in] An array to produce the symmetrical difference with.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

UnionWith

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```
void UnionWith(
   ICollection<T>*  collection     // collection
   );
```

A version for working with an array.

```
void UnionWith(
   T&  array[]                     // array
   );
```

Parameters

**collection*

[in] A collection with which the current set will be united.

&collection[]

[in] An array with which the current set will be united.

Note

The result is written to the current collection (array).

© 2000-2025, MetaQuotes Ltd.

IsProperSubsetOf

Determines whether the current sorted set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a proper subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsProperSupersetOf

Determines whether the current sorted set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsProperSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsProperSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a proper superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSubsetOf

Determines whether the current sorted set is a subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSubsetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSubsetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a subset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

IsSupersetOf

Determines whether the current sorted set is a superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool IsSupersetOf(
   ICollection<T>*  collection     // a collection to determine the relation
   );
```

A version for working with an array.

```
bool IsSupersetOf(
   T&  array[]                     // an array to determine the relation
   );
```

Parameters

**collection*

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a superset, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Overlaps

Determines whether the current sorted set overlaps the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool Overlaps(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool Overlaps(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to determine overlapping.

&collection[]

[in] An array to determine overlapping.

Return Value

Returns true if the current sorted set and a collection or an array overlap, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

SetEquals

Determines whether the current sorted set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```
bool SetEquals(
   ICollection<T>*  collection     // a collection to compare
   );
```

A version for working with an array.

```
bool SetEquals(
   T&  array[]                     // an array to compare
   );
```

Parameters

**collection*

[in] A collection to compare elements.

&collection[]

[in] An array to compare elements.

Return Value

Returns true if the current sorted set contains all elements of the specified collection or array, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

GetViewBetween

Gets from the current sorted set a subset specified by the minimum and maximum values.

```
bool GetViewBetween(
   T&  array[],          // an array for writing
   T   lower_value,      // the minimum value
   T   upper_value       // the maximum value
   );
```

Parameters

&array[]

[out] An array for writing the subset.

lower_value

[in] The minimum value of the range.

upper_value

[in] The maximum value of the range.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

GetReverse

Gets a copy of the current sorted set, in which all the elements are arranged in a reverse order.

```
bool GetReverse(
   T&  array[]     // an array for writing
   );
```

Parameters

&array[]

[out] An array for writing.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

CStack<T>

CStack<T> is a generic class that implements the ICollection<T> interface.

Description

The CStack<T> class is a dynamic collection of T type data, which is organized as a stack that operates on the LIFO (last in, first out) principle.

Declaration

```
template<typename T>
class CStack : public ICollection<T>
```

Header

```
#include <Generic\Stack.mqh>
```

Inheritance Hierarchy

ICollection

CStack

Class Methods

Method	Description
Add	Adds an element to a stack
Count	Returns the number of elements in a stack
Contains	Determines whether a stack contains an element with the specified value
TrimExcess	Sets the capacity of a stack to the actual number of elements
CopyTo	Copies all elements of a stack to the specified array starting at the specified index
Clear	Removes all elements from a stack
Remove	Removes the first occurrence of the specified element from a stack
Push	Adds an element to a stack
Peek	Returns the head element without removing it from a stack
Pop	Returns the head element and removes it from a stack

© 2000-2025, MetaQuotes Ltd.

Add

Adds an element to the stack.

```
bool Add(
   T  value     // the value of the element
   );
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Count

Returns the number of elements in the a stack.

```
int Count();
```

Return Value

Returns the number of elements.

© 2000-2025, MetaQuotes Ltd.

Contains

Determines whether a stack contains an element with the specified value.

```
bool Contains(
   T  item     // the search value
   );
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the stack, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

TrimExcess

Sets the capacity of a stack to the actual number of elements, and thus frees up unused memory.

```
void TrimExcess();
```

© 2000-2025, MetaQuotes Ltd.

CopyTo

Copies all elements of a stack to the specified array starting at the specified index.

```
int CopyTo(
   T&          dst_array[],      // an array for writing
   const int   dst_start=0       // the starting index for writing
   );
```

Parameters

&dst_array[]

[out] An array to which the elements of the stack will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.

© 2000-2025, MetaQuotes Ltd.

Clear

Removes all elements from a stack.

```
void Clear();
```

© 2000-2025, MetaQuotes Ltd.

Remove

Removes the first occurrence of the specified element from a stack.

```
bool Remove(
   T  item     // the element value
   );
```

Parameters

item

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Push

Adds an element to the stack.

```
bool Push(
   T  value     // element to add
   );
```

Parameters

value

[in] An element to be added.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Peek

Returns the head element without removing it from a stack.

```
T Peek();
```

Return Value

Returns the head element.

© 2000-2025, MetaQuotes Ltd.

Pop

Returns the head element and removes it from a stack.

```
T Pop();
```

Return Value

Returns the head element.

© 2000-2025, MetaQuotes Ltd.

ArrayBinarySearch

Searches for the specified value in an ascending-sorted one-dimensional array using the IComparable<T> interface to compare elements.

```
template<typename T>
int ArrayBinarySearch(
   T&              array[],          // an array for search
   const int       start_index,      // the starting index
   const int       count,            // the search range
   T               value,            // the search value
   IComparer<T>*   comparer          // interface to compare
   );
```

Parameters

&array[]

[out] The array to search in.

value

[in] The searched value.

**comparer*

[in] An interface for comparing elements.

start_index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

Return Value

Returns the index of the found element. If the search value is not found, it returns the index of the smallest element, which is closest in value.

© 2000-2025, MetaQuotes Ltd.

ArrayIndexOf

Searches for the first occurrence of a value in a one-dimensional array.

```
template<typename T>
int ArrayIndexOf(
   T&          array[],          // an array for search
   T           value,            // the search value
   const int   start_index,      // the starting index
   const int   count             // the search range
   );
```

Parameters

&array[]

[out] The array to search in.

value

[in] The searched value.

start_index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

Return Value

Returns the index of the first found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

ArrayLastIndexOf

Searches for the last occurrence of a value in a one-dimensional array.

```
template<typename T>
int ArrayLastIndexOf(
   T&          array[],          // an array for search
   T           value,            // the search value
   const int   start_index,      // the starting index
   const int   count             // the search range
   );
```

Parameters

&array[]

[out] The array to search in.

value

[in] The searched value.

start_index

[in] The starting index from which the search begins.

count

[in] The length of the search range.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.

© 2000-2025, MetaQuotes Ltd.

ArrayReverse

Changes the sequence of elements in a one-dimensional array.

```
template<typename T>
bool ArrayReverse(
   T&          array[],          // the source array
   const int   start_index,      // the starting index
   const int   count             // the number of elements
   );
```

Parameters

&array[]

[out] The source array.

start_index

[in] The starting index.

count

[in] The number of array elements participating in the operation.

Return Value

Returns true on successful, or false otherwise.

© 2000-2025, MetaQuotes Ltd.

Compare

Compares the two values, whether one of them is "greater than, less than or equal to" the other one.

A version for comparing two bool values.

```
int Compare(
   const bool  x,          // the first value
   const bool  y           // the second value
   );
```

A version for comparing two char values.

```
int Compare(
   const char  x,          // the first value
   const char  y           // the second value
   );
```

A version for comparing two uchar values.

```
int Compare(
   const uchar  x,         // the first value
   const uchar  y          // the second value
   );
```

A version for comparing two short values.

```
int Compare(
   const short  x,         // the first value
   const short  y          // the second value
   );
```

A version for comparing two ushort values.

```
int Compare(
   const ushort  x,        // the first value
   const ushort  y         // the second value
   );
```

A version for comparing two color values.

```
int Compare(
   const color  x,         // the first value
   const color  y          // the second value
   );
```

A version for comparing two int values.

```
int Compare(
   const int  x,           // the first value
   const int  y            // the second value
   );
```

© 2000-2025, MetaQuotes Ltd.

A version for comparing two uint values.

```
int Compare(
   const uint  x,          // the first value
   const uint  y           // the second value
   );
```

A version for comparing two datetime values.

```
int Compare(
   const datetime  x,      // the first value
   const datetime  y       // the second value
   );
```

A version for comparing two long values.

```
int Compare(
   const long  x,          // the first value
   const long  y           // the second value
   );
```

A version for comparing two ulong values.

```
int Compare(
   const ulong  x,         // the first value
   const ulong  y          // the second value
   );
```

A version for comparing two float values.

```
int Compare(
   const float  x,         // the first value
   const float  y          // the second value
   );
```

A version for comparing two double values.

```
int Compare(
   const double  x,        // the first value
   const double  y         // the second value
   );
```

A version for comparing two string values.

```
int Compare(
   const string  x,        // the first value
   const string  y         // the second value
   );
```

A version for comparing two values of other types.

```
template<typename T>
int Compare(
```

© 2000-2025, MetaQuotes Ltd.

```
   T  x,                  // the first value
   T  y                   // the second value
   );
```

Parameters

x

[in] The first value

y

[in] The second value

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, x is less than y (x<y)
- if the result is equal to zero, x is equal to y (x=y)
- if the result is greater than zero, x is greater than y (x>y)

Note

If the T type is an object that implements the IComparable<T> interface, then the objects will be compared based on its Compare method. In all other cases, 0 is returned.

© 2000-2025, MetaQuotes Ltd.

Equals

Compares two values for equality.

```
template<typename T>
bool Equals(
   T  x,      // the first value
   T  y       // the second value
   );
```

Parameters

x

[in] The first value

y

[in] The second value

Return Value

Returns true if the objects are equal, or false otherwise.

Note

If the T type is an object that implements the IEqualityComparable<T> interface, then the objects will be compared based on its Equals comparison method. The standard comparison for equality is used in all other cases.

© 2000-2025, MetaQuotes Ltd.

GetHashCode

Calculates the hash code value.

A version for working with the bool type.

```
int GetHashCode(
   const bool   value          // value
   );
```

A version for working with the char type.

```
int GetHashCode(
   const char   value          // value
   );
```

A version for working with the uchar type.

```
int GetHashCode(
   const uchar   value         // value
   );
```

A version for working with the short type.

```
int GetHashCode(
   const short   value         // value
   );
```

A version for working with the ushort type.

```
int GetHashCode(
   const ushort   value        // value
   );
```

A version for working with the color type.

```
int GetHashCode(
   const color   value         // value
   );
```

A version for working with the int type.

```
int GetHashCode(
   const int   value           // value
   );
```

A version for working with the uint type.

```
int GetHashCode(
   const uint   value          // value
   );
```

A version for working with the datetime type.

```
int GetHashCode(
```

© 2000-2025, MetaQuotes Ltd.

```
   const datetime   value      // value
   );
```

A version for working with the long type.

```
int GetHashCode(
   const long   value          // value
   );
```

A version for working with the ulong type.

```
int GetHashCode(
   const ulong   value         // value
   );
```

A version for working with the float type.

```
int GetHashCode(
   const float   value         // value
   );
```

A version for working with the double type.

```
int GetHashCode(
   const double   value        // value
   );
```

A version for working with the string type.

```
int GetHashCode(
   const string   value        // value
   );
```

A version for working with other types.

```
template<typename T>
int GetHashCode(
   T   value                   // value
   );
```

Parameters

value

[in] The value for which you want to get the hash code.

Return Value

Returns the hash code.

Note

If the T type is an object that implements the IEqualityComparable<T> interface, then the hash code will be obtained based on its HashCode method. In all other cases, the hash code will be calculated as the hash value of the value type name.

File Operations

This section contains the technical details of the file operations classes and descriptions of the corresponding components of the MQL5 standard library.

The file operations classes will save time in developing applications using file input/output operations.

The MQL5 Standard Library (in terms of file operations) is located in the working directory of the terminal in the Include\Files folder.

Class	Description
CFile	Base file operations class
CFileBin	Binary file operations class
CFileTxt	Text file operations class

© 2000-2025, MetaQuotes Ltd.

CFile

CFile is a base class for CFileBin and CFileTxt classes.

Description

CFile class provides the simplified access to MQL5 API file and folder functions for all of its descendants.

Declaration

```
class CFile: public CObject
```

Title

```
#include <Files\File.mqh>
```

Inheritance hierarchy

CObject

CFile

Direct descendants

CFileBin, CFilePipe, CFileTxt

Class Methods by Groups

Attributes	
Handle	Gets file handle
Filename	Gets file name
Flags	Gets file flags
SetUnicode	Sets/clears the FILE_UNICODE flag
SetCommon	Sets/clears the FILE_COMMON flag
General methods for files	
Open	Opens file
Close	Closes file
Delete	Deletes file
IsExist	Checks file for existence
Copy	Copies file
Move	Renames/moves file
Size	Gets file size
Tell	Gets current file position

© 2000-2025, MetaQuotes Ltd.

Attributes	
Seek	Sets current file position
Flush	Flushes data on disk
IsEnding	Checks file for end
IsLineEnding	Checks line for end
General methods for folders	
FolderCreate	Creates folder
FolderDelete	Deletes folder
FolderClean	Clears folder
Files and folders search methods	
FileFindFirst	Begins file search
FileFindNext	Continues file search
FileFindClose	Closes search handle

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

© 2000-2025, MetaQuotes Ltd.

Handle

Gets file handle of the opened file.

```
int  Handle()
```

Return Value

Handle of the opened file assigned to the class instance. If there is no file assigned, it returns -1.

© 2000-2025, MetaQuotes Ltd.

FileName

Gets file name of the opened file.

```
string  FileName()
```

Return Value

File name of the opened fil, assigned to the class instance. If there is no file assigned, it returns "".

© 2000-2025, MetaQuotes Ltd.

Flags

Gets flags of the opened file.

```
int  Flags()
```

Return Value

Flags of the opened file assigned to the class instance.

© 2000-2025, MetaQuotes Ltd.

SetUnicode

Sets/clears the FILE_UNICODE flag.

```
void  SetUnicode(
   bool  unicode      // flag value
   )
```

Parameters

unicode

[in] New value for FILE_UNICODE flag.

Note

The result of string operations is dependent on the FILE_UNICODE flag. If it is false, the ANSI codes are used (one byte symbols). If it set, the UNICODE codes are used (two byte symbols). If the file is already opened, the flag cannot be changed.

© 2000-2025, MetaQuotes Ltd.

SetCommon

Sets/clears the FILE_COMMON flag.

```
void  SetCommon(
   bool  common      // flag value
   )
```

Parameters

common

[in] New value for FILE_COMMON flag.

Note

The FILE_COMMON flag determines the current working folder. If it is false, the local terminal folder is used as the current working folder. If it is true, the common data folder is used as the current working folder. If the file is already opened, the flag cannot be changed.

© 2000-2025, MetaQuotes Ltd.

Open

Opens the specified file and, if it successful, assigns it to the class instance.

```
int  Open(
   const string  file_name,        // file name
   int           flags,            // flags
   short         delimiter=9       // separator
   )
```

Parameters

file_name

[in] File name to open.

flags

[in] File open flags.

delimiter=9

[in] CSV file separator.

Return Value

Handle of the opened file.

Note

The working folder is dependent on flag that was previously set/reset using the SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

Close

Closes file assigned to the class instance.

```
void  Close()
```

© 2000-2025, MetaQuotes Ltd.

Delete

Deletes the file assigned to the file instance.

```
void  Delete()
```

Delete

Deletes the specified file.

```
void  Delete(
   const string  file_name      // file name
   )
```

Parameters

file_name

[in] File name of the file to delete.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

IsExist

Checks file for existence

```
bool  IsExist(
   const string  file_name      // file name
   )
```

Parameters

file_name

[in] Name of the file to check.

Return Value

true - file exists.

© 2000-2025, MetaQuotes Ltd.

Copy

Copies a file.

```
bool  Copy(
   const string  src_name,      // file name
   int           src_flag,      // flag
   const string  dst_name,      // file name
   int           dst_flags      // flags
   )
```

Parameters

src_name

[in] Name of a source file.

src_flag

[in] Flags of a source file (only FILE_COMMON is used).

dst_name

[in] File name of the destination file.

dst_flags

[in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

Return Value

true - successful, false - cannot copy the file.

© 2000-2025, MetaQuotes Ltd.

Move

Renames/moves file.

```
bool  Move(
   const string  src_name,      // file name
   int           src_flag,      // flag
   const string  dst_name,      // file name
   int           dst_flags      // flags
   )
```

Parameters

src_name

[in] Source file name.

src_flag

[in] Source file flags (only FILE_COMMON is used).

dst_name

[in] File name of the destination file.

dst_flags

[in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

Return Value

true - successful, false - failed to move/rename the file.

© 2000-2025, MetaQuotes Ltd.

Size

Gets file size in bytes.

```
ulong  Size()
```

Return Value

file size in bytes. If there is no file assigned, it returns ULONG_MAX.

© 2000-2025, MetaQuotes Ltd.

Tell

Gets the current file pointer's position.

```
ulong  Tell()
```

Return Value

the current file position. If there no file assigned, it returns ULONG_MAX.

© 2000-2025, MetaQuotes Ltd.

Seek

Sets file pointer's position.

```
void  Seek(
   long                offset,     // offset
   ENUM_FILE_POSITION  origin      // origin
   )
```

Parameters

offset

[in] File offset in bytes (can be negative).

origin

[in] Origin of the offset.

Return Value

true - successful, false - cannot change the file pointer.

© 2000-2025, MetaQuotes Ltd.

Flush

Flushes all of the file input/output buffer data on disk.

```
void  Flush()
```

© 2000-2025, MetaQuotes Ltd.

IsEnding

Checks file for end during the file read operations.

```
bool  IsEnding()
```

Return Value

true - end of file has been achieved during read or seek operation.

© 2000-2025, MetaQuotes Ltd.

IsLineEnding

Checks a text file for end during the file read operations.

```
bool  IsLineEnding()
```

Return Value

true - end of line has been achieved during a txt or csv file read operation (CR-LF chars).

© 2000-2025, MetaQuotes Ltd.

FolderCreate

Creates new folder.

```
bool  FolderCreate(
   const string  folder_name      // folder name
   )
```

Parameters

folder_name

[in] Name of the folder to create. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, false - cannot create the folder.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

FolderDelete

Deletes specified folder.

```
bool  FolderDelete(
   const string  folder_name      // folder name
   )
```

Parameters

folder_name

[in] Name of the folder to delete. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, false - cannot delete the folder.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

FolderClean

Cleans specified folder.

```
bool  FolderClean(
   const string  folder_name      // folder name
   )
```

Parameters

folder_name

[in] Name of the folder to clean. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, and false - cannot change the folder.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

FileFindFirst

Begins file search using the specified filter.

```
int  FileFindFirst(
   const string  filter,         // search filter
   string&       file_name       // reference
   )
```

Parameters

filter

[in] Search filter.

file_name

[out] The reference to the string the name of the first found file is placed into in case of success.

Return Value

The handle that can be used for further file search using FileFindNext, or INVALID_HANDLE if there are no files corresponding to the filter.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.

© 2000-2025, MetaQuotes Ltd.

FileFindNext

Continues file search started by the FileFindFirst() method.

```
bool  FileFindNext(
   int      search_handle,     // search handle
   string&  file_name          // reference
   )
```

Parameters

search_handle

[in] Search handle returned by FileFindFirst() method.

file_name

[in] The reference to the string the name of the found file is placed into if successful.

Return Value

true - successful, false - there are no files corresponding to the filter.

© 2000-2025, MetaQuotes Ltd.

FileFindClose

Closes search handle.

```
void  FileFindClose(
   int  search_handle      // search handle
   )
```

Parameters

search_handle

[in] Search handle returned by FileFindFirst() method.

© 2000-2025, MetaQuotes Ltd.

CFileBin

CFileBin is a class for simplified access to binary files.

Description

CFileBin class provides access to binary files.

Declaration

```
class CFileBin: public CFile
```

Title

```
#include <Files\FileBin.mqh>
```

Inheritance hierarchy

CObject
  CFile
    CFileBin

Class Methods by Groups

Open methods	
Open	Opens a binary file
Write methods	
WriteChar	Writes char or uchar type variable
WriteShort	Writes short or ushort type variable
WriteInteger	Writes int or uint type variable
WriteLong	Writes long or ulong type variable
WriteFloat	Writes float type variable
WriteDouble	Writes double type variable
WriteString	Writes string type variable
WriteCharArray	Writes an array of char or uchar type variables
WriteShortArray	Writes an array of short or ushort type variables
WriteIntegerArray	Writes an array of int or uint type variables
WriteLongArray	Writes an array of long or ulong type variables
WriteFloatArray	Writes an array of float variables
WriteDoubleArray	Writes an array of double type variables
WriteObject	Writes data of the CObject class inheritor instance

© 2000-2025, MetaQuotes Ltd.

Open methods	
Read methods	
ReadChar	Reads char or uchar type variable
ReadShort	Reads short or ushort type variable
ReadInteger	Reads int or uint type variable
ReadLong	Reads long or ulong type variable
ReadFloat	Reads float type variable
ReadDouble	Reads double type variable
ReadString	Reads string type variable
ReadCharArray	Reads an array of char or uchar type variables
ReadShortArray	Reads an array of short or ushort type variables
ReadIntegerArray	Reads an array of int or uint type variables
ReadLongArray	Reads an array of long or ulong type variables
ReadFloatArray	Reads an array of float type variables
ReadDoubleArray	Reads an array of double type variables
ReadObject	Reads data of the CObject class inheritor instance

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CFile

Handle, FileName, Flags, SetUnicode, SetCommon, Open, Close, Delete, Size, Tell, Seek, Flush, IsEnding, IsLineEnding, Delete, IsExist, Copy, Move, FolderCreate, FolderDelete, FolderClean, FileFindFirst, FileFindNext, FileFindClose

© 2000-2025, MetaQuotes Ltd.

Open

Opens the specified binary file and, if successful, assigns it to the class instance.

```
int  Open(
   const string  file_name,      // file name
   int           flags           // flags
   )
```

Parameters

file_name

[in] File name of the file to open.

flags

[in] File open flags (the FILE_BIN flag is set forcibly).

Return Value

Handle of the opened file.

© 2000-2025, MetaQuotes Ltd.

WriteChar

Writes char or uchar type variable to file.

```
uint  WriteChar(
   char  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteShort

Writes short or ushort type variable to file.

```
uint  WriteShort(
   short  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteInteger

Writes int or uint type variable to file.

```
uint  WriteInteger(
   int  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteLong

Writes long or ulong type variable to file.

```
uint  WriteLong(
   long  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteFloat

Writes float type variable to file.

```
uint  WriteFloat(
   float  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteDouble

Writes double type variable to file.

```
uint  WriteDouble(
   double  value      // value
   )
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteString

Writes string type variable to file.

```
uint  WriteString(
   const string  value      // value
   )
```

Parameters

value

[in] String to write.

Return Value

Number of bytes written.

WriteString

Writes string type variable to file.

```
uint  WriteString(
   const string  value,     // value
   int           size       // size
   )
```

Parameters

value

[in] String to write.

size

[in] Number of bytes to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteCharArray

Writes an array of char or uchar type variables to file.

```
uint  WriteCharArray(
   char&  array[],            // array
   int    start_item=0,       // start element
   int    items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteShortArray

Writes an array of short or ushort type variables to file.

```
uint  WriteShortArray(
   short&  array[],            // array
   int     start_item=0,       // start element
   int     items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteIntegerArray

Writes an array of int or uint type variables to file.

```
uint  WriteIntegerArray(
   int&  array[],             // array
   int   start_item=0,        // start element
   int   items_count=-1       // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteLongArray

Writes an array of long or ulong type variables to file.

```
uint  WriteLongArray(
   long&  array[],            // array
   int    start_item=0,       // start element
   int    items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteFloatArray

Writes an array of float type variables to file.

```
uint  WriteFloatArray(
   float&  array[],            // array
   int     start_item=0,       // start element
   int     items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteDoubleArray

Writes an array of double type variables to file.

```
uint  WriteDoubleArray(
   double&  array[],             // array to write
   int      start_item=0,        // start element
   int      items_count=-1       // number of elements
   )
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

WriteObject

Writes data of the CObject class inheritor instance to file.

```
bool  WriteObject(
   CObject*  object      // reference to the object
   )
```

Parameters

object

[in] Reference to the CObject class inheritor instance to write.

Return Value

true - successful, false - cannot write the data.

© 2000-2025, MetaQuotes Ltd.

ReadChar

Reads char or uchar type variable from file.

```
bool  ReadChar(
   char&  value      // flag value
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadShort

Reads short or ushort type variable from file.

```
bool  ReadShort(
   short&  value
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadInteger

Reads int or uint type variable from file.

```
bool  ReadInteger(
   int&  value      // variable
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadLong

Reads long or ulong type variable from file.

```
bool  ReadLong(
   long&  value
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadFloat

Reads float type variable from file.

```
bool  ReadFloat(
   float&  value      // variable
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadDouble

Reads double type variable from file.

```
bool  ReadDouble(
   double&  value
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadString

Reads string type variable from file.

```
bool  ReadString(
   string&  value      // string
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadString

Reads string type variable from file.

```
bool  ReadString(
   string&  value
   )
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadCharArray

Reads an array of char or uchar type variables from file.

```
bool  ReadCharArray(
   char&  array[],            // array
   int    start_item=0,       // start element
   int    items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadShortArray

Reads an array of short or ushort type variables from file.

```
bool  ReadShortArray(
   short&  array[],            // array
   int     start_item=0,       // start element
   int     items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadIntegerArray

Reads an array of int or uint type variables from file.

```
bool  ReadIntegerArray(
   int&  array[],             // array
   int   start_item=0,        // start element
   int   items_count=-1       // number of elements
   )
```

Parameters

array[]

[in] Reference to the target array of type int or uint.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadLongArray

Reads an array of long or ulong type variables from file.

```
bool  ReadLongArray(
   long&  array[],            // array
   int    start_item=0,       // start element
   int    items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadFloatArray

Reads an array of float type variables from file.

```
bool  ReadFloatArray(
   float&  array[],            // array
   int     start_item=0,       // start element
   int     items_count=-1      // number of elements
   )
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadDoubleArray

Reads an array of double type variables from file.

```
bool  ReadDoubleArray(
   double&  array[],             // array
   int      start_item=0,        // start element
   int      items_count=-1       // number of elements
   )
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

ReadObject

Reads data of the CObject class inheritor instance from file.

```
bool  ReadObject(
   CObject*  object      // pointer
   )
```

Parameters

object

[in] Pointer to the CObject class inheritor instance to read.

Return Value

true - successful, false - cannot read the data.

© 2000-2025, MetaQuotes Ltd.

CFileTxt

CFileTxt is a class for simplified access to text files.

Description

CFileTxt class provides access to text files.

Declaration

```
class CFileTxt: public CFile
```

Title

```
#include <Files\FileTxt.mqh>
```

Inheritance hierarchy

CObject
  CFile
    CFileTxt

Class Methods by Groups

Open methods	
Open	Opens a text file
Write methods	
WriteString	Writes string type variable
Read methods	
ReadString	Reads string type variable

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CFile

Handle, FileName, Flags, SetUnicode, SetCommon, Open, Close, Delete, Size, Tell, Seek, Flush, IsEnding, IsLineEnding, Delete, IsExist, Copy, Move, FolderCreate, FolderDelete, FolderClean, FileFindFirst, FileFindNext, FileFindClose

© 2000-2025, MetaQuotes Ltd.

Open

Opens the specified text file and, if successful, assigns it to the class instance.

```
int  Open(
   const string  file_name,      // file name
   int           flags           // flags
   )
```

Parameters

file_name

[in] File name to open.

flags

[in] File open flags (FILE_TXT flag is forcibly set).

Return Value

Opened file handle.

© 2000-2025, MetaQuotes Ltd.

WriteString

Writes string type variable to file.

```
uint  WriteString(
   const string  value      // string
   )
```

Parameters

value

[in] String to write.

Return Value

Number of bytes written.

© 2000-2025, MetaQuotes Ltd.

ReadString

Reads string type variable from file.

```
string  ReadString()
```

Return Value

String which has been read.

© 2000-2025, MetaQuotes Ltd.

String operations

This section contains the technical details of the string operations classes and descriptions of the corresponding components of the MQL5 standard library.

The use of string operations classes will save time in developing applications processing textual data.

The MQL5 standard library (in terms of string operations) is located in the working directory of the terminal in the Include\Strings folder.

Class	Description
CString	Class for string operations

© 2000-2025, MetaQuotes Ltd.

CString

CString is a class for simplified access to the variables of string type.

Description

CString class provides simplified access to MQL5 API functions working with string variables.

Declaration

```
class CString: public CObject
```

Title

```
#include <Strings\String.mqh>
```

Inheritance hierarchy

CObject

CString

Class Methods by Groups

Data access methods	
Str	Gets a string
Len	Gets length of a string
Copy	Copies a string copy
Fill methods	
Fill	Fills a string
Assign	Assigns a string
Append	Appends a string
Insert	Inserts a string
Compare methods	
Compare	Compares strings
CompareNoCase	Performs a case insensitive string comparison
Substring methods	
Left	Gets a substring from the left
Right	Gets a substring from the right
Mid	Gets a substring from the middle
Trim/delete methods	

© 2000-2025, MetaQuotes Ltd.

Data access methods	
Trim	Trims a string from the left and from the right
TrimLeft	Trims a string from the left
TrimRight	Trims a string from the right
Clear	Clears a string
Convert methods	
ToUpper	Converts a string to uppercase.
ToLower	Converts a string to lowercase.
Reverse	Reverses a string
Search methods	
Find	Searches a substring left to right
FindRev	Searches a substring right to left
Remove	Deletes a substring
Replace	Replaces a substring

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type

© 2000-2025, MetaQuotes Ltd.

Str

Gets a string.

```
string  Str() const;
```

Return Value

Copy of a string.

© 2000-2025, MetaQuotes Ltd.

Len

Gets length of a string.

```
uint  Len() const;
```

Return Value

Length of a string.

© 2000-2025, MetaQuotes Ltd.

Copy

Copies a string by reference.

```
void  Copy(
   string&  copy      // reference
   ) const;
```

Parameters

copy

[in] Reference to a data string.

Copy

Copies a string to the CString class instance.

```
void  Copy(
   CString*  copy      // pointer
   ) const;
```

Parameters

copy

[in] Pointer to CString class instance for data.

© 2000-2025, MetaQuotes Ltd.

Fill

Fills a string with specified char.

```
bool  Fill(
   short  character      // character
   )
```

Parameters

character

[in] Character for filling a string.

Return Value

true - successful, false - cannot fill a string.

© 2000-2025, MetaQuotes Ltd.

Assign

Assigns a string.

```
void  Assign(
   const string  str      // string
   )
```

Parameters

str

[in] String to assign.

Assign

Assigns a string from the CString class instance.

```
void  Assign(
   CString*  str      // pointer
   )
```

Parameters

str

[in] Pointer to the CString class instance to assign.

© 2000-2025, MetaQuotes Ltd.

Append

Appends a string.

```
void  Append(
   const string  str      // string
   )
```

Parameters

str

[in] String to append.

Append

Appends a string from the CString class instance.

```
void  Append(
   CString*  string      // pointer
   )
```

Parameters

string

[in] Pointer to the CString class instance to append.

© 2000-2025, MetaQuotes Ltd.

Insert

Inserts a string to the specified position.

```
uint  Insert(
   uint          pos,     // position
   const string  str      // string
   )
```

Parameters

pos

[in] Insert position.

str

[in] String to insert.

Return Value

Resulted string length.

Insert

Inserts a string to the specified position from the CString class instance.

```
uint  Insert(
   uint      pos,     // position
   CString*  str      // pointer
   )
```

Parameters

pos

[in] Position to insert into.

str

[in] Pointer to the CString class instance to insert.

Return Value

Resulted string length.

© 2000-2025, MetaQuotes Ltd.

Compare

Compares to a string.

```
int  Compare(
   const string  str      // string
   ) const;
```

Parameters

str

[in] String to compare.

Return Value

0 - both strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.

Compare

Compares to a CString class instance string.

```
int  Compare(
   CString*  str      // pointer
   ) const;
```

Parameters

str

[in] Pointer to CString class instance to compare.

Return Value

0 - strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.

© 2000-2025, MetaQuotes Ltd.

CompareNoCase

Performs a case insensitive string comparison.

```
int  CompareNoCase(
   const string  str      // string
   ) const;
```

Parameters

str

[in] String to compare.

Return Value

0 - strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.

CompareNoCase

Compares a string (case insensitive) to a CString class instance string.

```
int  CompareNoCase(
   CString*  str      // pointer
   ) const;
```

Parameters

str

[in] Pointer to CString class instance to compare.

Return Value

0 - if strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.

© 2000-2025, MetaQuotes Ltd.

Left

Gets a substring of a specified length from the beginning of a string.

```
string  Left(
   uint  count      // length
   )
```

Parameters

count

[in] Substring length.

Return Value

Resulted substring.

© 2000-2025, MetaQuotes Ltd.

Right

Gets a substring of a specified length from the end of a string.

```
string  Right(
   uint  count       // length
   )
```

Parameters

count

[in] Substring length.

Return Value

Resulted substring.

© 2000-2025, MetaQuotes Ltd.

Mid

Gets a substring of a specified length from a specified string position.

```
string  Mid(
   uint  pos,        // position
   uint  count       // length
   )
```

Parameters

pos

[in] Substring position.

count

[in] Substring length.

Return Value

Resulted substring.

© 2000-2025, MetaQuotes Ltd.

Trim

Removes all characters within a set (as well as ' ','\t','\r','\n') at both ends of a string from this string.

```
int  Trim(
   const string  targets      // set
   )
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of removed characters.

Example:

```
//--- example for CString::Trim
#include <Strings\String.mqh>
//---
void OnStart()
  {
   CString str;
   //---
   str.Assign("   \t\tABCD\r\n");
   printf("Source string '%s'",str.Str());
   //---
   str.Trim("DA-DA-DA");
   printf("Result string '%s'",str.Str());
  }
```

© 2000-2025, MetaQuotes Ltd.

TrimLeft

Removes all characters within a set (as well as ' ','\t','\r','\n') at the beginning of a string from this string.

```
int  TrimLeft(
   const string  targets      // set
   )
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of characters removed.

© 2000-2025, MetaQuotes Ltd.

TrimRight

Removes all characters within a set (as well as ' ','\t','\r','\n') at the end of a string from this string.

```
int  TrimRight(
   const string  targets      // set
   )
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of characters removed.

© 2000-2025, MetaQuotes Ltd.

Clear

Clears a string.

```
bool  Clear()
```

Return Value

true - successful, false - cannot clear a string.

© 2000-2025, MetaQuotes Ltd.

ToUpper

Converts all string characters to uppercase.

```
bool  ToUpper()
```

Return Value

true - successful, false - cannot convert to uppercase.

© 2000-2025, MetaQuotes Ltd.

ToLower

Converts all string characters to lowercase.

```
bool  ToLower()
```

Return Value

true - successful, false - cannot convert to lowercase.

© 2000-2025, MetaQuotes Ltd.

Reverse

Reverses a string (initial and final characters exchange places pair-wise).

```
void  Reverse()
```

© 2000-2025, MetaQuotes Ltd.

Find

Searches for the first match of a substring from a specified position.

```
int  Find(
   uint           start,          // position
   const string   substring       // substring
   ) const;
```

Parameters

start

[in] Initial position for substring search.

substring

[in] Sample substring to search for.

Return Value

The index of the first match of a substring (-1 - substring is not found).

© 2000-2025, MetaQuotes Ltd.

FindRev

Searches for the last match of a substring.

```
int  FindRev(
   const string  substring      // substring
   ) const;
```

Parameters

substring

[in] Sample substring to search for.

Return Value

The index of the last match of a substring (-1 - substring is not found).

© 2000-2025, MetaQuotes Ltd.

Remove

Removes all substring matches.

```
uint  Remove(
   const string  substring      // substring
   )
```

Parameters

substring

[in] Sample substring to search for.

Return Value

Number of substring removals.

© 2000-2025, MetaQuotes Ltd.

Replace

Replaces all substring matches.

```
uint  Replace(
   const string  substring,      // substring
   const string  newstring       // substring
   )
```

Parameters

substring

[in] Sample substring to search for.

newstring

[in] Sample substring to replace with.

Return Value

Number of substring replacements.

Graphic Objects

This section contains the technical details of working with classes of graphical objects and a description of the relevant components of the MQL5 Standard Library.

The use of classes of graphical objects will save time when creating custom programs (scripts, Expert Advisors).

MQL5 Standard Library (in terms of graphical objects) is located in the working directory of the terminal in the Include\ChartObjects folder.

Class/Group	Description
CChartObject	Base class of a graphic object
Lines	Group classes "Lines"
Channels	Group classes "Channels"
Gann Tools	Group classes "Gann"
Fibonacci Tools	Group classes "Fibonacci"
Elliott Tools	Group classes "Elliott"
Shapes	Group classes "Shapes"
Arrows	Group classes "Arrows"
Controls	Group classes "Controls"

© 2000-2025, MetaQuotes Ltd.

CChartObject

CChartObject is a base class for the classes of chart graphical objects of the Standard MQL5 library.

Description

CChartObject class provides the simplified access to MQL5 API functions for all of its descendants.

Declaration

```
class CChartObject : public CObject
```

Title

```
#include <ChartObjects\ChartObject.mqh>
```

Inheritance hierarchy

CObject

CChartObject

Direct descendants

CChartObjectArrow, CChartObjectBitmap, CChartObjectBmpLabel, CChartObjectCycles, CChartObjectElliottWave3, CChartObjectEllipse, CChartObjectFiboArc, CChartObjectFiboFan, CChartObjectFiboTimes, CChartObjectHLine, CChartObjectRectangle, CChartObjectSubChart, CChartObjectText, CChartObjectTrend, CChartObjectTriangle, CChartObjectVLine

Class Methods by Groups

Attributes	
ChartId	Gets the ID of the chart a graphical object belongs to
Window	Gets the number of a chart window where a graphical object is located
Name	Gets/sets the name of a graphical object
NumPoints	Gets the number of anchor points
Assign	
Attach	Binds a chart graphical object
SetPoint	Sets the anchor point parameters
Delete	
Delete	Deletes a chart graphical object
Detach	Detaches a chart graphical object
Shift	
ShiftObject	The relative object shift

© 2000-2025, MetaQuotes Ltd.

Attributes	
ShiftPoint	The relative object point shift
Object properties	
Time	Gets/sets the time coordinates of an object point
Price	Gets/sets the price coordinate of an object point
Color	Gets/sets the color of the object
Style	Gets/sets the object line style
Width	Gets/sets the object line width
BackGround	Gets/sets the flag of drawing an object in the background
Selected	Gets/sets the "selected" flag of a graphical object
Selectable	Gets/sets the selectable object flag
Description	Gets/sets the text of the object
Tooltip	Gets/sets the tooltip of the object
Timeframes	Gets/sets the mask of the object visibility flags
Z_Order	Gets/sets the graphical object priority for receiving an event of mouse clicking on a chart
CreateTime	Gets the time of the object creation
Object level properties	
LevelsCount	Gets/sets the number of object levels
LevelColor	Gets/sets the level line color
LevelStyle	Gets/sets the level line style
LevelWidth	Gets/sets the level line width
LevelValue	Gets/sets the level
LevelDescription	Gets/sets the level text
Access to API MQL5 functions	
GetInteger	Gets the value of the object property
SetInteger	Sets the value of the object property
GetDouble	Gets the value of the object property
SetDouble	Sets the value of the object property
GetString	Gets the value of the object property
SetString	Sets the value of the object property
Input/Output	

© 2000-2025, MetaQuotes Ltd.

Attributes	
virtual Save	Virtual method of writing to a file
virtual Load	Virtual method of reading from a file
virtual Type	Virtual method of identification

Methods inherited from class CObject

Prev, Prev, Next, Next, Compare

© 2000-2025, MetaQuotes Ltd.

ChartId

Gets the ID of the chart a graphical object belongs to.

```
long  ChartId() const
```

Return Value

ID of the chart where the graphical object is located. If there is no bound object, it returns -1.

Example:

```
//--- example for CChartObject::ChartId
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get chart idintifier of chart object
   long chart_id=object.ChartId();
  }
```

© 2000-2025, MetaQuotes Ltd.

Window

Gets the index of the chart window where the graphical object is located.

```
int  Window() const
```

Return Value

The number of the chart window where the graphical object is located (0 - main window). If there is no bound object, it returns -1.

Example:

```
//--- example for CChartObject::Window
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get window of chart object
   int window=object.Window();
  }
```

© 2000-2025, MetaQuotes Ltd.

Name (Get Method)

Gets the name of the graphical object.

```
string  Name() const
```

Return Value

Name of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Name (Set Method)

Sets the name of the graphical object.

```
bool  Name(
   string  name      // new name
   )
```

Parameters

name

[in] The new name of the graphical object.

Return Value

true - success, false - cannot change the name.

Example:

```
//--- example for CChartObject::Name
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get name of chart object
   string object_name=object.Name();
   if(object_name!="MyChartObject")
     {
     //--- set name of chart object
     object.Name("MyChartObject");
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

NumPoints

Gets the number of anchor points of a graphical object.

```
int  NumPoints() const
```

Return Value

Number of points linking a graphical object attached to an instance of the class. If there is no attached object, it returns 0.

Example:

```
//--- example for CChartObject::NumPoints
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get points count of chart object
   int points=object.NumPoints();
  }
```

© 2000-2025, MetaQuotes Ltd.

Attach

Attaches a graphical object to an instance of the class.

```
bool  Attach(
   long     chart_id,      // chart ID
   string   name,          // name of the object
   int      window,        // chart window
   int      points         // number of points
   )
```

Parameters

chart_id

[out] Chart identifier.

name

[in] Name of the graphical object.

window

[in] Chart window number (0 - main window).

points

[in] Number of anchor points of the graphical object.

Return Value

true - success, false - cannot bind the object.

Example:

```
//--- example for CChartObject::Attach
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- attach chart object
   if(!object.Attach(ChartID(),"MyObject",0,2))
     {
      printf("Object attach error");
      return;
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

SetPoint

Sets new coordinates of the specified anchor point of the graphical object.

```
bool  SetPoint(
   int       point,          // point number
   datetime  new_time,       // time coordinate
   double    new_price       // price coordinate
   )
```

Parameters

point

[in] Number of the graphical object anchor point.

new_time

[in] New value for the time coordinate of the specified anchor point.

new_price

[in] New value for price coordinate of the specified anchor point.

Return Value

true - success, false - cannot change coordinates of the point.

Example:

```
//--- example for CChartObject::SetPoint
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   double       price;
   //---
   if(object.NumPoints()>0)
     {
      //--- set point of chart object
      object.SetPoint(0,CurrTime(),price);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Delete

Removes an attached graphical object from the chart.

```
bool  Delete()
```

Return Value

true - success, false - cannot remove the object.

Example:

```
//--- example for CChartObject::Delete
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- detach chart object
   if(!object.Delete())
     {
      printf("Object delete error");
      return;
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Detach

Detaches the graphical object.

```
void  Detach()
```

Return Value

None.

Example:

```
//--- example for CChartObject::Detach
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- detach chart object
   object.Detach();
  }
```

© 2000-2025, MetaQuotes Ltd.

ShiftObject

Shifts a graphical object.

```
bool  ShiftObject(
   datetime  d_time,      // increment of time coordinate
   double    d_price      // increment of price coordinate
   )
```

Parameters

d_time

[in] Increment of the time coordinate of all anchor points.

d_price

[in] Increment of the price coordinate of all anchor points.

Return Value

true - success, false - cannot shift the object.

Example:

```
//--- example for CChartObject::ShiftObject
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   datetime     d_time;
   double       d_price;
   //--- shift chart object
   object.ShiftObject(d_time,d_price);
  }
```

© 2000-2025, MetaQuotes Ltd.

ShiftPoint

Shifts a specified anchor point of the graphical object.

```
bool  ShiftPoint(
   int       point,       // point number
   datetime  d_time,      // increment of time coordinate
   double    d_price      // increment of price coordinate
   )
```

Parameters

point

[in] Number of a graphical object anchor point.

d_time

[in] Increment of the time coordinate of the specified point.

d_price

[in] Increment of the price coordinate of the specified point.

Return Value

true - success, false - cannot shift the point.

Example:

```
//--- example for CChartObject::ShiftPoint
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   datetime     d_time;
   double       d_price;
   //---
   if(object.NumPoints()>0)
     {
      //--- shift point of chart object
      object.ShiftPoint(0,d_time,d_price);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Time (Get Method)

Gets the time coordinate of the specified anchor point of a graphical object.

```
datetime  Time(
   int  point      // point number
   ) const
```

Parameters

point

[in] Number of a graphical object anchor point.

Return Value

Time coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns 0.

Time (Set Method)

Sets the time coordinate of the specified anchor point of a graphical object.

```
bool  Time(
   int       point,         // point number
   datetime  new_time       // time
   )
```

Parameters

point

[in] Number of a graphical object anchor point.

new_time

[in] New value for the time coordinate of the specified graphical object anchor point.

Return Value

true - success, false - cannot change the time coordinate.

Example:

```
//--- example for CChartObject::Time
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.NumPoints();i++)
     {
      //--- get time of the chart object point
      datetime point_time=object.Time(i);
      if(point_time==0)
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set time of the chart object point
          object.Time(i,TimeCurrent());
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

Price (Get Method)

Gets the price coordinate of the specified anchor point of a graphical object.

```
double  Price(
   int  point      // point number
   ) const
```

Parameters

point

[in] Number of a graphical object anchor point.

Return Value

Price coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns EMPTY_VALUE.

Price (Set Method)

Sets the price coordinate of the specified anchor point of a graphical object.

```
bool  Price(
   int     point,          // point number
   double  new_price       // price
   )
```

Parameters

point

[in] Number of a graphical object anchor point.

new_price

[in] New value for the price coordinate of the specified graphical object anchor point.

Return Value

true - success, false - cannot change the price coordinate.

Example:

```
//--- example for CChartObject::Price
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   double       price;
   //---
   for(int i=0;i<object.NumPoints();i++)
     {
      //--- get price of the chart object point
      double point_price=object.Price(i);
```

© 2000-2025, MetaQuotes Ltd.

```
      if(point_price!=price)
        {
         //--- set price for the chart object point
         object.Price(i,price);
        }
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Color (Get Method)

Gets the line color of the graphical object.

```
color  Color() const
```

Return Value

Line color of the graphical object attached to the class instance. If there is no object attached, it returns CLR_NONE.

Color (Set Method)

Sets the line color of the graphical object.

```
bool  Color(
   color  new_color      // new color
   )
```

Parameters

new_color

[in] New value of a graphical object line color.

Return Value

true - success, false - cannot change the color.

Example:

```
//--- example for CChartObject::Color
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get color of chart object
   color object_color=object.Color();
   if(object_color!=clrRed)
     {
     //--- set color of chart object
     object.Color(clrRed);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Style (Get Method)

Gets the line style of the graphical object.

```
ENUM_LINE_STYLE  Style() const
```

Return Value

Line style of the graphical object attached to the class instance. If there is no attached object, it returns WRONG_VALUE.

Style (Set Method)

Sets the line style of the graphical object.

```
bool  Style(
   ENUM_LINE_STYLE  new_style      // style
   )
```

Parameters

new_style

[in] New value of the graphical object line style.

Return Value

true - success, false - cannot change the style.

Example:

```
//--- example for CChartObject::Style
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get style of chart object
   ENUM_LINE_STYLE style=object.Style();
   if(style!=STYLE_SOLID)
     {
      //--- set style of chart object
      object.Style(STYLE_SOLID);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Width (Get Method)

Gets the line width of the graphical object.

```
int  Width() const
```

Return Value

The line width of the graphical object attached to an instance of the class. If there is no attached object, it returns -1.

Width (Set Method)

Sets the line width of the graphical object.

```
bool  Width(
   int  new_width      // thickness
   )
```

Parameters

new_width

[in] New value of the graphical object line width.

Return Value

true - success, false - cannot change the width.

Example:

```
//--- example for CChartObject::Width
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get width of chart object
   int width=object.Width();
   if(width!=1)
     {
      //--- set width of chart object
      object.Width(1);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Background (Get Method)

Gets the flag for drawing a graphical object on the background.

```
bool  Background() const
```

Return Value

Flag for drawing the graphical object, attached to an instance of the class, on the background. If there is no attached object, returns false.

Background (Set Method)

Sets the flag for drawing a graphical object on the background.

```
bool  Background(
   bool  background      // value of the flag
   )
```

Parameters

background

[in] New value of the flag for drawing a graphical object on the background.

Return Value

true - success, false - cannot change the flag.

Example:

```
//--- example for CChartObject::Background
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get background flag of chart object
   bool background_flag=object.Background();
   if(!background_flag)
     {
     //--- set background flag of chart object
     object.Background(true);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Selected (Get Method)

Gets the flag indicating that a graphical object is selected. In other words - if the graphical object is selected or not.

```
bool  Selected() const
```

Return Value

The state that the object, attached to an instance of the class, is selected. If there is no attached object, returns false.

Selected (Set Method)

Sets the flag indicating that the graphical object is selected.

```
bool  Selected(
   bool  selected      // value of the flag
   )
```

Parameters

selected

[in] New value of the flag indicating that a graphical object is selected.

Return Value

true - success, false - cannot change the flag.

Example:

```
//--- example for CChartObject::Selected
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get the "selected" flag of chart object
   bool selected_flag=object.Selected();
   if(selected_flag)
     {
     //--- set the "selected" flag of chart object
     object.Selected(false);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Selectable (Get Method)

Gets the flag indicating an ability of a graphical object to be selected. In other words - if the graphical object can be selected or not.

```
bool  Selectable() const
```

Return Value

Flag indicating the ability of the graphical object, attached to an instance of the class, to be selected. If there is no attached object, returns false.

Selectable (Set Method)

Sets the flag indicating the ability of a graphical object to be selected.

```
bool  Selectable(
   bool  selectable      // value of the flag
   )
```

Parameters

selectable

[in] New value of the flag indicating an ability of a graphical object to be selected.

Return Value

true - success, false - cannot change the flag.

Example:

```
//--- example for CChartObject::Selectable
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get the "selectable" flag of chart object
   bool selectable_flag=object.Selectable();
   if(selectable_flag)
     {
     //--- set the "selectable" flag of chart object
     object.Selectable(false);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Description (Get Method)

Gets a description (text) of a graphical object.

```
string  Description() const
```

Return Value

Description (text) of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Description (Set Method)

Sets the description (text) of the graphical object.

```
bool  Description(
   string  text      // text
   )
```

Parameters

text

[in] New description (text) of a graphical object.

Return Value

true - success, false - cannot change the description (text).

Example:

```
//--- example for CChartObject::Description
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get description of chart object
   string description=object.Description();
   if(description=="")
     {
      //--- set description of chart object
      object.Description("MyObject");
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Tooltip (Get Method)

Gets the tooltip text of a graphical object.

```
string  Tooltip() const
```

Return Value

The text of a tooltip of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Tooltip (Set Method)

Sets the text of the tooltip of a graphical object.

```
bool  Tooltip(
   string  new_tooltip      // new text of a tooltip
   )
```

Parameters

new_tooltip

[in] New text of a graphical object tooltip.

Return Value

true - success, false - cannot change the tooltip.

Note:

If the property is not set, then the tooltip generated automatically by the terminal is shown. A tooltip can be disabled by setting the "\n" (line feed) value.

© 2000-2025, MetaQuotes Ltd.

Timeframes (Get Method)

Gets visibility flags of a graphical object.

```
int  Timeframes() const
```

Return Value

Visibility flags of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

Timeframes (Set Method)

Sets visibility flags of a graphical object.

```
bool  Timeframes(
   int  new_timeframes      // visibility flags
   )
```

Parameters

new_timeframes

[in] New visibility flags of the graphical object.

Return Value

true - success, false - cannot change the flags of visibility.

Example:

```
//--- example for CChartObject::Timeframes
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get timeframes of chart object
   int timeframes=object.Timeframes();
   if(!(timeframes&OBJ_PERIOD_H1))
     {
      //--- set timeframes of chart object
      object.Timeframes(timeframes|OBJ_PERIOD_H1);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Z_Order (Get Method)

Gets the graphical object priority for receiving an event of mouse clicking on a chart (CHARTEVENT_CLICK).

```
long  Z_Order() const
```

Return Value

Priority of a graphical object, attached to the class instance. If there is no object attached, it returns 0.

Z_Order (Set Method)

Sets the graphical object priority for receiving an event of mouse clicking on a chart (CHARTEVENT_CLICK).

```
bool  Z_Order(
   long  value      // graphical object priority
   )
```

Parameters

value

[in] New value of priority of a graphical object for receiving the event CHARTEVENT_CLICK.

Return Value

true - success, false - cannot change the priority.

Note

Z_Order property manages a priority when handling clicks on graphical objects. By setting the value greater than 0 (default value), you can increase the object priority when handling mouse clicks.

© 2000-2025, MetaQuotes Ltd.

CreateTime

Gets the graphical object creation time.

```
datetime  CreateTime() const
```

Return Value

Creation time of the graphical object attached to the instance of the class. If there is no attached object, it returns 0.

Example:

```
//--- example for CChartObject::CreateTime
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get create time of chart object
   datetime create_time=object.CreateTime();
  }
```

© 2000-2025, MetaQuotes Ltd.

LevelsCount (Get Method)

Gets the number of levels of a graphical object.

```
int  LevelsCount() const
```

Return Value

Number of levels of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

LevelsCount (Set Method)

Sets the number of levels of the graphical object.

```
bool  LevelsCount(
   int  levels      // number of levels
   )
```

Parameters

levels

[in] The new number of levels of the graphical object.

Return Value

true - success, false - cannot change the number of levels.

Example:

```
//--- example for CChartObject::LevelsCount
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get levels count of chart object
   int levels_count=object.LevelsCount();
   //--- set levels count of chart object
   object.LevelsCount(levels_count+1);
  }
```

© 2000-2025, MetaQuotes Ltd.

LevelColor (Get Method)

Gets the line color of the specified level of a graphical object.

```
color  LevelColor(
   int  level      // level number
   ) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line color of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns CLR_NONE.

LevelColor (Set Method)

Sets the line color of the specified level of the graphical object.

```
bool  LevelColor(
   int    level,          // level number
   color  new_color       // new color
   )
```

Parameters

level

[in] Number of graphical object level.

new_color

[in] New line color of the specified level of a graphical object.

Return Value

true - success, false - cannot change the color.

Example:

```
//--- example for CChartObject::LevelColor
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- get level color of chart object
      color level_color=object.LevelColor(i);
      if(level_color!=clrRed)
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set level color of chart object
          object.LevelColor(i,clrRed);
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

LevelStyle (Get Method)

Gets the line style of the specified level of a graphical object.

```
ENUM_LINE_STYLE  LevelStyle(
   int  level      // level number
   ) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line style of the specified level of the graphical object attached to an instance of the class. If there is no attached object or the object does not have the specified level, it returns WRONG_VALUE.

LevelStyle (Set Method)

Sets the line style of the specified level of the graphic object.

```
int  LevelStyle(
   int               level,     // level number
   ENUM_LINE_STYLE   style      // line style
   )
```

Parameters

level

[in] Number of graphical object level.

style

[in] New line style of the specified level of a graphical object.

Return Value

true - success, false - cannot change the style.

Example:

```
//--- example for CChartObject::LevelStyle
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- get level style of chart object
      ENUM_LINE_STYLE level_style=object.LevelStyle(i);
      if(level_style!=STYLE_SOLID)
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set level style of chart object
          object.LevelStyle(i,STYLE_SOLID);
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

LevelWidth (Get Method)

Gets the line width of the specified level of a graphical object.

```
int  LevelWidth(
   int  level      // level number
   ) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line width of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns -1.

LevelWidth (Set Method)

Sets the line width of the specified level of the graphical object.

```
bool  LevelWidth(
   int  level,          // level number
   int  new_width       // new width
   )
```

Parameters

level

[in] Number of graphical object level.

new_width

[in] New line width of the specified level of a graphical object.

Return Value

true - success, false - cannot change the width.

Example:

```
//--- example for CChartObject::LevelWidth
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- get level width of chart object
      int level_width=object.LevelWidth(i);
      if(level_width!=1)
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set level width of chart object
          object.LevelWidth(i,1);
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

LevelValue (Get Method)

Gets the value of the specified level of a graphical object.

```
double  LevelValue(
   int  level      // level number
   ) const
```

Parameters

level

[in] Number of a graphical object level.

Return Value

The value of the specified level of a graphical object that is bound to an instance of the class. If there is no bound object or the object has no level specified, returns EMPTY_VALUE.

LevelValue (Set Method)

Sets the value of the specified level of the graphical object.

```
bool  LevelValue(
   int     level,          // level number
   double  new_value       // new value
   )
```

Parameters

level

[in] Number of a graphical object level.

new_value

[in] New value of the specified level of a graphical object.

Return Value

true - successful, false - cannot change the value.

Example:

```
//--- example for CChartObject::LevelValue
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- get level value of chart object
      double level_value=object.LevelValue(i);
      if(level_value!=0.1*i)
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set level value of chart object
          object.LevelValue(i,0.1*i);
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

LevelDescription (Get Method)

Gets a description (text) of the level of a graphical object.

```
string  LevelDescription(
   int  level       // level number
   ) const
```

Parameters

level

[in] Number of a graphical object level.

Return Value

Description (text) of the specified level of a graphical object that is bound to an instance of the class. Returns NULL if there is no bound object or the object has no specified level.

LevelDescription (Set Method)

Sets the description (text) of the specified graphical object level.

```
bool  LevelDescription(
   int     level ,     // level number
   string  text        // text
   )
```

Parameters

level

[in] Number of a graphical object level.

text

[in] New value of description (text) of the specified graphical object level.

Return Value

true - success, false - cannot change the description (text).

Example:

```
//--- example for CChartObject::LevelDescription
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //---
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- get level description of chart object
      string level_description=object.LevelDescription(i);
      if(level_description=="")
```

© 2000-2025, MetaQuotes Ltd.

```
         {
          //--- set level description of chart object
          object.LevelDescription(i,"Level_"+IntegerToString(i));
         }
      }
   }
```

© 2000-2025, MetaQuotes Ltd.

GetInteger

Provides simplified access to the functions of API MQL5 ObjectGetInteger() to receive values of integer properties (of bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to a class instance. There are two versions of the function call:

Getting a property value without checking the correctness

```
long  GetInteger(
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,          // integer property ID
   int                           modifier=-1       // modifier
   ) const
```

Parameters

prop_id

[in] ID of the graphical object double property.

modifier=-1

[in] Modifier (index) of a double property.

Return Value

Value of an integer property - success, 0 - cannot receive an integer property.

Getting a property value verifying the correctness of the operation

```
bool  GetInteger(
   ENUM_OBJECT_PROPERTY_INTEGER  prop_id,       // integer property ID
   int                           modifier,      // modifier
   long&                         value          // link to a variable
   ) const
```

Parameters

prop_id

[in] ID of a graphical object integer property.

modifier

[in] Modifier (index) of an integer property.

value

[out] Link to a variable to place an integer property value.

Return Value

true - success, false - cannot get an integer property.

Example:

```
//--- example for CChartObject::GetInteger
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
{
 CChartObject object;
 //--- get color of chart object by easy method
 printf("Objects color is %s",ColorToString(object.GetInteger(OBJPROP_COLOR),true));
 //--- get color of chart object by classic method
 long color_value;
 if(!object.GetInteger(OBJPROP_COLOR,0,color_value))
   {
    printf("Get integer property error %d",GetLastError());
    return;
   }
 else
    printf("Objects color is %s",color_value);
 for(int i=0;i<object.LevelsCount();i++)
   {
    //--- get levels width by easy method
    printf("Level %d width is %d",i,object.GetInteger(OBJPROP_LEVELWIDTH,i));
    //--- get levels width by classic method
    long width_value;
    if(!object.GetInteger(OBJPROP_LEVELWIDTH,i,width_value))
      {
       printf("Get integer property error %d",GetLastError());
       return;
      }
    else
       printf("Level %d width is %d",i,width_value);
   }
}
```

© 2000-2025, MetaQuotes Ltd.

SetInteger

Provides simplified access to the functions of API MQL5 ObjectSetInteger() to change integer properties (of type bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to class instance. There are two versions of the function call:

Setting a property value that does not require a modifier

```
bool  SetInteger(
   ENUM_OBJECT_PROPERTY_INTEGER   prop_id,      // integer property ID
   long                           value         // value
   )
```

Parameters

prop_id

[in] ID of a graphical object integer property.

value

[in] New value of a changed integer property.

Setting a property value indicating the modifier

```
bool  SetInteger(
   ENUM_OBJECT_PROPERTY_INTEGER   prop_id,      // integer property ID
   int                            modifier,     // modifier
   long                           value         // value
   )
```

Parameters

prop_id

[in] ID of a graphical object integer property.

modifier

[in] Modifier (index) of an integer property.

value

[in] New value of an integer property.

Return Value

true - success, false - cannot change the integer property.

Example:

```
//--- example for CChartObject::SetInteger
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- set new color of chart object
```

© 2000-2025, MetaQuotes Ltd.

```
   if(!object.SetInteger(OBJPROP_COLOR,clrRed))
     {
      printf("Set integer property error %d",GetLastError());
      return;
     }
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- set levels width
      if(!object.SetInteger(OBJPROP_LEVELWIDTH,i,i))
        {
         printf("Set integer property error %d",GetLastError());
         return;
        }
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

GetDouble

Provides simplified access to the functions of API MQL5 ObjectGetDouble() to receive double values (of float and double types) of a graphical object bound to a class instance. There are two versions of the function call:

Getting a property value without checking the correctness

```
double  GetDouble(
   ENUM_OBJECT_PROPERTY_DOUBLE  prop_id,          // integer property ID
   int                          modifier=-1      // modifier
   ) const
```

Parameters

prop_id

[in] ID of the graphical object double property.

modifier=-1

[in] Modifier (index) of a double property.

Return Value

Value of a double property - success, EMPTY_VALUE - cannot receive a double property.

Getting a property value in verifying the correctness of such treatment

```
bool  GetDouble(
   ENUM_OBJECT_PROPERTY_DOUBLE  prop_id,       // double property ID
   int                          modifier,      // modifier
   double&                      value          // link to a variable
   ) const
```

Parameters

prop_id

[in] ID of a graphical object double property.

modifier

[in] Modifier (index) of a double property.

value

[out] Link to a variable to place a double property value.

Return Value

true - success, false - cannot get a double property.

Example:

```
//--- example for CChartObject::GetDouble
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
```

© 2000-2025, MetaQuotes Ltd.

```
{
 CChartObject object;
 //---
 for(int i=0;i<object.LevelsCount();i++)
   {
    //--- get levels value by easy method
    printf("Level %d value=%f",i,object.GetDouble(OBJPROP_LEVELVALUE,i));
    //--- get levels value by classic method
    double value;
    if(!object.SetDouble(OBJPROP_LEVELVALUE,i,value))
      {
       printf("Get double property error %d",GetLastError());
       return;
      }
    else
       printf("Level %d value=%f",i,value);
   }
}
```

© 2000-2025, MetaQuotes Ltd.

SetDouble

Provides simplified access to the functions of API MQL5 ObjectSetDouble() to change double properties (of float and double types) of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```
bool  SetDouble(
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,      // double property ID
   double                        value         // value
   )
```

Parameters

prop_id

[in] ID of a graphical object double property.

value

[in] New value of a changed double property.

Setting a property value indicating the modifier

```
bool  SetDouble(
   ENUM_OBJECT_PROPERTY_DOUBLE   prop_id,       // double property ID
   int                           modifier,      // modifier
   double                        value          // value
   )
```

Parameters

prop_id

[in] ID of a graphical object double property.

modifier

[in] Modifier (index) of a double property.

value

[in] New value of a changed double property.

Return Value

true - success, false - cannot change the double feature.

Example:

```
//--- example for CChartObject::SetDouble
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
//---
```

© 2000-2025, MetaQuotes Ltd.

```
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- set level value of chart object
      if(!object.SetDouble(OBJPROP_LEVELVALUE,i,0.1*i))
        {
         printf("Set double property error %d",GetLastError());
         return;
        }
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

GetString

Provides simplified access to the functions of API MQL5 ObjectGetString() for string property values of a graphical object bound to a class instance. There are two versions of a function call:

Getting a property value without checking the correctness

```
string  GetString(
   ENUM_OBJECT_PROPERTY_STRING  prop_id,          // string property ID
   int                          modifier=-1      // modifier
   ) const
```

Parameters

prop_id

[in] ID of graphical object string property.

modifier=-1

[in] Modifier (index) of a string property.

Return Value

Value of a string property - success, "" - cannot receive a string property.

Getting a property value verifying the correctness of such treatment

```
bool  GetString(
   ENUM_OBJECT_PROPERTY_STRING  prop_id,       // string property ID
   int                          modifier,      // modifier
   string&                      value          // link to a variable
   ) const
```

Parameters

prop_id

[in] ID of a graphical object string property.

modifier

[in] Modifier (index) of a string property.

value

[out] Link to a variable to place a string property value.

Return Value

true - successful, false - cannot get a string property.

Example:

```
//--- example for CChartObject::GetString
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
```

SetString

Provides simplified access to the functions of API MQL5 ObjectSetString() for changing string properties of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```
bool  SetString(
   ENUM_OBJECT_PROPERTY_STRING   prop_id,      // string property ID
   string                        value         // value
   )
```

Parameters

prop_id

[in] ID of a graphical object string property.

value

[in] New value of a changed string property.

Setting a property value indicating the modifier

```
bool  SetString(
   ENUM_OBJECT_PROPERTY_STRING   prop_id,       // string property ID
   int                           modifier,      // modifier
   string                        value          // value
   )
```

Parameters

prop_id

[in] ID of a graphical object string property.

modifier

[in] Modifier (index) of a string property.

value

[in] New value of a changed string property.

Return Value

true - success, false - cannot change a string property.

Example:

```
//--- example for CChartObject::SetString
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- set new name of chart object
   if(!object.SetString(OBJPROP_NAME,"MyObject"))
```

© 2000-2025, MetaQuotes Ltd.

```
     {
      printf("Set string property error %d",GetLastError());
      return;
     }
   for(int i=0;i<object.LevelsCount();i++)
     {
      //--- set levels description
      if(!object.SetString(OBJPROP_LEVELTEXT,i,"Level_"+IntegerToString(i)))
        {
         printf("Set string property error %d",GetLastError());
         return;
        }
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves parameters of the object in the file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] Handle of the file previously opened using the function FileOpen (...).

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CChartObject::Save
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CChartObject object=new CChartObject;
   //--- set object parameters
   //--- . . .
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!object.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads the parameters of the object from the file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the file previously opened using the function FileOpen (...).

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CChartObject::Load
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   int           file_handle;
   CChartObject object;
   //--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!object.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
   //--- use object
   //--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Gets the graphical object type ID.

```
virtual int  Type() const
```

Return Value

Object type ID (0x8888 for CChartObject).

Example:

```
//--- example for CChartObject::Type
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
  {
   CChartObject object;
   //--- get object type
   int type=object.Type();
  }
```

Line Objects

A group of "Lines" graphical objects.

This section contains the technical details of working with a group of classes of "Lines" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
CChartObjectVLine	"Vertical Line" graphical object
CChartObjectHLine	"Horizontal Line" graphical object
CChartObjectTrend	"Trend Line" graphical object
CChartObjectTrendByAngle	"Trend Line by Angle" graphical object
CChartObjectCycles	"Cyclic Lines" graphical object

CChartObjectVLine

CChartObjectVLine is a class for simplified access to "Vertical Line" graphical object properties.

Description

CChartObjectVLine class provides access to "Vertical Line" object properties.

Declaration

```
class CChartObjectVLine : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Create

Creates "Vertical Line" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time           // time coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate of the anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_VLINE for CChartObjectVLine).

CChartObjectHLine

CChartObjectHLine is a class for simplified access to "Horizontal Line" graphical object properties.

Description

CChartObjectHLine class provides access to "Horizonal Line" object properties.

Declaration

```
class CChartObjectHLine : public CChartObject
```

Title

Create

Creates "Trend Line" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // 1st time coordinate
   double    price1,        // 1st price coordinate
   datetime  time2,         // 2nd time coordinate
   double    price2         // 2nd price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

RayLeft (Get Method)

Gets the value of "Ray Left" property.

```
bool  RayLeft() const
```

Return Value

The value of "Ray Left" property assigned to the class instance. If there is no object assigned, it returns false.

RayLeft (Set Method)

Sets new flag value for the "Ray Left" property.

```
bool  RayLeft(
   bool  ray      // flag
   )
```

Parameters

ray

[in] New value of the "Ray Left" property.

Return Value

true - successful, false - cannot change flag.

© 2000-2025, MetaQuotes Ltd.

RayRight (Get Method)

Gets the value of "Ray Right" property.

```
bool  RayRight() const
```

Return Value

The value of "Ray Right" property, assigned to the class instance. If there is no object assigned, it returns false.

RayRight (Set Method)

Sets new flag value for the "Ray Right" property.

```
bool  RayRight(
   bool  ray      // flag
   )
```

Parameters

ray

[in] New value of the "Ray Right" property.

Return Value

true - successful, false - cannot change flag.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of a file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_TREND for CChartObjectTrend).

© 2000-2025, MetaQuotes Ltd.

CChartObjectTrendByAngle

CChartObjectTrendByAngle is a class for simplified access to "Trend Line by Angle" graphical object properties.

Description

CChartObjectTrendByAngle class provides access to "Trend Line by Angle" object properties.

Declaration

```
class CChartObjectTrendByAngle : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

Create

Creates "Trend Line by Angle" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   long      window,        // chart window
   datetime  time1,         // 1st time coordinate
   double    price1,        // 1st price coordinate
   datetime  time2,         // 2nd time coordinate
   double    price2         // 2nd price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

Angle (Get Method)

Gets the value of "Angle" property.

```
double  Angle() const
```

Return Value

The value of "Angle" property assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Angle (Set Method)

Sets new value for the "Angle" property.

```
bool  Angle(
   double  angle      // angle
   )
```

Parameters

angle

[in] New value of the "Angle" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_TRENDBYANGLE for CChartObjectTrendByAngle).

Create

Creates "Linear Regression Channel" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   long      window,        // chart window
   datetime  time1,         // first time coordinate
   datetime  time2          // second time coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_REGRESSION for CChartObjectRegression).

© 2000-2025, MetaQuotes Ltd.

CChartObjectStdDevChannel

CChartObjectStdDevChannel is a class for simplified access to "Standard Deviation Channel" graphical object properties.

Description

CChartObjectStdDevChannel class provides access to "Standard Deviation Channel" object properties.

Declaration

```
class CChartObjectStdDevChannel : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectTrend
      CChartObjectStdDevChannel

Class Methods by Groups

Create	
Create	Creates "Standard Deviation Channel" graphical object
Properties	
Deviations	Gets/sets "Deviation" property
Input/output	
virtual Save	Virtual method for writing to file
virtual Load	Virtual method for reading from file
virtual Type	Virtual method of identification

Create

Creates "Standard Deviation Channel" graphical object.

```
bool  Create(
   long      chart_id,       // chart identifier
   string    name,           // object name
   int       window,         // chart window
   datetime  time1,          // first time coordinate
   datetime  time2,          // second time coordinate
   double    deviation       // deviation
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

deviation

[in] Numerical value for "Deviation" property.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Deviation (Get Method)

Gets "Deviation" property value.

```
double  Deviation() const
```

Return Value

Value of "Deviation" property assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Deviation (Set Method)

Sets "Deviation" property value.

```
bool  Deviation(
   double  deviation      // deviation
   )
```

Parameters

deviation

[in] New value for "Deviation" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_STDDEVCHANNEL for CChartObjectStdDevChannel).

© 2000-2025, MetaQuotes Ltd.

CChartObjectPitchfork

CChartObjectPitchfork is a class for simplified access to "Andrew's Pitchfork" graphical object properties.

Description

CChartObjectPitchfork class provides access to "Andrew's Pitchfork" object properties.

Declaration

```
class CChartObjectPitchfork : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectTrend

Create

Creates "Gann Line" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    ppb            // pips per bar
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double  PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool  PipsPerBar(
   double  ppb      // pips per bar
   )
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_GANNLINE for CChartObjectGannLine).

© 2000-2025, MetaQuotes Ltd.

CChartObjectGannFan

CChartObjectGannFan is a class for simplified access to "Gann Fan" graphical object properties.

Description

CChartObjectGannFan class provides access to "Gann Fan" object properties.

Declaration

```
class CChartObjectGannFan : public CChartObjectTrend
```

   datetime  time2,         // second time coordinate
   double    ppb            // pips per bar
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - base window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double  PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool  PipsPerBar(
   double  ppb      // pips per bar
   )
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Downtrend (Get Method)

Gets the value of "Downtrend" flag.

```
bool  Downtrend() const
```

Return Value

Value of the "Downtrend" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

Downtrend (Set Method)

Sets new value of "Downtrend" property.

```
bool  Downtrend(
   bool  downtrend      // flag value
   )
```

Parameters

downtrend

[in] New value for "Downtrend" property.

Return Value

true - successful, false - cannot change the flag.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_GANNFAN for CChartObjectGannFan).

© 2000-2025, MetaQuotes Ltd.

CChartObjectGannGrid

CChartObjectGannGrid is a class for simplified access to "Gann Grid" graphical object properties.

Description

CChartObjectGannGrid class provides access to "Gann Grid" object properties.

   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    ppb            // pips per bar
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double  PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool  PipsPerBar(
   double  ppb      // Pips per bar
   )
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Downtrend (Get Method)

Gets the value of "Downtrend" property.

```
bool  Downtrend() const
```

Return Value

Value of "Downtrend" property of the object assigned to the class instance. If there is no object assigned, it returns false.

Downtrend (Set Method)

Sets new value of "Downtrend" property.

```
bool  Downtrend(
   bool  downtrend      // flag value
   )
```

Parameters

downtrend

[in] New value for "Downtrend" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphic object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_GANNGRID for CChartObjectGannGrid).

© 2000-2025, MetaQuotes Ltd.

Create

Creates "Fibonacci Retracement" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2         // second price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_FIBO for CChartObjectFibo).

© 2000-2025, MetaQuotes Ltd.

CChartObjectFiboTimes

CChartObjectFiboTimes is a class for simplified access to "Fibonacci Time Zones" graphical object properties.

Description

CChartObjectFiboTimes class provides access to "Fibonacci Time Zones" object properties.

Declaration

```
class CChartObjectFiboTimes : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsFibo.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectFiboTimes

Class Methods by Groups

Create	
Create	Creates "Fibonacci Time Zones" graphical object
Input/output	
virtual Type	Virtual method of identification

Create

Creates "Fibonacci Time Zones" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2         // second price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_FIBOTIMES for CChartObjectFiboTimes).

© 2000-2025, MetaQuotes Ltd.

CChartObjectFiboFan

CChartObjectFiboFan is a class for simplified access to "Fibonacci Fan" graphical object properties.

Description

CChartObjectFiboFan class provides access to "Fibonacci Fan" object properties.

Declaration

```
class CChartObjectFiboFan : public CChartObject
```

Title

```

Create

Creates "Fibonacci Fan" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2         // second price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_FIBOFAN for CChartObjectFiboFan).

© 2000-2025, MetaQuotes Ltd.

CChartObjectFiboArc

CChartObjectFiboArc is a class for simplified access to "Fibonacci Arc" graphical object properties.

Description

CChartObjectFiboArc class provides access to "Fibonacci Arc" object properties.

Declaration

```
class CChartObjectFiboArc : public CChartObject
```

Create

Creates "Fibonacci Arc" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2,        // second price coordinate
   double    scale          // scale
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

scale

[in] Scale.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Scale (Get Method)

Gets the value of "Scale" property.

```
double  Scale() const
```

Return Value

Value of "Scale" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Scale (Set Method)

Sets new value for "Scale" property.

```
bool  Scale(
   double  scale      // scale
   )
```

Parameters

scale

[in] New value for "Scale" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Ellipse (Get Method)

Gets the value of "Ellipse" flag.

```
bool  Ellipse() const
```

Return Value

Value of "Ellipse" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

Ellipse (Set Method)

Sets "Ellipse" flag value.

```
bool  Ellipse(
   bool  ellipse      // flag value
   )
```

Parameters

ellipse

[in] New value for "Ellipse" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_FIBOARC for CChartObjectFiboArc).

© 2000-2025, MetaQuotes Ltd.

CChartObjectFiboChannel

CChartObjectFiboChannel is a class for simplified access to "Fibonacci Channel" graphical object properties.

Description

CChartObjectFiboChannel class provides access to "Fibonacci Channel" object properties.

Declaration

```
class CChartObjectFiboChannel : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsFibo.mqh>
```

Inheritance hierarchy

Create

Creates "Fibonacci Channel" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2,        // second price coordinate
   datetime  time3,         // third time coordinate
   double    price3         // third price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_FIBOCHANNEL for CChartObjectFiboChannel).

© 2000-2025, MetaQuotes Ltd.

CChartObjectFiboExpansion

CChartObjectFiboExpansion is a class for simplified access to "Fibonacci Expansion" graphical object properties.

Description

CChartObjectFiboExpansion class provides access to "Fibonacci Expansion" object properties.

Declaration

```
class CChartObjectFiboExpansion : public CChartObjectTrend

   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Time coordinate of the third anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Degree (Get Method)

Gets the value of "Degree" property.

```
ENUM_ELLIOT_WAVE_DEGREE  Degree() const
```

Return Value

Value of "Degree" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Degree (Set Method)

Sets new value for "Degree" property.

```
bool  Degree(
   ENUM_ELLIOT_WAVE_DEGREE  degree      // property value
   )
```

Parameters

degree

[in] New value for "Degree" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Lines (Get Method)

Gets the value of "Lines" property.

```
bool  Lines() const
```

Return Value

Value of "Lines" property of the object assigned to the class instance. If there is no object assigned, it returns false.

Lines (Set Method)

Sets new value for "Lines" property.

```
bool  Lines(
   bool  lines      // flag value
   )
```

Parameters

lines

[in] New value for "Lines" property.

Return Value

true - successful, false - cannot change the flag.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_ELLIOTWAVE3 for CChartObjectElliottWave3).

© 2000-2025, MetaQuotes Ltd.

CChartObjectElliottWave5

CChartObjectElliottWave5 is a class for simplified access to "Impulse Wave" graphical object properties.

Description

CChartObjectElliottWave5 class provides access to "Impulse Wave" object properties.

Declaration

```
class CChartObjectElliottWave5 : public CChartObjectElliottWave3
```

Title

```
#include <ChartObjects\ChartObjectsElliott.mqh>
```

Inheritance hierarchy

Create

Creates "Rectangle" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   long      window,        // chart window
   datetime  time1,         // first time coordinate
   double    price1,        // first price coordinate
   datetime  time2,         // second time coordinate
   double    price2         // second price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
int  Type() const
```

Return Value

Object type identifier (OBJ_RECTANGLE for CChartObjectRectangle).

© 2000-2025, MetaQuotes Ltd.

CChartObjectTriangle

CChartObjectTriangle is a class for simplified access to "Triangle" graphical object properties.

Description

CChartObjectTriangle class provides access to "Triangle" object properties.

Declaration

```
class CChartObjectTriangle : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsShapes.mqh>
```

   double    price2,        // second price coordinate
   datetime  time3,         // third time coordinate
   double    price3         // third price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Arrow Objects

Group for Arrows graphical objects.

This section contains the technical details of working with a group of classes of "Arrow" graphical objects and a description of the relevant components of the MQL5 Standard Library. In essence, the arrow is a certain icon which is associated with a specific code. There are two types of "Arrow" graphical object to display icons on the charts:

- "Arrow" object, which allows you to specify the code of the icon displayed by the object.
- Group of objects to display a certain type of icons (corresponding to a certain fixed code).

Class for working with arrows displaying arbitrary code icons

Class name	Name of the arrow object
CChartObjectArrow	Arrow

Classes for working arrows displaying a fixed code icon

Class name	Name of the arrow object
CChartObjectArrowCheck	Check
CChartObjectArrowDown	Arrow Up
CChartObjectArrowUp	Arrow Down
CChartObjectArrowStop	Stop Sign
CChartObjectArrowThumbDown	Thumbs Up
CChartObjectArrowThumbUp	Thumbs Down
CChartObjectArrowLeftPrice	Left Price Label
CChartObjectArrowRightPrice	Right Price Label

CChartObjectArrow

CChartObjectArrow is a class for simplified access to "Arrow" graphical object properties.

Description

CChartObjectArrow class provides access to common properties of "Arrow" objects to all of its descendants.

Declaration

```
class CChartObjectArrow : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsArrows.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectArrow

Direct descendants

CChartObjectArrowCheck, CChartObjectArrowDown, CChartObjectArrowLeftPrice, CChartObjectArrowRightPrice, CChartObjectArrowStop, CChartObjectArrowThumbDown, CChartObjectArrowThumbUp, CChartObjectArrowUp

Class Methods by Groups

Create	
Create	Creates "Arrow" graphical object
Properties	
ArrowCode	Gets/sets "Arrow Code" property
Anchor	Gets/sets "Anchor" property
Input/output	
virtual Save	Virtual method for writing to file
virtual Load	Virtual method for reading from file
virtual Type	Virtual method of identification

Create

Creates "Arrow" graphical object.

```
bool  Create(
   long      chart_id,      // chart ID
   string    name,          // object Name
   int       window,        // chart Window
   datetime  time,          // time
   double    price,         // price
   char      code           // arrow code
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique object name.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate.

price

[in] Price coordinate.

code

[in] "Arrow" code (Wingdings).

Return Value

true - success, false - error.

Example:

```
//--- example for CChartObjectArrow::Create
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   CChartObjectArrow arrow;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
     {
      //--- arrow create error
      printf("Arrow create: Error %d!",GetLastError());
      //---
```

© 2000-2025, MetaQuotes Ltd.

```
      return;
     }
//--- use arrow
//--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

ArrowCode (Get Method)

Gets "Arrow" symbol code.

```
char  ArrowCode() const
```

Return Value

"Arrow" symbol code of the object assigned to the class instance. If there is no object assigned, it returns 0.

ArrowCode (Set Method)

Sets symbol code for "Arrow"

```
bool  ArrowCode(
   char  code      // code value
   )
```

Parameters

code

[in] New value for "arrow" code (Wingdings).

Return Value

true - success, false - cannot change the code.

Example:

```
//--- example for CChartObjectArrow::ArrowCode
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   CChartObjectArrow arrow;
   char              code=181;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,code))
     {
      //--- arrow create error
      printf("Arrow create: Error %d!",GetLastError());
      //---
      return;
     }
//--- change the code of arrow
//--- . . .
//--- get code of arrow
   if(arrow.ArrowCode()!=code)
     {
     //--- set code of arrow
```

© 2000-2025, MetaQuotes Ltd.

```
      arrow.ArrowCode(code);
      }
//--- use arrow
//--- . . .
   }
```

© 2000-2025, MetaQuotes Ltd.

Anchor (Get Method)

Gets anchor type of the "Arrow" object

```
ENUM_ARROW_ANCHOR  Anchor() const
```

Return Value

Anchor type of the "Arrow" object assigned to the class instance (to the chart). If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets anchor type for the "Arrow" object

```
bool  Anchor(
   ENUM_ARROW_ANCHOR  anchor      // anchor type
   )
```

Parameters

anchor

[in] New anchor type value

Return Value

true - successful, false - cannot change the anchor type.

Example:

```
//--- example for CChartObject::Anchor
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   CChartObjectArrow arrow;
   ENUM_ARROW_ANCHOR anchor=ANCHOR_BOTTOM;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
     {
      //--- arrow create error
      printf("Arrow create: Error %d!",GetLastError());
      //---
      return;
     }
//--- get anchor of arrow
   if(arrow.Anchor()!=anchor)
     {
     //--- set anchor of arrow
     arrow.Anchor(anchor);
     }
```

© 2000-2025, MetaQuotes Ltd.

```
//--- use arrow
//--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Example:

```
//--- example for CChartObjectArrow::Save
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   int               file_handle;
   CChartObjectArrow arrow;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
     {
      //--- arrow create error
      printf("Arrow create: Error %d!",GetLastError());
      //---
      return;
     }
//--- open file
   file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!arrow.Save(file_handle))
        {
         //--- file save error
         printf("File save: Error %d!",GetLastError());
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
  }
```

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of file previously opened using the FileOpen(...) function.

Return Value

true - success, false - error.

Example:

```
//--- example for CChartObjectArrow::Load
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   int               file_handle;
   CChartObjectArrow arrow;
//--- open file
   file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
   if(file_handle>=0)
     {
      if(!arrow.Load(file_handle))
        {
         //--- file load error
         printf("File load: Error %d!",GetLastError());
         FileClose(file_handle);
         //---
         return;
        }
      FileClose(file_handle);
     }
//--- use arrow
//--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (for example, OBJ_ARROW for CChartObjectArrow)

Example:

```
//--- example for CChartObjectArrow::Type
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
   CChartObjectArrow arrow;
   //--- get arrow type
   int type=arrow.Type();
  }
```

© 2000-2025, MetaQuotes Ltd.

Arrows with fixed code

"Arrows with fixed code" are classes for simplified access to the properties of the following graphical objects:

Class name	Arrow object name
CChartObjectArrowCheck	"Arrow Check"
CChartObjectArrowDown	"Arrow Down"
CChartObjectArrowUp	"Arrow Up"
CChartObjectArrowStop	"Arrow Stop"
CChartObjectArrowThumbDown	"Good" ("Thumbs up")
CChartObjectArrowThumbUp	"Bad" ("Thumbs down")
CChartObjectArrowLeftPrice	"Left price" arrow
CChartObjectArrowRightPrice	"Right price" arrow

Description

"Arrows with fixed code" classes provide access to the object properties.

Declarations

```
class CChartObjectArrowCheck      : public CChartObjectArrow;
class CChartObjectArrowDown       : public CChartObjectArrow;
class CChartObjectArrowUp         : public CChartObjectArrow;
class CChartObjectArrowStop       : public CChartObjectArrow;
class CChartObjectArrowThumbDown  : public CChartObjectArrow;
class CChartObjectArrowThumbUp    : public CChartObjectArrow;
class CChartObjectArrowLeftPrice  : public CChartObjectArrow;
class CChartObjectArrowRightPrice : public CChartObjectArrow;
```

Title

```
<ChartObjects\ChartObjectsArrows.mqh>
```

Class Methods by Groups

Create	
Create	Creates the graphical object matching the class
Properties	
ArrowCode	"Stub" for symbol code change method
Input/output	
virtual Type	Virtual method of identification

© 2000-2025, MetaQuotes Ltd.

Create

Creates "Arrow with fixed code" graphical object.

```
bool  Create(
   long      chart_id,      // chart ID
   string    name,          // object Name
   int       window,        // chart Window
   datetime  time,          // time
   double    price          // price
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] Unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate.

price

[in] Price coordinate.

Return Value

true - successful, false - error.

Example:

```
//--- example for CChartObjectArrowCheck::Create
//--- example for CChartObjectArrowDown::Create
//--- example for CChartObjectArrowUp::Create
//--- example for CChartObjectArrowStop::Create
//--- example for CChartObjectArrowThumbDown::Create
//--- example for CChartObjectArrowThumbUp::Create
//--- example for CChartObjectArrowLeftPrice::Create
//--- example for CChartObjectArrowRightPrice::Create
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
//--- for example, take CChartObjectArrowCheck
   CChartObjectArrowCheck arrow;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))
```

© 2000-2025, MetaQuotes Ltd.

```
      {
       //--- arrow create error
       printf("Arrow create: Error %d!",GetLastError());
       //---
       return;
      }
//--- use arrow
//--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

ArrowCode

Prohibits "Arrow" symbol code changes.

```
bool  ArrowCode(
   char  code      // code value
   )
```

Parameters

code

[in] Any value

Return Value

Always false.

Example:

```
//--- example for CChartObjectArrowCheck::ArrowCode
//--- example for CChartObjectArrowDown::ArrowCode
//--- example for CChartObjectArrowUp::ArrowCode
//--- example for CChartObjectArrowStop::ArrowCode
//--- example for CChartObjectArrowThumbDown::ArrowCode
//--- example for CChartObjectArrowThumbUp::ArrowCode
//--- example for CChartObjectArrowLeftPrice::ArrowCode
//--- example for CChartObjectArrowRightPrice::ArrowCode
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
//--- for example, take CChartObjectArrowCheck
   CChartObjectArrowCheck arrow;
//--- set object parameters
   double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
   if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))
     {
      //--- arrow create error
      printf("Arrow create: Error %d!",GetLastError());
      //---
      return;
     }
//--- set code of arrow
   if(!arrow.ArrowCode(181))
     {
      //--- it is not error
      printf("Arrow code can not be changed");
     }
//--- use arrow
//--- . . .
  }
```

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier

```
virtual int  Type() const
```

Return Value

Object type identifier:

CChartObjectArrowCheck - OBJ_ARROW_CHECK,

CChartObjectArrowDown - OBJ_ARROW_DOWN,

CChartObjectArrowUp - OBJ_ARROW_UP,

CChartObjectArrowStop - OBJ_ARROW_STOP,

CChartObjectArrowThumbDown - OBJ_ARROW_THUMB_DOWN,

CChartObjectArrowThumbUp - OBJ_ARROW_THUMB_UP,

CChartObjectArrowLeftPrice - OBJ_ARROW_LEFT_PRICE,

CChartObjectArrowRightPrice - OBJ_ARROW_RIGHT_PRICE.

Example:

```
//--- example for CChartObjectArrowCheck::Type
//--- example for CChartObjectArrowDown::Type
//--- example for CChartObjectArrowUp::Type
//--- example for CChartObjectArrowStop::Type
//--- example for CChartObjectArrowThumbDown::Type
//--- example for CChartObjectArrowThumbUp::Type
//--- example for CChartObjectArrowLeftPrice::Type
//--- example for CChartObjectArrowRightPrice::Type
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
  {
//--- for example, take CChartObjectArrowCheck
   CChartObjectArrowCheck arrow;
//--- get arrow type
   int type=arrow.Type();
  }
```

Create

Creates "Text" graphical object.

```
bool  Create(
   long      chart_id,      // chart identifier
   string    name,          // object name
   int       window,        // chart window
   datetime  time,          // time coordinate
   double    price          // price coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate of the anchor point.

price

[in] Price coordinate of the anchor point.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Angle (Get Method)

Gets the value of "Angle" property.

```
double  Angle() const
```

Return Value

Value of "Angle" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Angle (Set Method)

Sets a value for "Angle" property.

```
bool  Angle(
   double  angle      // property value
   )
```

Parameters

angle

[in] New value for "Angle" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Font (Get Method)

Gets the value of "Font" property.

```
string  Font() const
```

Return Value

Value of "Font" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Font (Set Method)

Sets new value for "Font" property.

```
bool  Font(
   string  font      // property value
   )
```

Parameters

font

[in] New value for "Font" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

FontSize (Get Method)

Gets the value of "Font size" property.

```
int  FontSize() const
```

Return Value

Value of "FontSize" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

FontSize (Set Method)

Sets new value for "Font size" property.

```
bool  FontSize(
   int  size      // property value
   )
```

Parameters

size

[in] New value for "Font size" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Anchor (Get Method)

Gets the value of "Anchor" property.

```
ENUM_ANCHOR_POINT  Anchor() const
```

Return Value

Value of "Anchor" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets new value for "Anchor" property.

```
bool  Anchor(
   ENUM_ANCHOR_POINT  anchor      // property value
   )
```

Parameters

anchor

[in] New value for "Anchor" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by the FileOpen function.

Return Value

true - success, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by the FileOpen function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_TEXT for CChartObjectText).

© 2000-2025, MetaQuotes Ltd.

CChartObjectLabel

CChartObjectLabel is a class for simplified access to "Label" graphical object properties.

Description

CChartObjectLabel class provides access to "Label" object properties.

Declaration

```
class CChartObjectLabel : public CChartObjectText
```

Title

```
#include <ChartObjects\ChartObjectsTxtControls.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectText
      CChartObjectLabel

Direct descendants

CChartObjectEdit, CChartObjectRectLabel

© 2000-2025, MetaQuotes Ltd.

Create

Creates "Label" graphical object.

```
bool  Create(
   long     chart_id,      // chart identifier
   string   name,          // object name
   int      window,        // chart window
   int      X,             // X coordinate
   int      Y              // Y coordinate
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

X_Distance (Get Method)

Gets the value of "X_Distance" property.

```
int  X_Distance() const
```

Return Value

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for "X_Distance" property.

```
bool  X_Distance(
   int  X      // property value
   )
```

Parameters

X

[in] New value for "X_Distance" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```
int  Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```
bool  Y_Distance(
   int  Y      // property value
   )
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

X_Size

Gets the value of "X_Size" property.

```
int  X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

© 2000-2025, MetaQuotes Ltd.

Y_Size

Gets the value of "Y_Size" property.

```
int  Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

© 2000-2025, MetaQuotes Ltd.

Corner (Get Method)

Gets the value of "Corner" property.

```
ENUM_BASE_CORNER  Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```
bool  Corner(
   ENUM_BASE_CORNER  corner      // property value
   )
```

Parameters

corner

[in] New value for "Corner" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Time

Prohibits changes of the time coordinate.

```
bool  Time(
   datetime  time      // any value
   )
```

Parameters

time

[in] Any value of datetime type.

Return Value

always false.

© 2000-2025, MetaQuotes Ltd.

Price

Prohibits changes of the price coordinate.

```
bool  Price(
   double  price      // any value
   )
```

Parameters

price

[in] Any value of double type.

Return Value

always false.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by FileOpen function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by FileOpen function.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_LABEL for CChartObjectLabel).

© 2000-2025, MetaQuotes Ltd.

CChartObjectEdit

CChartObjectEdit is a class for simplified access to "Edit" graphical object properties.

Description

CChartObjectEdit class provides access to "Edit" object properties.

Declaration

```
class CChartObjectEdit : public CChartObjectLabel
```

Title

```
#include <ChartObjects\ChartObjectsTxtControls.mqh>
```

Create

Creates "Edit" graphical object.

```
bool  Create(
   long     chart_id,      // chart identifier
   string   name,          // object name
   int      window,        // chart window
   int      X,             // X coordinate
   int      Y,             // Y coordinate
   int      sizeX,         // X size
   int      sizeY          // Y size
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

sizeX

[in] X size.

sizeY

[in] Y size.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

TextAlign (Get method)

Gets the value of "TextAlign" property (text alignment mode).

```
ENUM_ALIGN_MODE  TextAlign() const
```

Return Value

Value of "TextAlign" property of the object assigned to the class instance.

TextAlign (Set method)

Sets the value of "TextAlign" property (text aligment mode).

```
bool  TextAlign(
   ENUM_ALIGN_MODE  align      // property value
   )
```

Parameters

align

[in] New value of "TextAlign" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

X_Size

Sets the value for "X_Size" property.

```
bool  X_Size(
   int  size      // property value
   )
```

Parameters

size

[in] New value for "X_Size" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Y_Size

Sets the value for "Y_Size" property.

```
bool  Y_Size(
   int  size      // property value
   )
```

Parameters

size

[in] New value for "Y_Size" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

BackColor (Get Method)

Gets the value of "BackColor" property.

```
color  BackColor() const
```

Return Value

Value of "BackColor" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

BackColor (Set Method)

Sets the value for "BackColor" property.

```
bool  BackColor(
   color  new_color      // property value
   )
```

Parameters

new_color

[in] New value for "BackColor" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

BorderColor (Get Method)

Gets the value of "Border Color" property.

```
color  BorderColor() const
```

Return Value

Value of "Border Color" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

BorderColor (Set Method)

Sets new value for "Border Color" property.

```
bool  BorderColor(
   color  new_color      // new property value
   )
```

Parameters

new_color

[in] New value for "Border Color" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

ReadOnly (Get Method)

Gets the value of "Read Only" property.

```
bool  ReadOnly() const
```

Return Value

Value of "Read Only" property of the object assigned to the class instance. If there is no object assigned, it returns false.

ReadOnly (Set Method)

Sets the value for "Read Only" property.

```
bool  ReadOnly(
   const  bool  flag      // new property value
   )
```

Parameters

flag

[in] New value for "Read Only" property (true means text editing is disabled).

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Angle

Prohibits changes of the "Angle" property.

```
bool  Angle(
   double  angle      // any value
   )
```

Parameters

angle

[in] Any value of double type.

Return Value

always false.

© 2000-2025, MetaQuotes Ltd.

Save

Saves object parameters to file.

```
virtual bool  Save(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by FileOpen function.

Return Value

true - success, false - error.

© 2000-2025, MetaQuotes Ltd.

Load

Loads object parameters from file.

```
virtual bool  Load(
   int  file_handle      // file handle
   )
```

Parameters

file_handle

[in] handle of the binary file already opened by FileOpen function.

Return Value

true - success, false - error.

© 2000-2025, MetaQuotes Ltd.

Type

Returns graphical object type identifier.

```
virtual int  Type() const
```

Return Value

Object type identifier (OBJ_EDIT for CChartObjectEdit).

© 2000-2025, MetaQuotes Ltd.

CChartObjectButton

CChartObjectButton is a class for simplified access to "Button" graphical object properties.

Description

CChartObjectButton class provides access to "Button" object properties.

State (Get Method)

Gets the value of "State" property.

```
bool  State() const
```

Return Value

Value of "State" property of the object assigned to the class instance. If there is no object assigned, it returns false.

State (Set Method)

Sets new value for "State" property.

```
bool  State(
   bool  state      // property value
   )
```

Parameters

X

[in] New value for "State" property.

Return Value

true - success, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Create

Creates "SubChart" graphical object.

```
bool  Create(
   long     chart_id,      // chart identifier
   string   name,          // object name
   int      window,        // chart window
   int      X,             // X coordinate
   int      Y,             // Y coordinate
   int      sizeX,         // X size
   int      sizeY          // Y size
   )
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

sizeX

[in] X size.

sizeY

[in] Y size.

Return Value

true - successful, false - error.

© 2000-2025, MetaQuotes Ltd.

X_Distance (Get Method)

Gets the value of "X_Distance" property.

```
int  X_Distance() const
```

Return Value

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for "X_Distance" property.

```
bool  X_Distance(
   int  X      // property value
   )
```

Parameters

X

[in] New value for "X_Distance" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```
int  Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```
bool  Y_Distance(
   int  Y      // property value
   )
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Corner (Get Method)

Gets the value of "Corner" property.

```
ENUM_BASE_CORNER Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```
bool  Corner(
   ENUM_BASE_CORNER  corner      // property value
   )
```

Parameters

corner

[in] New value for "Corner" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

X_Size (Get Method)

Gets the value of "X_Size" property.

```
int  X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Size (Set Method)

Sets new value for "X_Size" property.

```
bool  X_Size(
   int  X      // property value
   )
```

Parameters

X

[in] New value for "X_Size" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Y_Size (Get Method)

Gets the value of "Y_Size" property.

```
int  Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Size (Set Method)

Sets new value for "Y_Size" property.

```
bool  Y_Size(
   int  Y      // property value
   )
```

Parameters

Y

[in] New value for "Y_Size" property.

Return Value

true - successful, false - cannot change the property.

© 2000-2025, MetaQuotes Ltd.

Symbol (Get Method)

Gets the value of "Symbol" property.

```
string  Symbol() const
```

Return Value

Value of "Symbol" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Symbol (Set Method)

Sets new value for "Symbol" property.

```
bool  Symbol(
