**Methods inherited from class CObject**
- Prev, Prev, Next, Next, **Compare**

**Methods inherited from class CArray**
- **Step**, **Step**, **Total**, **Available**, **Max**, **IsSorted**, **SortMode**, **Clear**, **Sort**
Reserve

Allocates memory to increase the size of the array.

```cpp
bool Reserve{
    int size  // number
}
```

Parameters

`size`

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```cpp
//--- example for CArrayString::Reserve(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
Resize

Sets a new (smaller) size of the array.

```c
bool Resize(
    int size, // size
)
```

**Parameters**

`size`

[in] New size of the array.

**Return Value**

true - successful, false - there was an attempt to set the size less than zero.

**Note**

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the `Step(int)` method or the default step of 16.

**Example:**

```c
//--- example for CArrayString::Resize(int)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //--
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . .
    //--- resize array
    if(!array.Resize(10))
    {
        printf("Resize error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Shutdown

Clears the array with a full memory release.

```cpp
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```cpp
//--- example for CArrayString::Shutdown()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Add

Adds an element to the end of the array.

```cpp
bool Add(
    string element    // element to add
);
```

Parameters

**element**

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```cpp
//--- example for CArrayString::Add(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    for(int i=0;i<100;i++)
    {
        if(!array.Add(IntegerToString(i)))
        {
            printf("Element addition error");
            delete array;
            return;
        }
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
AddArray

Adds elements of one array to the end of another.

```cpp
bool AddArray(
    const string& src[]    // source array
)
```

**Parameters**

`src[]`

[in] Reference to an array of source elements to add.

**Return Value**

true - successful, false - cannot add items.

**Example:**

```cpp
#include "Arrays\ArrayString.mqh"

string src[];

void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add another array
    if(!array.AddArray(src))
    {
        printf("Array addition error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
AddArray

Adds elements of one array to the end of another.

```cpp
bool AddArray(
    const CArrayString* src  // pointer to the source
)
```

Parameters

`src`

[in] Pointer to an instance of CArrayString class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```cpp
#include <Arrays\ArrayString.mqh>
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayString *src=new CArrayString;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- add source arrays elements
    //--- . . .
    //--- add another array
    if(!array.AddArray(src))
    {
        printf("Array addition error");
        delete src;
        delete array;
        return;
    }
    //--- delete source array
    delete src;
}
```
```cpp
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
    }
```
Insert

Inserts an element to the specified position in the array.

```c
bool Insert(
    string element, // element to insert
    int pos        // position
);
```

Parameters

- `element`
  - [in] Value of the element to be inserted into an array
- `pos`
  - [in] Position in the array to insert

Return Value

- `true` - successful, `false` - cannot insert the element.

Example:

```c
#include <Arrays\ArrayString.mqh>

void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- insert elements
    for(int i=0;i<100;i++)
    {
        if(!array.Insert(IntegerToString(i),0))
        {
            printf("Insert error");
            delete array;
            return;
        }
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
InsertArray

Inserts elements of one array from the specified position of another array.

```cpp
bool InsertArray(
    const string & src[], // source array
    int pos // position
)
```

Parameters

- `src[]`
  - [in] Reference to an array used as a source of elements to insert

- `pos`
  - [in] Position in the array to insert

Return Value

- `true` - successful, `false` - cannot insert items.

Example:

```cpp
#include <Arrays\ArrayString.mqh>

void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- insert another array
    if(!array.InsertArray(src,0))
    {
        printf("Array inserting error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
InsertArray

Inserts elements of one array from the specified position of another array.

```cpp
bool InsertArray(
    CArrayString* src,  // pointer to the source
    int pos          // position
);
```

Parameters

- **src**
  - [in] Pointer to an instance of the CArrayString class used as a source of elements to insert.

- **pos**
  - [in] Position in the array to insert

Return Value

- true - successful, false - cannot insert items.

Example:

```cpp
//--- example for CArrayString::InsertArray(const CArrayString*,int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayString *src=new CArrayString;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- add source arrays elements
    //--- . . .
    //--- insert another array
    if(!array.InsertArray(src,0))
    {
        printf("Array inserting error");
        delete src;
        delete array;
    }
}
```

© 2000-2019, MetaQuotes Software Corp.
return;
}

//--- delete source array
delete src;

//--- use array
//--- . . .
//--- delete array
delete array;
}
AssignArray
Copies the elements of one array to another.

```
bool AssignArray(
    const string & src[] // source array
)
```

**Parameters**

*src[]*

[in] Reference to an array used as a source of elements to copy.

**Return Value**

true - successful, false - cannot copy the items.

**Example:**

```c
//--- example for CArrayString::AssignArray(const string &[])
#include <Arrays\ArrayString.mqh>
//---
string src[];
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- assign another array
    if(!array.AssignArray(src))
    {
        printf("Array assigned error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
AssignArray

Copies the elements of one array to another.

```cpp
bool AssignArray(
    const CArrayString* src  // pointer to the source
)
```

**Parameters**

`src`

[in] Pointer to an instance of the CArrayString class used as a source of elements to copy.

**Return Value**

true - successful, false - cannot copy the elements.

**Example:**

```cpp
//--- example for CArrayString::AssignArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
        {
            printf("Object create error");
            return;
        }
    //--- create source array
    CArrayString *src =new CArrayString;
    if(src==NULL)
        {
            printf("Object create error");
            delete array;
            return;
        }
    //--- add source arrays elements
    //--- . . .
    //--- assign another array
    if(!array.AssignArray(src))
        {
            printf("Array assigned error");
            delete src;
            delete array;
            return;
        }
    //--- arrays is identical
    //--- delete source array
```
delete src;
//--- use array
//--- . .
//--- delete array
delete array;
}
2894

Standard Library

Update
Changes the element at the specified array position.

bool Update(
int
pos,
string element
)

// position
// value

Parameters
pos
[in]

Position of the element in the array to change

element
[in]

New value of the element

Return Value
true - successful, false - cannot change the element.

Example:
//--- example for CArrayString::Update(int, string)
#include <Arrays\ArrayString.mqh>
//--void OnStart()
{
CArrayString *array=new CArrayString;
//--if(array==NULL)
{
printf("Object create error");
return;
}
//--- add arrays elements
//--- . . .
//--- update element
if(!array.Update(0,"ABC"))
{
printf("Update error");
delete array;
return;
}
//--- delete array
delete array;
}

© 2000-2019, MetaQuotes Software Corp.


**Shift**

Moves an item from a given position in the array to the specified offset.

```cpp
bool Shift(
    int pos,     // position
    int shift    // shift
)
```

**Parameters**

*pos*
- [in] Position of the moved element in the array

*shift*
- [in] The shift value (both positive and negative).

**Return Value**

true - successful, false - cannot move the element.

**Example:**

```cpp
//-- example for CArrayString::Shift(int,int)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shift element
    if(!array.Shift(10,-5))
    {
        printf("Shift error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Delete

Removes the element from the specified array position.

```cpp
bool Delete(
    int pos  // position
)
```

Parameters

`pos`

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```cpp
//--- example for CArrayString::Delete(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- delete element
    if(!array.Delete(0))
    {
        printf("Delete error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
DeleteRange

Deletes a group of elements from the specified array position.

```cpp
bool DeleteRange(
    int from,  // position of the first element
    int to     // position of last element
)
```

Parameters

- **from**
  - [in] Position of the first array element to be removed.

- **to**
  - [in] Position of the last array element to be removed.

Return Value

- true - successful, false - cannot remove the elements.

Example:

```cpp
#include "Arrays\ArrayString.mqh"

void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- delete elements
    if(!array.DeleteRange(0,10))
    {
        printf("Delete error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
At

Gets the element from the specified array position.

```cpp
string At(
    int pos  // position
) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, "" - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, "" may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```cpp
//--- example for CArrayString::At(int)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //--
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    for(int i=0;i<array.Total();i++)
    {
        string result=array.At(i);
        if(result=="" && GetLastError() == ERR_OUT_OF_RANGE)
        {
            //--- Error reading from array
            printf("Get element error");
            delete array;
            return;
        }
        //--- use element
        //--- . . .
    }
}
2900

Standard Library

CompareArray
Compares the array with another one.

bool CompareArray(
const string& src[]
) const

// source array

Parameters
src[]
[in]

Reference to an array used as a source of elements for comparison.

Return Value
true - arrays are equal, false - arrays are not equal.

Example:
//--- example for CArrayString::CompareArray(const string &[])
#include <Arrays\ArrayString.mqh>
//--string src[];
//--void OnStart()
{
CArrayString *array=new CArrayString;
//--if(array==NULL)
{
printf("Object create error");
return;
}
//--- compare with another array
int result=array.CompareArray(src);
//--- delete array
delete array;
}

© 2000-2019, MetaQuotes Software Corp.


2901

Standard Library

CompareArray
Compares the array with another one.

bool CompareArrays(
const CArrayString* src
) const

// pointer to the source

Parameters
src
[in]

Pointer to an instance of the CArrayString class used as a source of elements for comparison.

Return Value
true - successful, false - cannot copy the items.

Example:
//--- example for CArrayString::CompareArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
//--void OnStart()
{
CArrayString *array=new CArrayString;
//--if(array==NULL)
{
printf("Object create error");
return;
}
//--- create source array
CArrayString *src=new CArrayString;
if(src==NULL)
{
printf("Object create error");
delete array;
return;
}
//--- add source arrays elements
//--- . . .
//--- compare with another array
int result=array.CompareArray(src);
//--- delete arrays
delete src;
delete array;
}

© 2000-2019, MetaQuotes Software Corp.


InsertSort

Inserts an element in a sorted array.

```cpp
bool InsertSort(
    string element // element to insert
)
```

Parameters

`element`

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```cpp
//--- example for CArrayString::InsertSort(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- insert element
    if(!array.InsertSort("ABC"))
    {
        printf("Insert error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Search

Searches for an element equal to the sample in the sorted array.

```cpp
int Search(
    string element    // sample
) const
```

Parameters

`element`

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```cpp
//--- example for CArrayString::Search(string)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- search element
    if(array.Search("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```c
int SearchGreat(
    string element // sample
) const
```

**Parameters**

- `element`  
  [in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```c
//--- example for CArrayString::SearchGreat(string)  
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array= new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- 
    //--- sort array
    array.Sort();
    //--- search element
    if(array.SearchGreat("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
2905

Standard Library

SearchLess
Searches for an element with a value less than the value of the sample in the sorted array.

int SearchLess(
string element
) const

// sample

Parameters
element
[in]

The sample element to search in the array.

Return Value
The position of the found element - successful, -1 - the element not found.

Example:
//--- example for CArrayString:: SearchLess(string)
#include <Arrays\ArrayString.mqh>
//--void OnStart()
{
CArrayString *array=new CArrayString;
//--if(array==NULL)
{
printf("Object create error");
return;
}
//--- add arrays elements
//--- . . .
//--- sort array
array.Sort();
//--- search element
if(array.SearchLess("ABC")!=-1) printf("Element found");
else
printf("Element not found");
//--- delete array
delete array;
}

© 2000-2019, MetaQuotes Software Corp.


SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```c
int SearchGreatOrEqual(
    string element        // sample
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```c
//--- example for CArrayString:: SearchGreatOrEqual(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- search element
    if(array.SearchGreatOrEqual("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```c
int SearchLessOrEqual(
    string element // sample
) const
```

Parameters

- `element` [in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```c
//--- example for CArrayString::SearchLessOrEqual(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- 
    //--- sort array
    array.Sort();
    //--- search element
    if(array.SearchLessOrEqual("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchFirst

Searches for the first element equal to the sample in the sorted array.

```cpp
int SearchFirst(
    string element // sample
) const
```

**Parameters**

`element`

[in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```cpp
//--- example for CArrayString:: SearchFirst(string)
#include <Arrays\ArrayString.mqh>
//--
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- search element
    if(array.SearchFirst("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
2909

Standard Library

SearchLast
Searches for the last element equal to the sample in the sorted array.

int SearchLast(
string element
) const

// sample

Parameters
element
[in]

The sample element to search in the array.

Return Value
The position of the found element - successful, -1 - the element not found.

Example:
//--- example for CArrayString:: SearchLast(string)
#include <Arrays\ArrayString.mqh>
//--void OnStart()
{
CArrayString *array=new CArrayString;
//--if(array==NULL)
{
printf("Object create error");
return;
}
//--- add arrays elements
//--- . . .
//--- sort array
array.Sort();
//--- search element
if(array.SearchLast("ABC")!=-1) printf("Element found");
else
printf("Element not found");
//--- delete array
delete array;
}

© 2000-2019, MetaQuotes Software Corp.


SearchLinear

Searches for the element equal to the sample in the array.

```cpp
int SearchLinear(
    string element // sample
) const
```

Parameters

`element`

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```cpp
//--- example for CArrayString::SearchLinear(string)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
        {
            printf("Object create error");
            return;
        }
    //--- add arrays elements
    //--- . . .
    //--- search element
    if(array.SearchLinear("ABC")!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
Save

Saves data array in the file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

Parameters

`file_handle`

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

`true` - successfully completed, `false` - error.

Example:

```cpp
#include <Arrays\ArrayString.mqh>

void OnStart()
{
    int file_handle;
    CArrayString *array = new CArrayString;
    //---
    if(array!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add 100 arrays elements
    for(int i=0;i<100;i++)
    {
        array.Add(IntegerToString(i));
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!array.Save(file_handle))
        {
            //--- file save error
            printf("File save: Error %d!",GetLastError());
            delete array;
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
}
```
```
} delete array;
}
```
Load

Loads data array from the file.

```cpp
virtual bool Load(
    int file_handle  // file handle
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```cpp
//--- example for CArrayString::Load(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    int file_handle;
    CArrayString *array=new CArrayString;
    //---
    if(array!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
    if(file_handle>0)
    {
        if(!array.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!",GetLastError());
            delete array;
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
    //--- use arrays elements
    for(int i=0;i<array.Total();i++)
    {
        printf("Element[%d] = '%s'",i,array.At(i));
    }
    delete array;
}
```
```cpp
}  
delete array; 
```

Type

Gets the array type identifier.

```cpp
virtual int Type() const
```

Return Value

Array type identifier (for CArrayString - 89).

Example:

```cpp
//--- example for CArrayString::Type()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```
CArrayObj

CArrayObj class is a class of dynamic array of pointers to instances of CObject and its derived classes.

Description

Class CArrayObj provides the ability to work with a dynamic array of pointers to instances of CObject and its derived classes. This allows working both with multidimensional dynamic arrays of primitive data types and with data structures that have more complex organization of data.

The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are certain subtleties of the class CArrayObj.

Declaration

```cpp
#include <Arrays\ArrayObj.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CArrayObj

Direct descendants

- CIndicators, CSeries

</table>
sorted array

**SearchLessOrEqual**
Searches for an element with a value less than or equal to the value of the sample in the sorted array

**SearchFirst**
Searches for the first element equal to the sample in the sorted array

**SearchLast**
Searches for the last element equal to the sample in the sorted array

**Input/output**

**Save**
Saves data array in the file

**Load**
Loads data array from the file

**Type**
Gets the type identifier of the array

---

Methods inherited from class CObject

Prev, Prev, Next, Next, **Compare**

Methods inherited from class CArray

**Step**, **Step**, **Total**, **Available**, **Max**, **IsSorted**, **SortMode**, **Clear**, **Sort**

---

Arrays of the CObject class have practical application (including all classes of the Standard Library).

For example, consider the options for two-dimensional array:

```c
#include <Arrays\ArrayDouble.mqh>
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    int i,j;
    int first_size=10;
    int second_size=100;
    //--- create array
    CArrayObj *array=new CArrayObj;
    CArrayDouble *sub_array;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create subarrays
    for(i=0;i<first_size;i++)
    {
        sub_array=new CArrayDouble;
        if(sub_array==NULL)
```
```cpp
{
    delete array;
    printf("Object create error");
    return;
}
//--- fill array
for(j=0;j<second_size;j++)
{
    sub_array.Add(i*j);
} array.Add(sub_array);

//--- create array OK
for(i=0;i<first_size;i++)
{
    sub_array=array.At(i);
    for(j=0;j<second_size;j++)
    {
        double element=sub_array.At(j);
        //--- use array element
    }
}
delete array;

Subtleties

The class has a mechanism to control dynamic memory, so be careful when working with elements of
the array.

Mechanism of memory management can be switched on/off using the method FreeMode (bool). By
default, the mechanism is enabled.

Accordingly, there are two options for dealing with the CArrayObj class:

1. Mechanism of memory management is enabled. (default)

In this case, CArrayObj takes responsibility for releasing the memory used for the elements after their
removal from the array. A custom program should not release the array elements.

Example:
```
int i;
//--- create an array
CArrayObj *array=new CArrayObj;
//--- fill array elements
for(i=0;i<10;i++) array.Add(new CObject);
//--- do something
for(i=0;i<array.Total();i++)
{
```
2. Mechanism of memory management is disabled.

In this case, CArrayObj is not responsible for deallocating of the elements' memory after their removal from the array. Besides, the user program must deallocate the array elements.

Example:

```cpp
int i;
//--- create an array
CArrayObj *array = new CArrayObj;
//--- disable the mechanism of memory management
array.FreeMode(false);
//--- fill array with elements
for (i=0; i<10; i++) array.Add(new CObject);
//--- do something
for (i=0; i<array.Total(); i++)
{
    CObject *object = array.At(i);
    //--- actions performed with the element
    . . .
}
//--- remove array elements
while (!array.Total()) delete array.Detach();
//--- remove empty array
delete array;
```
FreeMode

Gets the flag of memory management.

```cpp
bool FreeMode() const
```

Return Value

Flag of memory management.

Example:

```cpp
//--- example for CArrayObj::FreeMode()
#include <Arrays\ArrayObj.mqh>
//--
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //--
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //-- get free mode flag
    bool array_free_mode=array.FreeMode();
    //-- delete array
    delete array;
}
FreeMode

Sets the flag of memory management.

```cpp
void FreeMode(
    bool mode /* new flag */
)
```

**Parameters**

`mode`

**Return Value**

None.

**Note**

Setting the memory management flag is an important part in the CArrayObj class use. Since the array elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the array.

If the flag is set, removing an element from the array, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, the user must understand his responsibility for the removal of the array before the termination of the program. Otherwise the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to crash of your terminal.

If the user does not reset the memory management flag, there is another pitfall. When pointer elements in array are stored somewhere in the local variables, then removing the array will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the array is responsible for freeing the memory elements.

**Example:**

```cpp
//--- example for CArrayObj::FreeMode(bool)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- reset free mode flag
    array.FreeMode(false);
```
//--- use array
//--- . . .
//--- delete array
delete array;
}
Reserve

Allocates memory to increase the size of the array.

```cpp
bool Reserve(
    int size // number
)
```

Parameters

- `size`
  
  [in] The number of additional elements of the array.

Return Value

- `true` - successful, `false` - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the `Step(int)` method or the default step of 16.

Example:

```cpp
//--- example for CArrayObj::Reserve(int)
#include <Arrays\ArrayObj.mqh>
//--
void OnStart()
{
    CArrayObj* array = new CArrayObj;
    //---
    if (array == NULL)
    {
        printf("Object create error");
        return;
    }
    if (!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
**Resize**

Sets a new (smaller) size of the array.

```cpp
bool Resize(
    int size  // size
)
```

**Parameters**

`size`

[in] New size of the array.

**Return Value**

true - successful, false - there was an attempt to set the size less than zero.

**Note**

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. The memory of the lost elements is released or not depending on the memory management mode.

To reduce fragmentation of memory, change the size of the array is made with a step previously given through the method of Step (int), or 16 (default).

**Example:**

```cpp
//--- example for CArrayObj::Resize(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- resize array
    if(!array.Resize(10))
    {
        printf("Resize error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}```
Clear

Removes all elements of the array without the release of the memory array.

```cpp
void Clear()
```

Return Value

No.

Note

If the memory management flag is enabled, the memory used for the deleted objects is released.

Example:

```cpp
//--- example for CArrayObj::Clear()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- clear array
    array.Clear();
    //--- delete array
    delete array;
}
```
**Shutdown**

Clears the array with full deallocation of memory for it (but not for its elements).

```cpp
bool Shutdown()
```

**Return Value**

true - successful, false - an error occurred.

**Note**

If memory management is enabled, the memory of deleted elements is deallocated.

**Example:**

```cpp
//--- example for CArrayObj::Shutdown()
#include <Arrays\ArrayObj.mqh>
//--
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
**CreateElement**

Creates a new array element at the specified position.

```cpp
bool CreateElement(  
    int index        // position
)
```

**Parameters**

index  
[in] Position in which you want to create a new element.

**Return Value**

true - successful, false - cannot create an element.

**Note**

Method CreateElement(int) in class CArrayObj always returns false and does not perform any action. If necessary, the CreateElement(int) method should be implemented in a derived class.

**Example:**

```cpp
//--- example for CArrayObj::CreateElement(int)
#include <Arrays\ArrayObj.mgh>
//---
void OnStart()  
{
    int size=100;
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- fill array
    array.Reserve(size);
    for(int i=0;i<size;i++)
    {
        if(!array.CreateElement(i))
        {
            printf("Element create error");
            delete array;
            return;
        }
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
```
Add

Adds an element to the end of the array.

```cpp
bool Add(
    CObject* element  // element to add
}
```

**Parameters**

`element`

[in] value of the element to add to the array.

**Return Value**

true - successful, false - cannot add an element.

**Note**

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

**Example:**

```cpp
//--- example for CArrayObj::Add(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj* array = new CArrayObj;
    //---
    if (array == NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add 100 arrays elements
    for (int i = 0; i < 100; i++)
    {
        if (!array.Add(new CObject))
        {
            printf("Element addition error");
            delete array;
            return;
        }
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```
AddArray

Adds elements from one array to the end of another.

```cpp
bool AddArray(
    const CArrayObj * src  // pointer to the source array
)
```

**Parameters**

`src`

[in] Pointer to an instance of the `CArrayDouble` class - source of elements to add.

**Return Value**

true - successful, false - cannot add items.

**Note**

Adding elements from array to array is actually copying the pointers. Therefore, when calling the method, there is a pitfall - there may be a pointer to a dynamic object in more than one variable.

```cpp
//--- example
extern bool make_error;
extern int error;
extern CArrayObj *src;
//--- create a new instance CArrayObj
//--- default memory management is turned on
CArrayObj *array=new CArrayObj;
//--- add (copy) the elements from the source array
if(array!=NULL)
    bool result=array.AddArray(src);
if(make_error)
{
    //--- perform erroneous actions
    switch(error)
    {
    case 0:
        //--- remove the source array without checking its memory management flag
        delete src;
        //--- result:
        //--- it is possible to address an element by invalid pointer in the receive
        break;
    case 1:
        //--- disable the mechanism of memory management in the source array
        if(src.FreeMode()) src.FreeMode(false);
        //--- but do not remove the source array
        //--- result:
        //--- after removing the receiver array, it is possible to address an element
        break;
    case 2:
```
//--- disable the mechanism of memory management in the source array
src.FreeMode(false);
//--- disable the mechanism of memory management in the receiver array
array.FreeMode(false);
//--- result:
//--- after the program termination, get a "memory leak"
break;

} else {
  //--- disable the mechanism of memory management in the source array
  if(src.FreeMode()) src.FreeMode(false);
  //--- delete the source array
  delete src;
  //--- result:
  //--- addressing the receiver array element will be correct
  //--- deleting the receiver array will lead to deleting its elements

Example:

//--- example for CArrayObj::AddArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
  CArrayObj *array=new CArrayObj;
  //---
  if(array==NULL)
  {
    printf("Object create error");
    return;
  }
  //--- create source array
  CArrayObj *src=new CArrayObj;
  if(src==NULL)
  {
    printf("Object create error");
    delete array;
    return;
  }
  //--- reset free mode flag
  src.FreeMode(false);
  //--- fill source array
  //--- ...
  //--- add another array
  if(!array.AddArray(src))
{
    printf("Array addition error");
    delete src;
    delete array;
    return;
}

///-- delete source array without elements
delete src;
///-- use array
///-- . . .
///-- delete array
delete array;
}
Insert

Inserts an element to the specified position in the array.

```cpp
bool Insert(
    CObject* element,    // element to insert
    int pos               // position
)
```

Parameters

- `element`
  - [in] Value of the element to be inserted into an array

- `pos`
  - [in] Position in the array to insert

Return Value

- `true` - successful, `false` - cannot insert the element.

Note

- Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```cpp
//--- example for CArrayObj::Insert(CObject*,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj* array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- insert elements
    for(int i=0;i<100;i++)
    {
        if(!array.Insert(new CObject,0))
        {
            printf("Insert error");
            delete array;
            return;
        }
    }
    //--- use array
    //--- . . .
    //--- delete array
```
delete array;
}

2935
InsertArray

Inserts elements of one array from the specified position of another array.

```cpp
bool InsertArray(
    const CArrayObj* src,  // pointer to the source
    int pos  // position
);
```

Parameters

- `src`  
  [in] Pointer to an instance of the CArrayObj class used as a source of elements to insert.

- `pos`  
  [in] Position in the array to insert

Return Value

- true - successful, false - cannot insert items.

Note

See: `CArrayObj::AddArray(const CArrayObj*)`.

Example:

```cpp
#include <Arrays\ArrayObj.mqh>
void OnStart()
{
    CArrayObj* array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayObj* src=new CArrayObj;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- reset free mode flag
    src.FreeMode(false);
    //--- fill source array
    //--- . . .
    //--- insert another array
```
if(!array.InsertArray(src,0))
{
    printf("Array inserting error");
    delete src;
    delete array;
    return;
}

//--- delete source array without elements
delete src;
//--- use array
//--- . . .
//--- delete array
delete array;
AssignArray

Compares the array with another one.

```c
bool AssignArray(
    const CArrayObj* src  // pointer to the source
)
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Note

If the receiver array is not empty when calling AssignArray, then all its elements will be removed; and if the memory management flag is set, the memory used for the deleted elements will be released. The receiver array becomes an exact copy of the source one. Additionally, see CArrayObj::AddArray(const CArrayObj*).

Example:

```c
#include <Arrays\ArrayObj.mqh>

void OnStart()
{
    CArrayObj *array = new CArrayObj;
    //---
    if(array == NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayObj *src = new CArrayObj;
    if(src == NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- reset free mode flag
    src.FreeMode(false);
    //--- fill source array
    //--- . . .
    //--- assign another array
    if(!array.AssignArray(src))
```
```c
{
    printf("Array assigned error");
    delete src;
    delete array;
    return;
}

//--- arrays is identical
//--- delete source array without elements
delete src;
//--- use array
//--- . . .
//--- delete array
delete array;
}```
Update

Changes the element at the specified array position.

```cpp
bool Update(
    int pos,     // position
    CObject* element     // value
)
```

Parameters

- **pos**
  
  [in] Position of the element in the array to change

- **element**
  
  [in] New value of the element

Return Value

true - successful, false - cannot change the element.

Note

The element will not change if an invalid pointer (for example, NULL) is passed as a parameter. If the memory management is enabled, the memory of a replaced element is deallocated.

Example:

```cpp
//--- example for CArrayObj::Update(int, CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array = new CArrayObj;
    //---
    if (array == NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- update element
    if (!array.Update(0, new CObject))
    {
        printf("Update error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Standard Library

Shift

Moves an item from a given position in the array to the specified offset.

```cpp
bool Shift(
    int pos,    // position
    int shift   // shift
)
```

Parameters

*pos*  
[in] Position of the moved element in the array

*shift*  
[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```cpp
//--- example for CArrayObj::Shift(int,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {  
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shift element
    if(!array.Shift(10,-5))
    {
        printf("Shift error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
### Detach

Removes an element from a given position in the array.

```
CObject* Detach(
    int pos  // position
)
```

**Parameters**

pos

[in] Position of a removed item in the array.

**Return Value**

Pointer to the removed element - success, NULL - cannot remove the element.

**Note**

When an element is removed from the array, it will not be deleted regardless of the memory management flag. Once the array element pointer is used, it has to be deallocated.

**Example:**

```c
#include <Arrays\ArrayObj.mgh>

void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    CObject *object=array.Detach(0);
    if(object==NULL)
    {
        printf("Detach error");
        delete array;
        return;
    }
    //--- use element
    //--- . . .
    //--- delete element
    delete object;
    //--- delete array
    delete array;
}
```
Delete

Removes the element from the specified array position.

```cpp
bool Delete(
    int pos  // position
)
```

**Parameters**

*pos*  
[in] Position of the array element to be removed.

**Return Value**

true - successful, false - cannot remove the element.

**Note**

If the memory management is enabled, the memory of deleted elements is deallocated.

**Example:**

```cpp
//--- example for CArrayObj::Delete(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    if(!array.Delete(0))
    {
        printf("Delete error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
DeleteRange

Deletes a group of elements from the specified array position.

```c
bool DeleteRange(
    int from, // position of the first element
    int to    // position of last element
)
```

Parameters

`from`
- [in] Position of the first array element to be removed.

`to`
- [in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove elements.

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```c
//--- example for CArrayObj::DeleteRange(int,int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- delete elements
    if(!array.DeleteRange(0,10))
    {
        printf("Delete error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
**At**

Gets the element from the specified array position.

```cpp
CObject* At(
    int pos    // position
)
```

**Parameters**

`pos`

[in] Position of the desired element in the array.

**Return Value**

The value of the element - successful, NULL- there was an attempt to get an element of a non-existent position.

**Example:**

```cpp
//--- example for CArrayObj::At(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add elements
    //--- . . .
    for(int i=0;i<array.Total();i++)
    {
        CObject *result=array.At(i);
        if(result==NULL)
        {
            //--- Error reading from array
            printf("Get element error");
            delete array;
            return;
        }
        //--- use element
        //--- . . .
    }
    delete array;
}
```
**CompareArray**

Compares the array with another one.

```cpp
bool CompareArray(
    const CArrayObj* src  // pointer to the source
) const
```

**Parameters**

*src*

[in] Pointer to an instance of the CArrayObj class used as a source of elements for comparison.

**Return Value**

true - the arrays are equal - the arrays are not equal.

**Example:**

```cpp
//--- example for CArrayObj::CompareArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayObj *src=new CArrayObj;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- fill source array
    //--- . . .
    //--- compare with another array
    int result=array memcmp(src);
    //--- delete arrays
    delete src;
    delete array;
}
```
### InsertSort

Inserts an element in a sorted array.

```cpp
bool InsertSort(
    CObject* element // element to insert
)
```

**Parameters**

- `element`  
  [in] Value of the element to be inserted into a sorted array

**Return Value**

- true - successful, false - cannot insert the element.

**Note**

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

**Example:**

```cpp
//--- example for CArrayObj::InsertSort(CObject*)
#include <Arrays\ArrayObj.mqh>
//--
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- insert element
    if(!array.InsertSort(new CObject))
    {
        printf("Insert error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```
Search

Searches for an element equal to the sample in the sorted array.

```c
int Search(
    CObject* element    // sample
) const
```

Parameters

`element`

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```c
//--- example for CArrayObj::Search(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj* array = new CArrayObj;
    //---
    if(array == NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject* sample = new CObject;
    if(sample == NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.Search(sample) != -1) printf("Element found");
    else                  printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```c
int SearchGreat(
    CObject* element // sample
) const
```

**Parameters**

*element*  
[in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```c
#include <Arrays\ArrayObj.mqh>

void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchGreat(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
**SearchLess**

Searches for an element with a value less than the value of the sample in the sorted array.

```c
int SearchLess(
    CObject* element // sample
) const
```

**Parameters**

- **element**
  
  [in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```c
//--- example for CArrayObj:: SearchLess(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }\n//--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchLess(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```cpp
int SearchGreatOrEqual(
    CObject*  element   // sample
) const
```

Parameters

**element**

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```cpp
//--- example for CArrayObj::SearchGreatOrEqual(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchGreatOrEqual(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
**SearchLessOrEqual**

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```cpp
int SearchLessOrEqual(
    CObject* element // sample
) const
```

**Parameters**

`element`

[in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```cpp
#include <Arrays\ArrayObj.mqh>

void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchLessOrEqual(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
SearchFirst

Searches for the first element equal to the sample in the sorted array.

```cpp
int SearchFirst(
    CObject* element // sample
) const
```

Parameters

- `element`  
  [in] The sample element to search in the array.

Return Value

- The position of the found element - successful, -1 - the element not found.

Example:

```cpp
//--- example for CArrayObj::SearchFirst(CObject*)
#include <Arrays\ArrayObj.mqh>
//--
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchFirst(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
**SearchLast**

Searches for the last element equal to the sample in the sorted array.

```cpp
int SearchLast(
    CObject* element      // sample
) const
```

**Parameters**

*element*

[in] The sample element to search in the array.

**Return Value**

The position of the found element - successful, -1 - the element not found.

**Example:**

```cpp
//--- example for CArrayObj:: SearchLast(CObject*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- sort array
    array.Sort();
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete array;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(array.SearchLast(sample)!=-1) printf("Element found");
    else printf("Element not found");
    //--- delete array
    delete array;
}
```
Save

Saves data array in the file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

Parameters

`file_handle`

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```cpp
//--- example for CArrayObj::Save(int)
#include <Arrays:ArrayObj.mqh>
//---
void OnStart()
{
    int file_handle;
    CArrayObj *array=new CArrayObj;
    //---
    if(array!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!array.Save(file_handle))
        {
            //--- file save error
            printf("File save: Error %d!",GetLastError());
            delete array;
            FileClose(file_handle);
            //---
            return;
        }
    FileClose(file_handle);
}
delete array;
}
```
Load

Loads data array from the file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] Handle of the binary file previously opened using the FileOpen(...) function.

**Return Value**

`true` - successfully completed, `false` - error.

**Note**

When reading array elements from the file, the `CArrayObj::CreateElement(int)` method is called to create each element.

**Example:**

```cpp
//--- example for CArrayObj::Load(int)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    int file_handle;
    CArrayObj *array = new CArrayObj;
    //---
    if (array!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!array.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!",GetLastError());
            delete array;
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
}
```
//--- use arrays elements
//--- . . .
//--- delete array
delete array;
}
Type

Gets the array type identifier.

```cpp
virtual int Type() const
```

**Return Value**

Array type identifier (for CArrayObj - 7778).

**Example:**

```cpp
//--- example for CArrayObj::Type()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=arr.array.Type();
    //--- delete array
    delete array;
}
```
CList

CList Class is a class of dynamic list of instances of the CObject class and its derived classes.

Description

Class CList provides the ability to work with a list of instances of CObject and its derived classes. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are some subtleties of working with the CList class. The class has a mechanism to control dynamic memory, so be careful when working with elements of the list.

Subtleties of the mechanism of memory management similar to those described in CArrayObj.

Declaration

```cpp
class CList : public CObject
```

Title

```cpp
#include <Arrays\List.mqh>
```

Inheritance hierarchy

- CObject
- CList

Methods inherited from class `CObject`

- Prev, Prev, Next, Next, **Compare**
FreeMode

Gets the flag of memory management when deleting list elements.

```cpp
bool FreeMode() const
```

Return Value

Flag of memory management.

Example:

```cpp
#include <Arrays\List.mqh>

void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get free mode flag
    bool list_free_mode=list.FreeMode();
    //--- delete list
    delete list;
}
```
FreeMode

Sets the flag of memory management when deleting list elements.

```c
void FreeMode(
    bool mode  // new value
)
```

Parameters

- `mode`
  

Note

Setting the memory management flag is an important part in the CList class use. Since the list elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the list.

If the flag is set, when removing an element from the list, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, users should understand their responsibility for the removal of the list elements before the termination of the program. Otherwise, the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to a terminal crash.

If the user program does not reset the memory management flag, there is another "pitfall". When pointer elements in list are stored somewhere in the local variables, then removing the list will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the list is responsible for releasing the memory elements.

Example:

```c
//--- example for CList::FreeMode(bool)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- reset free mode flag
    list.FreeMode(false);
    //--- use list
    //--- . . .
    //--- delete list
```
delete list;
}
**Total**

Gets the number of elements in the list.

```cpp
int Total() const
```

**Return Value**

Number of elements in the list.

**Example:**

```cpp
//--- example for CList::Total()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check total
    int total=list.Total();
    //--- use list
    //--- ...
    //--- delete list
    delete list;
}
```
IsSorted

Gets the sorted list flag.

```cpp
bool IsSorted(
    int mode=0 // sorting mode
) const
```

**Parameters**

`mode=0`

[in] Checked sort mode.

**Return Value**

Flag of the sorted list. Returns true if the list is sorted using the specified mode, otherwise returns false.

**Note**

Flag of the sorted list cannot be changed directly. The flag is set by `Sort(int)` and resets by any add/insert methods.

**Example:**

```cpp
//--- example for CList::IsSorted()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check sorted
    if(list.IsSorted(0))
    {
        //--- use methods for sorted list
        //--- ...
    }
    //--- delete list
    delete list;
}
```
SortMode

Gets the version of the sorting.

```
int SortMode() const
```

Return Value

Sorting mode, or -1 if the list is not sorted.

Example:

```
#include <Arrays\List.mqh>

void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check sort mode
    int sort_mode=list.SortMode();
    //--- use list
    //--- ...
    //--- delete list
    delete list;
}
```
CreateElement

Creates a new element of the list.

CObject* CreateElement()

Return Value

Pointer to the newly created element - successful, NULL - cannot create an element.

Note

Method CreateElement () in the CList class always returns NULL and does not perform any actions. If necessary, method CreateElement () should be implemented in a derived class.

Example:

```cpp
//--- example for CList::CreateElement(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    int size=100;
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- fill list
    for(int i=0;i<size;i++)
    {
        CObject *object=list.CreateElement();
        if(object==NULL)
        {
            printf("Element create error");
            delete list;
            return;
        }
        list.Add(object);
    }
    //--- use list
    //--- . . .
    //--- delete list
    delete list;
}
```
Add

Adds an element to the end of the list.

```
int Add(
    CObject* element  // element to add
)
```

Parameters

- `element`
  - [in] Value of the element to add to the list.

Return Value

- Index of the added element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```cpp
//--- example for CList::Add(CObject*)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add 100 elements
    for(int i=0;i<100;i++)
    {
        if(list.Add(new CObject)==-1)
        {
            printf("Element addition error");
            delete list;
            return;
        }
    }
    //--- use list
    //--- . . .
    //--- delete list
    delete list;
}
```
Insert

Inserts an element to the specified position in the list.

```cpp
int Insert(
    CObject* element, // element to insert
    int pos        // position
)
```

Parameters

- **element**
  
  [in] value of the element to insert in the list

- **pos**
  
  [in] position in the list to insert

Return Value

index of inserted element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```cpp
//--- example for CList::Insert(CObject*,int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- insert 100 elements
    for(int i=0;i<100;i++)
    {
        if(list.Insert( new CObject,0)==-1)
        {
            printf("Element insert error");
            delete list;
            return;
        }
    }
    //--- use list
    //--- . . .
```
//--- delete list
delete list;
}
**DetachCurrent**

Extracts an element from the current position in the list without its "physical" deletion.

```
CObject* DetachCurrent()
```

**Return Value**

Pointer to the removed element in case of success, NULL - cannot remove the element.

**Note**

When removed from the list, the element is not removed in any state of the memory management flag. The pointer to the extracted element should be released after it has been used.

**Example:**

```c
//--- example for CList::DetachCurrent()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.DetachCurrent();
    if(object==NULL)
    {
        printf("Detach error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- delete element
delete object;
    //--- delete list
delete list;
}
**DeleteCurrent**

Removes the element from the current position in the list.

```cpp
bool DeleteCurrent();
```

**Return Value**

true - successful, false - cannot remove the element.

**Note**

If the memory management is enabled, memory for the removed element is deallocated.

**Example:**

```cpp
//--- example for CList::DeleteCurrent()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    if(!list.DeleteCurrent())
    {
        printf("Delete error");
        delete list;
        return;
    }
    //--- delete list
    delete list;
}
```
Delete

Removes the element from the given position in the list.

```cpp
bool Delete(
    int pos        // position
)
```

Parameters

*pos*

* [in] position of element to be removed from the list.

Return Value

*true* - successful, *false* - cannot remove the element.

Note

If the memory management flag is enabled, the memory used for the deleted element is released.

Example:

```cpp
//--- example for CList::Delete(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    if(!list>Delete(0))
    {
        printf("Delete error");
        delete list;
        return;
    }
    //--- delete list
    delete list;
}```
Clear

Removes all elements of the list.

```cpp
void Clear()
```

**Note**

If the memory management is enabled, the memory of deleted elements is deallocated.

**Example:**

```cpp
//--- example for CList::Clear()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    //--- clear list
    list.Clear();
    //--- delete list
    delete list;
}
```
**IndexOf**

Gets the index of the specified list element.

```cpp
int IndexOf(
    CObject* element   // pointer to the element
)
```

**Parameters**

- `element`
  
  [in] pointer to the list element.

**Return Value**

List element index, or -1.

**Example:**

```cpp
//--- example for CList::IndexOf(CObject*)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    CObject *object=new CObject;
    if(object==NULL)
    {
        printf("Element create error");
        delete list;
        return;
    }
    if(list.Add(object))
    {
        int pos=list.IndexOf(object);
    }
    //--- delete list
    delete list;
}
```
**GetNodeAtIndex**

Gets an element from the specified position in the list.

```cpp
CObject* GetNodeAtIndex(int pos) // position
```

**Parameters**

`pos`

[in] element position in the list.

**Return Value**

pointer to the element - success, NULL - cannot receive a pointer.

**Example:**

```cpp
//--- example for CList::GetNodeAtIndex(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetNodeAtIndex(10);
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```
GetFirstNode

Gets the first element of the list.

```cpp
CObject* GetFirstNode()
```

Return Value

Pointer to the first element - success, NULL - cannot get a pointer.

Example:

```cpp
//--- example for CList::GetFirstNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetFirstNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```
GetPrevNode

Gets the previous element of the list.

CObject* GetPrevNode()

Return Value

Pointer to the previous element - successful, NULL - cannot get a pointer.

Example:

```cpp
//--- example for CList::GetPrevNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetPrevNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```
GetCurrentNode

Gets the current list element.

```cpp
CObject* GetCurrentNode()
```

Return Value

Pointer to the current element - successful, NULL - cannot get a pointer.

Example:

```cpp
#include <Arrays\List.mqh>

void OnStart()
{
  CList *list=new CList;
  //---
  if(list==NULL)
  {
    printf("Object create error");
    return;
  }
  //--- add list elements
  //--- . . .
  CObject *object=list.GetCurrentNode();
  if(object==NULL)
  {
    printf("Get node error");
    delete list;
    return;
  }
  //--- use element
  //--- . . .
  //--- do not delete element
  //--- delete list
  delete list;
}
```
**GetNextNode**

Gets the next element in the list.

```cpp
CObject* GetNextNode()
```

**Return Value**

Pointer to the next element - successful, NULL - cannot get a pointer.

**Example:**

```cpp
//--- example for CList::GetNextNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetNextNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```
GetLastNode

Gets the last element of the list.

CObject* GetLastNode()

Return Value

Pointer to the last element - success, NULL - cannot get a pointer.

Example:

```c
//--- example for CList::GetLastNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetLastNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
Sort

Sorts a list.

```cpp
void Sort(
    int mode // sorting mode
)
```

Parameters

- `mode`  
  [in] Sorting mode.

Return Value

- No.

Note

- The list is always sorted in ascending order.

Example:

```cpp
//--- example for CList::Sort(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- sorting by mode 0
    list.Sort(0);
    //---- use list
    //---- ...
    //--- delete list
    delete list;
}
```
**MoveToIndex**

Moves the current element in the list to the specified position.

```cpp
bool MoveToIndex(
    int  pos  // position
)
```

**Parameters**

`pos`

[in] position in the list to move.

**Return Value**

true - successful, false - cannot move the element.

**Example:**

```cpp
//--- example for CList::MoveToIndex(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- move current node to begin
    list.MoveToIndex(0);
    //--- use list
    //--- . . .
    //--- delete list
    delete list;
}
```
**Exchange**

Swaps two elements in the list.

```cpp
bool Exchange(
    CObject* node1, // list element
    CObject* node2  // list element
)
```

**Parameters**

- `node1` [in] list element
- `node2` [in] list element

**Return Value**

- `true` - successful, `false` - cannot swap the elements.

**Example:**

```cpp
#include <Arrays\List.mqh>

void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- exchange
    list.Exchange(list.GetFirstNode(),list.GetLastNode());
    //--- use list
    //--- . . .
    //--- delete list
    delete list;
}
```
**CompareList**

Compares the list with another one.

```cpp
bool CompareList(
    CList* list  // pointer to the source
)
```

**Parameters**

- `list`
  - [in] a pointer to an instance of the CList class used as a source of elements for comparison.

**Return Value**

- `true` - the lists are equal, `false` - the lists are not equal.

**Example:**

```cpp
//--- example for CList::CompareList(const CList*)
#include <Arrays\List.mqh>
//--
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source list
    CList *src=new CList;
    if(src==NULL)
    {
        printf("Object create error");
        delete list;
        return;
    }
    //--- fill source list
    //--- . . .
    //--- compare with another list
    bool result=list.CompareList(src);
    //--- delete lists
    delete src;
    delete list;
}
```
Search

Searches for an element equal to the sample in the sorted list.

```
CObject* Search(
    CObject* element    // sample
)
```

**Parameters**

- `element`
  
  [in] element sample to search for in the list.

**Return Value**

Pointer to the found element - successful, NULL - the element is not found.

**Example:**

```c
#include <Arrays\List.mqh>

void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add lists elements
    //--- . . .
    //--- sort list
    list.Sort(0);
    //--- create sample
    CObject *sample=new CObject;
    if(sample==NULL)
    {
        printf("Sample create error");
        delete list;
        return;
    }
    //--- set sample attributes
    //--- . . .
    //--- search element
    if(list.Search(sample)!=NULL) printf("Element found");
    else printf("Element not found");
    //--- delete list
    delete list;
}
```
Save

Saves list data in the file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  - [in] Handle of the binary file previously opened using the FileOpen() function.

**Return Value**

- true - successfully completed, false - error.

**Example:**

```cpp
//--- example for CList::Save(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    int file_handle;
    CList *list = new CList;
    //---
    if(list!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add lists elements
    //--- . . .
    //--- open file
    file_handle = FileOpen("MyFile.bin", FILE_WRITE|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!list.Save(file_handle))
        {
            //--- file save error
            printf("File save: Error %d", GetLastError());
            delete list;
            FileClose(file_handle);
            //---
            return;
        }
    }
    //--- delete list
    delete list;
}
```
Load

Loads list data from the file.

```c
virtual bool Load(
    int file_handle  // file handle
)
```

**Parameters**

`file_handle`

[in] Handle of the binary file previously opened using the FileOpen () function.

**Return Value**

true - successfully completed, false - error.

**Note**

When reading list elements from the file, the `CList::createElement(int)` method is called to create each element.

**Example:**

```c
//--- example for CLoad::Load(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    int file_handle;
    CList *list=new CList;
    //---
    if(list!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!list.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!",GetLastError());
            delete list;
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
```
//--- use list elements
//--- . . .
//--- delete list
delete list;
}
Type

Gets the list type identifier.

```cpp
virtual int Type()
```

**Return Value**

List type identifier (for CList - 7779).

**Example:**

```cpp
//--- example for CList::Type()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get list type
    int type=list.Type();
    //--- delete list
    delete list;
}
```
CTreeNode

CTreeNode is a class of the CTree binary tree node.

Description

CTreeNode provides the ability to work with nodes of the CTree binary tree. Options of navigation through the tree are implemented in the class. Besides, methods of working with the file are implemented.

Declaration

```cpp
class CTreeNode : public CObject
```

Title

```cpp
#include <Arrays\TreeNode.mqh>
```

Inheritance hierarchy

- CObject
- CTreeNode

Direct descendants

- CTree

Methods inherited from class CObject
    Prev, Prev, Next, Next, Save, Load, Compare

Trees of CTreeNode class descendants have practical application.

A descendant of CTreeNode class should have predefined methods: CreateSample creates a new instance of the descendant class of CTreeNode, Compare compares values of key fields of the descendant class of CTreeNode, Type (if it is necessary to identify a node), SaveNode and LoadNode (if it is necessary to work with a file).

Let’s consider an example of a CTree descendant class.

```c++
//+------------------------------------------------------------------+
//|                                                   MyTreeNode.m |

   else      m_string="";
//--- reading custom variable of datetime type
   m_datetime=FileReadLong(file_handle);
//---
   return(true);
}
Owner

Gets the pointer of the owner node.

```cpp
CTreeNode* Owner()
```

Return Value

Pointer of the owner node.

Owner

Sets the pointer of the owner node.

```cpp
void Owner(
    CTreeNode* node  // node
)
```

Parameters

`node`

[in] New value of the pointer of the owner node.

Return Value

None.
# Left

Gets the pointer of the left node.

```
CTreeNode* Left()
```

**Return Value**

Pointer of the left node.

# Left

Sets the pointer of the left node.

```
void Left(
    CTreeNode* node // node
)
```

**Parameters**

- `node`
  
  [in] New value of the pointer of the left node.

**Return Value**

None.
Right

Gets the pointer of the right node.

```cpp
CTreeNode* Right()
```

Return Value

The pointer of the right node.

Right

Sets the pointer of the right node.

```cpp
void Right(
    CTreeNode* node  // node
)
```

Parameters

`node`

[in] New value of the pointer of the right node.

Return Value

None.
Balance

Gets the node balance.

```cpp
int Balance() const
```

Return Value

Node balance.
BalanceL

Gets the balance of the left sub-branch of the node.

```cpp
int BalanceL() const
```

Return Value

Balance of the left sub-branch of the node.
BalanceR

Gets the balance of the right sub-branch of the node.

```cpp
int BalanceR() const
```

Return Value

Balance of the right sub-branch of the node.
CreateSample

Creates a new node sample.

```
virtual CTreeNode* CreateSample()
```

Return Value

Pointer to the new node sample or NULL.
**RefreshBalance**

Recalculates the node balance.

```cpp
int RefreshBalance()
```

**Return Value**

Node balance.
GetNext

Gets the pointer of the next node.

```cpp
CTreeNode* GetNext(
    CTreeNode* node // node
)
```

Parameters

- `node`  

Return Value

- Pointer of the next node.
SaveNode

Writes node data to a file.

```c
bool SaveNode(
    int file_handle  // handle
)
```

**Parameters**

`file_handle`

[in] Handle of a binary file that was earlier opened for writing.

**Return Value**

`true` - success, otherwise `false`. 
LoadNode

Reads node data from a file.

```cpp
bool LoadNode(
    int    file_handle,    // handle
    CTreeNode* main        // node
)
```

Parameters

- `file_handle` [in] Handle of a binary file that was earlier opened for reading.
- `main` [in] Node for data.

Return Value

- `true` - success, otherwise `false`.
**Type**

Gets the identifier of the node type.

```cpp
virtual int Type() const
```

Return Value

Identifier of the node type.
CTree

CTree is a class of the binary tree of the instances of CTreeNode class and its descendants.

Description

CTree class provides the possibility to work with the binary tree of CTreeNode class instances and its descendants. Options of adding/inserting/deleting of tree elements and search in the tree are implemented in the class. Besides that, methods of working with a file are implemented.

Note that mechanism of dynamic memory management is not implemented in class CTree (unlike classes CList and CArrayObj). All tree nodes are deleted with memory deallocation.

Declaration

```cpp
class CTree : public CTreeNode
```

Title

```
#include <Arrays\Tree.mqh>
```

Inheritance hierarchy

CObject  
CTreeNode

Trees of CTreeNode class descendants - descendants of class CTree - have practical application.

Descendant of CTree class should have a predefined method CreateElement that creates a new instance of the CTreeNode descendant class.

Let's consider an example of the CTree descendant class.

```cpp
//+------------------------------------------------------------------+
//|                                                       MyTree.m |

    }
    node.SetString(str_array[mode%10]);
    node.SetDateTime(10000*mode);
Root

Gets the root node of the tree.

```cpp
CTreeNode* Root() const
```

Return Value

Pointer of the root node of the tree.
**CreateElement**

Creates a new instance of the node.

```cpp
virtual CTreeNode* CreateElement();
```

**Return Value**

Pointer of the new instance of the node or NULL.
Insert

Adds a node to a tree.

```c
CTreeNode* Insert(
    CTreeNode* new_node  // node
)
```

**Parameters**

`new_node`

[in] Pointer of a node to insert to a tree.

**Return Value**

Pointer of the owner node or NULL.
Detach

Detaches a specified node from a tree.

```plaintext
bool Detach(
    CTreeNode* node // node
)
```

Parameters

- `node`
  - [in] Node pointer to detach.

Return Value

- true - success, otherwise false.

Note

- After detachment, the node pointer is not released. The tree is balanced.
Delete

Deletes a specified node from a tree.

```cpp
bool Delete(
    CTreeNode* node  // node
)
```

Parameters

node

[in] Node pointer to delete.

Return Value

true - success, otherwise false.

Note

After deletion, a node pointer is released. The tree is balanced.
Clear

Deletes all nodes of a tree.

```cpp
void Clear()
```

Return Value

None.

Note

After deletion, node pointers are released.
Find

Searches for a node in a tree by sample.

```cpp
CTreeNode* Find(
    CTreeNode* node // node
)
```

Parameters

node

[in] Node that contains data used as a search sample.

Return Value

Pointer of the found node or NULL.
Save

Writes tree data to a file.

```
virtual bool Save(
    int file_handle  // handle
)
```

Parameters

- `file_handle`

  [in] Handle of a binary file that was earlier opened for writing.

Return Value

- true - success, otherwise false.
Load

Reads tree data from a file.

```cpp
virtual bool Load(
    int file_handle // handle
)
```

Parameters

- `file_handle`
  - [in] Handle of a binary file that was earlier opened for reading.

Return Value

- `true` - success, otherwise `false`. 
Type

Gets identifier of the tree type.

```
virtual int Type() const
```

Return Value

Identifier of the tree type.
Generic Data Collections

The library provides classes and interfaces that define generic collections, which allow users to create strongly typed collections. These collections provide greater convenience and data handling performance than non-generic typed collections.

The library is available in the Include\Generic folder of the terminal working directory.

ICollection\<T\>

ICollection\<T\> is an interface for implementing generic data collections.

Description

The ICollection\<T\> interface determines basic methods to work with collections, including methods to count elements, to clear a collection, to add or delete elements, and others.

Declaration

```
template<typename T>
interface ICollection
```

Header

```
#include <Generic\Interfaces\ICollection.mgh>
```

Inheritance Hierarchy

ICollection

Direct descendants

CLinkedList, CQueue, CRedBlackTree, CStack, IList, IMap, ISet

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>Adds an element to a collection</td>
</tr>
<tr>
<td>Count</td>
<td>Returns the number of elements in a collection</td>

<tr>
<td>CopyTo</td>
<td>Copies all elements of a collection to the specified array starting at the specified index</td>
</tr>
<tr>
<td>Clear</td>
<td>Removes all elements from a collection</td>
</tr>
<tr>
<td>Remove</td>
<td>Removes the first occurrence of the specified element from a collection</td>
</tr>
</tbody>
</table>
Add

Adds an element to a collection.

```cpp
bool Add(
    T value  // the value of the element
);
```

Parameters

- `value`
  - [in] The value of the element to add.

Return Value

- Returns true on successful, or false otherwise.
Count

Returns the number of elements in a collection.

    int Count();

Return Value

Returns the number of elements.
Contains

Determines whether a collection contains an element with the specified value.

```cpp
bool Contains(
    T item // the search value
);
```

Parameters

- **item**
  - [in] The searched value.

Return Value

Returns true if an element with the specified value is found in the collection, or false otherwise.
CopyTo

Copies all elements of a collection to the specified array starting at the specified index.

```cpp
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // starting index for writing
);
```

Parameters

- `dst_array[]`
  - [out] An array to which the elements of the collection will be written.
- `dst_start=0`
  - [in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
Clear

Removes all elements of a collection.

```c
void Clear();
```
Remove

Removes the first occurrence of the specified element from a collection.

```cpp
bool Remove(
    T item       // the element value
);
```

Parameters

- `item`
  
  [in] The value of the element to be deleted.

Return Value

- Returns true on successful, or false otherwise.
**IEqualityComparable<T>**

IEqualityComparable<T> is an interface for implementing objects that can be compared.

**Description**

The IEqualityComparable<T> interface defines methods to retrieve the hash code of the current object and to check whether it is equal to another object of the same type.

**Declaration**

```cpp
template<typename T>
interface IEqualityComparable
```

**Header**

```
#include <Generic\Interfaces\IEqualityComparable.mqh>
```

**Inheritance Hierarchy**

IEqualityComparable

**Direct descendants**

IComparable

**Class Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Compares the current object with the specified value</td>
</tr>
<tr>
<td>HashCode</td>
<td>Calculates the hash code value for the current object</td>
</tr>
</tbody>
</table>
## Equals

Compares the current object with the specified value.

```cpp
bool Equals(T value) // the value to compare
```

### Parameters

- `value`  
  `[in]` The value to compare the current object with.

### Return Value

Returns true if the objects are equal, or false otherwise.
**HashCode**

Calculates the hash code value for the current object.

```cpp
int HashCode();
```

**Return Value**

Returns the hash code.
IComparable<T>

IComparable<T> is an interface for implementing objects that can be compared to find out whether one is greater than, less than or equal to the other one.

Description

The IComparable<T> interface defines a method to compare the current object to another object of the same type, on the basis of which the collection of these objects can be sorted.

Declaration

```cpp
template<typename T>
interface IComparable : public IEquityComparable<T>
```

Header

```cpp
#include <Generic\Interfaces\IComparable.mqh>
```

Inheritance Hierarchy

IEquityComparable
    IComparable

Direct descendants

CKeyValuePair

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare</td>
<td>Compares the current object with the specified value</td>
</tr>
</tbody>
</table>
Compare

Compares the current object with the specified value.

```cpp
int Compare(T value) // the value to compare
```

**Parameters**

- `value`  
  [in] The value to compare the current object with.

**Return Value**

Returns a number that expresses the ratio of the current and passed object:

- if the result is less than zero, the current object is less than the passed one
- if the result is zero, the current object is equal to the passed one
- if the result is greater than zero, the current object is greater than the passed one
**IComparer<T>**

IComparer<T> is an interface for implementing a generic class that compares two objects of the T type, whether one is greater than, less than or equal to the other one.

**Description**

The IComparer<T> interface determines a method to compare two objects of the T type, on the basis of which a collection of these objects can be sorted.

**Declaration**

```
template<typename T>
interface IComparer
```

**Header**

```
#include <Generic\Interfaces\IComparer.mqh>
```

**Inheritance Hierarchy**

IComparer

Direct descendants

CDefaultComparer

**Class Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare</td>
<td>Compares two values of type T</td>
</tr>
</tbody>
</table>
Compare

Compares two values of type T.

```cpp
int Compare(
    T x,  // the first value
    T y   // the second value
);
```

Parameters

x

[in] The first value to compare.

y

[in] The first value to compare.

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, x is less than y (x<y)
- if the result is equal to zero, x is equal to y (x=y)
- if the result is greater than zero, x is greater than y (x>y)
IEqualityComparer<T>

IEqualityComparer<T> is an interface for implementing a generic class that compares two object of the T type.

Description

The IEqualityComparer<T> interface defines methods to retrieve the hash code of a T type object and to check whether two objects of type T are equal.

Declaration

```cpp
template<typename T>
interface IEqualityComparer
```

Header

```cpp
#include <Generic\Interfaces\IEqualityComparer.mqh>
```

Inheritance Hierarchy

IEqualityComparer

Direct descendants

CDefaultEqualityComparer

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Compares two values of type T</td>
</tr>
<tr>
<td>HashCode</td>
<td>Calculates the hash code value based on the T type object</td>
</tr>
</tbody>
</table>
**Equals**

Compares two values of type `T`.

```cpp
bool Equals(
    T x,  // the first value
    T y   // the second value
);
```

**Parameters**

- `x`
  - `[in]` The first value to compare.

- `y`
  - `[in]` The second value to compare.

**Return Value**

Returns true if the values are equal, or false otherwise.
HashCode

Calculates the hash code value based on the T type object.

```cpp
int HashCode(
    T value // an object for calculation
);
```

**Parameters**

`value`

[in] The object for which you want to get the hash code.

**Return Value**

Returns the hash code.
IList<T>

IList<T> is an interface for implementing generic data lists.

Description

The IList<T> interface defines basic methods to work with lists, such as to access an element by index, to search and delete elements, sort, and others.

Declaration

```cpp
template<typename T>
interface IList : public ICollection<T>
```

Header

```cpp
#include <Generic\Interfaces\IList.mqh>
```

Inheritance Hierarchy

- ICollection
- IList

Direct descendants

- CArrayList

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TryGetValue</td>
<td>Gets a list element at the specified index</td>

</tr>
<tr>
<td>LastIndexOf</td>
<td>Searches for the last occurrence of a value in a list</td>
</tr>
<tr>
<td>RemoveAt</td>
<td>Removes a list element at the specified index</td>
</tr>
</tbody>
</table>
TryGetValue

Gets a list element at the specified index.

```cpp
bool TryGetValue(
    const int index, // element index
    T& value // a variable for writing
);
```

Parameters

index

[in] The index of the element from the list.

value

[out] The variable to which the specified value of the element from the list will be written.

Return Value

Returns true on successful, or false otherwise.
TrySetValue

Changes a value from the list at the specified index.

```cpp
bool TrySetValue(
    const int index, // element index
    T value        // new value
);
```

Parameters

index

[in] The index of the element from the list.

value

[in] The new value to assign to the specified list element.

Return Value

Returns true on successful, or false otherwise.
Insert

Inserts an element into the list at the specified index.

```cpp
bool Insert(
    const int index, // index to insert at
    T item         // the value to be inserted
);
```

Parameters

index

[in] The index to insert at.

item

[in] The value to be inserted at the specified index.

Return Value

Returns true on successful, or false otherwise.
**IndexOf**

Searches for the first occurrence of a value in a list.

```c
int IndexOf(
    T item // the search value
);
```

**Parameters**

*item*

[in] The searched value.

**Return Value**

Returns the index of the first found element. If the value is not found, returns -1.
LastIndexOf

Searches for the last occurrence of a value in a list.

```c
int LastIndexOf(
    T item // the search value
);
```

Parameters

- **item**
  - [in] The searched value.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.
RemoveAt

Removes a list element at the specified index.

```cpp
bool RemoveAt(
    const int index // element index
);
```

**Parameters**

*index*

[in] The index of the element that you want to delete.

**Return Value**

Returns true on successful, or false otherwise.
IMap<TKey, TValue>

IMap<TKey, TValue> is an interface for implementing generic collections of key/value pairs.

Description

The IMap<TKey, TValue> interface defines basic methods to work with collections whose data are stored as key/value pairs.

Declaration

```cpp
template<typename TKey, typename TValue>
interface IMap : public ICollection<TKey>
```

Header

```cpp
#include "Generic\Interfaces\IMap.mqh"
```

Inheritance Hierarchy

- ICollection
  - IMap

Direct descendants

- CHashMap, CSortedMap

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>Adds a key/value pair to a collection</td>
</tr>

</tr>
<tr>
<td>CopyTo</td>
<td>Copies all key/value pairs from a collection to specified arrays, starting at the specified index</td>
</tr>
</tbody>
</table>
Add

Adds a key/value pair to a collection.

```cpp
bool Add(
    TKey key,    // key
    TValue value  // value
);
```

**Parameters**

- **key**  
  [in] Key.

- **value**  
  [in] Value.

**Return Value**

Returns true on successful, or false otherwise.
Contains

Determines whether a collection contains the key/value table with the specified key.

```cpp
bool Contains(
    TKey key,       // key
    TValue value    // value
);
```

Parameters

- `key`
  - [in] Key.
- `value`
  - [in] Value.

Return Value

Returns true, if the collection contains the key/value pair with the specified key and value, or false otherwise.
# Remove

Removes the first occurrence of a key/value pair from a collection.

```cpp
bool Remove(
    TKey key // key
);
```

**Parameters**

- `key`  
  - `[in]` Key.

**Return Value**

- Returns true on successful, or false otherwise.
TryGetValue

Gets an element with the specified key from a collection.

```cpp
template<typename TKey, typename TValue>
bool TryGetValue(TKey key, TValue& value);```

Parameters

- **key**
  - [in] Key.

- **value**
  - [out] The variable to which the specified value of the key/value pair will be written.

Return Value

Returns true on successful, or false otherwise.
TrySetValue

Changes the value of the key/value pair from the collection at the specified key.

```cpp
bool TrySetValue(
    TKey key,  // key
    TValue value  // new value
);
```

**Parameters**

- **key**
  - [in] Key.

- **value**
  - [in] The new value to assign to the specified key-value pair.

**Return Value**

Returns true on successful, or false otherwise.
CopyTo

Copies all key/value pairs from a collection to the specified arrays, starting at the specified index.

```c
int CopyTo(
    TKey& dst_keys[], // an array for writing keys
    TValue& dst_values[], // an array for writing values
    const int dst_start=0 // the starting index for writing
);
```

Parameters

&dst_keys[]

[out] An array to which all keys from the collection will be written.

&dst_values[]

[out] An array to which values of corresponding keys from the collection will be written.

dst_start=0

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied key/value pairs.
**ISet<T>**

ISet<T> is an interface for implementing generic data sets.

**Description**

The ISet interface defines basic methods to work with sets, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

**Declaration**

```cpp
#include <Generic\Interfaces\ISet.mqh>
```

**Inheritance Hierarchy**

- ICollection
  - ISet
    - CHashSet, CSortedSet

**Class Methods**

</tbody>
</table>
**ExceptWith**

Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

**A version for working with the collection that implements the ICollection<T> interface.**

```csharp
void ExceptWith(
    ICollection<T>* collection          // collection
);
```

**A version for working with an array.**

```csharp
void ExceptWith(
    T& array[]                      // array
);
```

**Parameters**

*collection

  [in] A collection to be excepted from the current set.

&collection[]

  [in] An array to be excepted from the current set.

**Note**

The result is written to the current collection (array).
IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void IntersectWith(
    ICollection<T>* collection  // collection
);
```

A version for working with an array.

```csharp
void IntersectWith(
    T& array[]  // array
);
```

Parameters

*collection
  
  [in] A collection with which the current set will be intersected.

&collection[]
  
  [in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).
**SymmetricExceptWith**

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection\<T\> interface.

```csharp
void SymmetricExceptWith(
    ICollection\<T\>* collection // collection
);
```

A version for working with an array.

```csharp
void SymmetricExceptWith(
    T& array[] // array
);
```

**Parameters**

*collection
  
  [in] A collection to produce the symmetrical difference with.

&collection[]
  
  [in] An array to produce the symmetrical difference with.

**Note**

The result is written to the current collection (array).
UnionWith

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void UnionWith(
    ICollection<T>* collection  // collection
);
```

A version for working with an array.

```csharp
void UnionWith(
    T& array[]  // array
);
```

Parameters

*collection

[in] A collection with which the current set will be united.

&collection[]

[in] An array with which the current set will be united.

Note

The result is written to the current collection (array).
IsProperSubsetOf

Determines whether the current set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```cpp
bool IsProperSubsetOf(
    ICollection<T>* collection     // a collection to determine the relation
);
```

A version for working with an array.

```cpp
bool IsProperSubsetOf(
    T& array[]                   // an array to determine the relation
);
```

Parameters

*collection

  [in] A collection to determine the relation.

&collection[]

  [in] An array to determine the relation.

Return Value

Returns true if the current set is a proper subset, or false otherwise.
IsProperSupersetOf

Determines whether the current set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection\lt T \gt \ interface.

```csharp
bool IsProperSupersetOf(
    ICollection\lt T\gt* collection // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsProperSupersetOf(
    T\& array[]          // an array to determine the relation
);
```

Parameters

*collection

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper superset, or false otherwise.
**IsSubsetOf**

Determines whether the current set is a subset of the specified collection or array.

A version for working with the collection that implements the `IICollection<`T`>` interface.

```csharp
bool IsSubsetOf(
    ICollection<T>* collection // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsSubsetOf(
    T4 array[] // an array to determine the relation
);
```

**Parameters**

*collection

  [in] A collection to determine the relation.

&collection[]

  [in] An array to determine the relation.

**Return Value**

Returns true if the current set is a subset, or false otherwise.
IsSupersetOf

Determines whether the current set is a superset of the specified collection or array.

A version for working with the collection that implements the ICollection\<T\> interface.

```cpp
bool IsSupersetOf(
    ICollection\<T\>* collection          // a collection to determine the relation
);
```

A version for working with an array.

```cpp
bool IsSupersetOf(
    T& array[]                                   // an array to determine the relation
);
```

Parameters

*collection

[in] A collection to determine the relation.

&collection

[in] An array to determine the relation.

Return Value

Returns true if the current set is a superset, or false otherwise.
**Overlaps**

Determines whether the current set overlaps the specified collection or array.

A version for working with the collection that implements the `ICollection<T>` interface.

```cpp
bool Overlaps(
    ICollection<T>* collection  // a collection to compare
);
```

A version for working with an array.

```cpp
bool Overlaps(
    T& array[]               // an array to compare
);
```

**Parameters**

*`collection`

&`collection[]`

**Return Value**

Returns true if the current set and a collection or an array overlap, or false otherwise.
**SetEquals**

Determines whether the current set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool SetEquals(
    ICollection<T>* collection // a collection to compare
);
```

A version for working with an array.

```csharp
bool SetEquals(
    T& array[] // an array to compare
);
```

**Parameters**

*collection
  - [in] A collection to compare elements.

&collection[]
  - [in] A collection to compare elements.

**Return Value**

Returns true if the current set contains all elements of the specified collection or array, or false otherwise.
CDefaultComparer<T>

CDefaultComparer<T> is a helper class that implements the IComparer<T> generic interface based on Compare global methods.

Description

The CDefaultComparer<T> class is used by default in generic data collections, unless the user implicitly uses another class implementing the IComparer<T> interface.

Declaration

```
template<typename T>
class CDefaultComparer : public IComparer<T>
```

Header

```
#include <Generic\Internal\DefaultComparer.mqh>
```

Inheritance Hierarchy

- IComparer
- CDefaultComparer

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compare</td>
<td>Compares two values of type T</td>
</tr>
</tbody>
</table>
Compare

Compares two values of type T.

```c
int Compare(
    T x, // the first value
    T y  // the second value
);
```

Parameters

- `x`  
  [in] The first value to compare.

- `y`  
  [in] The second value to compare.

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, `x` is less than `y` (`x < y`)
- if the result is equal to zero, `x` is equal to `y` (`x = y`)
- if the result is greater than zero, `x` is greater than `y` (`x > y`)

Note

The `x` and `y` values are compared based on one of the overloads of the `Compare` global method depending on the `T` type.
CDefaultEqualityComparer<T>

CDefaultEqualityComparer<T> is a helper class that implements the IEqualityComparer<T> generic interface based on Equals<T> and GetHashCode global methods.

Description

The CDefaultEqualityComparer<T> class is used by default in generic data collections, unless the user implicitly uses another class implementing the IEqualityComparer<T> interface.

Declaration

```cpp
template<typename T>
class CDefaultEqualityComparer : public IEqualityComparer<T>
```

Header

```cpp
#include <Generic\Internal\DefaultEqualityComparer.mqh>
```

Inheritance Hierarchy

- IEqualityComparer
  - CDefaultEqualityComparer

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equals</td>
<td>Compares two values of type T</td>
</tr>
<tr>
<td>GetHashCode</td>
<td>Calculates the hash code value based on the T type object</td>
</tr>
</tbody>
</table>
Equals

Compares two values of type T.

```c
bool Equals(
    T x,  // the first value
    T y   // the second value
);
```

Parameters

x

[in] The first value to compare.

y

[in] The second value to compare.

Return Value

Returns true if the values are equal, or false otherwise.
HashCode

Calculates the hash code value based on the T type object.

```cpp
int HashCode(
    T value // an object for calculation
);
```

Parameters

value

[in] The object for which you want to get the hash code.

Return Value

Returns the hash code.
**CRedBlackTreeNode<T>**

CRedBlackTreeNode<T> is a helper class used in implementing the CRedBlackTree<T> class.

**Description**

The CRedBlackTreeNode<T> class is a node of the CRedBlackTree<T>. Tree navigation methods are implemented in the class.

**Declaration**

```cpp
template<typename T>
class CRedBlackTreeNode
```

**Header**

```cpp
#include <Generic\RedBlackTree.mqh>
```

**Class Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>Returns and sets a node value</td>
</tr>
<tr>
<td>Parent</td>
<td>Returns and sets a pointer to the parent node</td>
</tr>
<tr>
<td>Left</td>
<td>Returns and sets a pointer to the left node</td>
</tr>
<tr>
<td>Right</td>
<td>Returns and sets a pointer to the right node</td>
</tr>
<tr>
<td>Color</td>
<td>Returns and sets a node color</td>
</tr>
<tr>
<td>IsLeaf</td>
<td>Determines whether the specified node is a leaf</td>
</tr>
<tr>
<td>CreateEmptyNode</td>
<td>Creates a new black node with no parent and children, and returns a pointer to it</td>
</tr>
</tbody>
</table>
Value (the Get method)

Returns the node value.

```
T Value();
```

Return Value

Returns the node value.

**Value (the Set method)**

Sets the node value

```
void Value(
    T value     // node value
);
```

**Parameters**

*value*

[in] Node value.
**Parent (the Get method)**

Returns a pointer to the parent node.

```cpp
cRedBlackTreeNode<T>* Parent();
```

**Return Value**

Returns a pointer to the parent node.

**Parent (the Set method)**

Sets a pointer to the parent node.

```cpp
void Parent(
    cRedBlackTreeNode<T>* node // a pointer to the parent node
);
```

**Parameters**

*node

[in] A pointer to the parent node.
**Left (the Get method)**

Returns a pointer to the left node.

```cpp
CRedBlackTreeNode<T>* Left();
```

**Return Value**

Returns a pointer to the left node.

**Left (the Set method)**

Sets a pointer to the left node.

```cpp
void Left(
    CRedBlackTreeNode<T>* node  // a pointer to the left node
);
```

**Parameters**

*node

[in] A pointer to the left node.
Right (the Get method)

Returns a pointer to the right node.

```cpp
CRedBlackTreeNode<T>* Right();
```

Return Value

Returns a pointer to the right node.

Right (the Set method)

Sets a pointer to the right node.

```cpp
void Right(
    CRedBlackTreeNode<T>* node  // a pointer to the right node
);
```

Parameters

*node

[in] A pointer to the right node.
Color (Get method)

Returns a node color.

```cpp
ENUM_RED_BLACK_TREE_NODE_TYPE Color();
```

Return Value

Returns a node color.

Color (Set method)

Sets the node color.

```cpp
void Color(
    ENUM_RED_BLACK_TREE_NODE_TYPE clr  // node color
);
```

Parameters

- `clr`
  - [in] Node color.

Note

The color of the node is set using a value from ENUM_RED_BLACK_TREE_NODE_TYPE. It can be of two types:
- RED_BLACK_TREE_NODE_RED — the red color of the node;
- RED_BLACK_TREE_NODE_BLACK — the black color of the node.
IsLeaf

Determines whether the specified node is a leaf.

```cpp
bool IsLeaf();
```

Return Value

Returns true if the node is a leaf, or false otherwise.
CreateEmptyNode

Creates a new black node with no parent and children, and returns a pointer to it.

```
static CRedBlackTreeNode<T>* CreateEmptyNode();
```

Return Value

Returns a pointer to the new node.
CLinkedListNode<T>

CLinkedListNode<T> is a helper class used in implementing the CLinkedListNode<T> class.

Description

The CLinkedListNode<T> class is a node of the doubly linked list CLinkedListNode<T>. List navigation methods are implemented in the class.

Declaration

```cpp
template<typename T>
class CLinkedListNode
```

Header

```cpp
#include <Generic\LinkedList.mqh>
```

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List</td>
<td>Returns and sets a pointer to the CLinkedList&lt;T&gt;</td>
</tr>
<tr>
<td>Next</td>
<td>Returns and sets a pointer to the next node</td>
</tr>
<tr>
<td>Previous</td>
<td>Returns and sets a pointer to the previous node</td>
</tr>
<tr>
<td>Value</td>
<td>Returns and sets the node value</td>
</tr>
</tbody>
</table>
**List (the Get method)**

Returns a pointer to the `CLinkedList<T>`.

```
CLinkedList<T>* List();
```

**Return Value**

Returns a pointer to the `CLinkedList<T>` linked list.

**List (the Set method)**

Sets a pointer to the `CLinkedList<T>`.

```
void List(
    CLinkedList<T>* value  // a pointer to the list
);
```

**Parameters**

`*value`

[in] A pointer to the linked list `CLinkedList<T>`. 
Next (the Get method)

Returns a pointer to the next node.

```cpp
CLinkedList<T>* Next();
```

Return Value

Returns a pointer to the next node.

Next (the Set method)

Sets a pointer to the next node

```cpp
void Next(
    CLinkedList<T>* value; // a pointer to the next node
);
```

Parameters

*value

[in] A pointer to the next node.
**Previous (the Get method)**

Returns a pointer to the previous node.

```cpp
CLinkedListNode<T>* Previous();
```

**Return Value**

Returns a pointer to the previous node.

**Previous (the Set method)**

Sets a pointer to the previous node.

```cpp
void Previous(
    CLinkedListNode<T>* value  // a pointer to the previous node
);
```

**Parameters**

*value

  [in] A pointer to the previous node.
Value (the Get method)

Returns the node value.

```cpp
T Value();
```

Return Value

Returns the node value.

Value (the Set method)

Sets the node value

```cpp
void Value(
    T value  // Node value
);
```

Parameters

- `value`
  
  [in] Node value.
**CKeyValuePair<TKey,TValue>**

The CKeyValuePair<TKey,TValue> class implements a key/value pair.

**Description**

The CKeyValuePair<TKey,TValue> class implements methods for working with the key and the value of the key/value pair.

**Declaration**

```cpp
template<typename TKey, typename TValue>
class CKeyValuePair : public IComparable<CKeyValuePair<TKey,TValue>*,
```n

**Header**

```cpp
#include <Generic\HashMap.mqh>
```n

**Inheritance Hierarchy**

<table>
<thead>
<tr>
<th>IEqualityComparable</th>
</tr>
</thead>
<tbody>
<tr>
<td>IComparable</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>CKeyValuePair</td>
</tr>
</tbody>
</table>

**Class Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>Gets and sets the key in the key/value pair</td>
</tr>
<tr>
<td>Value</td>
<td>Gets and sets the value in the key/value pair</td>
</tr>
<tr>
<td>Clone</td>
<td>Creates a new key/value pair whose key and value are equal to the current ones</td>
</tr>
<tr>
<td>Compare</td>
<td>Compares the current key/value pair to the specified one</td>
</tr>
<tr>
<td>Equals</td>
<td>Checks whether the current key/value pair and the specified one are equal</td>
</tr>
<tr>
<td>HashCode</td>
<td>Calculates the hash value based on the key/value pair</td>
</tr>
</tbody>
</table>
Key (the Get method)

Gets the key in the key/value pair.

```cpp
TKey Key();
```

Return Value

Returns the key.

Key (the Set method)

Sets the key in the key/value pair.

```cpp
void Key(
    TKey key // key
);
```

Parameters

- **key**
  - [in] Key.
Value (the Get method)

Gets the value in the key/value pair.

```c
TValue Value();
```

Return Value

Returns the value.

Value (the Set method)

Sets the value in the key/value pair.

```c
void Value(
    TValue value  // value
);
```

Parameters

value

[in] Value
Clone

Creates a new key/value pair whose key and value are equal to the current ones.

```
TValue* Clone();
```

Return Value

Returns a new key/value pair
**Compare**

Compares the current key/value pair to the specified one.

```cpp
int Compare(
    CKeyValuePair<TKeyTValue>* pair  // the pair to compare
);
```

**Parameters**

*pair*

[in] The pair to compare.

**Return Value**

Returns a number that expresses the ratio of the current and passed key-value pairs:

- if the result is less than zero, the current key/value pair is less than the passed one
- if the result is zero, the current key/value pair is equal to than the passed one
- if the result is greater than zero, the current key/value pair is greater than the passed one

**Note**

Key/value pairs are compared based on their keys.
**Equals**

Checks whether the current key/value pair and the specified one are equal.

```cpp
bool Equals(
    CKeyValuePair<TKey, TValue>* pair  // the pair to compare
);
```

**Parameters**

*pair*

[in] The pair to compare

**Return Value**

Returns true if the key/value pairs are equal, or false otherwise.

**Note**

Key/value pairs are compared based on their keys.
HashCode

Calculates the hash value based on the key/value pair.

```cpp
int HashCode();
```

Return Value

Returns the hash code.

Note

The hash code of the key/value pair is equal to the key hash code.
CArrayList\<T\> is a generic class that implements the IList\<T\> interface.

**Description**

The CArrayList\<T\> class is an implementation of the dynamic data list of the T type. This class provides the basic methods to work with the list, such as to access an element by index, to search and delete elements, sort, and others.

**Declaration**

```cpp
template<typename T>
class CArrayList : public IList<T>
```

**Header**

```cpp
#include <Generic\Arraylist.mqh>
```

**Inheritance Hierarchy**

- ICollection
  - IList
    - CArrayList

**Class Methods**

<td>Removes an element at the specified index of the list</td>
</tr>
<tr>
<td>RemoveRange</td>
<td>Removes a range of elements from the list</td>
</tr>
<tr>
<td>Reverse</td>
<td>Reverses the order of elements in the list</td>
</tr>
<tr>
<td>Sort</td>
<td>Sorts elements in the list</td>
</tr>
</tbody>
</table>
Capacity (the Get method)

Returns the current list capacity.

```c
int Capacity();
```

Return Value

Returns the current list capacity.

Capacity (the Set method)

Sets the current capacity of a list.

```c
void Capacity(const int capacity); // capacity value
```

Parameters

`capacity`

**Count**

Returns the number of elements in the list.

```c
int Count();
```

**Return Value**

Returns the number of elements.
Contains

Determines whether the list contains an element with the specified value.

```c
bool Contains(
    T item     // the search value
);
```

Parameters

`item`

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the list, or false otherwise.
TrimExcess

Sets the capacity of a list to the actual number of elements, and thus frees up unused memory.

```cpp
void TrimExcess();
```
TryGetValue

Gets an element of the list at the specified index.

```cpp
bool TryGetValue(
const int index, // index
T& value     // a variable to write
);
```

Parameters

- `index`
  - [in] The index of the list element the value of which you want to get.

- `value`
  - [out] The variable to write the element value to.

Return Value

Returns true on successful, or false otherwise.
TrySetValue

Sets the value of the list element at the specified index.

```cpp
bool TrySetValue(
    // index
    const int index,
    // element value
    T value);
```

**Parameters**

- `index`
  - `[in]` The index of the list element the value of which you want to set.

- `value`
  - `[in]` Sets the value of the list element.

**Return Value**

Returns true on successful, or false otherwise.
Add

Adds an element to the list.

```c
bool Add(
    T value  // the value of the element
);
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.
AddRange

Adds a collection or an array of elements to the list.

The version that adds an array.

```cpp
bool AddRange(
    const T& array[] // an array to be added
);
```

The version that adds a collection.

```cpp
bool AddRange(
    ICollection<T>* collection // a collection to be added
);
```

Parameters

`&array[]`

[in] An array to be added.

`*collection`

[in] A collection to be added.

Return Value

Returns true on successful, or false otherwise.
Insert

Inserts an element into the list at the specified index.

```cpp
bool Insert(
    const int  index,  // index to insert at
    T          item    // the value to be inserted
);
```

Parameters

- **index**
  - [in] The index to insert at.

- **item**
  - [in] The value to be inserted at the specified index.

Return Value

Returns true on successful, or false otherwise.
**InsertRange**

Inserts a collection or an array of elements into the list at the specified index.

The version that inserts an array.

```cpp
bool InsertRange(
    const int index,  // index to insert at
    const T& array[]  // an array to be inserted
);
```

The version that inserts a collection.

```cpp
bool InsertRange(
    const int index,  // index to insert at
    ICollection<T>* collection  // a collection to be inserted
);
```

**Parameters**

- `index`  
  - [in] The index to insert at.

- `array[]`  
  - [in] An array to be inserted at the specified index.

- `collection`  
  - [in] A collection to be inserted at the specified index.

**Return Value**

Returns true on successful, or false otherwise.
CopyTo

Copies all elements of a list to the specified array starting at the specified index.

```c
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // the starting index for writing
);
```

Parameters

- `dst_array[]`
  - [out] An array to which the elements of the list will be written.

- `dst_start=0`
  - [in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
BinarySearch

Searches for the specified value in an ascending-sorted list.

The version that searches in the specified range of values using the class that implements the `IComparable<T>` interface for comparing elements.

```csharp
int BinarySearch(
    const int index,       // the starting index
    const int count,       // the search range
    T item,                // the search value
    IComparer<T>* comparer // interface to compare
);
```

The version that searches using the class that implements the `IComparable<T>` interface for comparing elements.

```csharp
int BinarySearch(
    T item,                // the search value
    IComparer<T>* comparer // interface to compare
);
```

The version that searches using the `::Compare` global method for comparing elements.

```csharp
int BinarySearch(
    T item                  // the search value
);
```

**Parameters**

`index`

[in] The starting index from which the search begins.

`count`

[in] The length of the search range.

`item`

[in] The searched value.

`*comparer`

**Return Value**

Returns the index of the found element. If the search value is not found, it returns the index of the smallest element, which is closest in value.
IndexOf

Searches for the first occurrence of a value in a list.

Version that searches in the entire list.

```c
int IndexOf(
    T item,       // the search value
);```

Version that searches from the specified position and to the end of the list.

```c
int IndexOf(
    T item,       // the search value
    const int start_index,   // the starting index
);```

Version that searches from the specified position in the specified range.

```c
int IndexOf(
    T item,       // the search value
    const int start_index,   // the starting index
    const int count,         // the search range
);```

Parameters

- `item`  
  [in] The searched value.

- `start_index`  
  [in] The starting index from which the search begins.

- `count`  
  [in] The length of the search range.

Return Value

Returns the index of the first found element. If the value is not found, returns -1.
LastIndexOf

Searches for the last occurrence of a value in a list.

Version that searches in the entire list.

```c++
int LastIndexOf(
    T item // the search value
);
```

Version that searches from the specified position and to the end of the list.

```c++
int LastIndexOf(
    T item, // the search value
    const int start_index // the starting index
);
```

Version that searches from the specified position in the specified range.

```c++
int LastIndexOf(
    T item, // the search value
    const int start_index, // the starting index
    const int count // the search range
);
```

Parameters

- **item** [in] The searched value.
- **start_index** [in] The starting index from which the search begins.
- **count** [in] The length of the search range.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.
Clear

Removes all elements of a collection.

```cpp
void Clear();
```
Remove

Removes the first occurrence of the specified element from the list.

```cpp
bool Remove(
    T item // the element value
);
```

Parameters

`item`

[in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.
RemoveAt

Removes an element at the specified index of the list.

```cpp
bool RemoveAt(
    const int index  // index
);
```

Parameters

index

[in] The index of the element to remove.

Return Value

Returns true on successful, or false otherwise.
RemoveRange

Removes a range of elements from the list.

```cpp
bool RemoveRange(
    const int start_index, // the starting index
    const int count // the number of elements
);
```

Parameters

- **start_index**
  - [in] The starting index from which the deletion begins.

- **count**
  - [in] The number of elements to be deleted.

Return Value

Returns true on successful, or false otherwise.
Reverse

Reverses the order of elements in the list.

The version for working with the entire list.

```cpp
bool Reverse();
```

The version for working with the specified range of list elements.

```cpp
bool Reverse(
    const int start_index, // the starting index
    const int count // the number of elements
);
```

Parameters

- `start_index`
  - [in] The starting index.

- `count`
  - [in] The number of list elements participating in the operation.

Return Value

Returns true on successful, or false otherwise.
Sort

Sorts elements in the list.

The version that sorts all elements in the list.

```c
bool Sort();
```

The version that sorts all elements in the list using the class that implements the `IComparable<T>` interface for comparing elements.

```c
bool Sort(IComparer<T>* comparer); // interface for comparing
```

The version that sorts the specified range of elements in the list using the class that implements the `IComparable<T>` interface for comparing elements.

```c
bool Sort(const int start_index, // the starting index
          const int count, // the number of elements
          IComparer<T>* comparer // interface to compare
);```

Parameters

start_index [in] The starting index from which sorting begins.

count [in] The length of the sorting range.

Return Value

Returns true on successful, or false otherwise.
CHashMap<TKey, TValue>

CHashMap<TKey, TValue> is a generic class that implements the IMap<TKey, TValue> interface.

**Description**

The CHashMap<TKey, TValue> class is an implementation of the dynamic hash table, the data of which are stored in the form of unordered key/value pairs taking into account the key uniqueness requirement. This class provides basic methods to work with a hash table, such as to access a value by key, to search and delete a key/value pair, and others.

**Declaration**

```cpp
template<typename TKey, typename TValue>
class CHashMap : public IMap<TKey, TValue>
```

**Header**

```cpp
#include <Generic\HashMap.mqh>
```

**Inheritance Hierarchy**

</tbody>
</table>
Add

Adds a key/value pair to the hash table.

A version that adds a generated key/value pair.

```cpp
bool Add(
    CKeyValuePair<TKeyValuePair>* pair  // the key/value pair
);
```

A version that adds a new key/value pair with the specified key and value.

```cpp
bool Add(
    TKey key,  // key
    TValue value // value
);
```

Parameters

*pair
  [in] The key/value pair.

key
  [in] Key.

value
  [in] Value.

Return Value

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the hash table.

```c
int Count();
```
Comparer

Returns a pointer to the IEqualityComparer\<T\> interface, used to organize a hash table.

```cpp
IEqualityComparer\<TKey\>* Comparer() const;
```

Return Value

Returns a pointer to the IEqualityComparer\<T\> interface.
**Contains**

Determines whether the hash table contains the specified key/value pair.

The version for working with a generated key/value pair.

```cpp
bool Contains(
    CKeyValuePair<TKey, TValue>* item // the key/value pair
);```

The version for working with a key/value pair in the form of a separately set key and value.

```cpp
bool Contains(
    TKey key, // key
    TValue value // value
);```

**Parameters**

- **item**
  - [in] The key/value pair.
- **key**
  - [in] Key.
- **value**
  - [in] Value.

**Return Value**

Returns true, if the hash table contains the key/value pair with the specified key and value, or false otherwise.
ContainsKey

Determines whether the hash table contains the key/value pair with the specified key.

```cpp
bool ContainsKey(
    TKey key  // key
);
```

Parameters

- `key`
  - [in] Key.

Return Value

Returns true if the hash table contains a key/value pair with the specified key, or false otherwise.
**ContainsValue**

Determines whether the hash table contains the key/value pair with the specified value.

```cpp
bool ContainsValue(
    TValue value    // value
);
```

**Parameters**

- `value` [in] Value.

**Return Value**

Returns true if the hash table contains a key/value pair with the specified value, or false otherwise.
**CopyTo**

Copies all key/value pairs from the hash table to the specified arrays, starting at the specified index.

The version that copies a hash table to the array of key/value pairs.

```cpp
int CopyTo(
    CKeyValuePair<TKeyTValue>*& dst_array[],  // an array for writing key/value pairs
    const int dst_start=0  // the starting index for writing
);
```

The version that copies a hash table to separate arrays for keys and values.

```cpp
int CopyTo(
    TKey& dst_keys[],  // an array for writing keys
    TValue& dst_values[],  // an array for writing values
    const int dst_start=0  // starting index for writing
);
```

**Parameters**

*`&dst_array[]`

[out] An array to which all pairs from the hash table will be written.

*`&dst_keys[]`

[out] An array to which all keys from the hash table will be written.

*`&dst_values[]`

[out] An array to which all values from the hash table will be written.

*`dst_start=0`

[in] The array index from which copying starts.

**Return Value**

Returns the number of copied key/value pairs.
Clear

Removes all elements from the hash table.

`void Clear();`
Remove

Removes the first occurrence of the key/value pair from the hash table.

The version that removes a key-value pair based on the generated key-value pair.

```cpp
bool Remove(
    CKeyValuePair<TKeyTValue>* item  // the key/value pair
);`
```

The version that removes a key-value pair based on the key.

```cpp
bool Remove(
    TKey key  // key
);`
```

Parameters

* `item`
  [in] The key/value pair.

* `key`
  [in] Key.

Return Value

Returns true on successful, or false otherwise.
TryGetValue

Gets an element with the specified key from the hash table.

```csharp
bool TryGetValue(
    TKey key,       // key
    TValue& value   // a variable for writing the value
);
```

**Parameters**

- **key**
  - [in] Key.
- **value**
  - [out] The variable to which the specified value of the key/value pair will be written.

**Return Value**

Returns true on successful, or false otherwise.
TrySetValue

Changes the value of a key/value pair from the hash table at the specified key.

```cpp
bool TrySetValue(
    TKey key,    // key
    TValue value  // new value
);
```

**Parameters**

*key*

[in] Key.

*value*

[in] The new value to assign to the specified key-value pair.

**Return Value**

Returns true on successful, or false otherwise.
CHashSet<T>

CHashSet<T> is a generic class that implements the ISet<T> interface.

Description

The CHashSet<T> class is an implementation of the unordered dynamic data set of type T, with the required uniqueness of each value. This class provides basic methods to work with sets and related operations, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

Declaration

```cpp
template<typename T>
class CHashSet : public ISet<T>
```

Header

```cpp
#include <Generic\HashSet.mqh>
```

Inheritance Hierarchy

```
ICollection
  ISet
    CHashSet

</table>
# Add

Adds an element to a set.

```cpp
bool Add(
    T value  // the value of the element
);
```

**Parameters**

`value`

[in] The value of the element to add.

**Return Value**

Returns true on successful, or false otherwise.
Count

Returns the number of elements in a set.

```c
int Count();
```

Return Value

Returns the number of elements.
Contains

Determines whether a set contains an element with the specified value.

```cpp
bool Contains(
    T item   // the search value
);
```

**Parameters**

- `item`
  - `[in]` The searched value.

**Return Value**

Returns true if an element with the specified value is found in the set, or false otherwise.
Comparer

Returns a pointer to the IEqualityComparer\textless T\textgreater interface, used to organize a set.

\begin{verbatim}
IEqualityComparer\textless T\textgreater * Comparator() const;
\end{verbatim}

Return Value

Returns a pointer to the IEqualityComparer\textless T\textgreater interface.
TrimExcess

Sets the capacity of a set to the actual number of elements, and thus frees up unused memory.

```cpp
void TrimExcess();
```
CopyTo

Copies all elements of a set to the specified array starting at the specified index.

```c++
int CopyTo(
    T& dst_array[],  // an array for writing
    const int dst_start=0  // starting index for writing
);
```

Parameters

* `dst_array[]`  
  [out] An array to which the elements of the set will be written.

* `dst_start=0`  
  [in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
Clear

Removes all elements from a set.

```cpp
void Clear();
```
## Remove

Removes the specified element from a set.

```cpp
bool Remove(
    T item       // the element value
);
```

### Parameters

* `item`
  
  [in] The value of the element to be deleted.

### Return Value

Returns true on successful, or false otherwise.
ExceptWith

 Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void ExceptWith(
    ICollection<T>* collection  // collection
);
```

A version for working with an array.

```csharp
void ExceptWith(
    T& array[]         // array
);
```

Parameters

*collection

[in] A collection to be excepted from the current set.

&collection[]

[in] An array to be excepted from the current set.

Note

The result is written to the current collection (array).
IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void IntersectWith(
    ICollection<T>* collection // collection
);
```

A version for working with an array.

```csharp
void IntersectWith(
    T& array[] // array
);
```

Parameters

*collection
    [in] A collection with which the current set will be intersected.
&collection[]
    [in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).
SymmetricExceptWith

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void SymmetricExceptWith(
    ICollection<T>* collection     // collection
);
```

A version for working with an array.

```csharp
void SymmetricExceptWith(
    T& array[]                     // array
);
```

Parameters

*collection

[in] A collection to produce the symmetrical difference with.

&collection[]

[in] An array to produce the symmetrical difference with.

Note

The result is written to the current collection (array).
**UnionWith**

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void UnionWith(
    ICollection<T>* collection // collection
);
```

A version for working with an array.

```csharp
void UnionWith(
    T& array[] // array
);
```

**Parameters**

*collection
  
  [in] A collection with which the current set will be united.

&collection[]

  [in] An array with which the current set will be united.

**Note**

The result is written to the current collection (array).
IsProperSubsetOf

Determines whether the current set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool IsProperSubsetOf(
    ICollection<T>* collection   // a collection to determine the relation
);```

A version for working with an array.

```csharp
bool IsProperSubsetOf(
    T* array[]                  // an array to determine the relation
);```

Parameters

*collection
  [in] A collection to determine the relation.

&collection[]
  [in] An array to determine the relation.

Return Value

Returns true if the current set is a proper subset, or false otherwise.
IsProperSupersetOf

Determines whether the current set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool IsProperSupersetOf(
    ICollection<T>* collection
    // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsProperSupersetOf(
    T& array[]
    // an array to determine the relation
);
```

Parameters

*collection

[in] A collection to determine the relation.

&collection[]

[in] An array to determine the relation.

Return Value

Returns true if the current set is a proper superset, or false otherwise.
IsSubsetOf

Determines whether the current set is a subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```cpp
bool IsSubsetOf(
    ICollection<T>* collection  // a collection to determine the relation
);
```

A version for working with an array.

```cpp
bool IsSubsetOf(
    T& array[]  // an array to determine the relation
);
```

Parameters

* `collection`
  - [in] A collection to determine the relation.

* `collection[]`
  - [in] An array to determine the relation.

Return Value

Returns true if the current set is a subset, or false otherwise.
**IsSupersetOf**

Determines whether the current set is a superset of the specified collection or array.

A version for working with the collection that implements the `I Collection<T>` interface.

```csharp
bool IsSupersetOf(
    ICollection<T>* collection // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsSupersetOf(
    T* array[] // an array to determine the relation
);
```

**Parameters**

`*collection`

[in] A collection to determine the relation.

`&collection[]`

[in] An array to determine the relation.

**Return Value**

Returns true if the current set is a superset, or false otherwise.
Overlaps

Determines whether the current set overlaps the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```cpp
bool Overlaps(
    ICollection<T>* collection  // a collection to compare
);
```

A version for working with an array.

```cpp
bool Overlaps(
    T& array[]                  // an array to compare
);
```

Parameters

* `collection`

* `collection[]`

Return Value

Returns true if the current set and a collection or an array overlap, or false otherwise.
SetEquals

Determines whether the current set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```c++
bool SetEquals(
    ICollection<T>* collection // a collection to compare
);
```

A version for working with an array.

```c++
bool SetEquals(
    T array[] // an array to compare
);
```

Parameters

*collection
  

&collection[]
  
  [in] An array to compare elements.

Return Value

Returns true if the current set contains all elements of the specified collection or array, or false otherwise.
CLinkedList<T>

CLinkedList<T> is a generic class that implements the ICollection<T> interface.

Description

The CLinkedList<T> class is an implementation of the dynamic doubly linked data list of the T type. This class provides basic methods to work with doubly linked lists, such as to add, delete, search elements, and others.

Declaration

```cpp
template<typename T>
class CLinkedList : public ICollection<T>
```

Header

```cpp
#include "Generic\LinkedList.mqh"
```

Inheritance Hierarchy

- ICollection
  - CLinkedList

</tbody>
</table>
Add

Adds an element to a linked list.

```cpp
bool Add(
    T value   // the value of the element
);
```

Parameters

value

[in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.
AddAfter

Adds an element after the specified node in the linked list.

The version that adds an element by value.

```cpp
CLinkedListNode<T>* AddAfter(
    CLinkedListNode<T>* node,       // the node after which the element should be added
    T value                      // the element to add
);
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```cpp
bool AddAfter(
    CLinkedListNode<T>* node,       // the node after which the element should be added
    CLinkedListNode<T>* new_node    // the node to be added
);
```

Parameters

*node

[in] The node of the linked list, after which a new element will be added.

value

[in] An element to be added.

*new_node

[in] A node to be added.

Return Value

Returns true on successful, or false otherwise.
AddBefore

Adds an element before the specified node in the linked list.

The version that adds an element by value.

```cpp
CLinkedListNode<T>* AddBefore(
    CLinkedListNode<T>* node, // the node before which the element should be added
    T value               // the element to add
);
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```cpp
bool AddBefore(
    CLinkedListNode<T>* node, // the node before which the element should be added
    CLinkedListNode<T>* new_node // the node to be added
);
```

Parameters

*node
   [in] The node of the linked list, before which a new element will be added.

value
   [in] An element to be added.

*new_node
   [in] A node to be added.

Return Value

Returns true on successful, or false otherwise.
**AddFirst**

Adds an element at the beginning of the linked list.

The version that adds an element by value.

```c
CLinkedListNode<T>* AddFirst(
    T value    // an element to add
);
```

Return Value

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```c
bool AddFirst(
    CLinkedListNode<T>* node  // the node to add
);
```

Parameters

- `value`
  - `in` An element to be added.
- `*node`
  - `in` A node to be added.

Return Value

Returns true on successful, or false otherwise.
**AddLast**

Adds an element at the end of the linked list

The version that adds an element by value.

```c++
CLinkedListNode<T>* AddLast(
    T value // an element to add
);
```

**Return Value**

Returns a pointer to the added node.

The version that adds an element as a formed node by value.

```c++
bool AddLast(
    CLinkedListNode<T>* node // the node to add
);
```

**Parameters**

- `value`  
  [in] An element to be added.

- `*node`  
  [in] A node to be added.

**Return Value**

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the linked list.

```c
int Count();
```

Return Value

Returns the number of elements.
Head

Returns a pointer to the first node of the linked list.

```cpp
CListNode<T>* Head();
```

Return Value

Returns a pointer to the first node.
First

Returns a pointer to the first node of the linked list.

```cpp
CLinkedListNode<T>* First();
```

Return Value

- Returns a pointer to the first node.
**Last**

Returns a pointer to the last node of the linked list.

```cpp
CListNode<T>* Last();
```

**Return Value**

Returns a pointer to the last node.
Contains

Determines whether the linked list contains an element with the specified value.

```cpp
bool Contains(
    T item,  // the search value
);
```

Parameters

`item`

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the linked list, or false otherwise.
CopyTo

Copies all elements of the linked list to the specified array starting at the specified index.

```cpp
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // the starting index for writing
);
```

Parameters

- `&dst_array[]`
  - [out] An array to which the elements of the linked list will be written.

- `dst_start=0`
  - [in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
Clear

Removes all elements of a collection.

```cpp
void Clear();
```
Remove

Removes the first occurrence of the specified element from the linked list.

The version that removes an element by value.

```cpp
bool Remove(
    T item // the element value
);
```

The version that removes an element by a pointer to a node.

```cpp
bool Remove(
    CLinkedListNode<T>* node // the element node
);
```

Parameters

- `item`
  - [in] The value of the element to be deleted.

- `node`
  - [in] The node of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.
RemoveFirst

Removes the first element of the linked list.

```cpp
bool RemoveFirst();
```

Return Value

Returns true on successful, or false otherwise.
**RemoveLast**

Removes the last element of the linked list.

```c
bool RemoveLast();
```

**Return Value**

Returns true on successful, or false otherwise.
Find

Searches for the first occurrence of the specified value in the linked list.

```cpp
CLinkedListNode<T>* Find(
    T value   // the search value
);
```

Parameters

- `value`
  - [in] The searched value.

Return Value

Returns a pointer to the first found node containing the search value on success, or NULL otherwise.
FindLast

Searches for the last occurrence of the specified value in the linked list.

```cpp
CLinkedListNode<T>* FindLast(
    T value    // the search value
);
```

Parameters

value

[in] The searched value.

Return Value

Returns a pointer to the last found node containing the search value on success, or NULL otherwise.
**CQueue<T>**

CQueue<T> is a generic class that implements the ICollection<T> interface.

**Description**

The CQueue<T> class is a dynamic collection of T type data, which is organized as a queue that operates on the FIFO (first in, first out) principle.

**Declaration**

```cpp
template<typename T>
class CQueue : public ICollection<T>
```

**Header**

```cpp
#include <Generic\Queue.mqh>
```

**Inheritance Hierarchy**

- ICollection
- CQueue

# Add

Adds an element to a queue.

```cpp
bool Add(
    T  value  // the value of the element
);
```

## Parameters

- **value**
  - `[in]` The value of the element to add.

## Return Value

Returns true on successful, or false otherwise.
Enqueue

Adds an element to a queue.

```cpp
bool Enqueue(
    T value // element to add
);
```

**Parameters**

`value`

[in] An element to be added.

**Return Value**

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the queue.

```c
int Count();
```

Return Value

Returns the number of elements.
Contains

Determines whether the queue contains an element with the specified value.

```cpp
bool Contains(
    T item // the search value
);
```

Parameters

- **item**
  
  [in] The searched value.

Return Value

Returns true if an element with the specified value is found in the queue, or false otherwise.
TrimExcess

Sets the capacity of a queue to the actual number of elements, and thus frees up unused memory.

```cpp
void TrimExcess();
```
**CopyTo**

Copies all elements of a queue to the specified array starting at the specified index.

```cpp
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // the starting index for writing
);
```

**Parameters**

- `&dst_array[]`
  - [out] An array to which the elements of the queue will be written.

- `dst_start=0`
  - [in] An index in the array from which copying starts.

**Return Value**

Returns the number of copied elements.
Clear

Removes all elements from a queue.

```cpp
void Clear();
```
Remove

Removes the first occurrence of the specified element from the queue.

```cpp
bool Remove(
    T item  // the element value
);
```

Parameters

- **item**
  - [in] The value of the element to be deleted.

Return Value

- Returns true on successful, or false otherwise.
Dequeue

Returns the first element and removes it from the queue.

```
T Dequeue();
```

Return Value

Returns the starting element.
**Peek**

Returns the first element not removing it from the queue.

```cpp
T Peek();
```

**Return Value**

Returns the starting element.
CRedBlackTree<T>

CRedBlackTree<T> is a generic class that implements the ICollection<T> interface.

Description

The CRedBlackTree<T> class is an implementation of a dynamic red-black tree whose nodes store T type data. The class provides basic methods to work with red-black trees, such as to add, delete, search for the maximum and minimum value, and more.

Declaration

```cpp
template<typename T>
class CRedBlackTree : public ICollection<T>
```

Header

```
#include <Generic\RedBlackTree.mqh>
```

Inheritance Hierarchy

```
ICollection

CRedBlackTree
```

</tr>
<tr>
<td>FindMin</td>
<td>Searches for an element with the minimum value in a red-black tree</td>
</tr>
</tbody>
</table>
Add

Adds an element to a red-black tree.

```cpp
bool Add(T value);  // element to add
```

Parameters

- `value`
  
  [in] An element to be added.

Return Value

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the red-black tree.

```c
int Count();
```

**Return Value**

Returns the number of elements.
**Root**

Returns a pointer to the root of the red-black tree.

```
CRedBlackTreeNode<T>* Root();
```

**Return Value**

Returns a pointer to the root.
Contains

Determines whether the red-black tree contains an element with the specified value.

```c++
bool Contains(
    T item // the search value
);
```

Parameters

`item`

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the red-black tree, or false otherwise.
Comparer

Returns a pointer to the IComparer<T> interface used to organize a red-black tree.

```cpp
IComparer<T>* Comparer() const;
```

Return Value

Returns a pointer to the IComparer<T> interface.
TryGetMin

Gets the minimum element of a red-black tree.

```cpp
bool TryGetMin(
    T& min // a variable for writing the value
);
```

Parameters

- `&min` [out] The variable to which the minimum value will be written.

Return Value

Returns true on successful, or false otherwise.
TryGetMax

Gets the maximum element of a red-black tree.

```cpp
bool TryGetMax(
    T& max  // a variable for writing the value
);
```

Parameters

- `&max`
  - `[out]` The variable to which the maximum value will be written.

Return Value

Returns true on successful, or false otherwise.
CopyTo

Copies all elements of a red-black tree to the specified array starting at the specified index.

```cpp
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // starting index for writing
);
```

**Parameters**

- `dst_array[]`
  - [out] An array to which the elements of the red-black tree will be written.

- `dst_start=0`
  - [in] An index in the array from which copying starts.

**Return Value**

Returns the number of copied elements.
Clear

Removes all elements from a red-black tree.

```c
void Clear();
```
Remove

Removes the occurrence of the specified element from a red-black tree.

The version that removes an element with the specified value.

```cpp
bool Remove(
    T value // the element value
);
```

The version that removes an element by a pointer to a node.

```cpp
bool Remove(
    CRedBlackTreeNode<T>* node // the element node
);
```

Parameters

- `item`
  - [in] The value of the element to be deleted.
- `*node`
  - [in] The node of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.
RemoveMin

Removes an element with the minimum value from a red-black tree.

    bool RemoveMin();

Return Value

    Returns true on successful, or false otherwise.
**RemoveMax**

Removes an element with the maximum value from a red-black tree.

```cpp
bool RemoveMax();
```

**Return Value**

Returns true on successful, or false otherwise.
Find

Searches for the occurrence of a specified value in a red-black tree.

```c
CRedBlackTreeNode<T>* Find(
    T value // the search value
);
```

Parameters

- **value**
  - [in] The searched value.

Return Value

Returns a pointer to the found node containing the search value on success, or NULL otherwise.
FindMin

Searches for an element with the minimum value in a red-black tree.

```
CRedBlackTreeNode<T>* FindMin();
```

Return Value

Returns a pointer to the node containing the minimum value on success, or NULL otherwise.
FindMax

Searches for an element with the maximum value in a red-black tree.

```
CRedBlackTreeNode<T>* FindMax();
```

Return Value

Returns a pointer to the node containing the maximum value on success, or NULL otherwise.
CSortedMap<TKey, TValue>

CSortedMap<TKey, TValue> is a generic class that implements the IMap<TKey, TValue> interface.

Description

The CSortedMap<TKey, TValue> class is an implementation of a dynamic hash table whose data are stored as key/value pairs sorted by key and taking into account the key uniqueness requirement. This class provides basic methods to work with a hash table, such as to access a value by key, to search and delete a key/value pair, and others.

Declaration

```cpp
template<typename TKey, typename TValue>
class CSortedMap : public IMap<TKey, TValue>
```

Header

```cpp
#include <Generic\SortedMap.mqh>
```

Inheritance Hierarchy

ICollection

</tr>
</tbody>
</table>
Add

Adds a key/value pair to the hash table.

A version that adds a generated key/value pair.

```cpp
bool Add(
    CKeyValuePair<TKeyTValue>* pair  // the key/value pair
);
```

A version that adds a new key/value pair with the specified key and value.

```cpp
bool Add(
    TKey key,  // key
    TValue value  // value
);
```

Parameters

*pair
  [in] The key/value pair.

key
  [in] Key.

value
  [in] Value.

Return Value

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the sorted hash table.

```c
int Count();
```
Comparer

Returns a pointer to the IComparer<T> interface, used to organize a sorted hash table.

IComparer<TKey>* Comparer() const;

Return Value

Returns a pointer to the IComparer<T> interface.
Contains

Determines whether the sorted hash table contains the specified key/value table.

The version for working with a generated key/value pair.

```cpp
bool Contains(
    CKeyValuePair<TKeyValuePair>* item  // the key/value pair
);
```

The version for working with a key/value pair in the form of a separately set key and value.

```cpp
bool Contains(
    TKey key,  // key
    TValue value  // value
);
```

Parameters

*item

[in] The key/value pair.

key

[in] Key.

value

[in] Value.

Return Value

Returns true, if the sorted hash table contains the key/value pair with the specified key and value, or false otherwise.
ContainsKey

Determines whether the sorted hash table contains the key/value table with the specified key.

```cpp
bool ContainsKey(
    TKey key // key
);
```

**Parameters**

`key`

[in] Key.

**Return Value**

Returns true, if the sorted hash table contains the key/value pair with the specified key, or false otherwise.
ContainsValue

Determines whether the sorted hash table contains the key/value table with the specified value.

```cpp
bool ContainsValue(
    TValue value  // value
);
```

Parameters

- `value` [in] Value.

Return Value

Returns true, if the sorted hash table contains the key/value pair with the specified value, or false otherwise.
**CopyTo**

Copies all key/value pairs from the sorted hash table to the specified arrays, starting at the specified index.

The version that copies a hash table to the array of key/value pairs.

```cpp
int CopyTo(
    CKeyValuePair<TKey, TValue>* dst_array[],
    const int dst_start=0
);  // an array for writing key/value pairs
```

The version that copies a hash table to separate arrays for keys and values.

```cpp
int CopyTo(
    TKey& dst_keys[],
    TValue& dst_values[],
    const int dst_start=0
);  // an array for writing keys
```

**Parameters**

* `*dst_array[]`
  [out] An array to which all pairs from the hash table will be written.

* `&dst_keys[]`
  [out] An array to which all keys from the hash table will be written.

* `&dst_values[]`
  [out] An array to which all values from the hash table will be written.

* `dst_start=0`
  [in] An index in the array from which copying starts.

**Return Value**

Returns the number of copied key/value pairs.
Clear

Removes all elements from the sorted hash table.

```cpp
void Clear();
```
Remove

Removes the first occurrence of the key/value pair from the sorted hash table.

The version that removes a key-value pair based on the generated key-value pair.

```cpp
bool Remove(
    CKeyValuePair<TKey, TValue>* item // the key/value pair
);
```

The version that removes a key-value pair based on the key.

```cpp
bool Remove(
    TKey key // key
);
```

Parameters

*item

[in] The key/value pair.

key

[in] Key.

Return Value

Returns true on successful, or false otherwise.
TryGetValue

Gets an element with the specified key from the sorted hash table.

```csharp
bool TryGetValue(
    TKey key,      // key
    TValue& value   // a variable for writing the value
);
```

Parameters

key
- [in] Key.

$value$
- [out] The variable to which the specified value of the key/value pair will be written.

Return Value

Returns true on successful, or false otherwise.
TrySetValue

Changes the value of the key/value pair from the sorted hash table at the specified key.

```c++
bool TrySetValue(
    TKey key,       // key
    TValue value    // new value
);
```

Parameters

- key
  - [in] Key.

- value
  - [in] The new value to assign to the specified key-value pair.

Return Value

- Returns true on successful, or false otherwise.
CSortedSet<T>

CSortedSet<T> is a generic class that implements the ISet<T> interface.

Description

The CSortedSet<T> class is an implementation of the sorted dynamic data set of type T, with the required uniqueness of each value. This class provides basic methods to work with sets and related operations, such as: the union and intersection of sets, definition of strict and non-strict subsets, and others.

Declaration

```
template<typename T>
class CSortedSet : public ISet<T>
```

Header

```
#include <Generic\SortedSet.mqh>
```

Inheritance Hierarchy

```
ICollection
   ISet
      CSortedSet
```

<td>Gets from the current sorted set a subset specified by the minimum and maximum values</td>
</tr>
<tr>
<td>GetReverse</td>
<td>Gets a copy of the current sorted set, in which all the elements are arranged in a reverse order</td>
</tr>
</tbody>
</table>
Add

Adds an element to a sorted set.

```cpp
bool Add(
    T value     // the value of the element
);
```

Parameters

- `value` [in] The value of the element to add.

Return Value

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the sorted set.

```c
int Count();
```

Return Value

Returns the number of elements.
Contains

Determines whether the sorted set contains an element with the specified value.

```cpp
bool Contains(
    T item // the search value
);
```

Parameters

item

[in] The searched value.

Return Value

Returns true if an element with the specified value is found in the set, or false otherwise.
Comparer

Returns a pointer to the IComparer<T> interface, used to organize a sorted set.

```
IComparer<T>* Comparator() const;
```

Return Value

Returns a pointer to the IComparer<T> interface.
TryGetMin

Gets the minimum element from the sorted set.

```cpp
bool TryGetMin(
    T& min  // a variable for writing the value
);
```

Parameters

`&min`

[out] The variable to which the minimum value will be written.

Return Value

Returns true on successful, or false otherwise.
TryGetMax

Gets the maximum element from the sorted set.

```cpp
bool TryGetMax(
    T& max  // a variable for writing the value
);
```

**Parameters**

- `&max`
  - `[out]` The variable to which the maximum value will be written.

**Return Value**

Returns true on successful, or false otherwise.
CopyTo

Copies all elements of a sorted set to the specified array starting at the specified index.

```cpp
int CopyTo(
    T& dst_array[],     // an array for writing
    const int dst_start=0  // the starting index for writing
);
```

Parameters

`dst_array[]`

[out] An array to which the elements of the set will be written.

`dst_start=0`

[in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
Clear

Removes all elements from a sorted set.

```c
void Clear();
```
Remove

Removes the occurrence of the specified element from the sorted set.

```cpp
bool Remove(T item) // the element value
```

Parameters

- `item`  
  [in] The value of the element to be deleted.

Return Value

Returns true on successful, or false otherwise.
**ExceptWith**

Produces the operation of difference between the current collection and a passed collection (array). It removes from the current collection (array) all elements that are present in the specified collection (array).

### A version for working with the collection that implements the ICollection<T> interface.

```csharp
void ExceptWith(
    ICollection<T>* collection    // collection
);
```

### A version for working with an array.

```csharp
void ExceptWith(
    T& array[]                     // array
);
```

**Parameters**

*collection*

[in] A collection to be excepted from the current sorted set.

&collection[]

[in] An array to be excepted from the current sorted set.

**Note**

The result is written to the current collection (array).
IntersectWith

Produces the operation of intersection of the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```csharp
void IntersectWith(
    ICollection<T>* collection    // collection
);
```

A version for working with an array.

```csharp
void IntersectWith(
    T& array[]                  // array
);
```

Parameters

*collection
  [in] A collection with which the current set will be intersected.

&collection[]
  [in] An array with which the current set will be intersected.

Note

The result is written to the current collection (array).
**SymmetricExceptWith**

Produces the operation of symmetrical difference between the current collection and a passed collection (array). It modifies the current collection to only contain elements that are present in the source object or in the specified collection (array), but not in both of them.

A version for working with the collection that implements the ICollection interface.

```csharp
void SymmetricExceptWith(
    ICollection<T>* collection     // collection
);
```

A version for working with an array.

```csharp
void SymmetricExceptWith(
    T& array[]                          // array
);
```

**Parameters**

*collection

  [in] A collection to produce the symmetrical difference with.

&collection[]

  [in] An array to produce the symmetrical difference with.

**Note**

The result is written to the current collection (array).
UnionWith

Produces the union of the current collection and a passed collection (array). It adds to the current collection (array) missing elements from the specified collection (array).

A version for working with the collection that implements the ICollection<T> interface.

```cpp
void UnionWith(
    ICollection<T>* collection // collection
);
```

A version for working with an array.

```cpp
void UnionWith(
    T& array[] // array
);
```

Parameters

*collection
  [in] A collection with which the current set will be united.

&collection[]
  [in] An array with which the current set will be united.

Note

The result is written to the current collection (array).
IsProperSubsetOf

Determines whether the current sorted set is a proper subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool IsProperSubsetOf(
    ICollection<T>* collection /* a collection to determine the relation */
);
```

A version for working with an array.

```csharp
bool IsProperSubsetOf(
    T* array[] /* an array to determine the relation */
);
```

Parameters

- *collection
  - [in] A collection to determine the relation.

- &collection()
  - [in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a proper subset, or false otherwise.
IsProperSupersetOf

Determines whether the current sorted set is a proper superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool IsProperSupersetOf(
    ICollection<T>* collection // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsProperSupersetOf(
    T4 array[] // an array to determine the relation
);
```

Parameters

`*collection`

[in] A collection to determine the relation.

`&collection[]`

[in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a proper superset, or false otherwise.
IsSubsetOf

Determines whether the current sorted set is a subset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool IsSubsetOf(
    ICollection<T>* collection // a collection to determine the relation
);
```

A version for working with an array.

```csharp
bool IsSubsetOf(
    T& array[] // an array to determine the relation
);
```

Parameters

*`collection`

- [in] A collection to determine the relation.

*`collection[]`

- [in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a subset, or false otherwise.
IsSupersetOf

Determines whether the current sorted set is a superset of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```cpp
bool IsSupersetOf(ICollection<T>* collection); // a collection to determine the relation
```

A version for working with an array.

```cpp
bool IsSupersetOf(T& array[]); // an array to determine the relation
```

Parameters

*collection
  
  [in] A collection to determine the relation.

&collection[]
  
  [in] An array to determine the relation.

Return Value

Returns true if the current sorted set is a superset, or false otherwise.
Overlaps

Determines whether the current sorted set overlaps the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool Overlaps(
    ICollection<T>* collection // a collection to compare
);
```

A version for working with an array.

```csharp
bool Overlaps(
    T& array[] // an array to compare
);
```

Parameters

*collection

&collection[]

Return Value

Returns true if the current sorted set and a collection or an array overlap, or false otherwise.
SetEquals

Determines whether the current sorted set contains all elements of the specified collection or array.

A version for working with the collection that implements the ICollection<T> interface.

```csharp
bool SetEquals(
    ICollection<T>* collection  // a collection to compare
);
```

A version for working with an array.

```csharp
bool SetEquals(
    T& array[]                   // an array to compare
);
```

**Parameters**

*collection
  

&collection[]
  
  [in] An array to compare elements.

**Return Value**

Returns true if the current sorted set contains all elements of the specified collection or array, or false otherwise.
GetViewBetween

Gets from the current sorted set a subset specified by the minimum and maximum values.

```cpp
bool GetViewBetween(
    T& array[], // an array for writing
    T lower_value, // the minimum value
    T upper_value // the maximum value
);
```

**Parameters**

* `array[]`
  - [out] An array for writing the subset.

* `lower_value`
  - [in] The minimum value of the range.

* `upper_value`
  - [in] The maximum value of the range.

**Return Value**

Returns true on successful, or false otherwise.
GetReverse

Gets a copy of the current sorted set, in which all the elements are arranged in a reverse order.

```cpp
bool GetReverse(
    T& array[] // an array for writing
);
```

**Parameters**

`array[]`

[out] An array for writing.

**Return Value**

Returns true on successful, or false otherwise.
CStack<T>

CStack<T> is a generic class that implements the ICollection<T> interface.

Description

The CStack<T> class is a dynamic collection of T type data, which is organized as a stack that operates on the LIFO (last in, first out) principle.

Declaration

```cpp
template<typename T>
class CStack : public ICollection<T>
```

Header

```cpp
#include <Generic\Stack.mqh>
```

Inheritance Hierarchy

- ICollection
  - CStack

Class Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>Adds an element to a stack</td>
</tr>
<tr>
<td>Count</td>
<td>Returns the number of elements in a stack</td>
</tr>
<tr>
<td>Contains</td>
<td>Determines whether a stack contains an element with the specified value</td>
</tr>
<tr>
<td>TrimExcess</td>
<td>Sets the capacity of a stack to the actual number of elements</td>
</tr>
<tr>

</tr>
<tr>
<td>Peek</td>
<td>Returns the head element without removing it from a stack</td>
</tr>
<tr>
<td>Pop</td>
<td>Returns the head element and removes it from a stack</td>
</tr>
</tbody>
</table>
**Add**

Adds an element to the stack.

```cpp
bool Add(
    T  value    // the value of the element
);
```

**Parameters**

- `value`
  - [in] The value of the element to add.

**Return Value**

Returns true on successful, or false otherwise.
Count

Returns the number of elements in the a stack.

```cpp
int Count();
```

Return Value

Returns the number of elements.
Contains

Determines whether a stack contains an element with the specified value.

```cpp
bool Contains(
    T item  // the search value
);
```

Parameters

- `item`
  - [in] The searched value.

Return Value

Returns true if an element with the specified value is found in the stack, or false otherwise.
TrimExcess

Sets the capacity of a stack to the actual number of elements, and thus frees up unused memory.

```c
void TrimExcess();
```
CopyTo

Copies all elements of a stack to the specified array starting at the specified index.

```c
int CopyTo(
    T& dst_array[], // an array for writing
    const int dst_start=0 // the starting index for writing
);
```

Parameters

- `dst_array[]` [out] An array to which the elements of the stack will be written.
- `dst_start=0` [in] An index in the array from which copying starts.

Return Value

Returns the number of copied elements.
Clear

Removes all elements from a stack.

```cpp
void Clear();
```
### Remove

Removes the first occurrence of the specified element from a stack.

```cpp
bool Remove(
    T item // the element value
);
```

**Parameters**

*item*

[in] The value of the element to be deleted.

**Return Value**

Returns true on successful, or false otherwise.
Push

Adds an element to the stack.

```cpp
bool Push(
    T value // element to add
);
```

Parameters

value

[in] An element to be added.

Return Value

Returns true on successful, or false otherwise.
Peek

Returns the head element without removing it from a stack.

\[ \text{T Peek();} \]

Return Value

Returns the head element.
Pop

Returns the head element and removes it from a stack.

\[
T \ Pop();
\]

Return Value

Returns the head element.
ArrayBinarySearch

Searches for the specified value in an ascending-sorted one-dimensional array using the IComparable\(<T>\) interface to compare elements.

```cpp
template<typename T>
int ArrayBinarySearch(
    T& array[],       // an array for search
    const int start_index, // the starting index
    const int count,     // the search range
    T value,             // the search value
    IComparer<T>* comparer // interface to compare
);
```

Parameters

- `array[]` [out] The array to search in.
- `value` [in] The searched value.
- `start_index` [in] The starting index from which the search begins.
- `count` [in] The length of the search range.

Return Value

Returns the index of the found element. If the search value is not found, it returns the index of the smallest element, which is closest in value.
ArrayIndexOf

Searches for the first occurrence of a value in a one-dimensional array.

```cpp
template<typename T>
int ArrayIndexOf(T& array[], // an array for search
                T value, // the search value
                const int start_index, // the starting index
                const int count // the search range
);
```

**Parameters**

- `array[]` [out] The array to search in.
- `value` [in] The searched value.
- `start_index` [in] The starting index from which the search begins.
- `count` [in] The length of the search range.

**Return Value**

Returns the index of the first found element. If the value is not found, returns -1.
ArrayLastIndexOf

Searches for the last occurrence of a value in a one-dimensional array.

```cpp
template<typename T>
int ArrayLastIndexOf(
    T& array[], // an array for search
    T value, // the search value
    const int start_index, // the starting index
    const int count // the search range
);
```

Parameters

- `array[]`: [out] The array to search in.
- `value`: [in] The searched value.
- `start_index`: [in] The starting index from which the search begins.
- `count`: [in] The length of the search range.

Return Value

Returns the index of the last found element. If the value is not found, returns -1.
ArrayReverse

Changes the sequence of elements in a one-dimensional array.

```cpp
template<typename T>
bool ArrayReverse(T& array[], const int start_index, const int count);
```

**Parameters**

- `array[]` [out] The source array.
- `start_index` [in] The starting index.
- `count` [in] The number of array elements participating in the operation.

**Return Value**

Returns true on successful, or false otherwise.
Compare

Compares the two values, whether one of them is “greater than, less than or equal to” the other one.

A version for comparing two bool values.

```c
int Compare(
    const bool x, // the first value
    const bool y  // the second value
);
```

A version for comparing two char values.

```c
int Compare(
    const char x,  // the first value
    const char y   // the second value
);
```

A version for comparing two uchar values.

```c
int Compare(
    const uchar x,  // the first value
    const uchar y   // the second value
);
```

A version for comparing two short values.

```c
int Compare(
    const short x,  // the first value
    const short y   // the second value
);
```

A version for comparing two ushort values.

```c
int Compare(
    const ushort x, // the first value
    const ushort y  // the second value
);
```

A version for comparing two color values.

```c
int Compare(
    const color x, // the first value
    const color y // the second value
);
```

A version for comparing two int values.

```c
int Compare(
    const int x,  // the first value
    const int y   // the second value
);
```
A version for comparing two uint values.

```cpp
int Compare(
    const uint x, // the first value
    const uint y  // the second value
);
```

A version for comparing two datetime values.

```cpp
int Compare(
    const datetime x, // the first value
    const datetime y // the second value
);
```

A version for comparing two long values.

```cpp
int Compare(
    const long x, // the first value
    const long y  // the second value
);
```

A version for comparing two ulong values.

```cpp
int Compare(
    const ulong x, // the first value
    const ulong y  // the second value
);
```

A version for comparing two float values.

```cpp
int Compare(
    const float x, // the first value
    const float y  // the second value
);
```

A version for comparing two double values.

```cpp
int Compare(
    const double x, // the first value
    const double y // the second value
);
```

A version for comparing two string values.

```cpp
int Compare(
    const string x, // the first value
    const string y  // the second value
);
```

A version for comparing two values of other types.

```cpp
template<typename T>
int Compare(
```
T x, // the first value
T y // the second value
;

Parameters

x
  [in] The first value

ty
  [in] The second value

Return Value

Returns a number that expresses the ratio of the two compared values:

- if the result is less than zero, x is less than y (x < y)
- if the result is equal to zero, x is equal to y (x = y)
- if the result is greater than zero, x is greater than y (x > y)

Note

If the T type is an object that implements the IComparable<T> interface, then the objects will be compared based on its Compare method. In all other cases, 0 is returned.
**Equals**

Compares two values for equality.

```cpp
template<typename T>
bool Equals(T x, T y);  // the first value
                       // the second value
```

**Parameters**

- **x**
  - [in] The first value
- **y**
  - [in] The second value

**Return Value**

Returns true if the objects are equal, or false otherwise.

**Note**

If the T type is an object that implements the IEqualityComparable<T> interface, then the objects will be compared based on its Equals comparison method. The standard comparison for equality is used in all other cases.
GetHashCode

Calculates the hash code value.

A version for working with the bool type.

```c
int GetHashCode(
    const bool value // value
);
```

A version for working with the char type.

```c
int GetHashCode(
    const char value // value
);
```

A version for working with the uchar type.

```c
int GetHashCode(
    const uchar value // value
);
```

A version for working with the short type.

```c
int GetHashCode(
    const short value // value
);
```

A version for working with the ushort type.

```c
int GetHashCode(
    const ushort value // value
);
```

A version for working with the color type.

```c
int GetHashCode(
    const color value // value
);
```

A version for working with the int type.

```c
int GetHashCode(
    const int value // value
);
```

A version for working with the uint type.

```c
int GetHashCode(
    const uint value // value
);
```

A version for working with the datetime type.

```c
int GetHashCode(
```

---

© 2000-2019, MetaQuotes Software Corp.
Standard Library

```c
const datetime value // value
```

A version for working with the `long` type.

```c
int GetHashCode(
    const long value // value
);
```

A version for working with the `ulong` type.

```c
int GetHashCode(
    const ulong value // value
);
```

A version for working with the `float` type.

```c
int GetHashCode(
    const float value // value
);
```

A version for working with the `double` type.

```c
int GetHashCode(
    const double value // value
);
```

A version for working with the `string` type.

```c
int GetHashCode(
    const string value // value
);
```

A version for working with other types.

```c
template<typename T>
t
```n`int GetHashCode(
    T value // value
);
```

**Parameters**

`value`

[in] The value for which you want to get the hash code.

**Return Value**

Returns the hash code.

**Note**

If the `T` type is an object that implements the `IEqualityComparer<T>` interface, then the hash code will be obtained based on its `HashCode` method. In all other cases, the hash code will be calculated as the hash value of the value type name.
**File Operations**

This section contains the technical details of the file operations classes and descriptions of the corresponding components of the MQL5 standard library.

The file operations classes will save time in developing applications using file input/output operations.

The MQL5 Standard Library (in terms of file operations) is located in the working directory of the terminal in the `Include\Files` folder.

<table>

</tbody>
</table>
CFile

CFile is a base class for CFileBin and CFileTxt classes.

Description

CFile class provides the simplified access to MQL5 API file and folder functions for all of its descendants.

Declaration

```
class CFile: public CObject
```

Title

```
#include <Files\File.mqh>
```

Inheritance hierarchy

CObject

CFile

**Methods inherited from class CObject**

- Prev, Prev, Next, Next, Save, Load, Type, Compare
Handle

Gets file handle of the opened file.

```c
int Handle()
```

Return Value

Handle of the opened file assigned to the class instance. If there is no file assigned, it returns -1.
FileName

Gets file name of the opened file.

```cpp
string FileName()
```

Return Value

File name of the opened file, assigned to the class instance. If there is no file assigned, it returns "". 
Flags

Gets flags of the opened file.

```cpp
int Flags()
```

Return Value

Flags of the opened file assigned to the class instance.
SetUnicode

Sets/clears the FILE_UNICODE flag.

```c
void SetUnicode(
    bool unicode  // flag value
)
```

Parameters

- `unicode`
  

Note

The result of string operations is dependent on the FILE_UNICODE flag. If it is false, the ANSI codes are used (one byte symbols). If it set, the UNICODE codes are used (two byte symbols). If the file is already opened, the flag cannot be changed.
SetCommon

Sets/clears the FILE_COMMON flag.

```c
void SetCommon(
    bool common    // flag value
);
```

Parameters

- `common`
  

Note

The FILE_COMMON flag determines the current working folder. If it is false, the local terminal folder is used as the current working folder. If it is true, the common data folder is used as the current working folder. If the file is already opened, the flag cannot be changed.
Open

Opens the specified file and, if it successful, assigns it to the class instance.

```cpp
int Open(
    const string file_name,  // file name
    int flags,               // flags
    short delimiter=9        // separator
)
```

Parameters

- `file_name`
  - [in] File name to open.
- `flags`
- `delimiter=9`
  - [in] CSV file separator.

Return Value

Handle of the opened file.

Note

The working folder is dependent on flag that was previously set/reset using the SetCommon() method.
## Close

Closes file assigned to the class instance.

```cpp
void Close()
```
Delete

Deletes the file assigned to the file instance.

```cpp
void Delete()
```

Delete

Deletes the specified file.

```cpp
void Delete(
    const string file_name // file name
)
```

Parameters

`file_name`

[in] File name of the file to delete.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.
IsExist

Checks file for existence

```cpp
bool IsExist(
    const string file_name  // file name
)
```

Parameters

- `file_name`
  - [in] Name of the file to check.

Return Value

- `true` - file exists.
Copy

Copies a file.

```c++
bool Copy(
    const string src_name, // file name
    int src_flag, // flag
    const string dst_name, // file name
    int dst_flags // flags
)
```

Parameters

- **src_name**

- **src_flag**
  - [in] Flags of a source file (only FILE_COMMON is used).

- **dst_name**
  - [in] File name of the destination file.

- **dst_flags**
  - [in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

Return Value

- true - successful, false - cannot copy the file.
Move

Renames/moves file.

```cpp
bool Move(
    const string src_name,  // file name
    int src_flag,           // flag
    const string dst_name,  // file name
    int dst_flags           // flags
)
```

**Parameters**

- `src_name`
  - [in] Source file name.

- `src_flag`
  - [in] Source file flags (only FILE_COMMON is used).

- `dst_name`
  - [in] File name of the destination file.

- `dst_flags`
  - [in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

**Return Value**

- true - successful, false - failed to move/rename the file.
Size

Gets file size in bytes.

```
ulong Size()
```

Return Value

- file size in bytes. If there is no file assigned, it returns ULONG_MAX.
Tell

Gets the current file pointer's position.

```c
ulong Tell()
```

Return Value

the current file position. If there no file assigned, it returns ULONG_MAX.
Seek

Sets file pointer's position.

```c
void Seek(
    long       offset,   // offset
    ENUM_FILE_POSITION origin,   // origin
);
```

Parameters

**offset**

[in] File offset in bytes (can be negative).

**origin**

Return Value

true - successful, false - cannot change the file pointer.
Flush

Flushes all of the file input/output buffer data on disk.

```cpp
void Flush()
```
**IsEnding**

Checks file for end during the file read operations.

```cpp
bool IsEnding()
```

**Return Value**

true - end of file has been achieved during read or seek operation.
IsLineEnding

Checks a text file for end during the file read operations.

```cpp
bool IsLineEnding()
```

**Return Value**

true - end of line has been achieved during a txt or csv file read operation (CR-LF chars).
FolderCreate

Creates new folder.

```cpp
bool FolderCreate(
    const string folder_name // folder name
)
```

Parameters

`folder_name`

[in] Name of the folder to create. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, false - cannot create the folder.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.
FolderDelete

Deletes specified folder.

```cpp
bool FolderDelete(
    const string folder_name  // folder name
)
```

**Parameters**

`folder_name`

[in] Name of the folder to delete. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

**Return Value**

true - successful, false - cannot delete the folder.

**Note**

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.
FolderClean

Cleans specified folder.

```cpp
bool FolderClean(
    const string folder_name  // folder name
)
```

Parameters

`folder_name`

[in] Name of the folder to clean. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, and false - cannot change the folder.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.
FileFindFirst

Begins file search using the specified filter.

```c
int FileFindFirst(
    const string filter,       // search filter
    string& file_name          // reference
)
```

Parameters

- **filter**
  - [in] Search filter.

- **file_name**
  - [out] The reference to the string the name of the first found file is placed into in case of success.

Return Value

The handle that can be used for further file search using FileFindNext, or INVALID_HANDLE if there are no files corresponding to the filter.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.
FileFindNext

Continues file search started by the FileFindFirst() method.

```c
bool FileFindNext(
    int            search_handle, // search handle
    string&       file_name      // reference
)
```

Parameters

**search_handle**

[in] Search handle returned by FileFindFirst() method.

**file_name**

[in] The reference to the string the name of the found file is placed into if successful.

Return Value

true - successful, false - there are no files corresponding to the filter.
**FileFindClose**

Closes search handle.

```c
void FileFindClose(
    int search_handle  // search handle
)
```

**Parameters**

- `search_handle`
  - [in] Search handle returned by `FileFindFirst()` method.
CFileBin

CFileBin is a class for simplified access to binary files.

Description

CFileBin class provides access to binary files.

Declaration

```
class CFileBin: public CFile
```

Title

```
#include <Files\FileBin.mqh>
```

Inheritance hierarchy

```
CObject
   CFile
      CFileBin
```

### Methods inherited from class CObject
- Prev, Prev, Next, Next, **Save**, **Load**, **Type**, **Compare**

### Methods inherited from class CFile
- Handle, FileName, Flags, SetUnicode, SetCommon, Open, Close, Delete, Size, Tell, Seek, Flush, IsEnding, IsLineEnding, Delete, IsExist, Copy, Move, FolderCreate, FolderDelete, FolderClean, FileFindFirst, FileFindNext, FileFindClose
Open

Opens the specified binary file and, if successful, assigns it to the class instance.

```cpp
int Open(
    const string file_name, // file name
    int flags          // flags
)
```

Parameters

- **file_name**
  - [in] File name of the file to open.

- **flags**
  - [in] File open flags (the FILE_BIN flag is set forcibly).

Return Value

Handle of the opened file.
WriteChar

Writes char or uchar type variable to file.

```c
uint WriteChar(
    char value     // value
)
```

**Parameters**

- **value**
  - [in] Variable to write.

**Return Value**

Number of bytes written.
WriteShort

Write short or ushort type variable to file.

```
uint WriteShort(
    short value  // value
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.
**WriteInteger**

Writes int or uint type variable to file.

```c
uint WriteInteger(
    int value    // value
)
```

**Parameters**

- **value**
  
  [in] Variable to write.

**Return Value**

Number of bytes written.
WriteLong

Writes long or ulong type variable to file.

```c
uint WriteLong(
    long value // value
)
```

Parameters

- `value`
  - `[in]` Variable to write.

Return Value

- Number of bytes written.
WriteFloat

Writes float type variable to file.

```c
uint   WriteFloat(
    float  value  // value
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.
**WriteDouble**

Writes double type variable to file.

```c
uint WriteDouble(
    double value // value
)
```

**Parameters**

- `value`
  - `[in]` Variable to write.

**Return Value**

Number of bytes written.
**WriteString**

Writes string type variable to file.

```c
uint WriteString(
    const string value  // value
)
```

**Parameters**

- `value` [in] String to write.

**Return Value**

- Number of bytes written.

**WriteString**

Writes string type variable to file.

```c
uint WriteString(
    const string value,  // value
    int size  // size
)
```

**Parameters**

- `value` [in] String to write.
- `size` [in] Number of bytes to write.

**Return Value**

- Number of bytes written.
WriteCharArray

Writes an array of char or uchar type variables to file.

```c
uint WriteCharArray(
    char& array[],        // array
    int start_item=0,     // start element
    int items_count=-1    // number of elements
)
```

**Parameters**

- `array[]`
  - [in] Array to write.
- `start_item=0`
  - [in] Start element to write from.
- `items_count=-1`
  - [in] Number of elements to write (-1 - whole array).

**Return Value**

Number of bytes written.
WriteShortArray

Writes an array of short or ushort type variables to file.

```c
uint WriteShortArray(
    short& array[],   // array
    int start_item=0,  // start element
    int items_count=-1 // number of elements
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.
**WriteIntegerArray**

Writes an array of int or uint type variables to file.

```c
uint WriteIntegerArray(
    int& array[], // array
    int start_item=0, // start element
    int items_count=-1 // number of elements
)
```

**Parameters**

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

**Return Value**

Number of bytes written.
WriteLongArray

Writes an array of long or ulong type variables to file.

```c
uint WriteLongArray(
    long& array[],   // array
    int start_item=0, // start element
    int items_count=-1 // number of elements
)
```

Parameters

- `array[]`
  - [in] Array to write.
- `start_item=0`
  - [in] Start element to write from.
- `items_count=-1`
  - [in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.
WriteFloatArray

Writes an array of float type variables to file.

```c
uint WriteFloatArray(
    float& array[], // array
    int start_item=0, // start element
    int items_count=-1 // number of elements
)
```

**Parameters**

*array[]*

[in] Array to write.

*start_item=0*

[in] Start element to write from.

*items_count=-1*

[in] Number of elements to write (-1 - whole array).

**Return Value**

Number of bytes written.
**WriteDoubleArray**

Writes an array of double type variables to file.

```cpp
uint WriteDoubleArray(  
    double& array[],   // array to write  
    int start_item=0,  // start element  
    int items_count=-1  // number of elements
)
```

**Parameters**

- `array[]`  
  [in] Array to write.

- `start_item=0`  
  [in] Start element to write from.

- `items_count=-1`  
  [in] Number of elements to write (-1 - whole array).

**Return Value**

Number of bytes written.
WriteObject

Writes data of the CObject class inheritor instance to file.

```cpp
bool WriteObject(
    CObject* object // reference to the object
)
```

Parameters

- `object`
  - [in] Reference to the CObject class inheritor instance to write.

Return Value

- true - successful, false - cannot write the data.
ReadChar

Reads char or uchar type variable from file.

```cpp
bool ReadChar(
    char& value // flag value
)
```

Parameters

- `value`:
  - [in] Reference to the variable for placing read data.

Return Value

- true - successful, false - cannot read the data.
ReadShort

Reads short or ushort type variable from file.

```cpp
bool ReadShort(
    short& value
)
```

Parameters

value

- [in] Reference to the variable for placing read data.

Return Value

- true - successful, false - cannot read the data.
ReadInteger

Reads int or uint type variable from file.

```c
bool ReadInteger(
    int& value  // variable
)
```

**Parameters**

- `value`
  - [in] Reference to the variable for placing read data.

**Return Value**

- `true` - successful, `false` - cannot read the data.
ReadLong

Reads long or ulong type variable from file.

```cpp
bool ReadLong(
    long& value
)
```

**Parameters**

value

[in] Reference to the variable for placing read data.

**Return Value**

true - successful, false - cannot read the data.
ReadFloat

Reads float type variable from file.

```cpp
bool ReadFloat(
    float& value // variable
)
```

**Parameters**

*value*

[in] Reference to the variable for placing read data.

**Return Value**

true - successful, false - cannot read the data.
ReadDouble

Reads double type variable from file.

```cpp
bool ReadDouble(
    double& value
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.
ReadString

Reads string type variable from file.

```cpp
bool ReadString(
    string& value  // string
)
```

**Parameters**

value

[in] Reference to the variable for placing read data.

**Return Value**

true - successful, false - cannot read the data.
ReadCharArray

Reads an array of char or uchar type variables from file.

```cpp
bool ReadCharArray(
    char& array[], // array
    int start_item=0, // start element
    int items_count=-1 // number of elements
)
```

Parameters

- `array[]`
  - [in] Reference to the variable for placing read data.
- `start_item=0`
  - [in] Start element to read from.
- `items_count=-1`
  - [in] Number of elements to read (-1 - read to the end of file).

Return Value

- true - successful, false - cannot read the data.
ReadShortArray

Reads an array of short or ushort type variables from file.

```cpp
bool ReadShortArray(
    short& array[],                // array
    int start_item=0,              // start element
    int items_count=-1             // number of elements
)
```

**Parameters**

- `array[]`
  - [in] Reference to the variable for placing read data.

- `start_item=0`
  - [in] Start element to read from.

- `items_count=-1`
  - [in] Number of elements to read (-1 - read to the end of file).

**Return Value**

- true - successful, false - cannot read the data.
ReadIntegerArray

Reads an array of int or uint type variables from file.

```cpp
bool  ReadIntegerArray(
    int&  array[],       // array
    int   start_item=0,   // start element
    int   items_count=-1  // number of elements
)
```

### Parameters

- **array[]**
  - [in] Reference to the target array of type int or uint.

- **start_item=0**
  - [in] Start element to read from.

- **items_count=-1**
  - [in] Number of elements to read (-1 - read to the end of file).

### Return Value

- true - successful, false - cannot read the data.
ReadLongArray

Reads an array of long or ulong type variables from file.

```c
bool ReadLongArray(
    long& array[],        // array
    int start_item=0,     // start element
    int items_count=-1    // number of elements
)
```

Parameters

- **array[]**
  - [in] Reference to the variable for placing read data.

- **start_item=0**
  - [in] Start element to read from.

- **items_count=-1**
  - [in] Number of elements to read (-1 - read to the end of file).

Return Value

- true - successful, false - cannot read the data.
ReadFloatArray

Reads an array of float type variables from file.

```cpp
bool ReadFloatArray(
    float& array[],     // array
    int start_item=0,    // start element
    int items_count=-1   // number of elements
)
```

Parameters

- `array[]`  
  - [in] Reference to the variable for placing read data.

- `start_item=0`  
  - [in] Start element to read from.

- `items_count=-1`  
  - [in] Number of elements to read (-1 - read to the end of file).

Return Value

- true - successful, false - cannot read the data.
ReadDoubleArray

Reads an array of double type variables from file.

```cpp
bool ReadDoubleArray(
    double& array[],       // array
    int start_item=0,      // start element
    int items_count=-1     // number of elements
)
```

Parameters

- `array[]`
  - [in] Reference to the variable for placing read data.
- `start_item=0`
  - [in] Start element to read from.
- `items_count=-1`
  - [in] Number of elements to read (-1 - read to the end of file).

Return Value

- true - successful, false - cannot read the data.
**ReadObject**

Reads data of the CObject class inheritor instance from file.

```cpp
bool ReadObject(
    CObject* object  // pointer
)
```

**Parameters**

- `object`
  - [in] Pointer to the CObject class inheritor instance to read.

**Return Value**

- true - successful, false - cannot read the data.
CFileTxt

CFileTxt is a class for simplified access to text files.

Description

CFileTxt class provides access to text files.

Declaration

```cpp
class CFileTxt: public CFile
```

Title

```cpp
#include <Files\FileTxt.mqh>
```

Inheritance hierarchy

- CObject
  - CFile
    - CFileTxt

Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CFile

- Handle, FileName, Flags, SetUnicode, SetCommon, Open, Close, Delete, Size, Tell, Seek, Flush, IsEnding, IsLineEnding, Delete, IsExist, Copy, Move, FolderCreate, FolderDelete, FolderClean, FindFirst, FindNext, FindClose
Open

Opens the specified text file and, if successful, assigns it to the class instance.

```cpp
int Open(
    const string file_name, // file name
    int flags // flags
)
```

Parameters

- `file_name` [in] File name to open.
- `flags` [in] File open flags (FILE_TXT flag is forcibly set).

Return Value

Opened file handle.
WriteString

Writes string type variable to file.

```c
uint WriteString(
    const string value // string
)
```

**Parameters**

- `value`  
  [in] String to write.

**Return Value**

- Number of bytes written.
**ReadString**

Reads string type variable from file.

```cpp
string ReadString()
```

Return Value

String which has been read.
String operations

This section contains the technical details of the string operations classes and descriptions of the corresponding components of the MQL5 standard library.

The use of string operations classes will save time in developing applications processing textual data.

The MQL5 standard library (in terms of string operations) is located in the working directory of the terminal in the Include\Strings folder.

<table>
<thead>
<tr>

CString

CString is a class for simplified access to the variables of string type.

Description

CString class provides simplified access to MQL5 API functions working with string variables.

Declaration

```cpp
class CString: public CObject
```

Title

```
#include <Strings\String.mqh>
```

Inheritance hierarchy

- CObject
- CString

**Convert methods**

- **ToUpper**
  - Converts a string to uppercase.
- **ToLower**
  - Converts a string to lowercase.
- **Reverse**
  - Reverses a string

**Search methods**

- **Find**
  - Searches a substring left to right
- **FindRev**
  - Searches a substring right to left
- **Remove**
  - Deletes a substring
- **Replace**
  - Replaces a substring

**Methods inherited from class CObject**

- Prev, Prev, Next, Next, Save, Load, Type
Str

Gets a string.

```cpp
string Str() const;
```

Return Value

Copy of a string.
Len

Gets length of a string.

```
uint Len() const;
```

Return Value

Length of a string.
Copy

Copies a string by reference.

```cpp
void Copy(
    string& copy  // reference
) const;
```

**Parameters**

`copy`

[in] Reference to a data string.

Copy

Copies a string to the CString class instance.

```cpp
void Copy(
    CString* copy  // pointer
) const;
```

**Parameters**

`copy`

[in] Pointer to CString class instance for data.
**Fill**

Fills a string with specified char.

```cpp
bool Fill(
    short character  // character
)
```

**Parameters**

*character*

[in] Character for filling a string.

**Return Value**

true - successful, false - cannot fill a string.
Assign

Assigns a string.

```cpp
void Assign(
    const string str // string
)
```

Parameters

- `str` [in] String to assign.

Assign

Assigns a string from the CString class instance.

```cpp
void Assign(
    CString* str // pointer
)
```

Parameters

- `str` [in] Pointer to the CString class instance to assign.
Append

Appends a string.

```cpp
void Append(
    const string str // string
)
```

Parameters

- `str`  
  [in] String to append.

Append

Appends a string from the CString class instance.

```cpp
void Append(
    CString* string // pointer
)
```

Parameters

- `string`  
  [in] Pointer to the CString class instance to append.
Insert

Inserts a string to the specified position.

```c
uint Insert(
    uint pos,  // position
    const string str  // string
)
```

**Parameters**

- `pos`  
  [in] Insert position.

- `str`  
  [in] String to insert.

**Return Value**

Resulted string length.

Insert

Inserts a string to the specified position from the CString class instance.

```c
uint Insert(
    uint pos,  // position
    CString* str  // pointer
)
```

**Parameters**

- `pos`  
  [in] Position to insert into.

- `str`  
  [in] Pointer to the CString class instance to insert.

**Return Value**

Resulted string length.
**Compare**

Compares to a string.

```cpp
int Compare(const string str) const;
```

**Parameters**

*str*

[in] String to compare.

**Return Value**

0 - both strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.

---

**Compare**

Compares to a CString class instance string.

```cpp
int Compare(CString* str) const;
```

**Parameters**

*str*

[in] Pointer to CString class instance to compare.

**Return Value**

0 - strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.
**CompareNoCase**

Perform a case insensitive string comparison.

```cpp
int CompareNoCase(
    const string str // string
) const;
```

**Parameters**

*str*

[in] String to compare.

**Return Value**

0 - strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.

**CompareNoCase**

Compares a string (case insensitive) to a CString class instance string.

```cpp
int CompareNoCase(
    CString* str // pointer
) const;
```

**Parameters**

*str*

[in] Pointer to CString class instance to compare.

**Return Value**

0 - if strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.
Left

Gets a substring of a specified length from the beginning of a string.

```cpp
string Left(
    uint count  // length
)
```

Parameters

- `count`
  - [in] Substring length.

Return Value

- Resulted substring.
Right

Gets a substring of a specified length from the end of a string.

```c
string Right(
    uint count  // length
)
```

Parameters

- `count`
  - `[in]` Substring length.

Return Value

- Resulted substring.
Mid

Gets a substring of a specified length from a specified string position.

```c
string Mid(
    uint pos,   // position
    uint count  // length
);
```

Parameters

- `pos`
  - [in] Substring position.

- `count`
  - [in] Substring length.

Return Value

Resulted substring.
Trim

Removes all characters within a set (as well as `、`, `	`, ``, `
`) at both ends of a string from this string.

```cpp
int Trim(
    const string targets // set
)
```

Parameters

`targets`

[in] Set of characters to remove.

Return Value

Number of removed characters.

Example:

```cpp
//--- example for CString::Trim
#include <Strings\String.mqh>
//---
void OnStart()
{
    CString str;
    //---
    str.Assign("   \tABC\r\n");
    printf("Source string '%s'",str.Str());
    //---
    str.Trim("DA-DA-DA");
    printf("Result string '%s'",str.Str());
}
```
**TrimLeft**

Removes all characters within a set (as well as `'`, `\`, `\t`, `\r`, `\n`) at the beginning of a string from this string.

```cpp
int TrimLeft(
    const string targets // set
)
```

**Parameters**

- `targets`
  - [in] Set of characters to remove.

**Return Value**

Number of characters removed.
TrimRight

Removes all characters within a set (as well as ' ', \t, \r, \n) at the end of a string from this string.

```cpp
int TrimRight(
    const string targets // set
)
```

Parameters

- **targets**
  - [in] Set of characters to remove.

Return Value

- Number of characters removed.
Clear

Clears a string.

```cpp
bool Clear()
```

Return Value

- true - successful, false - cannot clear a string.
ToUpper

Converts all string characters to uppercase.

```cpp
bool ToUpper()
```

Return Value

- true - successful, false - cannot convert to uppercase.
ToLower

Converts all string characters to lowercase.

    bool ToLower()

Return Value

    true - successful, false - cannot convert to lowercase.
Reverse

Reverses a string (initial and final characters exchange places pair-wise).

```c
void Reverse()
```
Find

Searches for the first match of a substring from a specified position.

```cpp
int Find(
    uint start,       // position
    const string substring // substring
) const;
```

**Parameters**

- `start` [in] Initial position for substring search.
- `substring` [in] Sample substring to search for.

**Return Value**

The index of the first match of a substring (-1 - substring is not found).
FindRev

Searches for the last match of a substring.

```cpp
int FindRev(
    const string substring // substring
) const;
```

Parameters

`substring`

[in] Sample substring to search for.

Return Value

The index of the last match of a substring (-1 - substring is not found).
Remove

Removes all substring matches.

```c
uint Remove(
    const string substring // substring
)
```

Parameters

* substring

    [in] Sample substring to search for.

Return Value

Number of substring removals.
Replace

Replaces all substring matches.

```c
uint Replace(
    const string substring,  // substring
    const string newstring   // substring
)
```

Parameters

`substring`
  [in]  Sample substring to search for.

`newstring`
  [in]  Sample substring to replace with.

Return Value

Number of substring replacements.
Graphic Objects

This section contains the technical details of working with classes of graphical objects and a description of the relevant components of the MQL5 Standard Library.

The use of classes of graphical objects will save time when creating custom programs (scripts, Expert Advisors).

MQL5 Standard Library (in terms of graphical objects) is located in the working directory of the terminal in the Include\ChartObjects folder.

**CChartObject**

CChartObject is a base class for the classes of chart graphical objects of the Standard MQL5 library.

**Description**

CChartObject class provides the simplified access to MQL5 API functions for all of its descendants.

**Declaration**

```cpp
class CChartObject : public CObject
```

**Title**

```cpp
#include <ChartObjects\ChartObject.mqh>
```

**Inheritance hierarchy**

- **CObject**
  - CChartObject

**Direct descendants**

**Class Methods by Groups**

<table>

</table>

**Methods inherited from class CObject**

- Prev, Prev, Next, Next, **Compare**
**ChartId**

Gets the ID of the chart a graphical object belongs to.

```cpp
long ChartId() const
```

**Return Value**

ID of the chart where the graphical object is located. If there is no bound object, it returns -1.

**Example:**

```cpp
//--- example for CChartObject::ChartId
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get chart identifier of chart object
    long chart_id=object.ChartId();
}
```
Window

Gets the index of the chart window where the graphical object is located.

```cpp
int Window() const
```

Return Value

The number of the chart window where the graphical object is located (0 - main window). If there is no bound object, it returns -1.

Example:

```cpp
//--- example for CChartObject::Window
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get window of chart object
    int window=object.Window();
}
```
**Name (Get Method)**

Gets the name of the graphical object.

\[ \text{string Name() const} \]

**Return Value**

Name of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

**Name (Set Method)**

Sets the name of the graphical object.

\[ \text{bool Name(string name) // new name} \]

**Parameters**

name  
[in] The new name of the graphical object.

**Return Value**

true - success, false - cannot change the name.

**Example:**

```cpp
//--- example for CChartObject::Name
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get name of chart object
    string object_name=object.Name();
    if(object_name!="MyChartObject")
    {
        //--- set name of chart object
        object.Name("MyChartObject");
    }
}
```
**NumPoints**

Gets the number of anchor points of a graphical object.

```cpp
int NumPoints() const
```

**Return Value**

Number of points linking a graphical object attached to an instance of the class. If there is no attached object, it returns 0.

**Example:**

```cpp
//--- example for CChartObject::NumPoints
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get points count of chart object
    int points=object.NumPoints();
}
```
### Attach

Attaches a graphical object to an instance of the class.

```cpp
bool Attach(
    long chart_id,  // chart ID
    string name,    // name of the object
    int window,     // chart window
    int points      // number of points
)
```

**Parameters**

- **chart_id**
  
  [out] Chart identifier.

- **name**
  
  [in] Name of the graphical object.

- **window**
  
  [in] Chart window number (0 - main window).

- **points**
  
  [in] Number of anchor points of the graphical object.

**Return Value**

- true - success, false - cannot bind the object.

### Example:

```cpp
//--- example for CChartObject::Attach
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- attach chart object
    if(!object.Attach(ChartID(),"MyObject",0,2))
    {
        printf("Object attach error");
        return;
    }
}
```
SetPoint

Sets new coordinates of the specified anchor point of the graphical object.

```c
bool SetPoint(
    int point,  // point number
    datetime new_time,  // time coordinate
    double new_price  // price coordinate
)
```

**Parameters**

- **point**
  - [in] Number of the graphical object anchor point.

- **new_time**
  - [in] New value for the time coordinate of the specified anchor point.

- **new_price**
  - [in] New value for price coordinate of the specified anchor point.

**Return Value**

- true - success, false - cannot change coordinates of the point.

**Example:**

```c
//--- example for CChartObject::SetPoint
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    double price;
    //---
    if(object.NumPoints()>0)
    {
        //--- set point of chart object
        object.SetPoint(0,CurrTime(),price);
    }
}
```
Delete

Removes an attached graphical object from the chart.

```cpp
bool Delete()
```

**Return Value**

true - success, false - cannot remove the object.

**Example:**

```cpp
//--- example for CChartObject::Delete
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- detach chart object
    if(!object.Delete())
    {
        printf("Object delete error");
        return;
    }
}
```
Detach

Detaches the graphical object.

```cpp
void Detach()
```

Return Value

None.

Example:

```cpp
//--- example for CChartObject::Detach
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- detach chart object
    object.Detach();
}
```
## ShiftObject

Shifts a graphical object.

```cpp
bool ShiftObject(
    datetime d_time, // increment of time coordinate
    double d_price   // increment of price coordinate
)
```

**Parameters**

- **d_time**
  - [in] Increment of the time coordinate of all anchor points.

- **d_price**
  - [in] Increment of the price coordinate of all anchor points.

**Return Value**

- true - success, false - cannot shift the object.

**Example:**

```cpp
//--- example for CChartObject::ShiftObject
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    datetime   d_time;
    double     d_price;
    //--- shift chart object
    object.ShiftObject(d_time, d_price);
}
```
ShiftPoint

Shifts a specified anchor point of the graphical object.

```cpp
bool ShiftPoint(
    int point,   // point number
    datetime d_time,   // increment of time coordinate
    double d_price    // increment of price coordinate
)
```

**Parameters**

- **point**
  - [in] Number of a graphical object anchor point.

- **d_time**
  - [in] Increment of the time coordinate of the specified point.

- **d_price**
  - [in] Increment of the price coordinate of the specified point.

**Return Value**

- true - success, false - cannot shift the point.

**Example:**

```cpp
//--- example for CChartObject::ShiftPoint
#include <ChartObjects\ChartObject.mgh>
//---
void OnStart()
{
    CChartObject object;
    datetime d_time;
    double d_price;
    //---
    if(object.NumPoints()>0)
    {
        //--- shift point of chart object
        object.ShiftPoint(0,d_time,d_price);
    }
}
```
**Time (Get Method)**

Gets the time coordinate of the specified anchor point of a graphical object.

```cpp
datetime Time(
    int point       // point number
) const
```

**Parameters**

- `point`  
  [in] Number of a graphical object anchor point.

**Return Value**

Time coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns 0.

**Time (Set Method)**

Sets the time coordinate of the specified anchor point of a graphical object.

```cpp
bool Time(
    int point,       // point number
    datetime new_time // time
)
```

**Parameters**

- `point`  
  [in] Number of a graphical object anchor point.

- `new_time`  
  [in] New value for the time coordinate of the specified graphical object anchor point.

**Return Value**

- true - success, false - cannot change the time coordinate.

**Example:**

```cpp
//--- example for CChartObject::Time
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //---
    for(int i=0;i<object.NumPoints();i++)
    {
        //--- get time of the chart object point
        datetime point_time=object.Time(i);
        if(point_time==0)
```

```cpp
{
    //--- set time of the chart object point
    object.Time(i, TimeCurrent());
}
```
Price (Get Method)

Gets the price coordinate of the specified anchor point of a graphical object.

double Price(
    int point            // point number
) const

Parameters

point
    [in] Number of a graphical object anchor point.

Return Value

Price coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns EMPTY_VALUE.

Price (Set Method)

Sets the price coordinate of the specified anchor point of a graphical object.

bool Price(
    int point,            // point number
    double new_price      // price
)

Parameters

point
    [in] Number of a graphical object anchor point.

new_price
    [in] New value for the price coordinate of the specified graphical object anchor point.

Return Value

true - success, false - cannot change the price coordinate.

Example:

//--- example for CChartObject::Price
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    double price;
    //---
    for(int i=0;i<object.NumPoints();i++)
    {
        //--- get price of the chart object point
        double point_price=object.Price(i);
if(point_price!=price)
{
    //--- set price for the chart object point
    object.Price(i,price);
}
}
**Color (Get Method)**

Gets the line color of the graphical object.

```cpp
color Color() const
```

**Return Value**

Line color of the graphical object attached to the class instance. If there is no object attached, it returns CLR_NONE.

**Color (Set Method)**

Sets the line color of the graphical object.

```cpp
bool Color(
    color new_color // new color
)
```

**Parameters**

`new_color`

[in] New value of a graphical object line color.

**Return Value**

true - success, false - cannot change the color.

**Example:**

```cpp
//--- example for CChartObject::Color
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get color of chart object
    color object_color=object.Color();
    if(object_color!=clrRed)
    {
        //--- set color of chart object
        object.Color(clrRed);
    }
}
```
**Style (Get Method)**

Gets the line style of the graphical object.

```cpp
ENUM_LINE_STYLE Style() const
```

**Return Value**

Line style of the graphical object attached to the class instance. If there is no attached object, it returns WRONG_VALUE.

**Style (Set Method)**

Sets the line style of the graphical object.

```cpp
bool Style(
    ENUM_LINE_STYLE new_style  // style
)
```

**Parameters**

`new_style`

[in] New value of the graphical object line style.

**Return Value**

true - success, false - cannot change the style.

**Example:**

```cpp
//-- example for CChartObject::Style
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get style of chart object
    ENUM_LINE_STYLE style=object.Style();
    if(style!=STYLE_SOLID)
    {
        //--- set style of chart object
        object.Style(STYLE_SOLID);
    }
}
```
**Width (Get Method)**

Gets the line width of the graphical object.

```cpp
int Width() const
```

**Return Value**

The line width of the graphical object attached to an instance of the class. If there is no attached object, it returns -1.

**Width (Set Method)**

Sets the line width of the graphical object.

```cpp
bool Width(
    int new_width // thickness
)
```

**Parameters**

`new_width`

[in] New value of the graphical object line width.

**Return Value**

true - success, false - cannot change the width.

**Example:**

```cpp
//--- example for CChartObject::Width

#include <ChartObjects\ChartObject.mqh>

//---

void OnStart()
{
    CChartObject object;
    //--- get width of chart object
    int width=object.Width();
    if(width!=1)
    {
        //--- set width of chart object
        object.Width(1);
    }
}
```
Background (Get Method)

Gets the flag for drawing a graphical object on the background.

```cpp
bool Background() const
```

Return Value

Flag for drawing the graphical object, attached to an instance of the class, on the background. If there is no attached object, returns false.

Background (Set Method)

Sets the flag for drawing a graphical object on the background.

```cpp
bool Background(bool background) // value of the flag
```

Parameters

`background`

[in] New value of the flag for drawing a graphical object on the background.

Return Value

true - success, false - cannot change the flag.

Example:

```cpp
//--- example for CChartObject::Background
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{

    CChartObject object;
    //--- get background flag of chart object
    bool background_flag=object.Background();
    if(!background_flag)
    {
        //--- set background flag of chart object
        object.Background(true);
    }
}
```
Selected (Get Method)

Gets the flag indicating that a graphical object is selected. In other words - if the graphical object is selected or not.

```cpp
bool Selected() const
```

**Return Value**

The state that the object, attached to an instance of the class, is selected. If there is no attached object, returns false.

Selected (Set Method)

Sets the flag indicating that the graphical object is selected.

```cpp
bool Selected(bool selected) // value of the flag
```

**Parameters**

*selected*  
[in] New value of the flag indicating that a graphical object is selected.

**Return Value**

true - success, false - cannot change the flag.

**Example:**

```cpp
//--- example for CChartObject::Selected
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get the "selected" flag of chart object
    bool selected_flag=object.Selected();
    if(selected_flag)
    {
        //--- set the "selected" flag of chart object
        object.Selected(false);
    }
}
```
Selectable (Get Method)

Gets the flag indicating an ability of a graphical object to be selected. In other words - if the graphical object can be selected or not.

```cpp
bool Selectable() const
```

Return Value

Flag indicating the ability of the graphical object, attached to an instance of the class, to be selected. If there is no attached object, returns false.

Selectable (Set Method)

Sets the flag indicating the ability of a graphical object to be selected.

```cpp
bool Selectable(bool selectable) // value of the flag
```

Parameters

`selectable`  
[in] New value of the flag indicating an ability of a graphical object to be selected.

Return Value

true - success, false - cannot change the flag.

Example:

```cpp
//--- example for CChartObject::Selectable
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get the "selectable" flag of chart object
    bool selectable_flag=object.Selectable();
    if(selectable_flag)
    {
        //--- set the "selectable" flag of chart object
        object.Selectable(false);
    }
}
```
Description (Get Method)

Gets a description (text) of a graphical object.

```cpp
string Description() const
```

Return Value

Description (text) of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Description (Set Method)

Sets the description (text) of the graphical object.

```cpp
bool Description(
    string text   // text
)
```

Parameters

text

[in] New description (text) of a graphical object.

Return Value

ture - success, false - cannot change the description (text).

Example:

```cpp
//--- example for CChartObject::Description
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get description of chart object
    string description=object.Description();
    if(description=="")
    {
        //--- set description of chart object
        object.Description("MyObject");
    }
}
```
Tooltip (Get Method)

Gets the tooltip text of a graphical object.

```cpp
string Tooltip() const
```

Return Value

The text of a tooltip of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Tooltip (Set Method)

Sets the text of the tooltip of a graphical object.

```cpp
bool Tooltip(
    string new_tooltip // new text of a tooltip
)
```

Parameters

new_tooltip

Return Value

true - success, false - cannot change the tooltip.

Note:

If the property is not set, then the tooltip generated automatically by the terminal is shown. A tooltip can be disabled by setting the "\n" (line feed) value.
**Timeframes (Get Method)**

Gets visibility flags of a graphical object.

```c
int Timeframes() const
```

**Return Value**

Visibility flags of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

**Timeframes (Set Method)**

Sets visibility flags of a graphical object.

```c
bool Timeframes(
    int new_timeframes  // visibility flags
)
```

**Parameters**

`new_timeframes`

[in] New visibility flags of the graphical object.

**Return Value**

true - success, false - cannot change the flags of visibility.

**Example:**

```c
//--- example for CChartObject::Timeframes
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get timeframes of chart object
    int timeframes = object.Timeframes();
    if(!(timeframes & OBJ_PERIOD_H1))
    {
        //--- set timeframes of chart object
        object.Timeframes(timeframes | OBJ_PERIOD_H1);
    }
}
```
Z_Order (Get Method)

Gets the graphical object priority for receiving an event of mouse clicking on a chart (CHARTEVENT_CLICK).

```cpp
long Z_Order() const
```

Return Value

Priority of a graphical object, attached to the class instance. If there is no object attached, it returns 0.

Z_Order (Set Method)

Sets the graphical object priority for receiving an event of mouse clicking on a chart (CHARTEVENT_CLICK).

```cpp
bool Z_Order(
    long value // graphical object priority
)
```

Parameters

value

[in] New value of priority of a graphical object for receiving the event CHARTEVENT_CLICK.

Return Value

true - success, false - cannot change the priority.

Note

Z_Order property manages a priority when handling clicks on graphical objects. By setting the value greater than 0 (default value), you can increase the object priority when handling mouse clicks.
createTime

Gets the graphical object creation time.

```c
datetime  CreateTime() const
```

Return Value

Creation time of the graphical object attached to the instance of the class. If there is no attached object, it returns 0.

Example:

```c
//--- example for CChartObject::CreateTime
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- get create time of chart object
    datetime create_time=object.CreateTime();
}
```
LevelsCount (Get Method)

Gets the number of levels of a graphical object.

```cpp
int LevelsCount() const
```

Return Value

Number of levels of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

LevelsCount (Set Method)

Sets the number of levels of the graphical object.

```cpp
bool LevelsCount(
    int levels /* number of levels */
)
```

Parameters

levels

[in] The new number of levels of the graphical object.

Return Value

true - success, false - cannot change the number of levels.

Example:

```cpp
void OnStart()
{
    CChartObject object;
    //--- get levels count of chart object
    int levels_count = object.LevelsCount();
    //--- set levels count of chart object
    object.LevelsCount(levels_count + 1);
}
```
LevelColor (Get Method)

Gets the line color of the specified level of a graphical object.

```cpp
color LevelColor(
    int level // level number
) const
```

Parameters

- **level**
  - [in] Number of graphical object level.

Return Value

- Line color of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns CLR_NONE.

LevelColor (Set Method)

Sets the line color of the specified level of the graphical object.

```cpp
bool LevelColor(
    int level, // level number
    color new_color // new color
)
```

Parameters

- **level**
  - [in] Number of graphical object level.
- **new_color**
  - [in] New line color of the specified level of a graphical object.

Return Value

- true - success, false - cannot change the color.

Example:

```cpp
//--- example for CChartObject::LevelColor
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //---
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get level color of chart object
        color level_color=object.LevelColor(i);
        if(level_color!=clrRed)
```
```cpp
{
    //--- set level color of chart object
    object.LevelColor(i, clrRed);
}
```
**LevelStyle (Get Method)**

Gets the line style of the specified level of a graphical object.

```cpp
ENUM_LINE_STYLE LevelStyle(int level) // level number
```

**Parameters**

- `level`  
  [in] Number of graphical object level.

**Return Value**

Line style of the specified level of the graphical object attached to an instance of the class. If there is no attached object or the object does not have the specified level, it returns WRONG_VALUE.

**LevelStyle (Set Method)**

Sets the line style of the specified level of the graphic object.

```cpp
int LevelStyle(int level, ENUM_LINE_STYLE style) // level number, line style
```

**Parameters**

- `level`  
  [in] Number of graphical object level.

- `style`  
  [in] New line style of the specified level of a graphical object.

**Return Value**

true - success, false - cannot change the style.

**Example:**

```cpp
//--- example for CChartObject::LevelStyle
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //---
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get level style of chart object
        ENUM_LINE_STYLE level_style=object.LevelStyle(i);
        if(level_style!=STYLE_SOLID)
        {
```
{  
    //--- set level style of chart object
    object.LevelStyle(i, STYLE_SOLID);
    
    }  
}
LevelWidth (Get Method)

Gets the line width of the specified level of a graphical object.

```cpp
int LevelWidth
    int level  // level number
) const
```

Parameters

**level**

[in] Number of graphical object level.

Return Value

Line width of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns -1.

LevelWidth (Set Method)

Sets the line width of the specified level of the graphical object.

```cpp
bool LevelWidth
    int level,       // level number
    int new_width  // new width
)
```

Parameters

**level**

[in] Number of graphical object level.

**new_width**

[in] New line width of the specified level of a graphical object.

Return Value

true - success, false - cannot change the width.

Example:

```cpp
//--- example for CChartObject::LevelWidth
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get level width of chart object
        int level_width=object.LevelWidth(i);
        if(level_width!=1)
```
```plaintext
{
    //--- set level width of chart object
    object.LevelWidth(i,1);
}
```
LevelValue (Get Method)

Gets the value of the specified level of a graphical object.

```c
double LevelValue(
    int level    // level number
) const
```

Parameters

- `level`
  - [in] Number of a graphical object level.

Return Value

The value of the specified level of a graphical object that is bound to an instance of the class. If there is no bound object or the object has no level specified, returns `EMPTY_VALUE`.

LevelValue (Set Method)

Sets the value of the specified level of the graphical object.

```c
bool LevelValue(
    int level,     // level number
    double new_value // new value
)
```

Parameters

- `level`
  - [in] Number of a graphical object level.

- `new_value`
  - [in] New value of the specified level of a graphical object.

Return Value

- `true` - successful, `false` - cannot change the value.

Example:

```c
//--- example for CChartObject::LevelValue
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //---
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get level value of chart object
        double level_value=object.LevelValue(i);
        if(level_value!=0.1*i)
```
{
    //--- set level value of chart object
    object.LevelValue(i, 0.1*i);
}
}
**LevelDescription (Get Method)**

Gets a description (text) of the level of a graphical object.

```c
string LevelDescription(int level) const
```

**Parameters**

`level`

[in] Number of a graphical object level.

**Return Value**

Description (text) of the specified level of a graphical object that is bound to an instance of the class. Returns NULL if there is no bound object or the object has no specified level.

**LevelDescription (Set Method)**

Sets the description (text) of the specified graphical object level.

```c
bool LevelDescription(int level, string text)
```

**Parameters**

`level`

[in] Number of a graphical object level.

`text`

[in] New value of description (text) of the specified graphical object level.

**Return Value**

true - success, false - cannot change the description (text).

**Example:**

```c
#include <ChartObjects\ChartObject.mqh>
---
void OnStart()
{
    CChartObject object;
    ---
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get level description of chart object
        string level_description=object.LevelDescription(i);
        if(level_description=="")
```

© 2000-2019, MetaQuotes Software Corp.
```cpp
{
    //--- set level description of chart object
    object.LevelDescription(i,"Level_{i}_{IntegerToString(i)}");
}
```
GetInteger

Provides simplified access to the functions of API MQL5 ObjectGetInteger() to receive values of integer properties (of bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to a class instance. There are two versions of the function call:

Getting a property value without checking the correctness

```cpp
long GetInteger{
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // integer property ID
    int modifier=-1 // modifier
} const
```

Parameters

`prop_id`

[in] ID of the graphical object double property.

`modifier=-1`

[in] Modifier (index) of a double property.

Return Value

Value of an integer property - success, 0 - cannot receive an integer property.

Getting a property value verifying the correctness of the operation

```cpp
bool GetInteger{
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // integer property ID
    int modifier, // modifier
    long\& value // link to a variable
} const
```

Parameters

`prop_id`

[in] ID of a graphical object integer property.

`modifier`

[in] Modifier (index) of an integer property.

`value`

[out] Link to a variable to place an integer property value.

Return Value

true - success, false - cannot get an integer property.

Example:

```cpp
//--- example for CChartObject::GetInteger
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
```
CChartObject object;

//--- get color of chart object by easy method
printf("Objects color is %s",ColorToString(object.GetInteger(OBJPROP_COLOR),true));

//--- get color of chart object by classic method
long color_value;
if(!object.GetInteger(OBJPROP_COLOR,0,color_value))
{
    printf("Get integer property error %d",GetLastError());
    return;
}
else
    printf("Objects color is %s",color_value);

for(int i=0;i<object.LevelsCount();i++)
{
    //--- get levels width by easy method
    printf("Level %d width is %d",i,object.GetInteger(OBJPROP_LEVELWIDTH,i));
    //--- get levels width by classic method
    long width_value;
    if(!object.GetInteger(OBJPROP_LEVELWIDTH,i,width_value))
    {
        printf("Get integer property error %d",GetLastError());
        return;
    }
    else
        printf("Level %d width is %d",i,width_value);
}
SetInteger

Provides simplified access to the functions of API MQL5 ObjectSetInteger() to change integer properties (of type bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to class instance. There are two versions of the function call:

Setting a property value that does not require a modifier

```cpp
bool SetInteger(
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // integer property ID
    long value // value
);
```

Parameters

- `prop_id`  
  [in] ID of a graphical object integer property.
- `value`  

Setting a property value indicating the modifier

```cpp
bool SetInteger(
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // integer property ID
    int modifier, // modifier
    long value // value
);
```

Parameters

- `prop_id`  
  [in] ID of a graphical object integer property.
- `modifier`  
  [in] Modifier (index) of an integer property.
- `value`  

Return Value

true - success, false - cannot change the integer property.

Example:

```cpp
//--- example for CChartObject::SetInteger
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- set new color of chart object
}
```
if(!object.SetInteger(OBJPROP_COLOR, clrRed))
{
    printf("Set integer property error %d", GetLastError());
    return;
}
for(int i=0;i<object.LevelsCount();i++)
{
    //--- set levels width
    if(!object.SetInteger(OBJPROP_LEVELWIDTH, i, i))
    {
        printf("Set integer property error %d", GetLastError());
        return;
    }
}
GetDouble

Provides simplified access to the functions of API MQL5 ObjectGetDouble() to receive double values (of float and double types) of a graphical object bound to a class instance. There are two versions of the function call:

### Getting a property value without checking the correctness

```cpp
double GetDouble(
    ENUM_OBJECTPROPERTY_DOUBLE prop_id, // integer property ID
    int modifier=-1 // modifier
) const
```

**Parameters**

- `prop_id`
  - [in] ID of the graphical object double property.

- `modifier`
  - [in] Modifier (index) of a double property.

**Return Value**

Value of a double property - success, **EMPTY_VALUE** - cannot receive a double property.

### Getting a property value in verifying the correctness of such treatment

```cpp
bool GetDouble(
    ENUM_OBJECTPROPERTY_DOUBLE prop_id, // double property ID
    int modifier, // modifier
    double &value // link to a variable
) const
```

**Parameters**

- `prop_id`
  - [in] ID of a graphical object double property.

- `modifier`
  - [in] Modifier (index) of a double property.

- `value`
  - [out] Link to a variable to place a double property value.

**Return Value**

true - success, false - cannot get a double property.

**Example:**

```cpp
//--- example for CChartObject::GetDouble
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
```
```c
{
    CChartObject object;
    //---
    for (int i=0;i<object.LevelsCount();i++)
    {
        //--- get levels value by easy method
        printf("Level %d value=%f",i,object.GetDouble(OBJPROP_LEVELVALUE, i));
        //--- get levels value by classic method
        double value;
        if (!object.SetDouble(OBJPROP_LEVELVALUE, i, value))
        {
            printf("Get double property error %d",GetLastError());
            return;
        }
        else
        {
            printf("Level %d value=%f", i, value);
        }
    }
}
```
SetDouble

Provides simplified access to the functions of API MQL5 ObjectSetDouble() to change double properties (of float and double types) of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```c
bool  SetDouble(
    ENUM_OBJECTPROPERTY_DOUBLE  prop_id,  // double property ID
double          value       // value
)
```

Parameters

prop_id  
[in]  ID of a graphical object double property.

value  
[in]  New value of a changed double property.

Setting a property value indicating the modifier

```c
bool  SetDouble(
    ENUM_OBJECTPROPERTY_DOUBLE  prop_id,  // double property ID
    int                modifier,  // modifier
double          value       // value
)
```

Parameters

prop_id  
[in]  ID of a graphical object double property.

modifier  
[in]  Modifier (index) of a double property.

value  
[in]  New value of a changed double property.

Return Value

true - success, false - cannot change the double feature.

Example:

```c
//--- example for CChartObject::SetDouble
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //---
```
for(int i=0;i<oobject.LevelsCount();i++)
{
    //--- set level value of chart object
    if(!oobject.SetDouble(OBJPROP_LEVELVALUE, i, 0.1*i))
    {
        printf("Set double property error %d", GetLastErr()());
        return;
    }
}

**GetString**

Provides simplified access to the functions of API MQL5 `ObjectGetString()` for string property values of a graphical object bound to a class instance. There are two versions of a function call:

**Getting a property value without checking the correctness**

```cpp
string GetString( 
    ENUM_OBJECT_PROPERTY_STRING prop_id,       // string property ID
    int modifier=-1,                           // modifier
} const
```

**Parameters**

- `prop_id`
  - [in] ID of graphical object string property.
- `modifier=-1`
  - [in] Modifier (index) of a string property.

**Return Value**

Value of a string property - success, "" - cannot receive a string property.

**Getting a property value verifying the correctness of such treatment**

```cpp
bool GetString( 
    ENUM_OBJECT_PROPERTY_STRING prop_id,       // string property ID
    int modifier,                              // modifier
    string& value,                             // link to a variable
} const
```

**Parameters**

- `prop_id`
  - [in] ID of a graphical object string property.
- `modifier`
  - [in] Modifier (index) of a string property.
- `value`
  - [out] Link to a variable to place a string property value.

**Return Value**

true - successful, false - cannot get a string property.

**Example:**

```cpp
//--- example for CChartObject::GetString
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
```
CChartObject object;
string value;

//--- get name of chart object by easy method
printf("Object name is '%s'", object.GetString(OBJPROP_NAME));

//--- get name of chart object by classic method
if(!object.GetString(OBJPROP_NAME,0,value))
{
    printf("Get string property error %d", GetLastError());
    return;
}
else
    printf("Object name is '%s'",value);

for(int i=0;i<object.LevelsCount();i++)
{
    //--- get levels description by easy method
    printf("Level %d description is '%s'",i,object.GetString(OBJPROP_LEVELTEXT,i));

    //--- get levels description by classic method
    if(!object.GetString(OBJPROP_LEVELTEXT,i,value))
    {
        printf("Get string property error %d", GetLastError());
        return;
    }
    else
        printf("Level %d description is '%s'",i,value);
}
}
SetString

Provides simplified access to the functions of API MQL5 `ObjectSetString()` for changing string properties of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```cpp
bool SetString(
    ENUM_OBJECTPROPERTY_STRING prop_id, // string property ID
    string value // value
)
```

**Parameters**

- `prop_id`  
  [in] ID of a graphical object string property.

- `value`  

Setting a property value indicating the modifier

```cpp
bool SetString(
    ENUM_OBJECTPROPERTY_STRING prop_id, // string property ID
    int modifier, // modifier
    string value // value
)
```

**Parameters**

- `prop_id`  
  [in] ID of a graphical object string property.

- `modifier`  
  [in] Modifier (index) of a string property.

- `value`  

**Return Value**

- true - success, false - cannot change a string property.

**Example:**

```cpp
//--- example for CChartObject::SetString
#include <ChartObjects\ChartObject.mqh>
//--
void OnStart()
{
    CChartObject object;
    //--- set new name of chart object
    if(!object.SetString(OBJPROP_NAME,"MyObject"))
```
for(int i=0;i<obj.LevelsCount();i++)
{
   //--- set levels description
   if(!obj.SetString(OBJPROP_LEVELTEXT,i,"Level_"+IntegerToString(i)))
   {
      printf("Set string property error %d",GetLastError());
      return;
   }
}

Save

Saves parameters of the object in the file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

Parameters

**file_handle**

[in] Handle of the file previously opened using the function FileOpen (...).

Return Value

true - successfully completed, false - error.

Example:

```cpp
//--- example for CChartObject::Save
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    int file_handle;
    CChartObject object=new CChartObject;
    //--- set object parameters
    //--- ...
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
    if(file_handle>0)
    {
        if(!object.Save(file_handle))
        {
            //--- file save error
            printf("File save: Error %d!",GetLastError());
            FileClose(file_handle);
            //---
            return;
        }
    }
    FileClose(file_handle);
}
```
Load

Loads the parameters of the object from the file.

```cpp
virtual bool Load(
    int file_handle   // file handle
)
```

Parameters

`file_handle`

[in] handle of the file previously opened using the function `FileOpen`(...).

Return Value

true - successfully completed, false - error.

Example:

```cpp
//--- example for CChartObject::Load
#include <ChartObjects\ChartObject.mgh>
//---
void OnStart()
{
    int    file_handle;
    CChartObject object;
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!object.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!",GetLastError());
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
    //--- use object
    //--- . . .
}
```
Type

Gets the graphical object type ID.

```cpp
virtual int Type() const
```

Return Value

Object type ID (0x8888 for `CChartObject`).

Example:

```cpp
#include <ChartObjects\ChartObject.mqh>

void OnStart()
{
    CChartObject object;
    //--- get object type
    int type=object.Type();
}
```
Line Objects

A group of “Lines” graphical objects.

This section contains the technical details of working with a group of classes of “Lines” graphical objects and a description of the relevant components of the MQL5 Standard Library.

CChartObjectVLine

CChartObjectVLine is a class for simplified access to "Vertical Line" graphical object properties.

Description

CChartObjectVLine class provides access to "Vertical Line" object properties.

Declaration

```cpp
class CChartObjectVLine : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

```
CObject
   CChartObject
      CChartObjectVLine

Create

Creates “Vertical Line” graphical object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name, // object name
    int window, // chart window
    datetime time // time coordinate
)
```

Parameters

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **time**
  - [in] Time coordinate of the anchor point.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_VLINE for `CChartObjectVLine`).
**CChartObjectHLine**

CChartObjectHLine is a class for simplified access to "Horizontal Line" graphical object properties.

**Description**

CChartObjectHLine class provides access to "Horizontal Line" object properties.

**Declaration**

```cpp
class CChartObjectHLine : public CChartObject
```

**Title**

```cpp
#include <ChartObjects\ChartObjectsLines.mqh>
```

**Inheritance hierarchy**

Create

Creates “Horizontal Line” graphical object.

```cpp
bool Create(
  long  chart_id,       // chart identifier
  string name,          // object name
  long  window,         // chart window
  double price           // price coordinate
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).
- `name`
  - [in] A unique name of the object to create.
- `window`
  - [in] Chart window number (0 - main window).
- `price`
  - [in] Price coordinate of the anchor point.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_HLINE for `CChartObjectHLine`).
CChartObjectTrend

CChartObjectTrend is a class for simplified access to “Trend Line” graphical object properties.

Description

CChartObjectTrend class provides access to “Trend Line” object properties.

Declaration

```cpp
class CChartObjectTrend : public CChartObject
```

Title

```cpp
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

- **CObject**
  - **CChartObject**
    - **CChartObjectTrend**

Direct descendants

- CChartObjectChannel, CChartObjectFibo, CChartObjectFiboChannel, CChartObjectFiboExpansion, CChartObjectGannFan, CChartObjectGannGrid, CChartObjectPitchfork, CChartObjectRegression, CChartObjectStdDevChannel, CChartObjectTrendByAngle

Object types, Graphic objects
Create

Creates "Trend Line" graphical object.

```cpp
bool Create(
    long  chart_id,  // chart identifier
    string name,    // object name
    int    window,  // chart window
    datetime timel, // 1st time coordinate
    double price1, // 1st price coordinate
    datetime time2, // 2nd time coordinate
    double price2 // 2nd price coordinate
)
```

Parameters

* **chart_id**
  - [in] Chart identifier (0 - current chart).

* **name**
  - [in] A unique name of the object to create.

* **window**
  - [in] Chart window number (0 - main window).

* **timel**
  - [in] Time coordinate of the first anchor point.

* **price1**
  - [in] Price coordinate of the first anchor point.

* **time2**
  - [in] Time coordinate of the second anchor point.

* **price2**
  - [in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.
RayLeft (Get Method)

Gets the value of “Ray Left” property.

```cpp
bool RayLeft() const
```

Return Value

The value of “Ray Left” property assigned to the class instance. If there is no object assigned, it returns false.

RayLeft (Set Method)

Sets new flag value for the “Ray Left” property.

```cpp
bool RayLeft(
    bool ray // flag
)
```

Parameters

- `ray`
  

Return Value

- true - successful, false - cannot change flag.
**RayRight (Get Method)**

 Gets the value of “Ray Right” property.

```cpp
bool RayRight() const
```

**Return Value**

The value of “Ray Right” property, assigned to the class instance. If there is no object assigned, it returns false.

**RayRight (Set Method)**

 Sets new flag value for the “Ray Right” property.

```cpp
bool RayRight(
    bool ray   // flag
)
```

**Parameters**

`ray`

**Return Value**

true - successful, false - cannot change flag.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] handle of a file opened previously using the FileOpen(...) function.

**Return Value**

true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

Parameters

- `file_handle`
  
  [in] handle of file opened previously using the FileOpen(...) function.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_TREND for `CChartObjectTrend`).
CChartObjectTrendByAngle

CChartObjectTrendByAngle is a class for simplified access to "Trend Line by Angle" graphical object properties.

Description

CChartObjectTrendByAngle class provides access to "Trend Line by Angle" object properties.

Declaration

```cpp
class CChartObjectTrendByAngle : public CChartObjectTrend
```

Title

```cpp
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

CObject  
  CChartObject  
    CChartObjectTrend  
      CChartObjectTrendByAngle

Direct descendants

CChartObjectGannLine

Create

Creates "Trend Line by Angle" graphical object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name, // object name
    long window, // chart window
    datetime time1, // 1st time coordinate
    double price1, // 1st price coordinate
    datetime time2, // 2nd time coordinate
    double price2 // 2nd price coordinate
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).

- `name`
  - [in] A unique name of the object to create.

- `window`
  - [in] Chart window number (0 - main window).

- `time1`
  - [in] Time coordinate of the first anchor point.

- `price1`
  - [in] Price coordinate of the first anchor point.

- `time2`
  - [in] Time coordinate of the second anchor point.

- `price2`
  - [in] Price coordinate of the second anchor point.

Return Value

- `true` - successful, `false` - error.
## Angle (Get Method)

Gets the value of “Angle” property.

```cpp
double Angle() const
```

### Return Value

The value of “Angle” property assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

## Angle (Set Method)

Sets new value for the “Angle” property.

```cpp
bool Angle(
    double angle // angle
)
```

### Parameters

- `angle`  

### Return Value

- `true` - successful, `false` - cannot change the property.
Type

Returns graphical object type identifier.

```cpp
int Type() const
```

Return Value

Object type identifier (OBJ_TRENDBYANGLE for `CChartObjectTrendByAngle`).
**CChartObjectCycles**

CChartObjectCycles is a class for simplified access to “Cyclic Lines” graphical object properties.

**Description**

CChartObjectCycles provides access to “Cyclic Lines” object properties.

**Declaration**

```cpp
class CChartObjectCycles : public CChartObject
```

**Title**

```cpp
#include <ChartObjects\ChartObjectCycles.mqh>
```

**Inheritance hierarchy**

- **CObject**
  - **CChartObject**
    - **CChartObjectCycles**

- Object types, Graphic objects
Create

Creates “Cyclic Lines” graphical object.

```csharp
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    long window,    // chart window
    datetime time1, // 1st time coordinate
    double price1,  // 1st price coordinate
    datetime time2, // 2nd time coordinate
    double price2   // 2nd price coordinate
)
```

Parameters

`chart_id`
  
  [in] Chart identifier (0 - current chart).

`name`
  
  [in] A unique name of the object to create.

`window`
  
  [in] Chart window number (0 - main window).

`time1`
  
  [in] Time coordinate of the first anchor point.

`price1`
  
  [in] Price coordinate of the first anchor point.

`time2`
  
  [in] Time coordinate of the second anchor point.

`price2`
  
  [in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_CYCLES for ChartObjectCycles).
**Channel Objects**

A group of “Channels” graphical objects.

Create

Creates “Equidistant Channel” graphic object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name, // object name
    int window, // chart window
    datetime time1, // time coordinate of the first anchor point
    double price1, // price coordinate of the first anchor point
    datetime time2, // time coordinate of the second anchor point
    double price2, // price coordinate of the second anchor point
    datetime time3, // time coordinate of the third anchor point
    double price3 // price coordinate of the third anchor point
)
```

Parameters

`chart_id`
[in] Chart ID (0 - current chart).

`name`
[in] A unique name of the object to create.

`window`
[in] Chart window number (0 - main window).

`time1`
[in] Time coordinate of the first anchor point.

`price1`
[in] Price coordinate of the first anchor point.

`time2`
[in] Time coordinate of the second anchor point.

`price2`
[in] Price coordinate of the second anchor point.

`time3`
[in] Time coordinate of the third anchor point.

`price3`
[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_CHANNEL for `CChartObjectChannel`).
CChartObjectRegression

CChartObjectRegression is a class for simplified access to "Linear Regression Channel" graphical object properties.

Description

CChartObjectRegression class provides access to "Linear Regression Channel" object properties.

Declaration

```
class CChartObjectRegression : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>

Create

Creates "Linear Regression Channel" graphical object.

```c
bool Create(
    long        chart_id,    // chart identifier
    string      name,        // object name
    long        window,      // chart window
    datetime    time1,       // first time coordinate
    datetime    time2        // second time coordinate
);
```

**Parameters**

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **time1**
  - [in] Time coordinate of the first anchor point.

- **time2**
  - [in] Time coordinate of the second anchor point.

**Return Value**

true - successful, false - error.
# Type

Returns graphical object type identifier.

```c
int Type() const
```

**Return Value**

Object type identifier (OBJ_REGRESSION for `ChartObjectRegression`).
CChartObjectStdDevChannel

CChartObjectStdDevChannel is a class for simplified access to "Standard Deviation Channel" graphical object properties.

Description

CChartObjectStdDevChannel class provides access to "Standard Deviation Channel" object properties.

Declaration

```cpp
class CChartObjectStdDevChannel : public CChartObjectTrend
```

Title

```cpp
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Inheritance hierarchy

Object types, Graphic objects
Create

Creates "Standard Deviation Channel" graphical object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name, // object name
    int window, // chart window
    datetime time1, // first time coordinate
    datetime time2, // second time coordinate
    double deviation // deviation
)
```

**Parameters**

- **chart_id**
  
  [in] Chart identifier (0 - current chart).

- **name**
  
  [in] A unique name of the object to create.

- **window**
  
  [in] Chart window number (0 - main window).

- **time1**
  
  [in] Time coordinate of the first anchor point.

- **time2**
  
  [in] Time coordinate of the second anchor point.

- **deviation**
  
  [in] Numerical value for "Deviation" property.

**Return Value**

- true - successful, false - error.
Deviation (Get Method)

Gets "Deviation" property value.

```cpp
double Deviation() const
```

Return Value

Value of "Deviation" property assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

Deviation (Set Method)

Sets "Deviation" property value.

```cpp
bool Deviation(
    double deviation // deviation
)
```

Parameters

deviation

[in] New value for "Deviation" property.

Return Value

true - successful, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of file opened previously using the FileOpen(...) function.

**Return Value**

- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] handle of file opened previously using the FileOpen(...) function.

**Return Value**

true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_STDDEVCHANNEL for `CChartObjectStdDevChannel`).
CChartObjectPitchfork

CChartObjectPitchfork is a class for simplified access to "Andrew's Pitchfork" graphical object properties.

Description

CChartObjectPitchfork class provides access to "Andrew's Pitchfork" object properties.

Declaration

```cpp
class CChartObjectPitchfork : public CChartObjectTrend
```

Title

```cpp

Create

Creates “Andrew’s Pitchfork” graphical object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name,   // object name
    long window,   // chart window
    datetime time1, // time coordinate of the first anchor point
    double price1, // price coordinate of the first anchor point
    datetime time2, // time coordinate of the second anchor point
    double price2, // price coordinate of the second anchor point
    datetime time3, // time coordinate of the third anchor point
    double price3 // price coordinate of the third anchor point
)
```

**Parameters**

*chart_id*

- [in] Chart identifier (0 - current chart).

*name*

- [in] Unique name of the object to create.

*window*

- [in] Chart window number (0 - main window).

*time1*

- [in] Time coordinate of the first anchor point.

*price1*

- [in] Price coordinate of the first anchor point.

*time2*

- [in] Time coordinate of the second anchor point.

*price2*

- [in] Price coordinate of the second anchor point.

*time3*

- [in] Time coordinate of the third anchor point.

*price3*

- [in] Price coordinate of the third anchor point.

**Return Value**

- true - successful, false - error.
Type

Returns graphical object type identifier.

```c
int Type() const
```

Return Value

Object type identifier (OBJ_PITCHFORK for `ChartObjectPitchfork`).

**Object types**, **Graphic objects**
**Create**

Creates "Gann Line" graphical object.

```csharp
bool Create(
    long chart_id, // chart identifier
    string name,   // object name
    int window,    // chart window
    datetime timel, // first time coordinate
    double price1, // first price coordinate
    datetime time2, // second time coordinate
    double ppb     // pips per bar
)
```

**Parameters**

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **timel**
  - [in] Time coordinate of the first anchor point.

- **price1**
  - [in] Price coordinate of the first anchor point.

- **time2**
  - [in] Time coordinate of the second anchor point.

- **ppb**
  - [in] Pips per bar.

**Return Value**

true - successful, false - error.
PipsPerBar (Get Method)

Gets the value of “Pips per bar” property.

```cpp
double PipsPerBar() const
```

Return Value

Value of “Pips per bar” property of the object assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

PipsPerBar (Set Method)

Sets new value for “Pips per bar” property.

```cpp
bool PipsPerBar(
    double ppb // pips per bar
)
```

Parameters

`ppb`

[in] New value for “Pips per bar” property.

Return Value

true - successful, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
);
```

Parameters

`file_handle`

[in] handle of the binary file already opened using the FileOpen(...) function

Return Value

true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened using the FileOpen(...) function

**Return Value**

- `true` - successful, `false` - error.
**Type**

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

**Return Value**

Object type identifier (OBJ_GANNLINE for ChartObjectGannLine).
**CChartObjectGannFan**

CChartObjectGannFan is a class for simplified access to "Gann Fan" graphical object properties.

**Description**

CChartObjectGannFan class provides access to "Gann Fan" object properties.

**Declaration**

```cpp
class CChartObjectGannFan : public CChartObjectTrend
```

**Title**

```cpp
#include <ChartObjects\ChartObjectsGann.mqh>
```

**Inheritance hierarchy**

- **CObject**

Create

Creates “Gann Fan” graphical object.

```c
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    int window,     // chart window
    datetime timel, // first time coordinate
    double price1,  // first price coordinate
    datetime time2, // second time coordinate
    double ppb      // pips per bar
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).
- `name`
  - [in] A unique name of the object to create.
- `window`
  - [in] Chart window number (0 - base window).
- `timel`
  - [in] Time coordinate of the first anchor point.
- `price1`
  - [in] Price coordinate of the first anchor point.
- `time2`
  - [in] Time coordinate of the second anchor point.
- `ppb`
  - [in] Pips per bar.

Return Value

- true - successful, false - error.
**PipsPerBar (Get Method)**

Gets the value of “Pips per bar” property.

```cpp
double PipsPerBar() const
```

**Return Value**

Value of “Pips per bar” property of the object assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

**PipsPerBar (Set Method)**

Sets new value for “Pips per bar” property.

```cpp
bool PipsPerBar(
    double ppb // pips per bar
)
```

**Parameters**

`ppb`

[in] New value for “Pips per bar” property.

**Return Value**

true - successful, false - cannot change the property.
**Downtrend (Get Method)**

Gets the value of “Downtrend” flag.

```cpp
bool Downtrend() const
```

**Return Value**

Value of the “Downtrend” flag of the object assigned to the class instance. If there is no object assigned, it returns false.

**Downtrend (Set Method)**

Sets new value of “Downtrend” property.

```cpp
bool Downtrend(
    bool downtrend  // flag value
)
```

**Parameters**

`downtrend`

**Return Value**

true - successful, false - cannot change the flag.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

**Parameters**

`file_handle`

[in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**

true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle    // file handle
)
```

Parameters

- `file_handle`
  - [in] handle of the binary file already opened using the `FileOpen(...)` function.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_GANNFAN for `CChartObjectGannFan`).
CChartObjectGannGrid

CChartObjectGannGrid is a class for simplified access to "Gann Grid" graphical object properties.

Description

CChartObjectGannGrid class provides access to "Gann Grid" object properties.

Declaration

```cpp
class CChartObjectGannGrid : public CChartObjectTrend
```

Title

```cpp
#include <ChartObjects\ChartObjects\Gann.mqh>
```

Inheritance hierarchy

- CObject
  - CChartObject
    - CChartObjectTrend

    double ppb    // pips per bar
)
```

Parameters

- `chart_id` [in] Chart identifier (0 - current chart).
- `name` [in] A unique name of the object to create.
- `window` [in] Chart window number (0 - main window).
- `time1` [in] Time coordinate of the first anchor point.
- `price1` [in] Price coordinate of the first anchor point.
- `time2` [in] Time coordinate of the second anchor point.
- `ppb` [in] Pips per bar.

Return Value

true - successful, false - error.
**PipsPerBar (Get Method)**

Gets the value of “Pips per bar” property.

```cpp
double PipsPerBar() const
```

**Return Value**

Value of “Pips per bar” property of the object assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

**PipsPerBar (Set Method)**

Sets new value for “Pips per bar” property.

```cpp
bool PipsPerBar(
    double ppb // Pips per bar
)
```

**Parameters**

`ppb`

[in] New value for “Pips per bar” property.

**Return Value**

true - successful, false - cannot change the property.
**Downtrend (Get Method)**

Gets the value of "Downtrend" property.

```cpp
bool Downtrend() const
```

Return Value

Value of "Downtrend" property of the object assigned to the class instance. If there is no object assigned, it returns false.

**Downtrend (Set Method)**

Sets new value of "Downtrend" property.

```cpp
bool Downtrend(
    bool downtrend // flag value
)
```

Parameters

- `downtrend`

Return Value

- true - successful, false - cannot change the property.
**Save**

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  
  [in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**

- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle  // file handle
)
```

**Parameters**

`file_handle`

[in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**

true - successful, false - error.
Type

Returns graphic object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_GANNGRID for `CChartObjectGannGrid`).

    double price1,      // first price coordinate
    datetime time2,      // second time coordinate
    double price2        // second price coordinate
)
```

Parameters

- `chart_id` [in] Chart identifier (0 - current chart).
- `name` [in] A unique name of the object to create.
- `window` [in] Chart window number (0 - main window).
- `time1` [in] Time coordinate of the first anchor point.
- `price1` [in] Price coordinate of the first anchor point.
- `time2` [in] Time coordinate of the second anchor point.
- `price2` [in] Price coordinate of the second anchor point.

Return Value

- `true` - successful, `false` - error.
**Type**

Returns graphical object type identifier.

```
virtual int Type() const
```

**Return Value**

Object type identifier (OBJ_FIBO for CChartObjectFibo).
CChartObjectFiboTimes

CChartObjectFiboTimes is a class for simplified access to "Fibonacci Time Zones" graphical object properties.

Description

CChartObjectFiboTimes class provides access to "Fibonacci Time Zones" object properties.

Create

Creates “Fibonacci Time Zones” graphical object.

```cpp
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    int window,     // chart window
    datetime time1, // first time coordinate
    double price1,  // first price coordinate
    datetime time2, // second time coordinate
    double price2   // second price coordinate
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).
- `name`
  - [in] A unique name of the object to create.
- `window`
  - [in] Chart window number (0 - main window).
- `time1`
  - [in] Time coordinate of the first anchor point.
- `price1`
  - [in] Price coordinate of the first anchor point.
- `time2`
  - [in] Time coordinate of the second anchor point.
- `price2`
  - [in] Price coordinate of the second anchor point.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOTIMES for `CChartObjectFiboTimes`).
CChartObjectFiboFan

CChartObjectFiboFan is a class for simplified access to "Fibonacci Fan" graphical object properties.

Description

CChartObjectFiboFan class provides access to "Fibonacci Fan" object properties.

Declaration

```cpp
class CChartObjectFiboFan : public CChartObject
```

Title

```cpp
#include <ChartObjects\ChartObjectsFibo.mqh>

Object types, Graphic objects
Create

Creates “Fibonacci Arc” graphical object.

```cpp
bool Create(
    long chart_id, // chart identifier
    string name,   // object name
    int window,    // chart window
    datetime time1, // first time coordinate
    double price1, // first price coordinate
    datetime time2, // second time coordinate
    double price2, // second price coordinate
    double scale   // scale
)
```

**Parameters**

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **time1**
  - [in] Time coordinate of the first anchor point.

- **price1**
  - [in] Price coordinate of the first anchor point.

- **time2**
  - [in] Time coordinate of the second anchor point.

- **price2**
  - [in] Price coordinate of the second anchor point.

- **scale**
  - [in] Scale.

**Return Value**

true - successful, false - error.

**Scale (Get Method)**

Gets the value of "Scale" property.

```cpp
double Scale() const
```

**Return Value**

Value of "Scale" property of the object assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

**Scale (Set Method)**

Sets new value for "Scale" property.

```cpp
bool Scale(
    double scale  // scale
)
```

**Parameters**

- `scale`
  - [in] New value for "Scale" property.

**Return Value**

- true - successful, false - cannot change the property.
### Ellipse (Get Method)

Gets the value of “Ellipse” flag.

```cpp
bool Ellipse() const
```

#### Return Value

Value of “Ellipse” flag of the object assigned to the class instance. If there is no object assigned, it returns false.

### Ellipse (Set Method)

Sets “Ellipse” flag value.

```cpp
bool Ellipse(
    bool ellipse // flag value
)
```

#### Parameters

- `ellipse`  
  

#### Return Value

- true - successful, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

**Parameters**

`file_handle`
- [in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**
- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

Parameters

- `file_handle`
  
  `[in]` handle of the binary file already opened using the FileOpen(...) function.

Return Value

- `true` - successful, `false` - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOARC for `CChartObjectFiboArc`).
CChartObjectFiboChannel

CChartObjectFiboChannel is a class for simplified access to "Fibonacci Channel" graphical object properties.

Description

CChartObjectFiboChannel class provides access to "Fibonacci Channel" object properties.

Declaration

```cpp
class CChartObjectFiboChannel : public CChartObjectTrend
```

Title

```cpp
#include <ChartObjects\ChartObjectsFibo.mqh>
```

Inheritance hierarchy

- CObject
  - CChartObject
    - CChartObjectTrend
      - CChartObjectFiboChannel

Create

Creates "Fibonacci Channel" graphical object.

```cpp
bool Create(
  long chart_id,  // chart identifier
  string name,   // object name
  int window,    // chart window
  datetime time1, // first time coordinate
  double price1, // first price coordinate
  datetime time2, // second time coordinate
  double price2, // second price coordinate
  datetime time3, // third time coordinate
  double price3  // third price coordinate
)
```

Parameters

- `chart_id` [in] Chart identifier (0 - current chart).
- `name` [in] A unique name of the object to create.
- `window` [in] Chart window number (0 - main window).
- `time1` [in] Time coordinate of the first anchor point.
- `price1` [in] Price coordinate of the first anchor point.
- `time2` [in] Time coordinate of the second anchor point.
- `price2` [in] Price coordinate of the second anchor point.
- `time3` [in] Time coordinate of the third anchor point.
- `price3` [in] Price coordinate of the third anchor point.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOCOMPANNEL for CChartObjectFiboChannel).
CChartObjectFiboExpansion

CChartObjectFiboExpansion is a class for simplified access to "Fibonacci Expansion" graphical object properties.

Description

CChartObjectFiboExpansion class provides access to "Fibonacci Expansion" object properties.

Declaration

```
class CChartObjectFiboExpansion : public CChartObjectTrend

    datetime time2, // second time coordinate
    double price2, // second price coordinate
    datetime time3, // third time coordinate
    double price3  // third price coordinate
)
```

**Parameters**

*chart_id*

[in] Chart identifier (0 - current chart).

*name*

[in] A unique name of the object to create.

*window*

[in] Chart window number (0 - main window).

*time1*

[in] Time coordinate of the first anchor point.

*price1*

[in] Price coordinate of the first anchor point.

*time2*

[in] Time coordinate of the second anchor point.

*price2*

[in] Price coordinate of the second anchor point.

*time3*

[in] Time coordinate of the third anchor point.

*price3*

[in] Price coordinate of the third anchor point.

**Return Value**

true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_EXPANSION for `CChartObjectFiboExpansion`).

Object types, Graphic objects
Create

Creates "Correcting Wave" graphical object.

```c
bool Create(
    long chart_id,   // chart identifier
    string name,     // object name
    int window,      // chart window
    datetime time1,  // first time coordinate
    double price1,   // first price coordinate
    datetime time2,  // second time coordinate
    double price2,   // second price coordinate
    datetime time3,  // third time coordinate
    double price3    // third price coordinate
)
```

**Parameters**

- **chart_id**
  - [in] Chart identifier (0 - current chart).
- **name**
  - [in] A unique name of the object to create.
- **window**
  - [in] Chart window number (0 - main window).
- **time1**
  - [in] Time coordinate of the first anchor point.
- **price1**
  - [in] Price coordinate of the first anchor point.
- **time2**
  - [in] Time coordinate of the second anchor point.
- **price2**
  - [in] Price coordinate of the second anchor point.
- **time3**
  - [in] Time coordinate of the third anchor point.
- **price3**
  - [in] Time coordinate of the third anchor point.

**Return Value**

- true - successful, false - error.
Degree (Get Method)

Gets the value of "Degree" property.

```cpp
enum EnumElliotWaveDegree
{ Degree{}, const
```

Return Value

Value of "Degree" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Degree (Set Method)

Sets new value for "Degree" property.

```cpp
def Degree(
    EnumElliotWaveDegree degree  // property value
)
```

Parameters

`degree`

[in] New value for "Degree" property.

Return Value

true - successful, false - cannot change the property.
**Lines (Get Method)**

Gets the value of "Lines" property.

```cpp
bool Lines() const
```

**Return Value**

Value of "Lines" property of the object assigned to the class instance. If there is no object assigned, it returns false.

**Lines (Set Method)**

Sets new value for "Lines" property.

```cpp
bool Lines(
    bool lines // flag value
)
```

**Parameters**

`lines`

**Return Value**

true - successful, false - cannot change the flag.
Save

Saves object parameters to file.

```
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**

- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle   // file handle
)
```

**Parameters**

- `file_handle`

  [in] handle of the binary file already opened using the FileOpen(...) function.

**Return Value**

- true - successful, false - error.
**Type**

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

**Return Value**

Object type identifier (OBJ_ELLIOTWAVE3 for `CChartObjectElliottWave3`).
CChartObjectElliottWave5

CChartObjectElliottWave5 is a class for simplified access to "Impulse Wave" graphical object properties.

Description

CChartObjectElliottWave5 class provides access to "Impulse Wave" object properties.

Declaration

```cpp
class CChartObjectElliottWave5 : public CChartObjectElliottWave3
```

Title

```cpp
#include <ChartObjects\ChartObjectsElliott.mqh>
```

Inheritance hierarchy

```
CObject
    CChartObject
        CChartObjectElliottWave3
            CChartObjectElliottWave5
```

Create

Creates "Impulse Wave" graphical object.

```cpp
bool Create(
    long chart_id,       // chart identifier
    string name,         // object name
    int window,          // chart window
    datetime time1,      // first time coordinate
    double price1,       // first price coordinate
    datetime time2,      // second time coordinate
    double price2,       // second price coordinate
    datetime time3,      // third time coordinate
    double price3,       // third price coordinate
    datetime time4,      // fourth time coordinate
    double price4,       // fourth price coordinate
    datetime time5,      // fifth time coordinate
    double price5        // fifth price coordinate
)
```

Parameters

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **time1**
  - [in] Time coordinate of the first anchor point.

- **price1**
  - [in] Price coordinate of the first anchor point.

- **time2**
  - [in] Time coordinate of the second anchor point.

- **price2**
  - [in] Price coordinate of the second anchor point.

- **time3**
  - [in] Time coordinate of the third anchor point.

- **price3**
  - [in] Price coordinate of the third anchor point.

- **time4**
  - [in] Time coordinate of the fourth anchor point.
Standard Library

*price4*
  [in] Price coordinate of the fourth anchor point.

*time5*
  [in] Time coordinate of the fifth anchor point.

*price5*
  [in] Price coordinate of the fifth anchor point.

**Return Value**

true - successful, false - error.
Type

Returns graphical object type identifier.

virtual int Type() const

Return Value

Object type identifier (OBJ_ELLIOITWAVES for CChartObjectElliottWave5).
Shape Objects

A group of “Shapes” graphical objects.

Create

Creates “Rectangle” graphical object.

```cpp
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    long window,    // chart window
    datetime time1, // first time coordinate
    double price1,  // first price coordinate
    datetime time2, // second time coordinate
    double price2   // second price coordinate
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).

- `name`
  - [in] A unique name of the object to create.

- `window`
  - [in] Chart window number (0 - main window).

- `time1`
  - [in] Time coordinate of the first anchor point.

- `price1`
  - [in] Price coordinate of the first anchor point.

- `time2`
  - [in] Time coordinate of the second anchor point.

- `price2`
  - [in] Price coordinate of the second anchor point.

Return Value

- true - successful, false - error.
**Type**

Returns graphical object type identifier.

```cpp
int Type() const
```

**Return Value**

Object type identifier (OBJ_RECTANGLE for `CChartObjectRectangle`).
CChartObjectTriangle

CChartObjectTriangle is a class for simplified access to “Triangle” graphical object properties.

Description

CChartObjectTriangle class provides access to “Triangle” object properties.

Declaration

```cpp
class CChartObjectTriangle : public CChartObject
```

- `price2`  
  [in] Price coordinate of the second anchor point.

- `time3`  
  [in] Time coordinate of the third anchor point.

- `price3`  
  [in] Price coordinate of the third anchor point.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
int Type() const
```

Return Value

Object type identifier (OBJ_ELLIPSE for `CChartObjectEllipse`).
Arrow Objects

Group for Arrows graphical objects.

This section contains the technical details of working with a group of classes of “Arrow” graphical objects and a description of the relevant components of the MQL5 Standard Library. In essence, the arrow is a certain icon which is associated with a specific code. There are two types of “Arrow” graphical object to display icons on the charts:

- “Arrow” object, which allows you to specify the code of the icon displayed by the object.
- Group of objects to display a certain type of icons (corresponding to a certain fixed code).

Class for working with arrows displaying arbitrary code icons

**CChartObjectArrow**

CChartObjectArrow is a class for simplified access to "Arrow" graphical object properties.

**Description**

CChartObjectArrow class provides access to common properties of "Arrow" objects to all of its descendants.

**Declaration**

```c
class CChartObjectArrow : public CChartObject
```

**Title**

```c
#include <ChartObjects\ChartObjectArrows.mqh>
```

**Inheritance hierarchy**

```
CObject
  CChartObject
    CChartObjectArrow
```

**Direct descendants**

- CChartObjectArrowCheck
- CChartObjectArrowDown
- CChartObjectArrowLeftPrice
- CChartObjectArrowRightPrice
- CChartObjectArrowStop
- CChartObjectArrowThumbDown
- CChartObjectArrowThumbUp
- CChartObjectArrowUp

See also

Object types, Methods of objects binding, Graphic objects
Create

Creates “Arrow” graphical object.

```cpp
bool Create(
    long chart_id,  // chart ID
    string name,  // object Name
    int window,  // chart Window
    datetime time,  // time
    double price,  // price
    char code  // arrow code
)
```

Parameters

- `chart_id`  
  [in] Chart identifier (0 - current chart).

- `name`  
  [in] A unique object name.

- `window`  
  [in] Chart window number (0 - main window).

- `time`  

- `price`  
  [in] Price coordinate.

- `code`  

Return Value

- `true` - success, `false` - error.

Example:

```cpp
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    CChartObjectArrow arrow;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
    }
}
```
return;
}
//--- use arrow
//--- ...
**ArrowCode (Get Method)**

Gets “Arrow” symbol code.

```
char   ArrowCode() const
```

**Return Value**

“Arrow” symbol code of the object assigned to the class instance. If there is no object assigned, it returns 0.

**ArrowCode (Set Method)**

Sets symbol code for “Arrow”

```
bool   ArrowCode(
    char   code  // code value
)
```

**Parameters**

`code`

[in] New value for “arrow” code (Wingdings).

**Return Value**

true - success, false - cannot change the code.

**Example:**

```c
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    CChartObjectArrow arrow;
    char    code=181;
    //--- set object parameters
    double  price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,code))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
        return;
    }
    //--- change the code of arrow
    //--- . . .
    //--- get code of arrow
    if(arrow.ArrowCode()!=code)
    {
        //--- set code of arrow
```
arrow.ArrowCode(code);
}
//--- use arrow
//--- . . .
}
Anchor (Get Method)

Gets anchor type of the "Arrow" object

```cpp
ENUM_ARROW_ANCHOR Anchor() const
```

Return Value

Anchor type of the "Arrow" object assigned to the class instance (to the chart). If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets anchor type for the "Arrow" object

```cpp
bool Anchor(
    ENUM_ARROW_ANCHOR anchor // anchor type
)
```

Parameters

`anchor`

[in] New anchor type value

Return Value

true - successful, false - cannot change the anchor type.

Example:

```cpp
//--- example for CChartObject::Anchor
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    CChartObjectArrow arrow;
    ENUM_ARROW_ANCHOR anchor=ANCHOR_BOTTOM;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
        return;
    }
    //--- get anchor of arrow
    if(arrow.Anchor()!=anchor)
    {
        //--- set anchor of arrow
        arrow.Anchor(anchor);
    }
}
//--- use arrow
//--- . . .
}

Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

ture - successful, false - error.

Example:

```cpp
//--- example for CChartObjectArrow::Save
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    int file_handle;
    CChartObjectArrow arrow;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
        return;
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!arrow.Save(file_handle))
        {
            //--- file save error
            printf("File save: Error %d!",GetLastError());
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
}
```
Load

Loads object parameters from file.

```
virtual bool Load(
    int file_handle   // file handle
)
```

**Parameters**

`file_handle`

[in] handle of file previously opened using the FileOpen(...) function.

**Return Value**

true - success, false - error.

**Example:**

```c
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    int file_handle;
    CChartObjectArrow arrow;

    //--- open file
    file_handle = FileOpen("MyFile.bin", FILE_READ|FILE_BIN|FILE_ANSI);
    if (file_handle >= 0)
    {
        if (!arrow.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!", GetLastError());
            FileClose(file_handle);
            //---
            return;
        }        
        FileClose(file_handle);
    }
    //--- use arrow
    //--- . . .
```
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (for example, OBJ_ARROW for `CChartObjectArrow`)

Example:

```cpp
//--- example for CChartObjectArrow::Type
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    CChartObjectArrow arrow;
    //--- get arrow type
    int type=arrow.Type();
}
```
## Arrows with fixed code

"Arrows with fixed code" are classes for simplified access to the properties of the following graphical objects:

<table>
<thead>
<tr>
<th>Class name</th>
<th>Arrow object name</th>
</tr>
</thead>
<tbody>
<tr>
<td>CChartObjectArrowCheck</td>
<td>&quot;Arrow Check&quot;</td>
</tr>
<tr>
<td>CChartObjectArrowDown</td>
<td>&quot;Arrow Down&quot;</td>
</tr>
<tr>
<td>CChartObjectArrowUp</td>
<td>&quot;Arrow Up&quot;</td>
</tr>
<tr>
<td>CChartObjectArrowStop</td>
<td>&quot;Arrow Stop&quot;</td>
</tr>
<tr>
<td>CChartObjectArrowThumbDown</td>
<td>&quot;Good&quot; (&quot;Thumbs up&quot;)</td>
</tr>
<tr>
<td>CChartObjectArrowThumbUp</td>
<td>&quot;Bad&quot; (&quot;Thumbs down&quot;)</td>
</tr>
<tr>
<td>CChartObjectArrowLeftPrice</td>
<td>&quot;Left price&quot; arrow</td>
</tr>
<tr>
<td>CChartObjectArrowRightPrice</td>
<td>&quot;Right price&quot; arrow</td>
</tr>
</tbody>
</table>

### Description

"Arrows with fixed code" classes provide access to the object properties.

### Declarations

```cpp
class CChartObjectArrowCheck : public CChartObjectArrow;
class CChartObjectArrowDown    : public CChartObjectArrow;
class CChartObjectArrowUp     : public CChartObjectArrow;
class CChartObjectArrowStop   : public CChartObjectArrow;
class CChartObjectArrowThumbDown : public CChartObjectArrow;
class CChartObjectArrowThumbUp   : public CChartObjectArrow;
class CChartObjectArrowLeftPrice : public CChartObjectArrow;
class CChartObjectArrowRightPrice : public CChartObjectArrow;
```

### Title

```python
<ChartObjects\ChartObjectsArrows.mqh>
```

Object types, Methods of object binding, Graphic objects
Create

Creates “Arrow with fixed code” graphical object.

```cpp
bool Create(
    long chart_id, // chart ID
    string name,   // object Name
    int window,    // chart Window
    datetime time, // time
    double price   // price
)
```

Parameters

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] Unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **time**

- **price**
  - [in] Price coordinate.

Return Value

- `true` - successful, `false` - error.

Example:

```cpp
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    //--- for example, take CChartObjectArrowCheck
    CChartObjectArrowCheck arrow;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))
```
```c
{
  //--- arrow create error
  printf("Arrow create: Error %d!", GetLastError());
  //---
  return;
}
//--- use arrow
//--- . . .
```
**ArrowCode**

Prohibits "Arrow" symbol code changes.

```cpp
bool ArrowCode(  
    char code     // code value
)
```

**Parameters**

- **code**
  - [in] Any value

**Return Value**

**Always false.**

**Example:**

```cpp
//--- example for CChartObjectArrowCheck::ArrowCode
//--- example for CChartObjectArrowDown::ArrowCode
//--- example for CChartObjectArrowUp::ArrowCode
//--- example for CChartObjectArrowStop::ArrowCode
//--- example for CChartObjectArrowThumbDown::ArrowCode
//--- example for CChartObjectArrowThumbUp::ArrowCode
//--- example for CChartObjectArrowLeftPrice::ArrowCode
//--- example for CChartObjectArrowRightPrice::ArrowCode
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    //--- for example, take CChartObjectArrowCheck
    CChartObjectArrowCheck arrow;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))
        //--- arrow create error
        printf("Arrow create: Error %d",GetLastError());
        //---
        return;
    //--- set code of arrow
    if(!arrow.ArrowCode(181))
        //--- it is not error
        printf("Arrow code can not be changed");
    }
    //--- use arrow
    //---...
}
```
### Type

Returns graphical object type identifier

```cpp
virtual int Type() const
```

**Return Value**

Object type identifier:

- `CChartObjectArrowCheck` - OBJ_ARROW_CHECK,
- `CChartObjectArrowDown` - OBJ_ARROW_DOWN,
- `CChartObjectArrowUp` - OBJ_ARROW_UP,
- `CChartObjectArrowStop` - OBJ_ARROW_STOP,
- `CChartObjectArrowThumbDown` - OBJ_ARROW_THUMB_DOWN,
- `CChartObjectArrowThumbUp` - OBJ_ARROW_THUMB_UP,
- `CChartObjectArrowLeftPrice` - OBJ_ARROW_LEFT_PRICE,
- `CChartObjectArrowRightPrice` - OBJ_ARROW_RIGHT_PRICE.

**Example:**

```cpp
#include <ChartObjects\ChartObjectsArrows.mqh>

void OnStart()
{
    //--- example for CChartObjectArrowCheck::Type
    //--- example for CChartObjectArrowDown::Type
    //--- example for CChartObjectArrowUp::Type
    //--- example for CChartObjectArrowStop::Type
    //--- example for CChartObjectArrowThumbDown::Type
    //--- example for CChartObjectArrowThumbUp::Type
    //--- example for CChartObjectArrowLeftPrice::Type
    //--- example for CChartObjectArrowRightPrice::Type
    CChartObjectArrowCheck arrow;
    //--- get arrow type
    int type=arrow.Type();
}
```

Derived classes:

- CChartObjectLabel

See also

Object types, Object properties, Methods of object binding, Graphic objects
Create

Creates "Text" graphical object.

```cpp
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    int window,     // chart window
    datetime time,  // time coordinate
    double price    // price coordinate
)
```

**Parameters**

- `chart_id`
  - `[in]` Chart identifier (0 - current chart).

- `name`
  - `[in]` A unique name of the object to create.

- `window`
  - `[in]` Chart window number (0 - main window).

- `time`
  - `[in]` Time coordinate of the anchor point.

- `price`
  - `[in]` Price coordinate of the anchor point.

**Return Value**

- `true` - successful, `false` - error.
Angle (Get Method)

Gets the value of “Angle” property.

```cpp
double Angle() const
```

Return Value

Value of “Angle” property of the object assigned to the class instance. If there is no object assigned, it returns `EMPTY_VALUE`.

Angle (Set Method)

Sets a value for “Angle” property.

```cpp
bool Angle(
    double angle // property value
)
```

Parameters

angle

Return Value

true - successful, false - cannot change the property.
Font (Get Method)

Gets the value of "Font" property.

```cpp
string Font() const
```

Return Value

Value of "Font" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Font (Set Method)

Sets new value for "Font" property.

```cpp
bool Font(
    string font    // property value
)
```

Parameters

font

[in] New value for "Font" property.

Return Value

true - success, false - cannot change the property.
FontSize (Get Method)

Gets the value of “Font size” property.

```
int FontSize() const
```

Return Value

Value of “FontSize” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

FontSize (Set Method)

Sets new value for “Font size” property.

```
bool FontSize(
    int size  // property value
)
```

Parameters

size

Return Value

true - successful, false - cannot change the property.
Anchor (Get Method)

Gets the value of “Anchor” property.

| ENUM_ANCHOR_POINT | Anchor() const |

Return Value

Value of “Anchor” property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets new value for “Anchor” property.

```c
bool Anchor(
    ENUM_ANCHOR_POINT anchor // property value
)
```

Parameters

anchor

Return Value

true - success, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
);
```

**Parameters**

- `file_handle`
  
  [in] handle of the binary file already opened by the [FileOpen](#) function.

**Return Value**

- true - success, false - error.
## Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

### Parameters

- `file_handle`
  
  [in] handle of the binary file already opened by the [FileOpen](#) function.

### Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_TEXT for `CChartObjectText`).
CChartObjectLabel

CChartObjectLabel is a class for simplified access to "Label" graphical object properties.

Description

CChartObjectLabel class provides access to "Label" object properties.

Declaration

```cpp
class CChartObjectLabel : public CChartObjectText
```

Title

```cpp
#include <ChartObjects\ChartObjects\TxtControls.mqh>
```

Inheritance hierarchy

CObject
  CChartObject
    CChartObjectText
      CChartObjectLabel

Direct descendants

CChartObjectEdit, CChartObjectRectLabel

Create

Creates "Label" graphical object.

```cpp
bool Create(
    long chart_id,     // chart identifier
    string name,       // object name
    int window,        // chart window
    int X,             // X coordinate
    int Y              // Y coordinate
);
```

### Parameters

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **X**
  - [in] X coordinate.

- **Y**
  - [in] Y coordinate.

### Return Value

- true - successful, false - error.
**X_Distance (Get Method)**

Gets the value of “X_Distance” property.

```c
int X_Distance() const
```

**Return Value**

Value of “X_Distance” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**X_Distance (Set Method)**

Sets new value for “X_Distance” property.

```c
bool X_Distance(
    int X  // property value
)
```

**Parameters**

- **X**
  - [in] New value for “X_Distance” property.

**Return Value**

- true - successful, false - cannot change the property.
Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```c++
int Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```c++
bool Y_Distance(
    int Y  // property value
)
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.
X_Size

Gets the value of "X_Size" property.

```cpp
int X_Size() const
```

**Return Value**

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.
Y_Size

Gets the value of “Y_Size” property.

```cpp
int Y_Size() const
```

Return Value

Value of “Y_Size” property of the object assigned to the class instance. If there is no object assigned, it returns 0.
Corner (Get Method)

Gets the value of "Corner" property.

```cpp
enum Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```cpp
bool Corner(
    enum Corner corner // property value
)
```

Parameters

`corner`

Return Value

true - successful, false - cannot change the property.
Time

Prohibits changes of the time coordinate.

```c
bool Time(
    datetime time    // any value
)
```

Parameters

time

Return Value

always false.
Price

Prohibits changes of the price coordinate.

```cpp
bool Price(
    double price  // any value
)
```

Parameters

price

Return Value

always false.
Save

Saves object parameters to file.

```cpp
virtual bool Save( 
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- `true` - successful, `false` - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

true - successful, false - error.
Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_LABEL for CChartObjectLabel).
CChartObjectEdit

CChartObjectEdit is a class for simplified access to "Edit" graphical object properties.

Description

CChartObjectEdit class provides access to "Edit" object properties.

Declaration

```cpp
class CChartObjectEdit : public CChartObjectLabel
```

Title

```cpp
#include <ChartObjects\ChartObjects\txtControls.mqh>
```

Inheritance hierarchy

- CObject
  - CChartObject
    - CChartObjectText
      - CChartObjectLabel
      - CChartObjectEdit

Direct descendants

- CChartObjectButton

Create

Creates "Edit" graphical object.

```c
bool Create(
    long  chart_id,  // chart identifier
    string name,    // object name
    int   window,   // chart window
    int   X,        // X coordinate
    int   Y,        // Y coordinate
    int   sizeX,    // X size
    int   sizeY     // Y size
)
```

**Parameters**

*chart_id*

[in] Chart identifier (0 - current chart).

*name*

[in] A unique name of the object to create.

>window*

[in] Chart window number (0 - main window).

*X*

[in] X coordinate.

*Y*

[in] Y coordinate.

*sizeX*

[in] X size.

*sizeY*

**Return Value**

true - successful, false - error.
**TextAlign (Get method)**

Gets the value of "TextAlign" property (text alignment mode).

```cpp
ENUM_ALIGN_MODE TextAlign() const
```

**Return Value**

Value of "TextAlign" property of the object assigned to the class instance.

---

**TextAlign (Set method)**

Sets the value of "TextAlign" property (text alignment mode).

```cpp
bool TextAlign(
    ENUM_ALIGN_MODE align     // property value
);
```

**Parameters**

*align*

[in] New value of "TextAlign" property.

**Return Value**

true - success, false - cannot change the property.
X_Size

Sets the value for "X_Size" property.

```cpp
bool X_Size(
    int size       // property value
)
```

**Parameters**

- `size`
  
  [in] New value for "X_Size" property.

**Return Value**

- `true` - success, `false` - cannot change the property.
Y_Size

Sets the value for "Y_Size" property.

```cpp
bool Y_Size(  
    int size  // property value
)
```

Parameters

size

[in] New value for "Y_Size" property.

Return Value

true - success, false - cannot change the property.
**BackColor (Get Method)**

Gets the value of "BackColor" property.

```cpp
    color BackColor() const
```

**Return Value**

Value of "BackColor" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

**BackColor (Set Method)**

Sets the value for "BackColor" property.

```cpp
    bool BackColor(
        color new_color  // property value
    )
```

**Parameters**

`new_color`

**Return Value**

true - success, false - cannot change the property.
BorderColor (Get Method)

Gets the value of "Border Color" property.

```cpp
    color  BorderColor() const
```

Return Value

Value of "Border Color" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

BorderColor (Set Method)

Sets new value for "Border Color" property.

```cpp
    bool  BorderColor(
        color  new_color  // new property value
    )
```

Parameters

new_color

Return Value

true - success, false - cannot change the property.
ReadOnly (Get Method)

Gets the value of “Read Only” property.

```cpp
bool ReadOnly() const
```

Return Value

Value of “Read Only” property of the object assigned to the class instance. If there is no object assigned, it returns false.

ReadOnly (Set Method)

Sets the value for “Read Only” property.

```cpp
bool ReadOnly(
    const bool flag  // new property value
)
```

Parameters

`flag`

[in] New value for “Read Only” property (true means text editing is disabled).

Return Value

true - success, false - cannot change the property.
Angle

Prohibits changes of the "Angle" property.

```cpp
bool Angle(
    double angle  // any value
)
```

Parameters

angle

Return Value

always false.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`  
  [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- true - success, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

true - success, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_EDIT for `CChartObjectEdit`).
CChartObjectButton

CChartObjectButton is a class for simplified access to “Button” graphical object properties.

Description

CChartObjectButton class provides access to “Button” object properties.

Declaration

```cpp
class CChartObjectButton : public CChartObjectEdit
```

Title

```cpp
#include <ChartObjects\ChartObjects\TxtControls.mqh>
```

Inheritance hierarchy

**State (Get Method)**

Gets the value of “State” property.

```cpp
bool State() const
```

**Return Value**

Value of “State” property of the object assigned to the class instance. If there is no object assigned, it returns false.

**State (Set Method)**

Sets new value for “State” property.

```cpp
bool State(
    bool state // property value
)
```

**Parameters**

- `X`  

**Return Value**

- true - success, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

Parameters

- `file_handle`
  
  [in] handle of the binary file already opened by `FileOpen` function.

Return Value

- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle   // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_BUTTON for `CChartObjectButton`).
**CChartObjectSubChart**

CChartObjectSubChart is a class for simplified access to "Chart" graphical object properties.

**Description**

CChartObjectSubChart class provides access to "Chart" object properties.

**Declaration**

```cpp
class CChartObjectSubChart : public CChartObject
```

**Title**

```
#include <ChartObjects\ChartObjectSubChart.mqh>
```

**Inheritance hierarchy**

- CObject
  - CChartObject
    - CChartObjectSubChart

#### Methods inherited from class CChartObject

#### See also

- **Object types**, **Object properties**, **Chart angle**, **Graphic objects**
Create

Creates “SubChart” graphical object.

```cpp
bool Create(
  long chart_id, // chart identifier
  string name,   // object name
  int  window,   // chart window
  int  X,        // X coordinate
  int  Y,        // Y coordinate
  int  sizeX,    // X size
  int  sizeY     // Y size
)
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).
- `name`
  - [in] A unique name of the object to create.
- `window`
  - [in] Chart window number (0 - main window).
- `X`
  - [in] X coordinate.
- `Y`
  - [in] Y coordinate.
- `sizeX`
  - [in] X size.
- `sizeY`

Return Value

- true - successful, false - error.
**X_Distance (Get Method)**

Gets the value of "X_Distance" property.

```cpp
int X_Distance() const
```

**Return Value**

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**X_Distance (Set Method)**

Sets new value for "X_Distance" property.

```cpp
bool X_Distance(int X // property value)
```

**Parameters**

- **X**
  - [in] New value for "X_Distance" property.

**Return Value**

- true - successful, false - cannot change the property.
**Y_Distance (Get Method)**

Gets the value of “Y_Distance” property.

```cpp
int Y_Distance() const
```

**Return Value**

Value of “Y_Distance” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**Y_Distance (Set Method)**

Sets new value for “Y_Distance” property.

```cpp
bool Y_Distance(
    int Y // property value
)
```

**Parameters**

Y  

[in] New value for “Y_Distance” property.

**Return Value**

true - successful, false - cannot change the property.
Corner (Get Method)

**get the value of “Corner” property.**

```cpp
ENUM_BASE_CORNER Corner() const
```

**Return Value**

Value of “Corner” property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

**Sets new value for “Corner” property.**

```cpp
bool Corner(
    ENUM_BASE_CORNER corner // property value
)
```

**Parameters**

*corner*

**Return Value**

true - successful, false - cannot change the property.
**X_Size (Get Method)**

Gets the value of "X_Size" property.

```c
int X_Size() const
```

**Return Value**

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**X_Size (Set Method)**

Sets new value for "X_Size" property.

```c
bool X_Size(
    int X  // property value
)
```

**Parameters**

*X*

[in] New value for "X_Size" property.

**Return Value**

true - successful, false - cannot change the property.
**Y_Size (Get Method)**

Gets the value of "Y_Size" property.

```cpp
int Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**Y_Size (Set Method)**

Sets new value for "Y_Size" property.

```cpp
bool Y_Size(
    int Y // property value
)
```

Parameters

Y

[in] New value for "Y_Size" property.

Return Value

true - successful, false - cannot change the property.
Symbol (Get Method)

Gets the value of "Symbol" property.

```cpp
string Symbol() const
```

Return Value

Value of "Symbol" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Symbol (Set Method)

Sets new value for "Symbol" property.

```cpp
bool Symbol(
    string symbol  // symbol
)
```

Parameters

symbol

Return Value

true - successful, false - cannot change the property.
**Period (Get Method)**

Gets the value of "Period" property.

```cpp
int Period() const
```

**Return Value**

Value of "Period" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**Period (Set Method)**

Sets new value for "Period" property.

```cpp
bool Period(
    int period // period
)
```

**Parameters**

`period`

**Return Value**

true - successful, false - cannot change the property.
**Scale (Get Method)**

Gets the value of “Scale” property.

```cpp
double Scale() const
```

**Return Value**

Value of “Scale” property of the object assigned to the class instance. If there is no object assigned, it returns **EMPTY_VALUE**.

**Scale (Set Method)**

Sets new value for “Scale” property.

```cpp
bool Scale(
    double scale // property value
)
```

**Parameters**

`scale`

[in] New value for “Scale” property.

**Return Value**

true - successful, false - cannot change the property.
**DateScale (Get Method)**

Gets the value of "DateScale" flag.

```cpp
bool DateScale() const
```

**Return Value**

Value of "DateScale" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

**DateScale (Set Method)**

Sets new value for "DateScale" property.

```cpp
bool DateScale(
    bool scale  // flag value
)
```

**Parameters**

- `scale`
  
  [in] New value for "DateScale" flag.

**Return Value**

- true - successful, false - cannot change the flag.
**PriceScale (Get Method)**

Gets the value of "PriceScale" flag.

```cpp
bool PriceScale() const
```

**Return Value**

Value of "PriceScale" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

**PriceScale (Set Method)**

Sets new value for "PriceScale" flag.

```cpp
bool PriceScale(
    bool scale // flag value
)
```

**Parameters**

* scale
  

**Return Value**

  true - successful, false - cannot change the flag.
Time

Prohibits changes of the time coordinate.

```cpp
bool Time(
    datetime time  // any value
)
```

Parameters

time
    [in]

Return Value

always false.
**Price**

Prohibits changes of the price coordinate.

```c
bool Price(
    double price  // any value
)
```

**Parameters**

`price`

[in]

**Return Value**

always false.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

**Parameters**

`file_handle`

- `[in]` handle of the binary file already opened by `FileOpen` function.

**Return Value**

- `true` - successful, `false` - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

Parameters

- `file_handle` [in] handle of the binary file already opened by `FileOpen` function.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

```cpp
virtual int Type() const
```

Return Value

Object type identifier (OBJ_CHART for `CChartObjectSubChart`).
**CChartObjectBitmap**

CChartObjectBitmap is a class for simplified access to “Bitmap” graphical object properties.

**Description**

CChartObjectBitmap class provides access to “Bitmap” object properties.

**Declaration**

```cpp
class CChartObjectBitmap : public CChartObject
```

**Title**

```cpp
#include <ChartObjects\ChartObjectsBmpControls.mqh>
```

**Inheritance hierarchy**

```cpp
COBJECT
   CChartObject
      CChartObjectBitmap
```

Create

Creates “Bitmap” graphical object.

```cpp
bool Create(  
  long    chart_id,  // chart identifier  
  string  name,     // object name  
  int     window,    // chart window  
  datetime time,     // time coordinate  
  double  price      // price coordinate
);  
```

Parameters

- `chart_id`
  - [in] Chart identifier (0 - current chart).

- `name`
  - [in] A unique name of the object to create.

- `window`
  - [in] Chart window number (0 - main window).

- `time`
  - [in] Time coordinate of the anchor point.

- `price`
  - [in] Price coordinate of the anchor point.

Return Value

- `true` - successful, `false` - error.
**BmpFile (Get Method)**

Gets the value of “BmpFile” property.

```cpp
string  BmpFile() const
```

**Return Value**

Value of “BmpFile” property of the object assigned to the class instance. If there is no object assigned, it returns false.

**BmpFile (Set Method)**

Sets new value for “BmpFile” property.

```cpp
bool  BmpFile(
    string  name    // property value
)
```

**Parameters**

`name`

**Return Value**

true - successful, false - cannot change the property.
X_Offset (Get Method)

Gets the value of "X_Offset" property (the upper left corner) of the CChartObjectBitmap graphical object.

```
int X_Offset() const
```

**Return Value**

Value of "X_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Offset (Set Method)

Sets new value for "X_Offset" property (the upper left corner) of the CChartObjectBitmap graphical object. The value is set in pixels relative to the upper left corner of the original image.

```
bool X_Offset(
    int X // property value
)
```

**Parameters**

*X*

[in] New value for "X_Offset" property.

**Return Value**

true - successful, false - cannot change the property.
**Y_Offset (Get Method)**

Gets the value of "Y_Offset" property (the upper left corner) of the `CChartObjectBitmap` graphical object.

```cpp
int Y_Offset() const
```

**Return Value**

Value of "Y_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**Y_Offset (Set Method)**

Sets new value for "Y_Offset" property (the upper left corner) of the `CChartObjectBitmap` graphical object. The value is set in pixels relative to the upper left corner of the original image.

```cpp
bool Y_Offset(
    int Y // property value
)
```

**Parameters**

- `Y`
  

**Return Value**

- true - successful, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

**Parameters**

`file_handle`

[in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

true - successful, false - error.
**Load**

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- true - successful, false - error.
**Type**

Returns graphical object type identifier.

```
virtual int Type() const
```

**Return Value**

Object type identifier (OBJ_BITMAP for `CChartObjectBitmap`).
**CChartObjectBmpLabel**

CChartObjectBmpLabel is a class for simplified access to "Bitmap Label" graphical object properties.

**Description**

CChartObjectBmpLabel class provides access to "Bitmap Label" object properties.

**Declaration**

```cpp
class CChartObjectBmpLabel : public CChartObject
```

**Title**

```cpp
#include <ChartObjects\ChartObjectsBmpControls.mqh>
```

**Inheritance hierarchy**

- **CObject**
- **CChartObject**
- **CChartObjectBmpLabel**

See also

Object types, Object properties, Chart angle, Graphic objects
Create

Creates "BmpLabel" graphical object.

```cpp
bool Create(
    long chart_id,  // chart identifier
    string name,    // object name
    int window,     // chart window
    int X,          // X coordinate
    int Y           // Y coordinate
)
```

**Parameters**

- **chart_id**
  - [in] Chart identifier (0 - current chart).

- **name**
  - [in] A unique name of the object to create.

- **window**
  - [in] Chart window number (0 - main window).

- **X**
  - [in] X coordinate.

- **Y**
  - [in] Y coordinate.

**Return Value**

- true - successful, false - error.
X_Distance (Get Method)

Gets the value of “X_Distance” property.

```cpp
int X_Distance() const
```

Return Value

Value of “X_Distance” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for “X_Distance” property.

```cpp
bool X_Distance(
    int X  // property value
)
```

Parameters

X

[in] New value for “X_Distance” property.

Return Value

true - successful, false - cannot change the property.
**Y_Distance (Get Method)**

Gets the value of "Y_Distance" property.

```cpp
int Y_Distance() const
```

**Return Value**

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

**Y_Distance (Set Method)**

Sets new value for "Y_Distance" property.

```cpp
bool Y_Distance(
    int Y // property value
)
```

**Parameters**

- `Y`

  [in] New value for "Y_Distance" property.

**Return Value**

true - successful, false - cannot change the property.
X_Offset (Get Method)

Gets the value of “X_Offset” property (the upper left corner) of the CChartObjectBitmap graphical object.

```cpp
int X_Offset() const
```

Return Value

Value of “X_Offset” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Offset (Set Method)

Sets new value for “X_Offset” property (the upper left corner) of the CChartObjectBitmap graphical object. The value is set in pixels relative to the upper left corner of the original image.

```cpp
bool X_Offset(
    int X // property value
)
```

Parameters

X

Return Value

true - successful, false - cannot change the property.
Y_Offset (Get Method)

Gets the value of “Y_Offset” property (the upper left corner) of the `CCartObjectBmpLabel` graphical object.

```cpp
int Y_Offset() const
```

Return Value

Value of “Y_Offset” property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Offset (Set Method)

Sets new value for “Y_Offset” property (the upper left corner) of the `CCartObjectBmpLabel` graphical object. The value is set in pixels relative to the upper left corner of the original image.

```cpp
bool Y_Offset(
    int Y // property value
)
```

Parameters

Y

Return Value

true - successful, false - cannot change the property.
**Corner (Get Method)**

Gets the value of "Corner" property.

```cpp
ENUM_BASE_CORNER Corner() const
```

**Return Value**

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

**Corner (Set Method)**

Sets new value for "Corner" property.

```cpp
bool Corner(
    ENUM_BASE_CORNER corner // property value
)
```

**Parameters**

- `corner`
  

**Return Value**

- `true` - successful, `false` - cannot change the property.
X_Size

Gets the value of "X_Size" property.

```c
int X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.
**Y_Size**

Gets the value of "Y_Size" property.

```cpp
int Y_Size() const
```

**Return Value**

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.
**BmpFileOn (Get Method)**

Gets the value of "BmpFileOn" property.

```cpp
string BmpFileOn() const
```

**Return Value**

Value of "BmpFileOn" property of the object assigned to the class instance. If there is no object assigned, it returns "".

**BmpFileOn (Set Method)**

Sets new value for "BmpFileOn" property.

```cpp
bool BmpFileOn(
    string name  // file name
)
```

**Parameters**

- **name**
  

**Return Value**

- true - successful, false - cannot change the property.
BmpFileOff (Get Method)

Gets the value of "BmpFileOff" property.

```cpp
string BmpFileOff() const
```

Return Value

Value of "BmpFileOff" property of the object assigned to the class instance. If there is no object assigned, it returns "".

BmpFileOff (Set Method)

Sets new value for "BmpFileOff" property.

```cpp
bool BmpFileOff(  
    string name    // file name
)
```

Parameters

name

Return Value

true - successful, false - cannot change the property.
**State (Get Method)**

Gets the value of “State” property.

```cpp
bool State() const
```

**Return Value**

Value of “State” property of the object assigned to the class instance. If there is no object assigned, it returns false.

**State (Set Method)**

Sets new value for “State” property.

```cpp
bool State(
    bool state  // property value
)
```

**Parameters**

`state`

**Return Value**

true - successful, false - cannot change the property.
Time

Prohibits changes of the time coordinate.

```cpp
bool Time(
    datetime time  // any value
)
```

Parameters

time

Return Value

always false.
# Price

Prohibits changes of the price coordinate.

```cpp
bool Price(
    double price  // any value
)
```

**Parameters**

- **price**
  - [in] Any value of double type.

**Return Value**

- always false.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

**Parameters**

- `file_handle`
  
  [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- `true` - successful, `false` - error.
Load

Load object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

Parameters

- `file_handle`
  - [in] handle of the binary file already opened by `FileOpen` function.

Return Value

- true - successful, false - error.
Type

Returns graphical object type identifier.

virtual int Type() const

Return Value

Object type identifier (OBJ_BITMAP_LABEL for ChartObjectBmpLabel).
CChartObjectRectLabel

CChartObjectRectLabel is a class for simplified access to "Rectangle Label" graphical object properties.

Description

CChartObjectRectLabel class provides access to "Rectangle Label" object properties.

Declaration

```cpp
class CChartObjectRectLabel : public CChartObjectLabel
```

Title

```cpp
#include <ChartObjects\ChartObjectsTxtControls.mgh>
```

Inheritance hierarchy

- CObject
  - CChartObject
    - CChartObjectText
      - CChartObjectLabel
        - CChartObjectRectLabel

Create

Creates the “CChartObjectRectLabel” graphic object.

```cpp
bool Create(
    long chart_id,  // chart ID
    string name,    // object name
    int window,     // chart window
    int X,          // X coordinate
    int Y,          // Y coordinate
    int sizeX,      // horizontal size
    int sizeY       // vertical size
)
```

Parameters

- **chart_id**
  
  [in] Chart identifier (0 - current chart).

- **name**
  
  [in] A unique name of the object to create.

- **window**
  
  [in] Chart window number (0 - main window).

- **X**
  
  [in] X coordinate.

- **Y**
  
  [in] Y coordinate.

- **sizeX**
  
  [in] Horizontal size.

- **sizeY**
  

Return Value

- true - successful, false - error.
X_Size

Sets the value of "X_Size" property.

```cpp
bool X_Size(
    int size   // property value
)
```

**Parameters**

size

[in] New horizontal size property value.

**Return Value**

true - successful, false - cannot change the property.

**Note**

To get the values of "X_Size" and "Y_Size" properties, use the X_Size and Y_Size methods of the parent CChartObjectLabel class.
**Y_Size**

Sets the value of "Y_Size" property.

```cpp
bool Y_Size(
    int size  // property value
)
```

**Parameters**

- **size**
  
  [in] New vertical size property value.

**Return Value**

- true - successful, false - cannot change the property.

**Note**

To get the values of "X_Size" and "Y_Size" properties, use the **X_Size** and **Y_Size** methods of the parent **CChartObjectLabel** class.
**BackColor**

Gets the background color property value.

```cpp
color BackColor() const
```

**Return Value**

Background color property value of the object assigned to the class instance. If there is no object assigned, it returns 0.

**BackColor**

Sets the background color property value.

```cpp
bool BackColor(
    color new_color // property value
)
```

**Parameters**

`new_color`

[in] New background color property value.

**Return Value**

true - successful, false - cannot change the property.
Angle

Prohibits changing the slope angle property.

```cpp
bool Angle(
    double angle  // any value
)
```

Parameters

- `angle`
  

Return Value

Always false.
**BorderType**

**Gets border type property value.**

```cpp
int BorderType() const
```

**Return Value**

Border type property value of the object assigned to the class instance. If there is no object assigned, it returns 0.

**BorderType**

**Sets border type property value.**

```cpp
bool BorderType(
    int type  // property value
)
```

**Parameters**

* type  
  [in] New border type property value.

**Return Value**

true - successful, false - cannot change the property.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle  // file handle
)
```

Parameters

- `file_handle`  
  [in] handle of the binary file already opened by `FileOpen` function.

Return Value

- `true` - successful, `false` - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle       // file handle
)
```

**Parameters**

- `file_handle`
  - [in] handle of the binary file already opened by `FileOpen` function.

**Return Value**

- true - successful, false - error.
## Type

Returns graphical object type identifier.

| virtual int Type() const |

### Return Value

Object type identifier (OBJ_RECTANGLE_LABEL for `CChartObjectRectangleLabel`).
Custom graphics

This section provides tools for working with custom graphics.

Their use greatly facilitates plotting custom charts, drawings and visualization of data.

There are individual classes for creating graphical objects and primitives, for drawing various types of pie charts and curves. Various options for displaying objects are implemented: changing the style and color of lines, filling, working with series of data on the chart, etc.

<table>

**CCanvas**

**Description**

CCanvas is a class for simplified creation of custom images.

CCanvas provides creation of a graphical resource (with or without binding to a chart object) and drawing graphic primitives.

**Declaration**

```cpp
class CCanvas
```

**Title**

```cpp
#include <Canvas\Canvas.mqh>
```

**Inheritance hierarchy**

Attach

Gets the graphical resource from an **OBJ_BITMAP_LABEL** object and attaches it to an instance of the **CCanvas** class.

```cpp
bool Attach(const long chart_id, // chart identifier
            const string objname, // object name
            ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // color processing method
)
```

Creates a graphical **resource** for an **OBJ_BITMAP_LABEL** object and attaches it to an instance of the **CCanvas** class.

```cpp
bool Attach(const long chart_id, // chart identifier
            const string objname, // object name
            const int width, // image width in pixels
            const int height, // image height in pixels
            ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // color processing method
)
```

**Parameters**

- **chart_id**
  
  [out] Chart identifier.

- **objname**
  
  [in] Name of the graphical object.

- **width**
  
  [in] Image width in the resource.

- **height**
  
  [in] Image height in the resource.

- **clrfmt=COLOR_FORMAT_XRGB_NOALPHA**
  
  [in] Alpha channel processing method. The alpha channel is ignored by default.

**Return Value**

- true - if successful, false - if failed to attach the object.
Arc

Draws an arc of an ellipse inscribed in a rectangle with corners at \((x_1,y_1)\) and \((x_2,y_2)\). The arc boundaries are clipped by lines from the center of the ellipse, which extend to two points with coordinates \((x_3,y_3)\) and \((x_4,y_4)\).

```c
void Arc(
    int x1, // X coordinate of the upper left corner of the rectangle
    int y1, // Y coordinate of the upper left corner of the rectangle
    int x2, // X coordinate of the bottom right corner of the rectangle
    int y2, // Y coordinate of the bottom right corner of the rectangle
    int x3, // X coordinate of the first point to find the arc boundaries
    int y3, // Y coordinate of the first point to find the arc boundaries
    int x4, // X coordinate of the second point to find the arc boundaries
    int y4, // Y coordinate of the second point to find the arc boundaries
    const uint clr // color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the top left corner forming the rectangle.

- **y1**
  - [in] Y coordinate of the top left corner forming the rectangle.

- **x2**
  - [in] X coordinate of the bottom right corner forming the rectangle.

- **y2**
  - [in] Y coordinate of the bottom right corner forming the rectangle.

- **x3**
  - [in] X coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

- **y3**
  - [in] Y coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

- **x4**
  - [in] X coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

- **y4**
  - [in] Y coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

- **clr**
  - [in] Color in ARGB format. Use the `ColorToARGB()` function to convert a color into the ARGB format.
Draws an arc of an ellipse with center at point \((x,y)\), inscribed in rectangle, with radii \(rx\) and \(ry\). The arc boundaries are cropped from the ellipse center using rays formed by angles \(fi3\) and \(fi4\).

```c
void Arc(
    int x,        // X coordinate of the ellipse center
    int y,        // Y coordinate of the ellipse center
    int rx,       // ellipse radius on the X axis
    int ry,       // ellipse radius on the Y axis
    int fi3,      // angle of ray from ellipse center, which defines the first boundary
    int fi4,      // angle of ray from ellipse center, which defines the second boundary
    const uint clr   // color
);
```

Draws an arc of an ellipse with center at point \((x,y)\), inscribed in rectangle, with radii \(rx\) and \(ry\), and also returns the coordinates of the arc boundaries. The arc boundaries are cropped from the ellipse center using rays formed by angles \(fi3\) and \(fi4\).

```c
void Arc(
    int x,        // X coordinate of the ellipse center
    int y,        // Y coordinate of the ellipse center
    int rx,       // ellipse radius on the X axis
    int ry,       // ellipse radius on the Y axis
    int fi3,      // angle of ray from ellipse center, which defines the first boundary
    int fi4,      // angle of ray from ellipse center, which defines the second boundary
    int&t x3,     // X coordinate of the first arc boundary
    int&t y3,     // Y coordinate of the first arc boundary
    int&t x4,     // X coordinate of the second arc boundary
    int&t y4,     // Y coordinate of the second arc boundary
    const uint clr   // color
);
```

**Parameters**

\(x\)
- [in] X coordinate of the ellipse center.

\(y\)
- [in] Y coordinate of the ellipse center.

\(rx\)
- [in] Ellipse radius on the X axis, in pixels.

\(ry\)
- [in] Ellipse radius on the Y axis, in pixels.

\(fi3\)
- [in] Angle in radians, which defines the first boundary of the arc.

\(fi4\)
[in] Angle in radians, which defines the second boundary of the arc.

x3
[out] Variable to get the X coordinate of the first arc boundary.

y3
[out] Variable to get the Y coordinate of the first arc boundary.

x4
[out] Variable to get the X coordinate of the second arc boundary.

y4
[out] Variable to get the Y coordinate of the second arc boundary.

clr
[in] Color in ARGB format. Use the ColorToARGB() function to convert a color into the ARGB format.

Examples of calling the class methods:

```c
define Canvas <Canvas\Canvas.mgh>
CCanvas canvas;
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
{
  int Width=600;
  int Height=400;
  //--- create canvas
  if(!canvas.CreateBitmapLabel(0,0,"CirclesCanvas",30,30,Width,Height))
    { Print("Error creating canvas: ",GetLastError()); }
  //--- clear canvas
  canvas.Erase(clrWhite);
  //--- draw rectangle
  canvas.Rectangle(215-190,215-120,215+190,215+120,clrGray);
  //--- draw first arc
  canvas.Arc(215,215, 190,120,M_PI_4,2*M_PI-M_PI_4,ColorToARGB(clrRed));
  int x1,y1,x2,y2;
  //--- draw second arc
  canvas.Arc(215,215, 190,120,2*M_PI-M_PI_4,2*M_PI+M_PI_4,x1,y1,x2,y2,ColorToARGB(clrBlue));
  //--- print coordinates of arc
  PrintFormat("First point of arc at (%G,%G), second point of arc at (%G,%G)",x1,y1,
                canvas.CircleAA(x1,y1,3, ColorToARGB(clrRed));
                canvas.CircleAA(x2,y2,3, ColorToARGB(clrBlue));
  //--- show updated canvas
  canvas.Update();
}
```
Pie

Draws a filled sector of an ellipse inscribed in a rectangle with corners at \((x_1,y_1)\) and \((x_2,y_2)\). The sector boundaries are clipped by lines from the center of the ellipse, which extend to two points with coordinates \((x_3,y_3)\) and \((x_4,y_4)\).

```cpp
void Pie(
    int x1, // X coordinate of the upper left corner of the rectangle
    int y1, // Y coordinate of the upper left corner of the rectangle
    int x2, // X coordinate of the bottom right corner of the rectangle
    int y2, // Y coordinate of the bottom right corner of the rectangle
    int x3, // X coordinate of the first point to find the arc boundaries
    int y3, // Y coordinate of the first point to find the arc boundaries
    int x4, // X coordinate of the second point to find the arc boundaries
    int y4, // Y coordinate of the second point to find the arc boundaries
    const uint clr, // line color
    const uint fill_clr // fill color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the top left corner forming the rectangle.
- **y1**
  - [in] Y coordinate of the top left corner forming the rectangle.
- **x2**
  - [in] X coordinate of the bottom right corner forming the rectangle.
- **y2**
  - [in] Y coordinate of the bottom right corner forming the rectangle.
- **x3**
  - [in] X coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.
- **y3**
  - [in] Y coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.
- **x4**
  - [in] X coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.
- **y4**
  - [in] Y coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.
- **clr**
  - [in] Border color of the sector in the ARGB format.
- **fill_clr**
  - [in] Fill color of the sector.
[in] Fill color of the sector in the ARGB format. Use the `ColorToARGB()` function to convert a color into the ARGB format.

Draws a filled sector of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry. The sector boundaries are cropped from the ellipse center by rays formed by angles fi3 and fi4.

```c
void Pie(
    int x,           // X coordinate of the ellipse center
    int y,           // Y coordinate of the ellipse center
    int rx,          // ellipse radius on the X axis
    int ry,          // ellipse radius on the Y axis
    int fi3,         // angle of ray from ellipse center, which defines the first boundary of the arc
    int fi4,         // angle of ray from ellipse center, which defines the second boundary of the arc
    const uint clr,  // line color
    const uint fill_clr // fill color
);```

Draws a filled sector of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry, and also returns the coordinates of the arc boundaries. The sector boundaries are cropped from the ellipse center by rays formed by angles fi3 and fi4.

```c
void Pie(
    int x,           // X coordinate of the ellipse center
    int y,           // Y coordinate of the ellipse center
    int rx,          // ellipse radius on the X axis
    int ry,          // ellipse radius on the Y axis
    int fi3,         // angle of ray from ellipse center, which defines the first boundary of the arc
    int fi4,         // angle of ray from ellipse center, which defines the second boundary of the arc
    int& x3,         // X coordinate of the first arc boundary
    int& y3,         // Y coordinate of the first arc boundary
    int& x4,         // X coordinate of the second arc boundary
    int& y4,         // Y coordinate of the second arc boundary
    const uint clr,  // line color
    const uint fill_clr // fill color
);```

**Parameters**

- x
  - [in] X coordinate of the ellipse center.
- y
  - [in] Y coordinate of the ellipse center.
- rx
  - [in] Ellipse radius on the X axis, in pixels.
- ry
  - [in] Ellipse radius on the X axis, in pixels.
fi3
[in] Angle in radians, which defines the first boundary of the arc.

fi4
[in] Angle in radians, which defines the second boundary of the arc.

x3
[out] Variable to get the X coordinate of the first arc boundary.

y3
[out] Variable to get the Y coordinate of the first arc boundary.

x4
[out] Variable to get the X coordinate of the second arc boundary.

y4
[out] Variable to get the Y coordinate of the second arc boundary.

clr
[in] Border color of the sector in the ARGB format.

fill clr
[in] Fill color of the sector in the ARGB format. Use the ColorToARGB() function to convert a color into the ARGB format.

Examples of calling the class methods:

```csharp
#include <Canvas\Canvas.mqh>
CCanvas canvas;

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
{
    int Width=600;
    int Height=400;
    //--- create canvas
    if(!canvas.CreateBitmapLabel(0,0,"CirclesCanvas",30,30,Width,Height))
    {
        Print("Error creating canvas: ",GetLastError());
    }
    //--- clear canvas
    canvas.Erase(clrWhite);
    //--- draw rectangle
    canvas.Rectangle(215-190,215-120,215+190,215+120,clrGray);
    //--- draw first pie
    canvas.Pie(215,215, 190,120,M_PI_4,2*M_PI-M_PI_4,ColorToARGB(clrBlue),ColorToARGB(clrRed));
    //--- draw second pie
    canvas.Pie(215,215, 190,120,2*M_PI-M_PI_4,2*M_PI+M_PI_4,ColorToARGB(clrGreen),ColorToARGB(clrGreen));
    //--- show updated canvas
    canvas.Update();
```
```cpp
    DebugBreak();
    }
```
**FillPolygon**

Draws a filled polygon.

```cpp
void FillPolygon(
    int& x,       // array with the X coordinates of polygon points
    int& y,       // array with the Y coordinates of polygon points
    const uint clr // color
);
```

**Parameters**

- `x`
  [in] Array of the X coordinates of the polygon points.

- `y`
  [in] Array of the Y coordinates of the polygon points.

- `clr`
  [in] Color in ARGB format.
**FillEllipse**

Draws a filled ellipse inscribed in a rectangle with the specified coordinates.

```cpp
void FillPolygon(
    int x1, // X coordinate of the upper left corner of the rectangle
    int y1, // Y coordinate of the upper left corner of the rectangle
    int x2, // X coordinate of the bottom right corner of the rectangle
    int y2, // Y coordinate of the bottom right corner of the rectangle
    const uint clr // ellipse color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the top left corner forming the rectangle.

- **y1**
  - [in] Y coordinate of the top left corner forming the rectangle.

- **x2**
  - [in] X coordinate of the bottom right corner forming the rectangle.

- **y2**
  - [in] Y coordinate of the bottom right corner forming the rectangle.

- **clr**
  - [in] Color in ARGB format.
GetDefaultColor

Returns a predefined color by its index.

```c
static uint GetDefaultColor(
    const uint i  // index
);
```

Parameters

- **i**
  
  [in] Index to get the color.

Return Value

- Color.
ChartObjectName

Receives the name of a bound chart object.

```csharp
string ChartObjectName();
```

Return Value

the name of a bound chart object
Circle

Draws a circle

```c
void Circle(
    int x,  // X coordinate
    int y,  // Y coordinate
    int r,  // radius
    const uint clr // color
);
```

Parameters

- **x**
  - [in] X coordinate of the center of the circle.

- **y**
  - [in] Y coordinate of the center of the circle.

- **r**
  - [in] Circle radius.

- **clr**
  - [in] Color in ARGB format.
CircleAA

Draws a circle using antialiasing algorithm

```cpp
void CircleAA(
    const int  x,  // X coordinate
    const int  y,  // Y coordinate
    const double r,  // radius
    const uint clr  // color
);
```

**Parameters**

- **x**
  - [in] X coordinate of the center of the circle.

- **y**
  - [in] Y coordinate of the center of the circle.

- **r**
  - [in] Circle radius.

- **clr**
  - [in] Color in ARGB format.
CircleWu

Draws a circle using Wu's anti-aliasing algorithm

```c
void CircleWu(
    const int x,  // X coordinate
    const int y,  // Y coordinate
    const double r,  // radius
    const uint clr  // color
);
```

**Parameters**

- `x`  
  
  [in] X coordinate of the center of the circle.

- `y`  
  
  [in] Y coordinate of the center of the circle.

- `r`  
  
  [in] Circle radius.

- `clr`  
  
  [in] Color in ARGB format.
Creates a graphical resource without binding to a chart object.

```cpp
virtual bool Create(
    const string name, // name
    const int width,   // width
    const int height,  // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

**Parameters**

- **name**
  - [in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

- **width**
  - [in] Width (size along X axis) in pixels.

- **height**
  - [in] Height (size along Y axis) in pixels.

- **clrfmt=COLOR_FORMAT_XRGB_NOALPHA**
  - [in] Color processing method. See ResourceCreate() function description to learn more about color processing methods.

**Return Value**

- **true** - successful, otherwise **false**
CreateBitmap

Creates a graphical resource bound to a chart object.

1. Creates a graphical resource in the main window of the current chart.

```cpp
bool CreateBitmap(
    const string name,       // name
    const datetime time,     // time
    const double price,      // price
    const int width,         // width
    const int height,        // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

2. Creates a graphical resource using a chart ID and a subwindow number.

```cpp
bool CreateBitmap(
    const long chart_id,     // chart ID
    const int subwin,        // subwindow number
    const string name,       // name
    const datetime time,     // time
    const double price,      // price
    const int width,         // width
    const int height,        // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

**Parameters**

- **chart_id**
  - [in] Chart ID for creating an object.

- **subwin**
  - [in] Chart subwindow number for creating an object.

- **name**
  - [in] Chart object name and a basis for a graphical resource name.

- **time**
  - [in] Chart object anchor point time coordinate.

- **price**
  - [in] Chart object anchor point price coordinate.

- **width**
  - [in] Graphical resource width (size along X axis) in pixels.

- **height**
  - [in] Graphical resource height (size along Y axis) in pixels.

- **clrfmt=COLOR_FORMAT_XRGB_NOALPHA**
[in] Color processing method. See ResourceCreate() function description to learn more about color processing methods.

Return Value
true - successful, otherwise - false

Note
If the first function version is used, the object is created in the main window of the current chart. Object size coincides with the size of a graphical resource.
CreateBitmapLabel

Creates a graphical resource bound to a chart object.

1. Creates a graphical resource in the main window of the current chart.

```cpp
bool CreateBitmapLabel(
    const string name, // name
    const int x,        // X coordinate
    const int y,        // Y coordinate
    const int width,    // width
    const int height,   // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

2. Creates a graphical resource using a chart ID and a subwindow number.

```cpp
bool CreateBitmapLabel(
    const long chart_id, // chart ID
    const int subwin,     // subwindow number
    const string name,    // name
    const int x,          // X coordinate
    const int y,          // Y coordinate
    const int width,      // width
    const int height,     // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

**Parameters**

- **chart_id**
  - [in] Chart ID for creating an object.

- **subwin**
  - [in] Chart subwindow number for creating an object.

- **name**
  - [in] Chart object name and a basis for a graphical resource name.

- **x**
  - [in] Chart object anchor point X coordinate.

- **y**
  - [in] Chart object anchor point Y coordinate.

- **width**
  - [in] Graphical resource width (size along X axis) in pixels.

- **height**
  - [in] Graphical resource height (size along Y axis) in pixels.

- **clrfmt=COLOR_FORMAT_XRGB_NOALPHA**
[in] Color processing method. See ResourceCreate() function description to learn more about color processing methods.

**Return Value**

true - successful, otherwise - false

**Note**

If the first function version is used, the object is created in the main window of the current chart. Object size coincides with the size of a graphical resource.
Destroy

Destroys a graphical resource.

```cpp
void Destroy();
```

Note

If a graphical resource has been bound to a chart object, the latter is deleted.
**Ellipse**

Draws an ellipse using two points.

```cpp
void Ellipse(
    int x1,  // X coordinate
    int y1,  // Y coordinate
    int x2,  // X coordinate
    int y2,  // Y coordinate
    const uint clr  // color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the first point forming an ellipse.
- **y1**
  - [in] Y coordinate of the first point forming an ellipse.
- **x2**
  - [in] X coordinate of the second point forming an ellipse.
- **y2**
  - [in] Y coordinate of the second point forming an ellipse.
- **clr**
  - [in] Color in ARGB format.
EllipseAA

Draws an ellipse based on two points using anti-aliasing algorithm.

```c
void EllipseAA(
    int x1, // X coordinate
    int y1, // Y coordinate
    int x2, // X coordinate
    int y2, // Y coordinate
    const uint clr // color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the first point forming an ellipse.

- **y1**
  - [in] Y coordinate of the first point forming an ellipse.

- **x2**
  - [in] X coordinate of the second point forming an ellipse.

- **y2**
  - [in] Y coordinate of the second point forming an ellipse.

- **clr**
  - [in] Color in ARGB format.
**EllipseWu**

Draws an ellipse based on two points using Wu's anti-aliasing algorithm.

```c
void EllipseWu(
    int x1,     // X coordinate
    int y1,     // Y coordinate
    int x2,     // X coordinate
    int y2,     // Y coordinate
    const uint clr     // color
);
```

**Parameters**

- `x1`  
  [in] X coordinate of the first point forming an ellipse.

- `y1`  
  [in] Y coordinate of the first point forming an ellipse.

- `x2`  
  [in] X coordinate of the second point forming an ellipse.

- `y2`  
  [in] Y coordinate of the second point forming an ellipse.

- `clr`  
  [in] Color in ARGB format.
Erase

Erases or fills with the specified color.

```cpp
void Erase(
    const uint clr=0    // color
);
```

Parameters

clr=0

[in] Color in ARGB format.
Fill

Fills an area.

```cpp
void Fill(
    int x, // X coordinate
    int y, // Y coordinate
    const uint clr // color
);
```

**Parameters**

- `x` [in] X coordinate of filling starting point.
- `y` [in] Y coordinate of filling starting point.
- `clr` [in] Color in ARGB format.
**FillCircle**

Draws a filled circle.

```cpp
void FillCircle(
    int x, // X coordinate
    int y, // Y coordinate
    int r, // radius
    const uint clr // color
);
```

**Parameters**

- `x`
  
  [in] X coordinate of a filled circle center.

- `y`
  
  [in] Y coordinate of a filled circle center.

- `r`
  
  [in] Filled circle radius.

- `clr`
  
  [in] Color in ARGB format.
**FillRectangle**

Draws a filled rectangle.

```cpp
void FillRectangle(
    int x1,  // X coordinate
    int y1,  // Y coordinate
    int x2,  // X coordinate
    int y2,  // Y coordinate
    const uint clr // color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the first point forming a rectangle.

- **y1**
  - [in] Y coordinate of the first point forming a rectangle.

- **x2**
  - [in] X coordinate of the second point forming a rectangle.

- **y2**
  - [in] Y coordinate of the second point forming a rectangle.

- **clr**
  - [in] Color in ARGB format.
**FillTriangle**

Draws a filled triangle.

```c
void FillTriangle(
    int x1,       // X coordinate
    int y1,       // Y coordinate
    int x2,       // X coordinate
    int y2,       // Y coordinate
    int x3,       // X coordinate
    int y3,       // Y coordinate
    const uint clr // color
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the triangle's first corner.
- **y1**
  - [in] Y coordinate of the triangle's first corner.
- **x2**
  - [in] X coordinate of the triangle's second corner.
- **y2**
  - [in] Y coordinate of the triangle's second corner.
- **x3**
  - [in] X coordinate of the triangle's third corner.
- **y3**
  - [in] Y coordinate of the triangle's third corner.
- **clr**
  - [in] Color in ARGB format.
FontAngleGet

Receives font slope angle.

```c
uint FontAngleGet();
```

Return Value

font slope angle
FontAngleSet

Sets font slope angle.

```cpp
bool FontAngleSet(
    uint angle // angle
);
```

Parameters

`angle`

Return Value

true - successful, otherwise - false
FontFlagsGet

Receives font flags.

```c
uint FontFlagsGet();
```

Return Value

font flags
**FontFlagsSet**

Sets font flags.

```c
bool FontFlagsSet(
    uint flags // flags
);
```

**Parameters**

*flags*

[in] Font creation flags. See TextSetFont() function description to learn more about the flags.

**Return Value**

true - successful, otherwise - false
FontGet

Receives the current font parameters.

```c
void FontGet(
    string& name,  // name
    int& size,    // size
    uint& flags,  // flags
    uint& angle   // slope angle
);
```

Parameters

name
- [out] Reference to the variable for returning a font name.

size
- [out] Reference to the variable for returning a font size.

flags
- [out] Reference to the variable for returning font flags.

angle
- [out] Reference to the variable for returning a font slope angle.
FontNameGet

Receives font name.

```cpp
string FontNameGet();
```

Return Value

`font name`
**FontNameSet**

Sets font name.

```csharp
bool FontNameSet(
    string name  // name
);
```

**Parameters**

- **name**
  - [in] Font name. For example, "Arial".

**Return Value**

- `true` - successful, otherwise `false`
FontSet

Sets the current font.

```cpp
bool FontSet(
    const string name, // name
    const int size,    // size
    const uint flags=0, // flags
    const uint angle=0 // angle
);
```

Parameters

name

[in] Font name. For example, "Arial".

size

[in] Font size. See TextSetFont() function description to learn more about setting a size.

flags=0

[in] Font creation flags. See TextSetFont() function description to learn more about the flags.

angle=0

Return Value

true - successful, otherwise - false
FontSizeGet

Receives font size.

```c
int FontSizeGet();
```

Return Value

font size
FontSizeSet

Sets font size.

```cpp
bool FontSizeSet(
    int size // size
);
```

Parameters

size

[in] Font size. See TextSetFont() function description to learn more about setting a size.

Return Value

true - successful, otherwise - false
Height

Receives the height of a graphical resource.

```cpp
int Height();
```

Return Value

height of a graphical resource
Line

Draws a segment of a freehand line.

```c
void Line(
    int x1,     // X coordinate
    int y1,     // Y coordinate
    int x2,     // X coordinate
    int y2,     // Y coordinate
    const uint clr // color
);
```

Parameters

**x1**
- [in] X coordinate of the segment's first point.

**y1**
- [in] Y coordinate of the segment's first point.

**x2**
- [in] X coordinate of the segment's second point.

**y2**
- [in] Y coordinate of the segment's second point.

**clr**
- [in] Color in ARGB format.
LineAA

Draws a segment of a freehand line using antialiasing algorithm.

```c
void LineAA(
    const int x1, // X coordinate
    const int y1, // Y coordinate
    const int x2, // X coordinate
    const int y2, // Y coordinate
    const uint clr, // color
    const uint style=UINT_MAX // line style
);
```

**Parameters**

- **x1**
  - [in] X coordinate of the segment's first point.

- **y1**
  - [in] Y coordinate of the segment's first point.

- **x2**
  - [in] X coordinate of the segment's second point.

- **y2**
  - [in] Y coordinate of the segment's second point.

- **clr**
  - [in] Color in ARGB format.

- **style=UINT_MAX**
  - [in] Line style is one of `ENUM_LINE_STYLE` enumeration's values or a custom value.
LineWu

Draws a segment of a freehand line using Wu's anti-aliasing algorithm.

```c
void LineWu(
    const int x1,       // X coordinate
    const int y1,       // Y coordinate
    const int x2,       // X coordinate
    const int y2,       // Y coordinate
    const uint clr,     // color
    const uint style=UINT_MAX // line style
);
```

Parameters

- **x1**
  - [in] X coordinate of the segment's first point.

- **y1**
  - [in] Y coordinate of the segment's first point.

- **x2**
  - [in] X coordinate of the segment's second point.

- **y2**
  - [in] Y coordinate of the segment's second point.

- **clr**
  - [in] Color in ARGB format.

- **style=UINT_MAX**
  - [in] Line style is one of `ENUM_LINE_STYLE` enumeration's values or a custom value.
**LineHorizontal**

Draws a segment of a horizontal line.

```cpp
void LineHorizontal(
    int x1, // X coordinate
    int x2, // X coordinate
    int y,  // Y coordinate
    const uint clr // color
);
```

**Parameters**

- **x1**
  
  [in] X coordinate of the segment's first point.

- **x2**
  
  [in] X coordinate of the segment's second point.

- **y**
  
  [in] Segment's Y coordinate.

- **clr**
  
  [in] Color in ARGB format.
LineVertical

Draws a segment of a vertical line.

```c
void LineVertical(
    int x,          // X coordinate
    int y1,         // Y coordinate
    int y2,         // Y coordinate
    const uint clr  // color
);
```

Parameters

`x`

[in] Segment's X coordinate.

`y1`

[in] Y coordinate of the segment's first point.

`y2`

[in] Y coordinate of the segment's second point.

`clr`

[in] Color in ARGB format.
LineStyleSet

Sets the line style.

```cpp
void LineStyleSet(
    const uint style  // style
);
```

Parameters

- `style`
  - [in] Line style.

Note

The input parameter can have any of `ENUM_LINE_STYLE` enumeration values. Besides, it is possible to create a custom line drawing style.
**LineThick**

Draws a segment of a freehand line having a specified width using antialiasing algorithm.

```cpp
void LineThick(
    const int x1,       // X coordinate of the segment's first point
    const int y1,       // Y coordinate of the segment's first point
    const int x2,       // X coordinate of the segment's second point
    const int y2,       // Y coordinate of the segment's second point
    const uint clr,     // color
    const int size,     // line width
    const uint style,   // line style
    ENUM_LINE_END end_style  // line ends style
)
```

### Parameters

**x1**

- [in] X coordinate of the segment's first point.

**y1**

- [in] Y coordinate of the segment's first point.

**x2**

- [in] X coordinate of the segment's second point.

**y2**

- [in] Y coordinate of the segment's second point.

**clr**

- [in] Color in ARGB format.

**size**

- [in] Line width.

**style**

- [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

**end_style**

- [in] Line style is one of the ENUM_LINE_END enumeration's values

<table>
<thead>
<tr>
<th>ENUM_LINE_END</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINE_END_ROUND</td>
<td>Line ends are rounded.</td>
</tr>
<tr>
<td>LINE_END_BUTT</td>
<td>Line ends are cut.</td>
</tr>
<tr>
<td>LINE_END_SQUARE</td>
<td>A line ends in a filled rectangle.</td>
</tr>
</tbody>
</table>
LineThickVertical

 Draws a vertical segment of a freehand line having a specified width using antialiasing algorithm.

```cpp
void LineThickVertical(
    const int x,         // X coordinate of the segment
    const int y1,        // Y coordinate of the segment's first point
    const int y2,        // Y coordinate of the segment's second point
    const uint clr,      // color
    const int size,      // line width
    const uint style,    // line style
    ENUM_LINE_END end_style  // line ends style
)
```

**Parameters**

- `x`  
  [in] Segment's X coordinate.

- `y1`  
  [in] Y coordinate of the segment's first point.

- `y2`  
  [in] Y coordinate of the segment's second point.

- `clr`  
  [in] Color in ARGB format.

- `size`  
  [in] Line width.

- `style`  
  [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

- `end_style`  
  [in] Line style is one of the ENUM_LINE_END enumeration's values.
LineThickHorizontal

Draws a horizontal segment of a freehand line having a specified width antialiasing.

```c
void LineThickHorizontal(
    const int x1,       // X coordinate of the segment's first point
    const int x2,       // X coordinate of the segment's second point
    const int y,        // Y coordinate of the segment
    const uint clr,     // color
    const int size,     // line width
    const uint style,   // line style
    ENUM_LINE_END end_style  // line ends style
)
```

**Parameters**

- **x1**
  - [in] X coordinate of the segment's first point.

- **x2**
  - [in] X coordinate of the segment's second point.

- **y**
  - [in] Segment's Y coordinate.

- **clr**
  - [in] Color in ARGB format.

- **size**
  - [in] Line width.

- **style**
  - [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

- **end_style**
  - [in] Line style is one of the ENUM_LINE_END enumeration's values.
LoadFromFile

Reads an image from a BMP file.

```cpp
bool LoadFromFile(
    const string filename  // file name
);
```

**Parameters**

- `filename`  
  [in] File name (including "BMP" extension).

**Return Value**

- `true` - successful, otherwise - `false`
**PixelGet**

Receives color of the point with the specified coordinates.

```c
uint PixelGet(const int x, const int y);
```

**Parameters**

- `x`
  - [in] Point's X coordinate.
- `y`
  - [in] Point's Y coordinate.

**Return Value**

Point color in ARGB format.
**PixelSet**

Sets color of the point with the specified coordinates.

```cpp
void PixelSet(
    const int x,       // X coordinate
    const int y,       // Y coordinate
    const uint clr     // color
);
```

**Parameters**

- `x`  
  [in] Point's X coordinate.

- `y`  
  [in] Point's Y coordinate.

- `clr`  
  [in] Color in ARGB format.
PixelSetAA

Draws a point using antialiasing algorithm.

```c
void PixelSetAA(
    const double x,       // X coordinate
    const double y,       // Y coordinate
    const uint clr        // color
);
```

Parameters

- **x**
  - [in] Point's X coordinate.

- **y**
  - [in] Point's Y coordinate.

- **clr**
  - [in] Color in ARGB format.
Polygon

Draws a polygon.

```cpp
void Polygon(
    int& x[],   // array of X coordinates
    int& y[],   // array of Y coordinates
    const uint clr  // color
);
```

Parameters

- **x[]**
  - [in] Array of X coordinates of a polygon points.

- **y[]**

- **clr**
  - [in] Color in ARGB format.
PolygonAA

Draws a polygon using antialiasing algorithm.

```cpp
void PolygonAA(
    int& x[], // array of X coordinates
    int& y[], // array of Y coordinates
    const uint clr, // color
    const uint style=UINT_MAX // line style
);
```

Parameters

x

[in] Array of X coordinates of a polygon points.

y

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of ENUM_LINESTYLE enumeration's values or a custom value.
PolygonWu

Draws a polygon using Wu's anti-aliasing algorithm.

```cpp
void PolygonWu(
    int& x[], // array of X coordinates
    int& y[], // array of Y coordinates
    const uint clr, // color
    const uint style=UINT_MAX // line style
);
```

**Parameters**

- `x[]`  
  [in] Array of X coordinates of a polygon points.

- `y[]`  

- `clr`  
  [in] Color in ARGB format.

- `style=UINT_MAX`  
  [in] Line style is one of `ENUM_LINE_STYLE` enumeration's values or a custom value.
PolygonThick

Draws a polygon with a specified width using antialiasing algorithm.

```c
void PolygonThick(
    const int& x[],       // array with the X coordinates of polygon points
    const int& y[],       // array with the Y coordinates of polygon points
    const uint clr,       // color
    const int size,       // line width
    const uint style,     // line style
    ENUM_LINE_END end_style   // line ends style
)
```

Parameters

- **x[]**
  - [in] Array of X coordinates of polygon points.

- **y[]**
  - [in] Array of Y coordinates of polygon points.

- **clr**
  - [in] Color in ARGB format.

- **size**
  - [in] Line width.

- **style**
  - [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

- **end_style**
  - [in] Line style is one of the ENUM_LINE_END enumeration's values.
PolygonSmooth

Draws a polygon with a specified width consecutively using two antialiasing algorithms. First, individual segments are smoothed based on Bezier curves. Then, the raster antialiasing algorithm is applied to the polygon built from these segments to improve the rendering quality.

```c
void PolygonSmooth(
    int& x[], // array with the X coordinates of polygon points
    int& y[], // array with the Y coordinates of polygon points
    const uint clr, // color
    const int size, // line width
    const ENUM_LINE_STYLE style=STYLE_SOLID, // line style
    const ENUM_LINE_END end_style=LINE_END_ROUND, // line ends style
    const double tension=0.5, // antialiasing parameter value
    const double step=10 // length of approximation lines
);
```

**Parameters**

&*x[]*

[in] Array of X coordinates of polygon points.

&*y[]*

*clr*

[in] Color in ARGB format.

*size*

[in] Line width.

*style=STYLE_SOLID*

[in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

*end_style=LINE_END_ROUND*

[in] Line style is one of the ENUM_LINE_END enumeration's values.

*tension=0.5*

[in] Smoothing parameter value.

*step=10*

[in] Length of approximating lines.
Polyline

Draws a polyline.

```cpp
void Polyline(
    int& x[], // array of X coordinates
    int& y[], // array of Y coordinates
    const uint clr // color
);
```

Parameters

- **x[]**

- **y[]**

- **clr**
  - [in] Color in ARGB format.
PolylineSmooth

Draws a polyline with a specified width consecutively using two antialiasing algorithms. First, individual line segments are smoothed based on Bezier curves. Then, the raster antialiasing algorithm is applied to the polyline built from these segments to improve the rendering quality.

```c
void PolylineSmooth(
    const int& x[], // array with the X coordinates of polyline
    const int& y[], // array with the Y coordinates of polyline
    const uint clr,  // color
    const int size, // line width
    ENUM_LINE_STYLE style=STYLE_SOLID, // line style
    ENUM_LINE_END end_style=LINE_END_ROUND, // line ends style
    double tension=0.5, // antialiasing parameter value
    double step=10     // approximation step
)
```

**Parameters**

- `&x[]`

- `&y[]`

- `clr`
  - [in] Color in ARGB format.

- `size`
  - [in] Line width.

- `style=STYLE_SOLID`
  - [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

- `end_style=LINE_END_ROUND`
  - [in] Line style is one of the ENUM_LINE_END enumeration's values.

- `tension=0.5`
  - [in] Smoothing parameter value.

- `step=10`
PolylineThick

Draws a polyline with a specified width using antialiasing algorithm.

```c
void PolylineThick(
    const int &x[], // array with the X coordinates of polyline points
    const int &y[], // array with the Y coordinates of polyline points
    const uint clr, // color
    const int size, // line width
    const uint style, // line style
    ENUM_LINE_END end_style // line ends style
)
```

Parameters

- `&x[]`
  

- `&y[]`
  

- `clr`
  
  [in] Color in ARGB format.

- `size`
  
  [in] Line width.

- `style`
  
  [in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

- `end_style`
  
  [in] Line style is one of the ENUM_LINE_END enumeration's values
PolylineWu

Draws a polyline using Wu's anti-aliasing algorithm.

```c
void PolylineWu(
    int& x[],                    // array of X coordinates
    int& y[],                    // array of Y coordinates
    const uint clr,              // color
    const uint style=UINT_MAX    // line style
);
```

Parameters

- `clr` [in] Color in ARGB format.
- `style=UINT_MAX` [in] Line style is one of `ENUM_LINE_STYLE` enumeration's values or a custom value.
PolylineAA

Draws a polyline using antialiasing algorithm.

```c
void PolylineAA(
    int& x[],          // array of X coordinates
    int& y[],          // array of Y coordinates
    const uint clr,    // color
    const uint style=UINT_MAX   // line style
);
```

**Parameters**

- `x[]`  

- `y[]`  

- `clr`  
  - [in] Color in ARGB format.

- `style=UINT_MAX`  
  - [in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.
Rectangle

Draws a rectangle using two points.

```c
void Rectangle(
    int x1, // X coordinate
    int y1, // Y coordinate
    int x2, // X coordinate
    int y2, // Y coordinate
    const uint clr // color
);
```

Parameters

- `x1`
  - [in] X coordinate of the first point forming a rectangle.
- `y1`
  - [in] Y coordinate of the first point forming a rectangle.
- `x2`
  - [in] X coordinate of the second point forming a rectangle.
- `y2`
  - [in] Y coordinate of the second point forming a rectangle.
- `clr`
  - [in] Color in ARGB format.
**Resize**

Resizes a graphical resource.

```cpp
bool Resize(const int width, // width
const int height // height
);
```

**Parameters**

- **width**
  - [in] New width of a graphical resource.

- **height**

**Return Value**

- `true` - successful, otherwise - `false`

**Note**

- When resizing, the previous image is not saved.
ResourceName

Receives the name of a graphical resource.

```cpp
string ResourceName();
```

Return Value

name of a graphical resource
TextHeight

Receives the text height.

```cpp
int TextHeight(
    const string text // text
);
```

Parameters

text

Return Value

text height in pixels

Note

The current font is used for measuring the text.
TextOut

Displays text.

```c
void TextOut(
    int x,       // X coordinate
    int y,       // Y coordinate
    string text, // text
    const uint clr,  // color
    uint alignment=0 // alignment
);
```

Parameters

- `x`  

- `y`  

- `text`  
  [in]  Text to be displayed.

- `clr`  
  [in]  Color in ARGB format.

- `alignment=0`  
  [in]  Text anchoring method. See TextOut() function description to learn more about anchoring methods.

Note

The current font is used to display the text.
TextSize

Receives the text size.

```cpp
void TextSize(
    const string text,  // text
    int& width,         // width
    int& height         // height
);
```

**Parameters**

- `text`  

- `width`  
  [out] Reference to the variable for returning a text width.

- `height`  
  [out] Reference to the variable for returning a text height.

**Note**

The current font is used to measure the text.
**TextWidth**

Receives the text width.

```cpp
int TextWidth(const string text);  // text
```

**Parameters**

- `text`

**Return Value**

- text height in pixels

**Note**

- The current font is used to measure the text.
TransparentLevelSet

Sets transparency level.

```c
void TransparentLevelSet(
    const uchar value   // value
);
```

**Parameters**

`value`

[in] New value of the transparency level.

**Note**

0 stands for full transparency, while 255 - for full opacity.

Setting a transparency level affects all that was previously drawn. The specified transparency level does not affect further constructions.
**Triangle**

Draws a triangle.

```c
void Triangle(
    int x1,  // X coordinate
    int y1,  // Y coordinate
    int x2,  // X coordinate
    int y2,  // Y coordinate
    int x3,  // X coordinate
    int y3,  // Y coordinate
    const uint clr // color
);
```

**Parameters**

- `x1`  
  [in] X coordinate of the triangle's first corner.

- `y1`  
  [in] Y coordinate of the triangle's first corner.

- `x2`  
  [in] X coordinate of the triangle's second corner.

- `y2`  
  [in] Y coordinate of the triangle's second corner.

- `x3`  
  [in] X coordinate of the triangle's third corner.

- `y3`  
  [in] Y coordinate of the triangle's third corner.

- `clr`  
  [in] Color in ARGB format.
TriangleAA

Draws a triangle using antialiasing algorithm.

```c
void TriangleAA(
    const int x1,       // X coordinate
    const int y1,       // Y coordinate
    const int x2,       // X coordinate
    const int y2,       // Y coordinate
    const int x3,       // X coordinate
    const int y3,       // Y coordinate
    const uint clr,     // color
    const uint style=UINT_MAX  // line style
);```

Parameters

- **x1**
  - [in] X coordinate of the triangle's first corner.

- **y1**
  - [in] Y coordinate of the triangle's first corner.

- **x2**
  - [in] X coordinate of the triangle's second corner.

- **y2**
  - [in] Y coordinate of the triangle's second corner.

- **x3**
  - [in] X coordinate of the triangle's third corner.

- **y3**
  - [in] Y coordinate of the triangle's third corner.

- **clr**
  - [in] Color in ARGB format.

- **style=UINT_MAX**
  - [in] Line style is one of ENUM_LINE_STYLE enumeration's values or a custom value.
TriangleWu

Draws a triangle using Wu's anti-aliasing algorithm.

```c
void TriangleWu(
    const int x1,          // X coordinate
    const int y1,          // Y coordinate
    const int x2,          // X coordinate
    const int y2,          // Y coordinate
    const int x3,          // X coordinate
    const int y3,          // Y coordinate
    const uint clr,        // color
    const uint style=UINT_MAX // line style
);```

Parameters

- `x1`  
  [in] X coordinate of the triangle's first corner.

- `y1`  
  [in] Y coordinate of the triangle's first corner.

- `x2`  
  [in] X coordinate of the triangle's second corner.

- `y2`  
  [in] Y coordinate of the triangle's second corner.

- `x3`  
  [in] X coordinate of the triangle's third corner.

- `y3`  
  [in] Y coordinate of the triangle's third corner.

- `clr`  
  [in] Color in ARGB format.

- `style=UINT_MAX`  
  [in] Line style is one of `ENUM_LINE_STYLE` enumeration's values or a custom value.
Update

Displays changes on the screen.

```cpp
void Update(
    const bool redraw=true  // flag
);
```

Parameters

- **redraw=true**
  
  Flag of a chart redrawing necessity.
Width

Receives the width of a graphical resource.

```c
int Width();
```

Return Value

graphical resource width
**CChartCanvas**

Base class for implementing classes, which are used for drawing charts and their elements.

**Description**

This class includes methods for working with the basic elements of any chart: coordinate axes and their marks, chart legend, grid, background, etc. Here you can customize the options for displaying elements: visibility, text color, etc.

**Declaration**

```cpp
class CChartCanvas : public CCanvas
```

**Title**

```cpp
#include <Canvas\Charts\ChartCanvas.mqh>
```

**Inheritance hierarchy**

- CCanvas
  - CChartCanvas

**Direct descendants**

- CHistogramChart, CLineChart, CPieChart

**Class methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>

</tbody>
</table>

**Methods inherited from class CCanvas**

**ColorBackground (Get method)**

Returns the background color.

```c
uint ColorBackground()
```

**Return Value**

Background color.

**ColorBackground (Set method)**

Sets the background color.

```c
void ColorBackground(
    const uint value,  // background color
)
```

**Parameters**

`value`

[in] Background color.
ColorBorder (Get method)

Returns the border color.

```cpp
uint ColorBorder()
```

Return Value

Border color.

ColorBorder (Set method)

Sets the border color.

```cpp
void ColorBorder(
    const uint value, // border color
)
```

Parameters

`value`

[in] Border color.
ColorText (Get method)

Returns the text color.

```
uint ColorText()
```

Return Value

Text color.

ColorText (Set method)

Sets the text color.

```
void ColorText(
    const uint value,  // text color
)
```

Parameters

value

**ColorGrid (Get method)**

Returns the grid color.

```c
uint ColorGrid()
```

**Return Value**

Grid color.

**ColorGrid (Set method)**

Sets the grid color.

```c
void ColorGrid(
    const uint value,  // grid color
)
```

**Parameters**

- `value`
  
MaxData (Get method)

Returns the maximum amount of data (series) allowed.

```c
uint MaxData()
```

Return Value

The maximum amount of data (series).

MaxData (Set method)

Sets the maximum amount of data (series) allowed.

```c
void MaxData(
    const uint value, // amount of data
)
```

Parameters

value

[in] The maximum amount of data (series).
**MaxDescrLen (Get method)**

Returns the maximum length of the descriptors.

```cpp
uint MaxDescrLen()
```

**Return Value**

The value of the maximum length of the descriptors.

**MaxDescrLen (Set method)**

Sets the maximum length of the descriptors.

```cpp
void MaxDescrLen(
    const uint value,  // maximum length
)
```

**Parameters**

*value*

[in] The value of the maximum length of the descriptors.
ShowFlags (Get method)

Returns the visibility flag of the chart elements.

```cpp
bool ShowFlags()
```

Return Value

Value of the visibility flag of the chart elements.

ShowFlags (Set method)

Sets the visibility flag of the chart elements.

```cpp
void ShowFlags(
    const uint flags, // flag
)
```

Parameters

- `flags`
  
  [in] Value of the visibility flag of the chart elements.
IsShowLegend

Returns and sets the visibility flag of the legend on the chart.

```
bool IsShowLegend()
```

Return Value

true if the legend is visible, otherwise – false.
**IsShowScaleLeft**

Returns the visibility flag of the scale of values on the left.

```
bool IsShowScaleLeft()
```

**Return Value**

true if the scale of values is visible, otherwise — false.
IsShowScaleRight

Returns the visibility flag of the scale of values on the right.

```cpp
bool IsShowScaleRight()
```

Return Value

true if the scale of values is visible, otherwise — false.
IsShowScaleTop

Returns the visibility flag of the scale of values at the top.

```cpp
bool IsShowScaleTop()
```

Return Value

true if the scale of values is visible, otherwise — false.
**IsShowScaleBottom**

Returns the visibility flag of the scale of values at the bottom.

```cpp
bool IsShowScaleBottom()
```

**Return Value**

true if the scale of values is visible, otherwise — false.
IsShowGrid

Returns the visibility flag of the grid on the chart.

```cpp
bool IsShowGrid()
```

Return Value

true if the grid is visible, otherwise – false.
IsShowDescriptors

Returns the visibility flag of the descriptors on the chart.

bool IsShowDescriptors()

Return Value

true if the descriptors are visible, otherwise — false.
IsShowPercent

Returns the visibility flag of the percentages on the chart.

```cpp
bool IsShowPercent()
```

Return Value

true if the percentages are visible, otherwise — false.
VScaleMin (Get method)

Returns the minimum on the vertical scale of values.

```cpp
double VScaleMin()
```

Return Value

The minimum value on the vertical scale.

VScaleMin (Set method)

Sets the minimum on the vertical scale of values.

```cpp
void VScaleMin(
    const double value,  // value on the vertical scale
)
```

Parameters

value

[in] The minimum value.
**VScaleMax**

Returns the maximum on the vertical scale of values.

```csharp
double VScaleMax()
```

**Return Value**

The maximum value on the vertical scale.

**VScaleMax**

Sets the maximum on the vertical scale of values.

```csharp
void VScaleMax(const double value, // value on the vertical scale
                )
```

**Parameters**

`value`

[in] The maximum value.
**NumGrid**

Returns the number of vertical scale divisions when plotting the chart grid.

```c
uint NumGrid()
```

**Return Value**

The number of divisions.

**NumGrid**

Sets the number of vertical scale divisions when plotting the chart grid.

```c
void NumGrid(const uint value, // number of divisions
)
```

**Parameters**

`value`

[in] The number of divisions.
**DataOffset**

Returns the data offset value.

```cpp
int DataOffset()
```

**Return Value**

Data offset.

**DataOffset**

Sets the data offset value.

```cpp
void DataOffset(
    const int value,  // offset
)
```

**Parameters**

- `value`
  
  [in] Data offset.
DataTotal

Returns the total number of data series on the chart.

```cpp
uint DataTotal()
```

Return Value

The number of series.
DrawDescriptors

Virtual method for drawing descriptors.

```cpp
virtual void DrawDescriptors()
```
DrawData

Virtual method for drawing data series at the specified index.

```
virtual void DrawData(
    const uint idx=0, // index
)
```

Parameters

*idx=0*

[in] Index of the series.
Create

Virtual method that creates a graphical resource.

```cpp
virtual bool Create(
    const string name,  // resource name
    const int width,   // width
    const int height,  // height
    ENUM_COLOR_FORMAT clrfmt // format
);
```

Parameters

- **name**
  - [in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

- **width**
  - [in] Width (size along X axis) in pixels.

- **height**
  - [in] Height (size along Y axis) in pixels.

- **clrfmt**
  - [in] Color processing method. See the ResourceCreate() function description to learn more about color processing methods.

Return Value

- true if successful, otherwise — false.
AllowedShowFlags

Sets the set of allowed visibility flags for chart elements.

```cpp
void AllowedShowFlags(
    const uint flags,  // flags
)
```

Parameters

- `flags`
ShowLegend

Sets the visibility flag value for the legend (FLAG_SHOW_LEGEND).

```c
void ShowLegend(
    const bool flag,  // flag value
)
```

**Parameters**

*flag*

[in] Flag value:

- **true** – the legend becomes visible.
- **false** – the legend becomes invisible.
ShowScaleLeft

Sets the visibility flag value for the left scale (FLAG_SHOW_SCALE_LEFT).

```c
void ShowScaleLeft(
    const bool flag,  // flag value
)
```

Parameters

- **flag**
  - [in] Flag value:
    - true — the left scale becomes visible.
    - false — the left scale becomes invisible.
ShowScaleRight

Sets the visibility flag value for the right scale (FLAG_SHOW_SCALE_RIGHT).

```cpp
void ShowScaleRight(
    const bool flag, // flag value
)
```

Parameters

`flag`

[in] Flag value:

- true — the right scale becomes visible.
- false — the right scale becomes invisible.
ShowScaleTop

Sets the visibility flag value for the top scale (FLAG_SHOW_SCALE_TOP).

```cpp
void ShowScaleTop(
    const bool flag,  // flag value
)
```

Parameters

* **flag**
  
  [in] Flag value:
  
  - true — the top scale becomes visible.
  - false — the top scale becomes invisible.
ShowScaleBottom

Sets the visibility flag value for the bottom scale (FLAG_SHOW_SCALE_BOTTOM).

```cpp
void ShowScaleBottom(
    const bool flag,  // flag value
)
```

Parameters

`flag`

[in] Flag value:

- true — the bottom scale becomes visible.
- false — the bottom scale becomes invisible.
ShowGrid

Sets the visibility flag value for the grid (FLAG_SHOW_GRID).

```cpp
void ShowGrid(
    const bool flag, // flag value
)
```

Parameters

- **flag**
  
  [in] Flag value:
  
  - true — the grid becomes visible.
  - false — the grid becomes invisible.
ShowDescriptors

Sets the visibility flag value for the descriptors (FLAG_SHOW_DESCRIPTORS).

```c
void ShowDescriptors(
   const bool flag,  // flag value
)
```

Parameters

flag

[in] Flag value:

- true — the descriptor becomes visible.
- false — the descriptor becomes invisible.
ShowValue

Sets the visibility flag for the values (FLAG_SHOW_VALUE).

```c
void ShowValue(
    const bool flag, // flag value
)
```

Parameters

- `flag`
  
  [in] Flag value:
  
  - true – the value becomes visible.
  - false – the value becomes invisible.
ShowPercent

Sets the visibility flag value for the percentages (FLAG_SHOW_PERCENT).

```c
void ShowPercent(const bool flag, // flag value
```

**Parameters**

- **flag**
  - [in] Flag value:
    - true — the percentage becomes visible.
    - false — the percentage becomes invisible.
LegendAlignment

Sets the text alignment for the legend.

```c
void LegendAlignment(
    const ENUM_ALIGNMENT value, // flag
)
```

Parameters

`value`

[in] Takes one of the values of the ENUM_ALIGNMENT enumeration:

- ALIGNMENT_LEFT — alignment to the left.
- ALIGNMENT_TOP — alignment to the top.
- ALIGNMENT_RIGHT — alignment to the right.
- ALIGNMENT_BOTTOM — alignment to the bottom.
Accumulative

Sets the value accumulation flag for the series.

```c
void Accumulative(
    const bool flag=true, // flag value
)
```

**Parameters**

*flag=true*

*[in] Flag value:

- true — the current value of the series is replaced by the sum of all previous values.
- false — the standard mode for drawing series.*
VScaleParams

Sets the parameters for the vertical scale of values.

```c
void VScaleParams(
    const double max,   // maximum
    const double min,   // minimum
    const uint grid,    // number of divisions
)
```

**Parameters**

*max*

[in] The minimum value.

*min*

[in] The maximum value.

*grid*

[in] The number of scale divisions.
DescriptorUpdate

Updates the value of the series descriptor (at the specified position).

```cpp
bool DescriptorUpdate(
    const uint pos, // index
    const string descr, // value
)
```

Parameters

**pos**

[in] Index of the series — the serial number of its addition, starting with 0.

**descr**

[in] Descriptor value.

Return Value

true if successful, otherwise — false.
ColorUpdate

Updates the series colors (at the specified position).

```cpp
bool ColorUpdate(
   const uint pos, // index
   const uint clr, // color
)
```

Parameters

**pos**

[in] Index of the series — the serial number of its addition, starting with 0.

**clr**

[in] Color value.

Return Value

true if successful, otherwise — false.
ValuesCheck

Auxiliary virtual method, performs internal calculations for plotting the chart.

```cpp
virtual void ValuesCheck()
```
Redraw

Virtual method for redrawing the chart.

```
virtual void Redraw()
```
DrawBackground

Virtual method for redrawing the background.

```cpp
virtual void DrawBackground()
```
DrawLegend

Virtual method for redrawing the legend.

```cpp
virtual void DrawLegend()
```
**DrawLegendVertical**

Draws a vertical legend.

```cpp
int DrawLegendVertical(
    const int w, // width
    const int h, // height
)
```

**Parameters**

- `w`
  - [in] The maximum width of the text in the legend.
- `h`
  - [in] The maximum height of the text in the legend.

**Return Value**

Width of the legend in pixels.
DrawLegendHorizontal

Draws a horizontal legend.

```c
int DrawLegendHorizontal(
    const int w, //
    const int h, //
)
```

Parameters

- `w`
  - [in] The maximum width of the text in the legend.

- `h`
  - [in] The maximum height of the text in the legend.

Return Value

Height of the legend in pixels.
CalcScales

Virtual method for calculating the coordinates of labels for the scale of values.

```cpp
virtual void CalcScales()
```
DrawScales

Virtual method for redrawing the all scales of values.

```
virtual void DrawScales()
```
**DrawScaleLeft**

Virtual method for redrawing the left scale of values.

```cpp
virtual int DrawScaleLeft(
    const bool draw,  // flag
)
```

**Parameters**

*draw*

[in] Flag that indicates if the scale needs to be redrawn.

**Return Value**

Width of the scale of values.
DrawScaleRight

Virtual method for redrawing the right scale of values.

```cpp
virtual int DrawScaleRight(
    const bool draw, // flag
)
```

Parameters

- **draw**
  - [in] Flag that indicates if the scale needs to be redrawn.

Return Value

- Width of the scale of values.
**DrawScaleTop**

Virtual method for redrawing the top scale of values.

```cpp
virtual int DrawScaleTop(
    const bool draw,  // flag
)
```

**Parameters**

*draw*

[in] Flag that indicates if the scale needs to be redrawn.

**Return Value**

Height of the scale of values.
DrawScaleBottom

Virtual method for redrawing the bottom scale of values.

```cpp
virtual int DrawScaleBottom(const bool draw, // flag
)
```

Parameters

- `draw`
  
  [in] Flag that indicates if the scale needs to be redrawn.

Return Value

- Height of the scale of values.
DrawGrid

Virtual method for redrawing the grid.

```cpp
virtual void DrawGrid()
```
DrawChart

Virtual method for redrawing the chart.

```cpp
virtual void DrawChart()
```
CHistogramChart

Class for plotting histograms.

Description

All methods for working with the plotting of histograms are implemented in this class. They can be used to set the column width and for configuring the work with data series. The methods for working with gradient filling of histogram columns are included, which allow to visualize the data more clearly.

The code of the above figure is provided below.

Declaration

```cpp
class CHistogramChart : public CChartCanvas
```

Title

```cpp
#include <Canvas\Charts\HistogramChart.mqh>
```

Inheritance hierarchy

CCanvas
CChartCanvas
CHistogramChart

Example
#--- include <Canvas\Charts\HistogramChart.mqh>

// inputs
input bool Accumulative=true;

// Script program start function
int OnStart(void)
{
    int k=100;
    double arr[10];
    //--- create chart
    CHistogramChart chart;
    if(!chart.CreateBitmapLabel("SampleHistogramChart",10,10,600,450))
    {
        Print("Error creating histogram chart: ",GetLastError());
        return(-1);
    }
    if(Accumulative)
    {
        chart.Accumulative();
        chart.VScaleParams(20*k*10,-10*k*10,20);
    }
    else
    chart.VScaleParams(20*k,-10*k,20);
    chart.ShowValue(true);
    chart.ShowScaleTop(false);
    chart.ShowScaleBottom(false);
    chart.ShowScaleRight(false);
    chart.ShowLegend();
    for(int j=0;j<5;j++)
    {
        for(int i=0;i<10;i++)
        {
            k=-k;
            if(k>0)
                arr[i]=-k*(i+10-j);
            else
                arr[i]=k*(i+10-j)/2;
        }
        chart.SeriesAdd(arr,"Item"+IntegerToString(j));
    }
    //--- play with values
    while(!IsStopped())
    {
        int i=rand()%5;
        int j=rand()%10;
        k=rand()%3000-1000;
        chart.ValueUpdate(i,j,k);
        Sleep(200);
    }
}
//--- finish
    chart.Destroy();
    return(0);
}
Gradient

Sets the flag indicating whether the gradient fill of the histogram columns will be applied.

```cpp
void Gradient(
    const bool flag=true, // flag value
)
```

**Parameters**

*flag=true*

Flag value: true if the gradient fill is enabled, otherwise — false.
BarGap

Set the value of the histogram offset from the origin.

```c
void BarGap(
    const uint value,  // offset
);
```

Parameters

- **value**
  
  [in] Value of the histogram offset.
BarMinSize

Sets the minimum width of the histogram columns.

```c
void BarMinSize(
    const uint value, // minimum width
)
```

Parameters

value

[in] The minimum width.
BarBorder

Sets the flag indicating the need to draw the border for each column.

```c
void BarBorder(
    const uint value, // flag
)
```

Parameters

- `value`
  
  `[in]` Flag value:
  
  - `true` – borders will be drawn
  - `false` – borders will not be drawn
Create

Virtual method that creates a graphical resource.

```cpp
virtual bool Create(
    const string name,  // name
    const int width,    // width
    const int height,   // height
    ENUM_COLOR_FORMAT clrfmt  // format
)
```

**Parameters**

- `name`
  - [in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

- `width`
  - [in] Width (size along X axis) in pixels.

- `height`
  - [in] Height (size along Y axis) in pixels.

- `clrfmt`
  - [in] Color processing method. See the ResourceCreate() function description to learn more about color processing methods.

**Return Value**

- true if successful, otherwise — false.
SeriesAdd

Adds a new data series.

```cpp
bool SeriesAdd(
    const double& value[], // values
    const string descr,    // label
    const uint clr,         // color
)
```

**Parameters**

- `value[]`
  - [in] Data series.

- `descr`
  - [in] Series label.

- `clr`
  - [in] Series display color.

**Return Value**

true if successful, otherwise — false.
**SeriesInsert**

Inserts data series to the chart.

```cpp
bool SeriesInsert(
    const uint pos,  // index
    const double& value[], // values
    const string descr, // label
    const uint clr   // color
)
```

**Parameters**

- **pos**
  - [in] Index for insertion.

- **value[]**
  - [in] Data series.

- **descr**
  - [in] Series label.

- **clr**
  - [in] Series display color.

**Return Value**

- true if successful, otherwise — false.
SeriesUpdate

Updates data series on the chart.

```cpp
bool SeriesUpdate(
    const uint pos,       // index
    const double &value[], // values
    const string descr,   // label
    const uint clr        // color
)
```

Parameters

- **pos**
  - [in] Index of the series — the serial number of its addition, starting with 0.

- **value[]**
  - [in] New values for the data series.

- **descr**
  - [in] Series label.

- **clr**
  - [in] Series display color.

Return Value

- true if successful, otherwise false.
**SeriesDelete**

Deletes data series from the chart.

```cpp
bool SeriesDelete(
    const uint pos, // index
)
```

**Parameters**

*pos*

[in] Index of the series — the serial number of its addition, starting with 0.

**Return Value**

true if successful, otherwise — false.
ValueUpdate

Updates the specified value in the specified series.

```cpp
bool ValueUpdate(
    const uint series,  // index of the series
    const uint pos,     // index of the element
    double value        // value
)
```

Parameters

- `series`
  - [in] Index of the series — the serial number of its addition, starting with 0.

- `pos`
  - [in] Index of element in the series.

- `value`
  - [in] New value.

Return Value

- true if successful, otherwise — false.
DrawData

Virtual method that plots a histogram for the specified series.

```cpp
virtual void DrawData(
    const uint index, // index
)
```

Parameters

*index*

[in] Index of the series — the serial number of its addition, starting with 0.
DrawBar

Draws a histogram column as a filled rectangle.

```c
void DrawBar(
    const int x,  // X coordinate
    const int y,  // Y coordinate
    const int w,  // width
    const int h,  // height
    const uint clr,  // color
)
```

**Parameters**

x

[in] X coordinate of the top left point of the rectangle.

y

[in] Y coordinate of the top left point of the rectangle.

w

[in] The width of the rectangle.

h

[in] The height of the rectangle.

clr

[in] The color of the rectangle.
GradientBrush

Creates a brush for the gradient fill.

```c
void GradientBrush(
    const int size,  // size
    const uint fill_clr,  // fill color
)
```

Parameters

- **size**
  - [in] Brush thickness

- **fill_clr**
  - [in] Fill color
**CLineChart**

A class for plotting curves.

**Description**

The methods included in this class are designed for working with curves on the chart. It features the ability to fill the area limited by the plotted curve.

The code of the above figure is provided below.

**Declaration**

```cpp
class CLineChart : public CChartCanvas
```

**Title**

```cpp
#include <Canvas\Charts\LineChart.mqh>
```

**Inheritance hierarchy**

- CCanvas
  - CChartCanvas
    - CLineChart

                else
                    arr[i]=k*(i+10-j)/2;
            }
            chart.SeriesAdd(arr,"Item"+IntegerToString(j));
        }
    }

    //--- play with values
    while(!IsStopped())
    {
        int i=rand()%5;
        int j=rand()%10;
        k=rand()%3000-1000;
        chart.ValueUpdate(i,j,k);
        Sleep(200);
    }
}
//--- finish
chart_Destroy();
return(0);
}
Filled

Sets the flag indicating whether it is necessary to fill the area under the curve defined by the data series.

```cpp
void Filled(
    const bool flag=true, // flag
)
```

Parameters

`flag=true`

[in] Flag value:

- true — fill the area under the curve
- false — do not fill the area under the curve
Create

Virtual method that creates a graphical resource.

```cpp
virtual bool Create(
    const string name,  // name
    const int width,   // width
    const int height,  // height
    ENUM_COLOR_FORMAT clrfmt);  // format
```

Parameters

name
- [in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

width
- [in] Width (size along X axis) in pixels.

height
- [in] Height (size along Y axis) in pixels.

clrfmt
- [in] Color processing method. See the ResourceCreate() function description to learn more about color processing methods.

Return Value

true if successful, otherwise — false.
**SeriesAdd**

Adds a new data series.

```cpp
bool SeriesAdd(
    const double value[], // values
    const string descr,   // label
    const uint clr,       // color
)
```

**Parameters**

- `value[]`  

- `descr`  
  [in] Series label.

- `clr`  
  [in] Series display color.

**Return Value**

- true if successful, otherwise — false.
SeriesInsert

Inserts data series to the chart.

```cpp
bool SeriesInsert(
    const uint pos,  // index
    const double value[],  // values
    const string descr,  // label
    const uint clr,  // color
)
```

Parameters

- `pos`
  - [in] Index for insertion.
- `value[]`
  - [in] Data series.
- `descr`
  - [in] Series label.
- `clr`
  - [in] Series display color.

Return Value

- true if successful, otherwise — false.
SeriesUpdate

Updates data series on the chart.

```cpp
bool SeriesUpdate(
    const uint pos,  // index
    const double& value[], // values
    const string descr, // label
    const uint clr     // color
);
```

Parameters

- **pos**
  - [in] Index of the series — the serial number of its addition, starting with 0.

- **value[]**
  - [in] New values for the data series.

- **descr**
  - [in] Series label.

- **clr**
  - [in] Series display color.

Return Value

true if successful, otherwise — false.
SeriesDelete

Deletes data series from the chart.

```cpp
bool SeriesDelete(
    const uint pos, // index
)
```

Parameters

`pos`

[in] Index of the series — the serial number of its addition, starting with 0.

Return Value

true if successful, otherwise — false.
ValueUpdate

Updates the specified value in the specified series.

```c
bool ValueUpdate(
    const uint series,  // index of the series
    const uint pos,     // index of the element
    double value        // value
)
```

**Parameters**

- **series**
  - [in] Index of the series — the serial number of its addition, starting with 0.
- **pos**
  - [in] Index of element in the series.
- **value**
  - [in] New value.

**Return Value**

- true if successful, otherwise — false.
DrawChart

Virtual method which draws a curve and all its elements.

```cpp
virtual void DrawChart()
```

**DrawData**

Virtual method which draws a curve for the specified series.

```cpp
virtual void DrawData(
    const uint index, // index
)
```

**Parameters**

*index*

[in] Index of the series — the serial number of its addition, starting with 0.
CalcArea

Calculates the area under the curve defined by the data series.

```c
double CalcArea(
    const uint index,  // index
)
```

**Parameters**

`index`

[in] Index of the series — the serial number of its addition, starting with 0.

**Return Value**

Area of the figure limited by the curve which is defined by the data series.
CPieChart

Class for plotting pie charts.

The code of the above figure is provided below.

Description

The methods included in this class are designed for full-scale operation with pie charts, from the creating a graphical resource to designing labels to segments.

Declaration

```cpp
class CPieChart : public CChartCanvas
```

Title

```
#include <Canvas\Charts\PieChart.mqh>
```

Inheritance hierarchy

```
CCanvas
  CChartCanvas
    CPieChart
```

{
    pie_chart.ColorUpdate(i%total,RandomRGB());
    Sleep(1000);
}
//--- rotate
while(!IsStopped())
{
    pie_chart.DataOffset(pie_chart.DataOffset()+1);
    Sleep(200);
}
//--- finish
pie_chart.Destroy();
return(0);

//+------------------------------------------------------------------+
//| Random RGB color                                                 |
//+------------------------------------------------------------------+
uint RandomRGB(void)
{
    return(XRGB(rand()%255,rand()%255,rand()%255));
}
Create

Virtual method that creates a graphical resource.

```cpp
virtual bool Create(
    const string name,  // name
    const int width,    // width
    const int height,   // height
    ENUM_COLOR_FORMAT clrfmt  // format
)
```

**Parameters**

- **name**
  
  [in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

- **width**
  
  [in] Width (size along X axis) in pixels.

- **height**
  
  [in] Height (size along Y axis) in pixels.

- **clrfmt**
  
  [in] Color processing method. See the ResourceCreate() function description to learn more about color processing methods.

**Return Value**

- true if successful, otherwise — false.
SeriesSet

Sets a series of values that will be shown on the pie chart.

```
bool SeriesSet(
    const double& value[],  // values
    const string& text[],   // labels
    const uint& clr[]       // color
)
```

Parameters

`value[]`

[in] Array of values.

`text[]`

`clr[]`

Return Value

true if successful, otherwise — false.
**ValueAdd**

Adds a new value to the pie chart (to the end).

```cpp
bool ValueAdd(
    const double value, // value
    const string descr, // label
    const uint clr,     // color
)
```

**Parameters**

- `value`
  - [in] Value.

- `descr`
  - [in] Value label.

- `clr`
  - [in] Value color.

**Return Value**

- true if successful, otherwise — false.
ValueInsert

Inserts a new value to the pie chart (at the specified position).

```cpp
bool ValueInsert(
    const uint pos,  // index
    const double value,  // value
    const string descr,  // label
    const uint clr,  // color
)
```

Parameters

*pos*

[in] Index for insertion.

*value*

[in] Value.

*descr*

[in] Value label.

*clr*

[in] Value color.

Return Value

true if successful, otherwise — false.
ValueUpdate

Updates the value on the pie chart (at the specified position).

```cpp
bool ValueUpdate(
    const uint pos, // index
    const double value, // value
    const string descr, // label
    const uint clr, // color
)
```

Parameters

- `pos` [in] Index of the value — the serial number of its addition, starting with 0.
- `value` [in] Value.
- `descr` [in] Value label.

Return Value

- true if successful, otherwise — false.
ValueDelete

Removes a value from the pie chart (at the specified position).

```cpp
bool ValueDelete(
    const uint pos, // index
)
```

Parameters

pos

[in] Index of the value — the serial number of its addition, starting with 0.

Return Value

true if successful, otherwise — false.
DrawChart

Virtual method which draws a pie chart and all its elements.

```cpp
virtual void DrawChart()
```
DrawPie

Draws a segment of the pie chart, which corresponds to a specified value.

```cpp
void DrawPie(
    double fi3,  // angle of ray from pie chart center, which defines the first boundary of the arc
    double fi4,  // angle of ray from pie chart center, which defines the second boundary of the arc
    int idx,     // index
    CPoint& p[], // array of reference points (x, y) for plotting the segments.
    const uint clr // color of the segment.
)
```

Parameters

- `fi3`  
  [in] Angle in radians, which defines the first boundary of the arc.

- `fi4`  
  [in] Angle in radians, which defines the second boundary of the arc.

- `idx`  
  [in] Index of the value the segment corresponds to.

- `p[]`  
  [in] Array of reference points (x, y) for plotting the segments.

- `clr`  
  [in] Color of the segment.
## LabelMake

Generates a segment label based on its value and the original label.

```cpp
string LabelMake(
    const string text,   // label
    const double value,  // value
    const bool to_left,  // flag
)
```

### Parameters

- **text**
  - [in] Label.

- **value**
  - [in] Value.

- **to_left**
  - [in] Defines the order of the label layout:
    - true — label, then value.
    - false — value, then label.

### Return Value

Label of the segment.
CChart

CChart is a class for simplified access to “Chart” graphic object properties.

Description

CChart class provides access to “Chart” object properties.

Declaration

```cpp
class CChart : public CObject
```

Title

```cpp
#include <Charts\Chart.mqh>
```

Inheritance hierarchy

CObject
  CChart

</table>

Methods inherited from class CObject

- Prev, Prev, Next, Next, Compare
ChartID

Returns identifier of the chart.

```
long ChartID() const
```

Return Value

Chart identifier assigned to the chart class instance. If there is no chart assigned, it returns -1.
Mode (Get Method)

Gets the value of “Mode” property (bars, candles, or line).

```c
ENUM_CHART_MODE Mode() const
```

Return Value

Value of “Mode” property of the object assigned to the class instance. If there is no chart assigned, it returns WRONG_VALUE.

Mode (Set Method)

Sets new value for “Mode” property (bars, candles, or line).

```c
bool Mode(
    ENUM_CHART_MODE mode  // chart mode
)
```

Parameters

mode

[in] Chart mode (candles, bars or line) of ENUM_CHART_MODE enumeration.

Return Value

true - successful, false - cannot change the mode.
Foreground (Get Method)

Gets the value of “Foreground” property.

```cpp
bool Foreground() const
```

Return Value

Value of “Foreground” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

Foreground (Set Method)

Sets new value for “Foreground” property.

```cpp
bool Foreground(
    bool foreground // flag value
)
```

Parameters

foreground

Return Value

true - successful, false - cannot change the property.
**Shift (Get Method)**

Gets the value of "Shift" property.

```cpp
bool Shift() const
```

**Return Value**

Value of "Shift" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

**Shift (Set Method)**

Sets new value for "Shift" property.

```cpp
bool Shift(
    bool shift // flag value
)
```

**Parameters**

`shift`

**Return Value**

- true - successful, false - cannot change the property.
**ShiftSize (Get Method)**

Gets the value of "ShiftSize" property (in percents).

```cpp
double ShiftSize() const
```

**Return Value**

Value of "ShiftSize" property of the chart assigned to the class instance. If there is no chart assigned, it returns `EMPTY_VALUE`.

**ShiftSize (Set Method)**

Sets new value for "Shift" property (in percents).

```cpp
bool ShiftSize(
    double shift_size // property value
)
```

**Parameters**

`shift_size`

**Return Value**

true - successful, false - cannot change the property.
AutoScroll (Get Method)

Gets the value of "AutoScroll" property.

```cpp
bool AutoScroll() const
```

Return Value

Value of "AutoScroll" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

AutoScroll (Set Method)

Sets new value for "AutoScroll" property.

```cpp
bool AutoScroll(
    bool autoscroll // flag value
)
```

Parameters

autoscroll

Return Value

true - successful, false - cannot change the property.
Scale (Get Method)

Gets the value of “Scale” property.

```cpp
int Scale() const
```

Return Value

Value of “Scale” property of the chart assigned to the class instance. If there is no chart assigned, it returns 0.

Scale (Set Method)

Sets new value for “Scale” property.

```cpp
bool Scale(
    int scale // property value
)
```

Parameters

scale

[in] New value for “Scale” property.

Return Value

true - successful, false - cannot change the property.
ScaleFix (Get Method)

Gets the value of “ScaleFix” property (fixed chart scale or not).

```cpp
bool ScaleFix() const
```

**Return Value**

Value of “ScaleFix” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ScaleFix (Set Method)

Sets new value for “ScaleFix” property.

```cpp
bool ScaleFix(
    bool scale_fix // property value
)
```

**Parameters**

- `scale_fix`
  

**Return Value**

- true - successful, false - cannot change the property.
**ScaleFix_11 (Get Method)**

Gets the value of “ScaleFix_11” property (chart scale is 1:1, or not).

```cpp
bool ScaleFix_11() const
```

Return Value

Value of “ScaleFix_11” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

**ScaleFix_11 (Set Method)**

Sets new value for “ScaleFix_11” property.

```cpp
bool ScaleFix_11(
    string scale_11  // property value
)
```

Parameters

scale_11

[in] New value for “ScaleFix_11” property.

Return Value

true - successful, false - cannot change the property.
FixedMax (Get Method)

Gets the value of "FixedMax" property (fixed maximal price).

```cpp
double FixedMax() const
```

**Return Value**

Value of "FixedMax" property of the chart assigned to the class instance. If there is no chart assigned, it returns `EMPTY_VALUE`.

FixedMax (Set Method)

Sets the new value for "FixedMax" property.

```cpp
bool FixedMax(
    double max // fixed maximum
)
```

**Parameters**

- `max`
  - [in] New value for "FixedMax" property.

**Return Value**

- true - successful, false - cannot change the property.
FixedMin (Get Method)

Gets the value of "FixedMin" property (fixed minimal price).

```cpp
double FixedMin() const
```

**Return Value**

Value of "FixedMin" property of the chart assigned to the class instance. If there is no chart assigned, it returns `EMPTY_VALUE`.

FixedMin (Set Method)

Sets new value for "FixedMin" property.

```cpp
bool FixedMax(
    double min // fixed minimum
)
```

**Parameters**

- `max`

**Return Value**

- true - successful, false - cannot change the property.
PointsPerBar (Get Method)

Gets the value of "PointsPerBar" property (in points per bar).

```cpp
double PointsPerBar() const
```

Return Value

Value of "PointsPerBar" property of the chart assigned to the class instance. If there is no chart assigned, it returns EMPTY_VALUE.

PointsPerBar (Set Method)

Sets new value for "PointsPerBar" property.

```cpp
bool PointsPerBar(
    double ppb // scale
)
```

Parameters

- ppb
  - [in] New scale (in points per bar).

Return Value

- true - successful, false - cannot change the scale.
**ScalePPB (Get Method)**

Gets the value of "ScalePPB" property (scale is "point per bar" or not).

```cpp
bool ScalePPB() const
```

**Return Value**

Value of "ScalePPB" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

**ScalePPB (Set Method)**

Sets new value for "ScalePPB" property.

```cpp
bool ScalePPB(
    bool scale_ppb // flag value
)
```

**Parameters**

`scale_ppb`

**Return Value**

true - successful, false - cannot change the property.
ShowOHLC (Get Method)

Gets the value of "ShowOHLC" property.

```cpp
bool ShowOHLC() const
```

Return Value

Value of "ShowOHLC" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowOHLC (Set Method)

Sets new value for "ShowOHLC" property.

```cpp
bool ShowOHLC(
    bool show // property value
)
```

Parameters

- `show`  

Return Value

- true - success, false - cannot change the property.
ShowLineBid (Get Method)

Gets the value of "ShowLineBid" property.

```cpp
bool ShowLineBid() const
```

Return Value

Value of "ShowLineBid" property of the char, assigned to the class instance. If there is no chart assigned, it returns false.

ShowLineBid (Set Method)

Sets new value for "ShowLineBid" property.

```cpp
bool ShowLineBid(
    bool show  // property value
)
```

Parameters

`show`

Return Value

true - successful, false - cannot change the property.
ShowLineAsk (Get Method)

Gets the value of “ShowLineAsk” property.

```cpp
bool ShowLineAsk() const
```

Return Value

Value of “ShowLineAsk” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowLineAsk (Set Method)

Sets new value for “ShowLineAsk” property.

```cpp
bool ShowLineAsk(
    bool show // property value
)
```

Parameters

- **show**

Return Value

- true - successful, false - cannot change the property.
ShowLastLine (Get Method)

Gets the value of “ShowLastLine” property.

```cpp
bool ShowLastLine() const
```

Return Value

Value of “ShowLastLine” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowLastLine (Set Method)

Sets new value for “ShowLastLine” property.

```cpp
bool ShowLastLine(
    bool show // property value
)
```

Parameters

show

[in] New value for “ShowLastLine” property.

Return Value

true - successful, false - cannot change the property.
ShowPeriodSep (Get Method)

Gets the value of “ShowPeriodSep” property (show period separators).

```cpp
bool ShowPeriodSep() const
```

Return Value

Value of “ShowPeriodSep” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowPeriodSep (Set Method)

Sets new value for “ShowPeriodSep” property.

```cpp
bool ShowPeriodSep(
    bool show  // property value
)
```

Parameters

- `show`  

Return Value

- true - successful, false - cannot change the property.
ShowGrid (Get Method)

Gets the value of “ShowGrid” property.

```cpp
bool ShowGrid() const
```

Return Value

Value of “ShowGrid” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowGrid (Set Method)

Sets new value for “ShowGrid” property.

```cpp
bool ShowGrid(
    bool show  // property value
)
```

Parameters

`show`

Return Value

true - successful, false - cannot change the property.
ShowVolumes (Get Method)

Gets the value of “ShowVolumes” property.

```c++
bool ShowVolumes() const
```

Return Value

Value of “ShowVolumes” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowVolumes (Set Method)

Sets new value for “ShowVolumes” property.

```c++
bool ShowVolumes(
    bool show // property value
)
```

Parameters

show

Return Value

true - successful, false - cannot change the property.
ShowObjectDescr (Get Method)

Gets the value of “ShowObjectDescr” property (show description for graphic objects).

```cpp
bool ShowObjectDescr() const
```

Return Value

Value of “ShowObjectDescr” property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowObjectDescr (Set Method)

Sets new value for “ShowObjectDescr” property.

```cpp
bool ShowObjectDescr(
    bool show  // property value
)
```

Parameters

- `show`
  - [in] New value for “ShowObjectDescr” property.

Return Value

- true - successful, false - cannot change the property.
ShowDateScale

Sets new value for “ShowDateScale” property.

```cpp
bool ShowDateScale(
    bool show // property value
)
```

Parameters

`show`

[in] New value for “ShowDateScale” property.

Return Value

true - successful, false - cannot change the property.
ShowPriceScale

Sets new value for "ShowPriceScale" property.

```c
bool ShowPriceScale(
    bool show  // property value
)
```

Parameters

`show`

Return Value

true - successful, false - cannot change the property.
ColorBackground (Get Method)

Gets the value of “ColorBackground” property (background color of the chart).

```cpp
    ColorBackground() const
```

Return Value

Value of “ColorBackground” property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorBackground (Set Method)

Sets new value for “ColorBackground” property.

```cpp
    ColorBackground{
        color new_color // color
    }
```

Parameters

new_color

Return Value

true - successful, false - cannot change the color.
ColorForeground (Get Method)

Gets the value of "ColorForeground" property (color of axes, scale and OHLC strings of the chart).

```cpp
color ColorForeground() const
```

Return Value

Value of "ColorForeground" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorForeground (Set Method)

Sets new value for "ColorForeground" property (for axes, scale, and OHLC string).

```cpp
bool ColorForeground{
    color new_color     // color
}
```

Parameters

`new_color`

[in] New color for axes, scale and OHLC string.

Return Value

`true` - successful, `false` - cannot change the color.
**ColorGrid (Get Method)**

Gets the value of "ColorGrid" property (color of the grid).

```cpp
    color ColorGrid() const
```

**Return Value**

Value of "ColorGrid" property of the chart assigned to the class instance. If there is no chart assigned, it returns `CLR_NONE`.

**ColorGrid (Set Method)**

Sets new value for "ColorGrid" property.

```cpp
    bool ColorGrid(
        color new_color  // color
    )
```

**Parameters**

- `new_color`  

**Return Value**

- `true` - successful, `false` - cannot change the color.
ColorBarUp (Get Method)

Gets the value of "ColorBarUp" property (color for bullish bars, their shadow, and candle body outlines).

```cpp
    color ColorBarUp() const
```

Return Value

Value of "ColorBarUp" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorBarUp (Set Method)

Sets new value for "ColorBarUp" property.

```cpp
    bool ColorBarUp(
        color new_color  // color
    )
```

Parameters

new_color

[in] New color for bullish bars, their shadow and candle body outlines.

Return Value

true - successful, false - cannot change the color.
ColorBarDown (Get Method)

Gets the value of “ColorBarDown” property (color for bearish bars, their shadow, and candle body outlines).

```cpp
color  ColorBarDown()  const
```

Return Value

Value of “ColorBarDown” property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorBarDown (Set Method)

Sets new value for “ColorBarDown” property.

```cpp
bool  ColorBarDown(
    color  new_color  // color
)
```

Parameters

new_color

[in] New color for bearish bars, their shadow, and candle body outlines.

Return Value

true - successful, false - cannot change the color.
ColorCandleBull (Get Method)

Gets the value of "ColorCandleBull" property (body color of the bullish candle).

```cpp
    color ColorCandleBull() const
```

Return Value

Value of "ColorCandleBull" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorCandleBull (Set Method)

Sets new value for "ColorCandleBull" property.

```cpp
    bool ColorCandleBull(
            color new_color // color
    )
```

Parameters

new_color

[in] New color of the bullish candle body.

Return Value

true - successful, false - cannot change the color.
ColorCandleBear (Get Method)

Gets the value of “ColorCandleBear” property (body color of the bearish candle).

```cpp
  color  ColorCandleBear() const
```

Return Value

Value of “ColorCandleBear” property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorCandleBear (Set Method)

Sets new value for “ColorCandleBear” property.

```cpp
  bool  ColorCandleBear(
      color  new_color    // color
  )
```

Parameters

new_color

[in]  New color of the bearish candle body.

Return Value

true - successful, false - cannot change the color.
ColorChartLine (Get Method)

Gets the value of "ColorChartLine" property (color for line chart and Doji candles).

```cpp
   color ColorChartLine() const
```

Return Value

Value of "ColorChartLine" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

ColorChartLine (Set Method)

Sets new value for "ColorChartLine" property.

```cpp
   bool ColorChartLine(
   color new_color // color
   )
```

Parameters

`new_color`

[in] New color of the chart lines and Doji candles.

Return Value

true - successful, false - cannot change the color.
**ColorVolumes (Get Method)**

Gets the value of “ColorVolumes” property (color for volumes and levels of opened positions).

```c++
color ColorVolumes() const
```

**Return Value**

Value of “ColorVolumes” property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

**ColorVolumes (Set Method)**

Sets new value for “ColorVolumes” property.

```c++
bool ColorVolumes(
    color new_color // color
)
```

**Parameters**

`new_color`

[in] New color of the volumes and open position levels.

**Return Value**

true - successful, false - cannot change the color.
**ColorLineBid (Get Method)**

Gets the value of "ColorLineBid" property (color of Bid line).

```cpp
  color  ColorLineBid() const
```

**Return Value**

Value of "ColorLineBid" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

**ColorLineBid (Set Method)**

Sets new value for "ColorLineBid" property.

```cpp
  bool  ColorLineBid(
      color  new_color    // color
  )
```

**Parameters**

`new_color`

[in] New color for Bid line.

**Return Value**

true - successful, false - cannot change the color.
**ColorLineAsk (Get Method)**

Gets the value of "ColorLineAsk" property (color of Ask line).

```cpp
color ColorLineAsk() const
```

**Return Value**

Value of "ColorLineAsk" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

**ColorLineAsk (Set Method)**

Sets new value for "ColorLineAsk" property.

```cpp
bool ColorLineAsk(
    color new_color // color
)
```

**Parameters**

- `new_color`
  - [in] New color for Ask line.

**Return Value**

- true - successful, false - cannot change the color.
**ColorLineLast (Get Method)**

Gets the value of “ColorLineLast” property (color of the last deal price line).

```cpp
  color  ColorLineLast() const
```

**Return Value**

Value of “ColorLineLast” property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

**ColorLineLast (Set Method)**

Sets new value for “ColorLineLast” property.

```cpp
  bool  ColorLineLast(
      color  new_color  // color
  )
```

**Parameters**

*new_color*

[in] New color of the last deal price line.

**Return Value**

true - successful, false - cannot change the color.
**ColorStopLevels (Get Method)**

Gets the value of "ColorStopLevels" property (color of the SL and TP levels).

```cpp
    color ColorStopLevels() const
```

**Return Value**

Value of "ColorStopLevels" property of the chart assigned to the class instance. If there is no chart assigned, it returns CLR_NONE.

**ColorStopLevels (Set Method)**

Sets new value for "ColorStopLevels" property.

```cpp
    bool ColorStopLevels(
            color new_color // color
    )
```

**Parameters**

- `new_color`
  
  [in] New color of the Stop Loss and Take Profit price levels.

**Return Value**

- true - successful, false - cannot change the color.
VisibleBars

Gets total number of visible chart bars.

\[
\text{int VisibleBars()} \text{ const}
\]

Return Value

Gets total number of visible bars of the chart assigned to the class instance. If there is no chart assigned, it returns 0.
WindowsTotal

Gets total number of chart windows, including the chart indicator subwindows.

```cpp
int WindowsTotal() const
```

**Return Value**

Total number of windows, including the chart indicator subwindows, assigned to the class instance. If there is no chart assigned, it returns 0.
WindowIsVisible

Gets visibility flag of the specified chart subwindow.

```c
bool WindowIsVisible(
    int num // subwindow
) const
```

**Parameters**

- `num`
  - [in] Subwindow number (0 means main window).

**Return Value**

Returns visibility flag of the specified chart subwindow assigned to the chart instance. If there is no chart assigned, it returns false.
WindowHandle

Gets window handle of the chart (HWND).

```
int WindowHandle() const
```

Return Value

Window handle of the chart assigned to the chart instance. If there is no chart assigned, it returns `INVALID_HANDLE`. 
FirstVisibleBar

Gets the number of the first visible bar of the chart.

```cpp
int FirstVisibleBar() const
```

Return Value

Number of the first visible bar of the chart assigned to the class instance. If there is no chart assigned, it returns -1.
**WidthInBars**

Gets chart width in bars.

```cpp
int WidthInBars() const
```

**Return Value**

Width in chart bars of the chart assigned to the class instance. If there is no chart assigned, it returns 0.
**WidthInPixels**

Gets chart width in pixels.

```cpp
int WidthInPixels() const
```

**Return Value**

Width in pixels of the chart assigned to the chart instance. If there is no chart assigned, it returns 0.
HeightInPixels

Gets window height in pixels.

```c
int HeightInPixels(
    int    num    // subwindow
) const
```

**Parameters**

- `num`

  [in] Checked subwindow number (0 means main window).

**Return Value**

Window height in pixels of the chart assigned to the class instance. If there is no chart assigned, it returns 0.
**PriceMin**

Gets window minimal price.

```cpp
double PriceMin(
    int num  // subwindow
) const
```

**Parameters**

- `num`
  - [in] Subwindow number (0 means main window).

**Return Value**

Window minimal price value of the chart assigned to the class instance. If there is not chart assigned, it returns `EMPTY_VALUE`. 
**PriceMax**

Gets window maximal price.

```cpp
double PriceMax(
    int num    // subwindow
) const
```

**Parameters**

- `num`:
  - [in] Subwindow number (0 means main window).

**Return Value**

Window maximal price value of the chart assigned to the class instance. If there is not chart assigned, it returns `EMPTY_VALUE`. 
Attach

Assigns the current chart to the class instance.

```c
void Attach()
```

**Attach**

Assigns the specified chart to the class instance.

```c
void Attach(
    long chart  // chart identifier
)
```

**Parameters**

- `chart`  
  - [in] Identifier of the assigned chart.
FirstChart

Assigns the first chart of the client terminal to the class instance.

```cpp
void FirstChart()
```
NextChart

Assigns the next chart (following the already assigned one) to the class instance.

```cpp
void NextChart()
```
Open

Opens chart with specified parameters and assigns it to the class instance.

```cpp
long Open(
    const string symbol_name,  // symbol
    ENUM_TIMEFRAMES timeframe   // period
)
```

Parameters

symbol_name
- [in] Chart symbol. NULL means the symbol of the current chart (to which an expert is attached).

timeframe
- [in] Chart timeframe (from ENUM_TIMEFRAMES enumeration). 0 means the current timeframe.

Return Value

chart identifier.
Detach

Detaches chart from the class instance.

```c
void Detach()
```
Close

Closes chart assigned to the class instance.

```cpp
void Close()
```
BringToTop

Show chart on top of other charts.

```cpp
bool BringToTop() const
```

Return Value

- true - successful, false - error.
EventObjectCreate

Sets a flag to send notifications of events of a graphical object creation.

```c
bool EventObjectCreate(
    bool flag  // flag
);
```

Parameters

*flag*

[in] New value of a flag to send notifications of events of a graphical object creation.

Return Value

true - successful, false - cannot change the flag.
EventObjectDelete

Sets a flag to send notifications of events of a graphical object deletion.

```cpp
bool EventObjectDelete(
    bool flag    // flag
)
```

**Parameters**

*flag*

[in] New value of a flag to send notifications of events of a graphical object deletion.

**Return Value**

true - successful, false - cannot change the flag.
**IndicatorAdd**

Adds an indicator with the specified handle into a specified chart window.

```cpp
bool IndicatorAdd(
    int sub_win // number of the subwindow
    int handle   // handle of the indicator
);```

**Parameters**

* sub_win
  - [in] The number of the chart subwindow. 0 means the main chart window. If the number of a non-existing window is specified, a new window will be created.

* handle
  - [in] The handle of the indicator.

**Return Value**

The function returns true in case of success, otherwise it returns false. In order to obtain information about the error, call the `GetLastError()` function.

**See also**

`IndicatorDelete()`, `IndicatorsTotal()`, `IndicatorName()`.
**IndicatorDelete**

Removes an indicator with a specified name from the specified chart window.

```cpp
bool IndicatorDelete(
    int sub_win // number of the subwindow
    const string name // short name of the indicator
);
```

**Parameters**

*sub_win*  
[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

*name*  
[in] The short name of the indicator which is set in the **INDICATOR_SHORTNAME** property with the **IndicatorSetString()** function. To get the short name of an indicator, use the **IndicatorName()** function.

**Return Value**

Returns true in case of successful deletion of the indicator. Otherwise it returns false. To get error details, use the **GetLastError()** function.

**Note**

If two indicators with identical short names exist in the chart subwindow, the first one in a row will be deleted.

If other indicators on this chart are based on the values of the indicator that is being deleted, such indicators will also be deleted.

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions **iCustom()** and **IndicatorCreate()**. If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

Deletion of an indicator from a chart does not mean that its calculation part will be deleted from the terminal memory. To release the indicator handle, use the **IndicatorRelease()** function.

The indicator's short name should be formed correctly. It will be written to the **INDICATOR_SHORTNAME** property using the **IndicatorSetString()** function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the **IndicatorDelete()** function is identified by the short name.

**See also**

**IndicatorAdd(), IndicatorsTotal(), IndicatorName(), iCustom(), IndicatorCreate(), IndicatorSetString().**
**IndicatorsTotal**

Returns the number of all indicators applied to the specified chart window.

```c
int IndicatorsTotal(
    long chart_id, // chart identifier
    int sub_win   // number of the subwindow
);
```

**Parameters**

- `chart_id`
  - `[in]` Chart identifier. 0 denotes the main chart.

- `sub_win`
  - `[in]` Number of the chart subwindow. 0 denotes the main chart window.

**Return Value**

The number of indicators in the specified chart window. To get error details, use the `GetLastError()` function.

**Note**

The function allows going searching through all the indicators attached to the chart. The number of all the windows of the chart can be obtained from the `CHART_WINDOWS_TOTAL` property using the `GetInteger()` function.

**See also**

- `IndicatorAdd()`, `IndicatorDelete()`, `IndicatorsTotal()`, `iCustom()`, `IndicatorCreate()`, `IndicatorSetString()`.
IndicatorName

Returns the short name of the indicator by the index in the indicators list on the specified chart window.

```c
string IndicatorName{
    int sub_win  // number of the subwindow
    int index    // index of the indicator in the list of indicators added to the
};
```

**Parameters**

- `sub_win`:
  - [in] Number of the chart subwindow. 0 denotes the main chart window.

- `index`:
  - [in] Index of the indicator in the list of indicators. The numeration of indicators start with zero, i.e. the first indicator in the list has the 0 index. To obtain the number of indicators in the list, use the `IndicatorsTotal()` function.

**Return Value**

The short name of the indicator which is set in the `INDICATOR_SHORTNAME` property with the `IndicatorSetString()` function. To get error details, use the `GetLastError()` function.

**Note**

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions `iCustom()` and `IndicatorCreate()`. If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

The indicator's short name should be formed correctly. It will be written to the `INDICATOR_SHORTNAME` property using the `IndicatorSetString()` function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the `IndicatorDelete()` function is identified by the short name.

**See also**

`IndicatorAdd()`, `IndicatorDelete`, `IndicatorsTotal`, `iCustom()`, `IndicatorCreate()`, `IndicatorSetString()`.
Navigate

Shfts the chart.

```cpp
bool Navigate(
    ENUM_CHART_POSITION position,  // position
    int shift=0  // shift
)
```

Parameters

*position*

[in] Chart position (from `ENUM_CHART_POSITION` enumeration), relative to which a shift is performed.

*shift=0*

[in] Number of bars to shift.

Return Value

true - successful, false - cannot shift the chart.
Symbol

Gets chart symbol name.

```cpp
string Symbol() const
```

Return Value

Symbol name of the chart, assigned to the class instance. If there is no chart assigned, it returns "".
**Period**

Gets period of the chart.

| ENUM_TIMEFRAMES | Period() const |

**Return Value**

Period of the chart (from `ENUM_TIMEFRAMES`) assigned to the class instance. If there is no chart assigned, it returns 0.
Redraw

Redraws chart assigned to the class instance.

```cpp
void Redraw()
```
**GetInteger**

The function returns the value of the corresponding chart property. The chart property should be of the **integer** type. There are two variants of the function.

1. Immediately returns the property value.

```cpp
long GetInteger( 
    ENUM_CHARTPROPERTY_INTEGER prop_id, // property identifier 
    int sub_window=0 // subwindow number
) const
```

2. If successful, puts the value of property to the specified variable of integer type, passed by reference as last parameter.

```cpp
bool GetInteger( 
    ENUM_CHARTPROPERTY_INTEGER prop_id, // property identifier 
    int sub_window, // subwindow number
    long& value // link to the variable
) const
```

**Parameters**

- **prop_id**
  

- **sub_window**
  
  [in] Chart subwindow number.

- **value**
  
  [in] Link to the variable that receives the value of the requested property.

**Return Value**

Value of property of the chart assigned to the class instance. If there is not any chart assigned, it returns -1.

For the second variant, the function returns true, if this property is maintained and the value has been placed into the value variable, otherwise it returns false. To read more about the error, call **GetLastError()**.

© 2000-2019, MetaQuotes Software Corp.
SetInteger

Sets new value for the property of the integer type.

```cpp
bool SetInteger(
    ENUM_CHARTPROPERTYINTEGER prop_id,  // property identifier
    long value                            // value
)
```

**Parameters**

`prop_id`
- [in] Chart property identifier (from `ENUM_CHARTPROPERTYINTEGER` enumeration).

`value`
- [in] New value of the property.

**Return Value**

true - successful, false - cannot change the integer property.
GetDouble

The function returns the value of the corresponding chart property. The object property should be of the double type. There are two variants of the function.

1. Immediately returns the property value.

```cpp
double GetDouble(
    ENUM_CHART_PROPERTY_DOUBLE prop_id, // property identifier
    int sub_window=0 // subwindow number
) const
```

2. If successful, puts the value of property to the specified variable of double type, passed by reference as last parameter.

```cpp
bool GetDouble(
    ENUM_CHART_PROPERTY_DOUBLE prop_id, // property identifier
    int sub_window, // subwindow number
    double& value // link to the variable
) const
```

### Parameters

- **prop_id**
  - [in] Chart property identifier (from `ENUM_CHARTPROPERTY_DOUBLE` enumeration).

- **sub_window**
  - [in] Chart subwindow number.

- **value**
  - [in] Variable of the double type that received the value of the requested property.

### Return Value

Value of property of the chart assigned to the class instance. If there is not any chart assigned, it returns `EMPTY_VALUE`.

For the second variant the function, it returns true if the property value is received, otherwise returns false. To read more about the error, call `GetLastError()`.
SetDouble

Sets new value for the chart property of the double type.

```c
bool SetDouble(
    ENUM_CHART_PROPERTY_DOUBLE prop_id,     // property identifier
double value                                   // new value
)
```

Parameters

**prop_id**

[in] Chart property identifier (from ENUM_CHARTPROPERTYDOUBLE enumeration).

**value**

[in] New value for the property.

Return Value

true - successful, false - cannot change the double property.
**GetString**

The function returns the value of the corresponding chart property. The chart property should be of the string type. There are two variants of the function.

1. Immediately returns the property value.

```cpp
string GetString(
    ENUM_CHARTPROPERTY_STRING prop_id  // property identifier
) const
```

2. If successful, puts the value of property to the specified variable of string type, passed by reference as last parameter.

```cpp
bool GetString(
    ENUM_CHARTPROPERTY_STRING prop_id,  // property identifier
    string& value  // link to the variable
) const
```

**Parameters**

*prop_id*

[in] Chart property identifier (from ENUM_CHARTPROPERTY_STRING enumeration).

*value*

[in] Link to the variable that receives the value of the requested property.

**Return Value**

Value of a chart property assigned to the class instance. If there is no chart assigned, it returns "".

For the second variant, the function returns true, if this property is maintained and the value has been placed into the value variable, otherwise it returns false. To read more about the error, call GetLastError().
SetString

Sets new value for the chart property of the string type.

```cpp
bool SetString(
    ENUM_CHARTPROPERTYSTRING prop_id, // property identifier
    string value                       // value
)
```

Parameters

- **prop_id**
  - [in] Chart property identifier (from `ENUM_CHARTPROPERTYSTRING` enumeration).

- **value**
  - [in] New value for the property.

Return Value

true - successful, false - cannot change the string property.
SetSymbolPeriod

Changes symbol and period of the chart assigned to the class instance.

```cpp
bool SetSymbolPeriod(
    const string symbol_name,  // symbol
    ENUM_TIMEFRAMES timeframe   // period
)
```

Parameters

**symbol_name**

[in] New chart symbol. **NULL** means the symbol of the current chart (to which an expert is attached).

**timeframe**

[in] New chart timeframe (from **ENUM_TIMEFRAMES** enumeration). 0 means the current chart timeframe.

Return Value

true - successful, false - cannot change the property.
ApplyTemplate

Applies specified template to the chart.

```cpp
bool ApplyTemplate(
    const string filename  // template
)
```

**Parameters**

*filename*

[in] File name of the template.

**Return Value**

true - successful, false - cannot apply the template.
**ScreenShot**

Creates a screenshot of the specified chart in its current state in .gif format.

```cpp
bool ScreenShot(
    string filename, // file name
    int width,       // width
    int height,      // height
    ENUM_ALIGN_MODE align_mode=ALIGN_RIGHT // align type
) const
```

**Parameters**

- **filename**
  - [in] File name for screenshot.

- **width**
  - [in] Screenshot width in pixels.

- **height**
  - [in] Screenshot height in pixels.

- **align_mode=ALIGN_RIGHT**
  - [in] Align mode, if screenshot is narrow.

**Return Value**

- true - successful, false - error.
WindowOnDropped

Gets chart subwindow number corresponding to the object (expert or script) drop point.

```cpp
int WindowOnDropped() const
```

Return Value

Chart subwindow number of the object drop point. 0 means main chart window.
**PriceOnDropped**

Gets price coordinate corresponding to the object (expert or script) drop point.

```cpp
double PriceOnDropped() const
```

**Return Value**

Price coordinate of the object drop point.
**TimeOnDropped**

Gets time coordinate corresponding to the object (expert or script) drop point.

```cpp
datetime TimeOnDropped() const
```

**Return Value**

Time coordinate of the object drop point.
XOnDropped

Gets X coordinate corresponding to the object (expert or script) drop point.

```c
int XOnDropped() const
```

Return Value

X coordinate of the object drop point.
**YOnDropped**

Gets Y coordinate corresponding to the object (expert or script) drop point.

```
int YOnDropped() const
```

**Return Value**

Y coordinate of the object drop point.
Save

Saves object parameters to file.

```cpp
virtual bool Save(
    int file_handle // file handle
)
```

Parameters

- `file_handle` [in] handle of the binary file already opened by `FileOpen(...)` function.

Return Value

- true - successful, false - error.
Load

Loads object parameters from file.

```cpp
virtual bool Load(
    int file_handle // file handle
)
```

Parameters

file_handle

[in] handle of the binary file already opened by `FileOpen(...)` function.

Return Value

true - successful, false - error.
Type

Returns type identifier.

```cpp
virtual int Type() const
```

Return Value

Type identifier (0x1111 for CChart).
Graphics

The graphics library contains classes and global functions for quick plotting of custom charts.

The library provides convenient ready-made solutions for building axes, curves, as well as the methods for quick access to changing common properties of a custom chart.

The graphics library is placed to the Include\Graphics folder of the terminal's working directory.

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAxis</td>
<td>Class for working with coordinate axes</td>
</tr>
<tr>
<td>ColorGenerator</td>
<td>Class specifying the default color scheme</td>
</tr>
<tr>
<td>CCurve</td>
<td>Class for working with curves</td>
</tr>
<tr>
<td>CGraphic</td>
<td>Base class for creating custom charts</td>
</tr>
</tbody>
</table>
**GraphPlot**

Functions for quick curve plotting.

**Version for plotting a single curve using Y coordinates.**

```cpp
string GraphPlot(
    const double y[],           // Y coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS  // curve type
}
```

**Note**

Y array indices are used as X coordinates for the curve.

**Version for plotting a single curve using X and Y coordinates**

```cpp
string GraphPlot(
    const double x[],           // X coordinates
    const double y[],           // Y coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS  // curve type
}
```

**Version for plotting two curves using X and Y coordinates**

```cpp
string GraphPlot(
    const double x1[],          // X coordinates
    const double y1[],          // Y coordinates
    const double x2[],          // X coordinates
    const double y2[],          // Y coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS  // curve type
}
```

**Version for plotting three curves using X and Y coordinates**

```cpp
string GraphPlot(
    const double x1[],          // X coordinates
    const double y1[],          // Y coordinates
    const double x2[],          // X coordinates
    const double y2[],          // Y coordinates
    const double x3[],          // X coordinates
    const double y3[],          // Y coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS  // curve type
}
```
### Version for plotting a curve using CPoint2D points coordinates

```c
string GraphPlot(
    const CPoint2D &points[], // curve coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)
```

### Version for plotting two curves using CPoint2D points coordinates

```c
string GraphPlot(
    const CPoint2D &points1[], // curve coordinates
    const CPoint2D &points2[], // curve coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)
```

### Version for plotting three curves using CPoint2D points coordinates

```c
string GraphPlot(
    const CPoint2D &points1[], // curve coordinates
    const CPoint2D &points2[], // curve coordinates
    const CPoint2D &points3[], // curve coordinates
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)
```

### Version for plotting a curve using the pointer to CurveFunction

```c
string GraphPlot(
    CurveFunction function, // pointer to the function
    const double from, // initial value of the argument
    const double to, // final value of the argument
    const double step, // increment by the argument
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)
```

### Version for plotting two curves using the pointers to the CurveFunction functions

```c
string GraphPlot(
    CurveFunction function1, // pointer to the function
    CurveFunction function2, // pointer to the function
    const double from, // initial value of the argument
    const double to, // final value of the argument
    const double step, // increment by the argument
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)
```
Version for plotting three curves using the pointers to the CurveFunction functions

```c
string GraphPlot(
    CurveFunction function1,    // pointer to the function
    CurveFunction function2,    // pointer to the function
    CurveFunction function3,    // pointer to the function
    const double from,          // initial value of the argument
    const double to,            // final value of the argument
    const double step,          // increment by the argument
    ENUM_CURVE_TYPE type=CURVE_POINTS  // curve type
)
```

Parameters

- `x[]`
  
  [in] X coordinates.

- `y[]`
  

- `x1[]`
  
  [in] X coordinates for the first curve.

- `y1[]`
  
  [in] Y coordinates for the first curve.

- `x2[]`
  
  [in] X coordinates for the second curve.

- `y2[]`
  
  [in] Y coordinates for the second curve.

- `x3[]`
  
  [in] X coordinates for the third curve.

- `y3[]`
  
  [in] Y coordinates for the third curve.

- `points[]`
  
  [in] Coordinates of the curve dots.

- `points1[]`
  
  [in] Coordinates of the first curve dots.

- `points2[]`
  
  [in] Coordinates of the second curve dots.

- `points3[]`
  
  [in] Coordinates of the third curve dots.
function
    [in] Pointer to the CurveFunction function.

function1
    [in] Pointer to the first function.

function2
    [in] Pointer to the second function.

function3
    [in] Pointer to the third function.

from
    [in] Corresponds to the first X coordinate.

to
    [in] Corresponds to the last X coordinate.

step
    [in] Parameter for calculating the X coordinates.

type=CURVE_POINTS
    [in] Curve type.

Return Value

Name of a graphical resource.
CAxis

CAxis is an auxiliary graphics library class for working with the coordinate axes.

Description

The CAxis class receives and stores various parameters of the coordinate axes. The class implements the ability to auto scale the coordinate axes dynamically.

Declaration

```cpp
class CAxis
```

Title

```cpp
#include <Graphics\Axis.mqh>
```

Class methods

<table>

<td>Auto scale the axis.</td>
</tr>
</tbody>
</table>
**AutoScale (Get method)**

Returns the flag defining the need for auto-scale.

```cpp
bool AutoScale()  
```

**Return Value**

The flag value.

**Note**

- true — perform auto-scaling.
- false — do not perform auto-scaling.

**AutoScale (Set method)**

Sets the flag defining the need for auto-scale.

```cpp
void AutoScale(
    const bool auto  // flag value
)
```

**Parameters**

- `auto`[in]

**Note**

- true — perform auto-scaling.
- false — do not perform auto-scaling.
**Min (Get method)**

Returns the minimum axis value.

```c
double Min()
```

**Return Value**

Minimum axis value.

**Min (Set method)**

Sets the minimum axis value.

```c
void Min(
    const double min,  // minimum value
)
```

**Parameters**

`min`

**Max (Get method)**

Returns the maximum axis value.

```
double Max()
```

**Return Value**

*Maximum axis value.*

**Max (Set method)**

Sets the maximum axis value.

```
void Max(
    const double max  // maximum value
)
```

**Parameters**

`max`

Step (Get method)

Return the step value by axis.

```cpp
double Step();
```

Return Value

Step value.
Name (Get method)

Returns the axis name.

```c
string Name()
```

Return Value

Axis name.

Name (Set method)

Sets the axis name.

```c
void Name(
    const string name  // axis name
)
```

Parameters

name

[in] Axis name.
Color (Get method)

Returns the axis color.

```cpp
    color Color();
```

Return Value

Axis color.

Color (Set method)

Sets the axis color.

```cpp
    void Color(
        const color clr  // axis color
    );
```

Parameters

- `clr`
ValuesSize (Get method)

Returns the size of the axis numbers.

```cpp
int ValuesSize()
```

Return Value

Size of the axis numbers.

ValuesSize (Set method)

Sets the size of the axis numbers.

```cpp
void ValuesSize(
    const int size  // size of the axis numbers
)
```

Parameters

`size`

[in] Size of the axis numbers
ValuesWidth (Get method)

Returns the maximum allowed length in pixels for displaying the axis numbers.

```cpp
int ValuesWidth()
```

Return Value

Length of the axis numbers in pixels.

Note

If a length in pixels for a specified number exceeds the maximum allowed display length, it is truncated and ends in dots.

ValuesWidth (Set method)

Sets the maximum allowed length in pixels for displaying the axis numbers.

```cpp
void ValuesWidth(
    const int width,  // maximum allowed length in pixels
)
```

Parameters

width

- [in] Maximum allowed length of the axis numbers.

Note

If a length in pixels for a specified number exceeds the maximum allowed display length, it is truncated and ends in dots.
ValuesFormat (Get method)

Returns the format of the axis numbers.

```
string ValuesFormat()
```

Return Value

Number format.

ValuesFormat (Set method)

Sets the format of the axis numbers.

```
void ValuesFormat(
    const string format       // format of the axis numbers
)
```

Parameters

*format*

ValuesDateTimeMode (Get method)

Get the format of converting a date into a string.

```cpp
int ValuesDateTimeMode()
```

Return Value

Format of converting a date into a string.

ValuesDateTimeMode (Set method)

Set the format of converting a date into a string.

```cpp
void ValuesDateTimeMode(
    const int mode     // format of converting a date into a string
)
```

Parameters

- `mode`
  - [in] Conversion format.

Note

Find out more about the formats of converting a date into a string in the `TimeToString()` function description.
ValuesFunctionFormat (Get method)

Get the pointer to the function defining the format of displaying values on the axis.

```cpp
DoubleToStringFunction ValuesFunctionFormat()
```

Return Value

Pointer to the function defining the format of displaying values on the axis.

ValuesFunctionFormat (Set method)

Set the pointer to the function defining the format of displaying values on the axis.

```cpp
void ValuesFunctionFormat(
    DoubleToStringFunction func // function for converting numerical values into a string
)
```

Parameters

`func`

- [in] Custom function for converting numerical values into a string.

Example:

The format of displaying X axis values has been changed using the following code:
```csharp
#include <Graphics\Graphic.mqh>

//--- array for store values
double arrX[];
double arrY[];

//--- Custom function for create values on X-axis
string TimeFormat(double x, void *cbdata)
{
    return (TimeToString((datetime)arrX[ArraySize(arrX)-(int)x-1]));
}

void OnStart()
{
    MqlRates rates[];
    CopyRates(Symbol(), Period(), 0, 100, rates);
    ArraySetAsSeries(rates, true);
    int size=ArraySize(rates);
    ArrayResize(arrX, size);
    ArrayResize(arrY, size);
    for(int i=0; i<size; ++i)
    {
        arrX[i]=(double)rates[i].time;
        arrY[i]=rates[i].close;
    }

    //--- create graphic
    CGraphic graphic;
    if(!graphic.Create(0,"DateAxisGraphic",0,30,30,780,380))
    {
        graphic.Attach(0,"DateAxisGraphic");
    }

    //--- create curve
    CCurve *curve=graphic.CurveAdd(arrY, CURVE_LINES);
    //--- gets the X-axis
    CAxis *xAxis=graphic.XAxis();
    //--- sets the X-axis properties
    xAxis.AutoScale(false);
    xAxis.Type(AXIS_TYPE_CUSTOM);
    xAxis.ValuesFunctionFormat(TimeFormat);
    xAxis.DefaultStep(20.0);
    //--- plot
    graphic.CurvePlotAll();
    graphic.Update();
}
```
ValuesFunctionFormatCBData (Get method)

Get the pointer to the object that may contain additional data on converting axis values.

```c
void* ValuesFunctionFormatCBData()
```

Return Value

The pointer to the object that may contain additional data on converting axis values.

ValuesFunctionFormatCBData (Set method)

Set the pointer to the class object that may contain additional data on converting axis values.

```c
void ValuesFunctionFormatCBData(
    void* cbdata   // pointer to the class object
)
```

Parameters

`cbdata`

[in] Pointer to any class object containing additional data on converting axis values
NameSize (Get method)

Returns the font size of the axis name.

```c
int NameSize()
```

Return Value

Font size of the axis name.

NameSize (Set method)

Sets the font size of the axis name.

```c
void NameSize(
    const int size  // font size of the axis name
)
```

Parameters

- `size`

  [in] Font size of the axis name.
ZeroLever (Get method)

Returns the "zero lever" value.

    double ZeroLever()

Return Value

"Zero lever".

Note

The value is used to define when the axis scale range should be expanded to include a zero value.

ZeroLever (Set method)

Sets the "zero lever" value.

    void ZeroLever(
        const double value  // "zero lever" value
    )

Parameters

value

    [in] "Zero lever" value.

Note

The value is used to define when the axis scale range should be expanded to include a zero value.
DefaultStep (Get method)

Returns the initial step value by axis

```c
double DefaultStep()
```

Return Value

- Step by axis.

DefaultStep (Set method)

Sets the initial step value by axis

```c
void DefaultStep(
    const double value  // step by axis
)
```

Parameters

- `value`
  - [in] Initial step value by axis.
MaxLabels (Get method)

Returns the maximum allowed amount of numbers displayed on the axis.

```cpp
double MaxLabels()
```

Return Value

Maximum amount of numbers on the axis.

MaxLabels (Set method)

Sets the maximum allowed amount of numbers displayed on the axis.

```cpp
void MaxLabels(
    const double value  // maximum number
)
```

Parameters

value

[in] Maximum allowed amount of numbers displayed on the axis
MinGrace (Get method)

Returns the “tolerance” applied to the axis minimum.

```cpp
double MinGrace()
```

Return Value

“Tolerance” value for the axis minimum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.

MinGrace (Set method)

Sets the “tolerance” applied to the axis minimum.

```cpp
void MinGrace(const double value)  // "tolerance" value
```

Parameters

value

[in] “Tolerance” applied to the axis minimum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.
MaxGrace (Get method)

Returns the “tolerance” applied to the axis maximum.

```cpp
double MaxGrace()
```

Return Value

“Tolerance” value for the axis maximum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MaxGrace is equal to 0.1, then 10% of the axis length (or 1.2) is added to the maximum value. As a result, the axis covers the interval from 4.0 to 17.2.

MaxGrace (Set method)

Sets the “tolerance” applied to the axis maximum.

```cpp
void MaxGrace(
    const double value  // "tolerance" value
)
```

Parameters

value

[in] “Tolerance” value applied to the axis maximum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.
SelectAxisScale

Auto scale the axis.

```c
void SelectAxisScale()
```
**CColorGenerator**

CColorGenerator class is an auxiliary graphics library class for working with the color palette.

**Description**

The CColorGenerator class contains the initial color palette used for curves by default (if a color is not specified by a user).

If all colors from the initial palette are used already, new colors are automatically generated and the palette is refilled.

**Declaration**

```cpp
class CColorGenerator
```

**Title**

```cpp
#include <Graphics\ColorGenerator.mqh>
```

**Class methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Next</td>
<td>Returns the next color from the palette</td>
</tr>
<tr>
<td>Reset</td>
<td>Resets the generator</td>
</tr>
</tbody>
</table>
Next

Returns the next color from the palette.

```c
uint Next()
```

Return Value

Color.

Note

If all colors from the palette have already been passed through, new colors are automatically generated in order to replace the old ones in the palette.
Reset

Resets the generator.

```cpp
void Reset()
```
CCurve

The CCurve class works with the properties of the curves generated on the chart.

Description

The CCurve class sets, installs and receives the coordinates and various properties of the curves when working with the CGraphic class.

There are three curve plotting modes: dots, lines and histogram. Separate parameters are implemented for each plotting mode in the class.

Declaration

```cpp
class CCurve : public CObject
```

Title

```cpp
#include <Graphics\Curve.mqh>
```

Inheritance hierarchy

Methods inherited from class CObject

Prev, Prev, Next, Next, **Save, Load, Compare**
## Type

Return the curve type.

<table>
<thead>
<tr>
<th>ENUM_CURVE_TYPE</th>
<th>Type()</th>
</tr>
</thead>
</table>

### Return Value

Curve type.
Name

Returns the curve name.

```
string Name()
```

Return Value

Curve name.
Color

Returns the curve color.

```
uint Color()
```

Return Value

Curve color.
XMax

Returns the maximum value of the X function (real numbers only).

```c
double XMax()
```

Return Value

Maximum real number among all the function arguments.
XMin

Returns the minimum value of the X function (real numbers only).

```c
double XMin()
```

Return Value

Minimum real number among all the function arguments.
YMax

Returns the maximum value of the Y function (real numbers only).

```cpp
double YMax()
```

Return Value

Maximum value of the Y function (real numbers only).
YMin

Returns the minimum value of the Y function (real numbers only).

```c
double YMin()
```

Return Value

Minimum value of the Y function (real numbers only).
Size

Returns the number of dots defining the curve.

```c
int Size()
```

Return Value

Number of dots defining the curve.
**PointsSize (Get method)**

Returns the linear size (in pixels) of dots used in plotting the curve.

```c
int PointsSize()
```

**Return Value**

Size of dots defining the curve in pixels.

**PointsSize (Set method)**

Sets the linear size (in pixels) of dots used in plotting the curve.

```c
void PointsSize(const int size) // dot size in pixels
```

**Parameters**

`size`

[in] Linear size (in pixels) of dots used in plotting the curve.
PointsFill (Get method)

Returns a flag determining if a filling for dots defining a curve should be performed.

```cpp
bool PointsFill ()
```

Return Value

The flag value.

Note

- `true` — perform a filling
- `false` — do not perform a filling

PointsFill (Set method)

Sets a flag determining if a filling for dots defining a curve should be performed.

```cpp
void PointsFill(
    const bool fill  // flag value
)
```

Parameters

- `fill`
  - `[in]` Flag value.

Note

- `true` — perform a filling
- `false` — do not perform a filling
PointsColor (Get method)

Returns the dot filling color.

```cpp
uint PointsColor ()
```

**Return Value**

Color of filling dots defining the curve.

PointsColor (Set method)

Sets the dot filling color

```cpp
void PointsColor (const uint clr)        // dot filling color
```

**Parameters**

`clr`

[in] Color of filling dots defining the curve.
**GetX**

 Gets X values of all curve dots to the array.

```c
void GetX(
    double& x[] // array for writing X values
)
```

**Parameters**

- `x[]`
  
  [out] Array for getting X values of all curve dots.

**Note**

Each curve dot is defined by a couple of X and Y values. These values are not coordinates in pixels for drawing in the `CGraphic` class.
### GetY

Gets Y values of all curve dots to the array.

```cpp
void GetY(
    double& y[]  // array for writing Y values
)
```

#### Parameters

- **y[]**
  - [out] Array for getting Y values of all curve dots.

#### Note

Each curve dot is defined by a couple of X and Y values. These values are not coordinates in pixels for drawing in the `CGraphic` class.
LinesStyle (Get method)

Returns a line style when plotting a curve using lines.

```c
enum LinesStyle()
```

Return Value

Line style.

LinesStyle (Set method)

Sets a line style when plotting a curve using lines.

```c
void LinesStyle(
    enum LinesStyle style // line style
)
```

Parameters

- `style`
  - [in] Line style.
LinesIsSmooth (Get method)

Returns a flag defining if smoothing should be done when plotting a curve by lines.

```cpp
bool LinesIsSmooth()
```

Return Value

Flag value

Note

true — perform smoothing
false — do not perform smoothing

LinesIsSmooth (Set method)

Sets a flag defining if smoothing should be done when plotting a curve by lines.

```cpp
void LinesIsSmooth(
    const bool smooth // flag value
)
```

Parameters

smooth

[in] Flag value

Note

true — perform smoothing
false — do not perform smoothing
**LinesSmoothTension (Get method)**

Returns the curve smoothing parameter when drawing using lines.

```c
double LinesSmoothTension()
```

**Return Value**

Smoothing parameter value

**Note**

The 'tension' value is within the (0.0; 1.0] range.

**LinesSmoothTension (Set method)**

Sets the curve smoothing parameter when drawing using lines.

```c
void LinesSmoothTension(
    const double tension // parameter value
)
```

**Parameters**

`tension`

[in] Smoothing parameter value.

**Note**

The 'tension' value is within the (0.0; 1.0] range.
LinesSmoothStep (Get method)

Returns the length of the approximating lines for smoothing when plotting by lines.

```cpp
double LinesSmoothStep()
```

**Return Value**

Length of approximating lines in pixels.

LinesSmoothStep (Set method)

Sets the length of the approximating lines for smoothing when plotting by lines.

```cpp
void LinesSmoothStep(
    const double step  // line length
)
```

**Parameters**

*step*

[in] Length of approximating lines
LinesEndStyle (Set method)

Get the flag indicating lines end plotting style when using lines to plot a curve.

```cpp
ENUM_LINE_END LinesEndStyle()
```

Return Value

A value of the flag indicating lines end plotting style when using lines to plot a curve.

LinesEndStyle (Get method)

Set the flag indicating lines end plotting style when using lines to plot a curve.

```cpp
void LinesEndStyle(
    ENUM_LINE_END _end_style  // flag value
)
```

Parameters

`end_style`

[in] A value of the flag indicating line end plotting style when using lines to plot a curve.
**LinesWidth (Get method)**

Get lines width when plotting a curve using lines.

```c
int LinesWidth()
```

**Return Value**

Lines width.

**LinesWidth (Set method)**

Set lines width when plotting a curve using lines.

```c
void LinesWidth(
    const int width // lines width
)
```

**Parameters**

- `width`
  - `[in]` Lines width when plotting a curve using lines.

**Example:**

A line width has been changed using the following code:
//+------------------------------------------------------------------+
//|                                                Candle
//|                        Copyright 2016, MetaQuotes Software Corp. |
//|                                             https://www.mql5.com |
//+------------------------------------------------------------------+
#include <Graphics\Graphic.mqh>
//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
{
    double x[] = {-100,-40,-10,20,30,40,50,60,70,80,120};
    double y[] = {-5,4,-10,23,17,18,-9,13,17,4,9};
    //--- create graphic
    CGraphic graphic;
    if(!graphic.Create(0,"ThickLineGraphic",0,30,30,780,380))
    {
        graphic.Attach(0,"ThickLineGraphic");
    }
    //--- create curve
    CCurve *curve=graphic.CurveAdd(x,y,CURVE_LINES);
    //--- sets the curve properties
    curve.LinesSmooth(true);
    curve.LinesStyle(STYLE_DASH);
    curve.LinesEndStyle(LINE_END_ROUND);
    curve.LinesWidth(10);
    //--- plot
    graphic.CurvePlotAll();
    graphic.Update();
}
HistogramWidth (Get method)

Returns the width of columns when plotting using a histogram.

```cpp
int HistogramWidth()
```

Return Value

Column width in pixels.

HistogramWidth (Set method)

Sets the width of columns when plotting using a histogram.

```cpp
void HistogramWidth(
    const int width  // column width
)
```

Parameters

- `width`
  - [in] Column width in pixels.
CustomPlotCBData (Get method)

Get the pointer to the object to be used in the custom curve plotting mode.

```c
void* CustomPlotCBData()
```

Return Value

Pointer to the object for the custom curve plotting mode.

CustomPlotCBData (Set method)

Set the pointer to the object to be used in the custom curve plotting mode.

```c
void CustomPlotCBData(
    void* cbdata  // pointer to the object
)
```

Parameters

- `cbdata`  
  
  [in] The pointer to the object to be used in the custom curve plotting mode
CustomPlotFunction (Get method)

Get the pointer to the function implementing the custom curve plotting mode.

```
PlotFunction CustomPlotFunction()
```

Return Value

Pointer to the function implementing the custom curve plotting mode.

CustomPlotFunction (Set method)

Set the pointer to the function implementing the custom curve plotting mode.

```
void CustomPlotFunction(
    PlotFunction func // pointer to the function
)
```

Parameters

`func`

[in] Pointer to the function implementing the custom curve plotting mode

Example:

This curve consisting of bars is built using the following code:
```cpp
#include <Graphics\Graphic.mqh>

//+------------------------------------------------------------------+
//|                                                Candle Graphic.mq5 |

    graphic.Update();
}
PointsType (Get method)

Get the flag pointing at the type of dots used when plotting a dotted curve.

```c
ENUM_POINT_TYPE  PointsType()
```

Return Value

A value of the flag indicating a type of dots.

PointsType (Set method)

Set the flag pointing at the type of dots used when plotting a dotted curve.

```c
void  PointsType( 
    ENUM_POINT_TYPE  type  // flag value
)
```

Parameters

type

[in] A value of the flag pointing at the type of dots used when plotting a dotted curve.
**StepsDimension (Get method)**

Get the value indicating the dimension used in step-type curve rendering.

```c
int StepsDimension()
```

**Return Value**

Dimension used in step-type curve rendering.

**StepsDimension (Set method)**

Set the value indicating the dimension used in step-type curve rendering.

```c
void StepsDimension(
    const int dimension // dimension
)
```

**Parameters**

- `dimension`
  
  [in] Dimension (0 or 1).

**Note**

- 0 — x (the horizontal line is followed by the vertical one).
- 1 — y (the vertical line is followed by the horizontal one).
**TrendLineCoefficients (Get method)**

Get trend line ratios for writing them into an array.

```csharp
double& TrendLineCoefficients()
```

**Return Value**

Trend line ratios.

**TrendLineCoefficients (Set method)**

Set trend line ratios for writing them into an array.

```csharp
void TrendLineCoefficients(
    double& coefficients[] // array for writing ratios
)
```

**Parameters**

`coefficients[]`

[out] Array for writing ratios.
**TrendLineColor (Get method)**

Get a color of a trend line for a curve.

```cpp
uint TrendLineColor()
```

**Return Value**

Color of the trend line.

**TrendLineColor (Set method)**

Set a color of a trend line for a curve.

```cpp
void TrendLineColor(
    const uint clr // trend line color
)
```

**Parameters**

- `clr`
  - [in] Line color
TrendLineVisible (Get method)

Get the trend line visibility flag.

```csharp
bool TrendLineVisible()
```

Return Value

A value of the flag that specifies if a trend line is visible.

TrendLineVisible (Set method)

Set the trend line visibility flag.

```csharp
void TrendLineVisible(
    const bool visible  // flag value
)
```

Parameters

visible

[in] A value of the trend line visibility flag.

Example:

Below is the code of the mentioned trend line and its plotting on the chart:
//+------------------------------------------------------------------+
//|                                             TrendLineGraphic.mq5 |

//+------------------------------------------------------------------+
//| Script program start function                                    |
//+------------------------------------------------------------------+
void OnStart()
{
    double x[]={12.0,11.5,11.0,12.0,10.5,10.0,9.0,8.5,10.0,8.5,10.0,8.0,9.5,10.0,15.0};
    double y[]={130.0,165.0,150.0,150.0,140.0,198.0,220.0,215.0,225.0,190.0,170.0,160.0};
    //--- create graphic
    CGraphic graphic;
    if (!graphic.Create(0,"TrendLineGraphic",0,30,30,780,380))
        graphic.Attach(0,"TrendLineGraphic");
    //--- create curve
    CCurve *curve=graphic.CurveAdd(x,y,CURVE_POINTS);
    //--- sets the curve properties
    curve.TrendLineVisible(true);
    curve.TrendLineColor(ColorToARGB(clrRed));
    //--- plot
    graphic.CurvePlotAll();
    graphic.Update();
}
Update

Update the curve coordinates.

The version for working by Y coordinate. Passed array indexes are used as X coordinates here.

```c
void Update(
    const double& y[], // Y coordinates
)
```

This version uses X and Y coordinates.

```c
void Update(
    const double& x[], // X coordinates
    const double& y[]   // Y coordinates
)
```

The version for working with CPoint2D points.

```c
void Update(
    const CPoint2D& points[] // Curve coordinates
)
```

The version for working with a pointer to the CurveFunction function.

```c
void Update(
    CurveFunction function, // pointer to the function describing a curve
    const double from,       // initial value of the function argument
    const double to,         // final value of the function argument
    const double step        // argument increment
)
```

Parameters

- `x[]` [in] X coordinates.
- `points[]` [in] Curve coordinates.
- `function` [in] A pointer to the function describing a curve
- `from` [in] Initial value of the function argument
- `to` [in] End value of the function argument
- `step` [in] Argument increment
Visible (Get method)

Get the flag defining if a function is visible on the chart.

```cpp
void Visible(
    const bool visible  //
)
```

Return Value

A value of the flag defining a function visibility on the chart.

Visible (Set method)

Set the flag defining if a function is visible on the chart.

```cpp
void Visible(
    const bool visible  // flag value
)
```

Parameters

visible

[in] A value of the flag defining a function visibility on the chart.
CGraphic

CGraphic is a base class for creating custom charts.

Description

The CGraphic class provides numerous aspects of working with custom charts.

The class stores the main chart elements, sets their parameters and performs plotting.

Also, the class stores the curves for the chart and provides various display options.

Declaration

```cpp
#include <Graphics\Graphic.mqh>

class CGraphic
```

Create

Creates a graphical resource bound to a chart object.

```cpp
bool Create(
    const long chart,    // chart ID
    const string name,   // name
    const int subwin,    // sub-window index
    const int x1,        // x1 coordinate
    const int y1,        // y1 coordinate
    const int x2,        // x2 coordinate
    const int y2)        // y1 coordinate
)
```

**Parameters**

*chart*

[in] Chart ID.

*name*

[in] Name.

$subwin$

[in] Sub-window index.

*x1*

[in] X1 coordinate.

*y1*

[in] Y1 coordinate.

*x2*

[in] X2 coordinate.

*y2*

[in] Y2 coordinate.
Destroy

Removes a chart and destroys a graphical resource.

```c
void Destroy()
```
Update

Displays implemented changes.

```cpp
void Update(
    const bool redraw=true  // flag
)
```

Parameters

- `redraw=true`
  
  [in] Flag value
**ChartObjectName**

Gets the name of an object bound to a chart.

```c
string ChartObjectName()
```

**Return Value**

Name of an object bound to a chart.
**ResourceName**

Receives the name of a graphical resource.

```c
string ResourceName()
```

Return Value

Name of a graphical resource.
**XAxis**

Returns the pointer to the X axis.

```
CAxis *XAxis()
```

**Return Value**

*Pointer to the X axis.*
YAxis

Returns the pointer to the Y axis.

C Axis * YAxis() 

Return Value

Pointer to the Y axis.
**GapSize (Get method)**

Returns the size of indents between the chart elements.

```c
int GapSize()
```

**Return Value**

Indent size in pixels.

**GapSize (Set method)**

Sets the size of indents between the chart elements.

```c
void GapSize(
    const int size  // indent size
)
```

**Parameters**

* size
  
  [in] Indent size in pixels.
BackgroundColor (Get method)

Returns the background color.

```cpp
color BackgroundColor()
```

BackgroundColor (Set method)

Sets the background color.

```cpp
void BackgroundColor(
    const color clr // background color
)
```

Parameters

- `clr`  
  [in] Background color.
BackgroundMain (Get method)

Returns a chart header

```cpp
string BackgroundMain()
```

BackgroundMain (Set method)

Sets a chart header text.

```cpp
void BackgroundMain(
    const string main  // header text
)
```

Parameters

- `main`
  
  `[in]` Chart header text
**BackgroundMainSize (Get method)**

Returns the header size.

```c
int BackgroundMainSize()
```

**Return Value**

Header font size.

**BackgroundMainSize (Set method)**

Sets the header size.

```c
void BackgroundMainSize(
    const int size  // header size
)
```

**Parameters**

- `size`
  - `[in]` Header font size.
BackgroundMainColor (Get method)

Returns the header color.

```c
color BackgroundMainColor()
```

Return Value

Header color.

BackgroundMainColor (Set method)

Sets the header color.

```c
void BackgroundMainColor(
    const color clr  // header color
)
```

Parameters

- `clr`
  
**BackgroundSub (Get method)**

Returns the sub-header.

```
string BackgroundSub()
```

**Return Value**

Sub-header text.

**BackgroundSub (Set method)**

Sets the sub-header text.

```
void BackgroundSub (Set method) {
    const string sub  // sub-header text
}
```

**Parameters**

`sub`

[in] Sub-header text.
**BackgroundSubSize (Get method)**

Returns the sub-header font size

```c
int BackgroundSubSize()
```

**BackgroundSubSize (Get method)**

Sets the sub-header size

```c
void BackgroundSubSize(
    const int size  // sub-header font size
)
```

**Parameters**

`size`

[in] Sub-header font size
BackgroundSubColor (Get method)

Returns the sub-header color.

```cpp
color BackgroundSubColor() { }
```

BackgroundSubColor (Set method)

Sets the sub-header color.

```cpp
void BackgroundSubColor(
    const color clr // sub-header color
)
```

Parameters

`clr`

[in] Sub-header color.
GridLineColor (Get method)

Returns the grid line color

```cpp
color GridLineColor()
```

Return Value

Grid line color.

GridLineColor (Set method)

Sets the grid line color.

```cpp
void GridLineColor(
    const color clr  // line color
)
```

Parameters

`clr`

GridBackgroundColor (Get method)

Returns the grid background color

```cpp
color GridBackgroundColor()
```

Return Value

Grid background color

GridBackgroundColor (Set method)

Sets the grid background color

```cpp
void GridBackgroundColor(
    const color clr          // grid background color
)
```

Parameters

- `clr`
  - [in] Grid background color
GridCircleRadius (Get method)

Returns radius of dots in the grid nodes.

```cpp
int GridCircleRadius()
```

Return Value

Dot radius in pixels.

GridCircleRadius (Set method)

Sets the dot radius in the grid nodes.

```cpp
void GridCircleRadius(const int r // radius
```

Parameters

r

[in] Dot radius in pixels.
GridCircleColor (Get method)

Returns color of dots in the grid nodes.

```cpp
  color GridCircleColor()
```

Return Value

Dot color.

GridCircleColor (Set method)

Sets the dot color in the grid nodes.

```cpp
  void   GridCircleColor(
    const color clr    // dot color
  )
```

Parameters

`clr`

[in] Dot color.
GridHasCircle (Get method)

Returns the flag defining whether the dots in the grid nodes should be displayed.

```c
bool GridHasCircle()
```

Return Value

The flag value.

Note

true — display the dots
false — do not display the dots

GridHasCircle (Set method)

Sets the flag defining whether the dots in the grid nodes should be displayed.

```c
void GridHasCircle(
    const bool has
)
```

Parameters

has

[in] Flag value.

Note

true — display the dots
false — do not display the dots
**GridAxisLineColor (Get method)**

Get the value of a real chart axes color.

```c
uint GridAxisLineColor()
```

**Return Value**

Color of real chart axes.

**GridAxisLineColor (Set method)**

Set the value of a real chart axes color.

```c
void GridAxisLineColor(
    const uint clr // chart axes color
)
```

**Parameters**

- `clr`
  - [in] Color of real chart axes.
**HistoryNameWidth (Get method)**

Returns the maximum allowed length for displaying a curve name.

```c
int HistoryNameWidth()
```

**Return Value**

Maximum length in pixels.

**Note**

If the curve name exceeds the maximum allowed length, it is truncated and dots are added to its end.

**HistoryNameWidth (Set method)**

Sets the maximum allowed length for displaying a curve name.

```c
void HistoryNameWidth(
    const int width  // maximum length
)
```

**Parameters**

`width`

**Note**

If the curve name exceeds the maximum allowed length, it is truncated and dots are added to its end.
**HistoryNameSize (Get method)**

Returns the font size of the curve name.

```c
int HistoryNameSize()
```

**Return Value**

Font size of the curve name.

**HistoryNameSize (Set method)**

Sets the font size of the curve name.

```c
void HistoryNameSize (Set method)
{
    const int size // name font size
}
```

**Parameters**

- `size`
  
  [in] Name font size.
**HistorySymbolSize (Get method)**

Returns a size of a chart's notational convention symbols

```c
int HistorySymbolSize()
```

**Return Value**

Size of notational convention symbols

**HistorySymbolSize (Set method)**

Sets a size of a chart's notational convention symbols

```c
void HistorySymbolSize(
    const int size // symbol size
)
```

**Parameters**

`size`

[in] Size of notational convention symbols.
TextAdd

Adds a text to a chart.

Version for working with X and Y coordinates

```cpp
void TextAdd(
    const int x,          // X coordinate
    const int y,          // Y coordinate
    const string text,    // text
    const uint clr,       // color
    const uint alignment=0 // alignment
)
```

Version for CPoint

```cpp
void TextAdd(
    const CPoint &point,    // point coordinate
    const string text,      // text
    const uint clr,         // color
    const uint alignment=0  // alignment
)
```

Parameters

- **x**
  - [in] X coordinate.

- **y**
  - [in] Y coordinate.

- **&point**
  - [in] Point coordinate.

- **text**
  - [in] Text.

- **clr**
  - [in] Color.

- **alignment=0**
LineAdd

Adds a line to a chart.

This version uses X and Y coordinates

```c
void LineAdd(
    const int x1, // x1 coordinate
    const int y1, // y1 coordinate
    const int x2, // x2 coordinate
    const int y2, // y2 coordinate
    const uint clr, // color
    const uint style // style
)
```

Version for CPoint

```c
void LineAdd2(
    const CPoint &point1, // first point coordinate
    const CPoint &point2, // second point coordinate
    const uint clr, // color
    const uint style // style
)
```

Parameters

- `x1`  
  [in] X1 coordinate.

- `y1`  
  [in] Y1 coordinate.

- `x2`  
  [in] X2 coordinate.

- `y2`  
  [in] Y2 coordinate.

- `&point1`  
  [in] First point coordinate.

- `&point2`  
  [in] Second point coordinate.

- `clr`  
  [in] Color.

- `style`  
  [in] Style.
**CurveAdd**

Create and add a new curve to the chart.

This version uses the Y coordinate (a curve color is set automatically)

```cpp
CCurve* CurveAdd{
    const double  y[],       // Y coordinates
    ENUM_CURVE_TYPE  type,  // curve type
    const string  name=NULL  // curve name
}
```

**Note**

Y array indices are used as X coordinates for the curve.

This version uses the X and Y coordinates (a curve color is set automatically)

```cpp
CCurve* CurveAdd(
    const double  x[],         // X coordinates
    const double  y[],         // Y coordinates
    ENUM_CURVE_TYPE  type,    // curve type
    const string  name=NULL   // curve name
}
```

The version for working with CPoint2D dots (curve color is set automatically)

```cpp
CCurve* CurveAdd(
    const CPoint2D  points[],    // dot coordinates
    ENUM_CURVE_TYPE  type,      // curve type
    const string  name=NULL      // curve name
}
```

Version for working with the pointer to the CurveFunction function (curve color is set automatically)

```cpp
CCurve* CurveAdd(
    CurveFunction  function,  // pointer to the function
    const double  from,       // initial value of the argument
    const double  to,         // final value of the argument
    const double  step,       // increment by the argument
    ENUM_CURVE_TYPE  type,    // curve type
    const string  name=NULL   // curve name
}
```
### Version for working by Y coordinate (a curve color is set by a user)

```cpp
CCurve* CurveAdd(
    const double& y[], // Y coordinates
    const uint clr, // curve color
    ENUM_CURVE_TYPE type, // curve type
    const string name=NULL // curve name
)
```

**Note**

Y array indices are used as X coordinates for the curve.

### This version uses the X and Y coordinates (a curve color is set by a user)

```cpp
CCurve* CurveAdd(
    const double& x[], // X coordinates
    const double& y[], // Y coordinates
    const uint clr, // curve color
    ENUM_CURVE_TYPE type, // curve type
    const string name=NULL // curve name
)
```

### The version for working with CPoint2D dots (curve color is set by a user)

```cpp
CCurve* CurveAdd(
    const CPoint2D& points[], // dot coordinates
    const uint clr, // curve color
    ENUM_CURVE_TYPE type, // curve type
    const string name=NULL // curve name
)
```

### Version for working with the pointer to the CurveFunction function (curve color is set by a user)

```cpp
CCurve* CurveAdd(
    CurveFunction function, // pointer to the function
    const double from, // initial value of the argument
    const double to, // final value of the argument
    const double step, // increment by the argument
    const uint clr, // curve color
    ENUM_CURVE_TYPE type, // curve type
    const string name=NULL // curve name
)
```
Parameters

\( \& x[] \)
  [in] X coordinate.

\( \& y[] \)
  [in] Y coordinate.

\( \& \text{points[]} \)
  [in] Coordinates of dots.

function
  [in] Pointer to the function.

from
  [in] Initial value of the argument.

to
  [in] Final value of the argument.

step
  [in] Increment by the argument.

type
  [in] Curve type.

name=NULL
  [in] Curve name.

clr
  [in] Curve color.

Return Value

Pointer to the created curve.
CurvePlot

Displays the previously created curve with a specified index.

```cpp
bool CurvePlot(
    const int index // index
)
```

**Parameters**

- `index`
  - [in] Curve index

**Return Value**

- `true` - successful, otherwise `false`.
CurvePlotAll

Displays all curves previously added to a chart.

bool CurvePlotAll()

Return Value

true - successful, otherwise - false.
CurvesTotal

Returns the number of curves added to the chart.

```cpp
int CurvesTotal()
```

Return Value

Number of curves.
CurveGetByIndex

Gets the curve by a specified index.

```cpp
CCurve* CurveGetByIndex(const int index) // curve index
```

Parameters

- `index`
  - [in] Curve index.

Return Value

- Pointer to the curve with a specified index.
CurveGetByName

Gets a curve by a specified name.

```cpp
CCurve* CurveGetByName(const string name) // curve name
```

**Parameters**

- **name**
  
  [in] Curve name.

**Return Value**

Pointer to the first found curve having a specified name.
CurveRemoveByIndex

Remove a curve by a specified index.

```cpp
bool CurveRemoveByIndex(
    const int index  // curve index
)
```

Parameters

index

[in] Index of the curve to be removed.

Return Value

true — successful, otherwise — false.
CurveRemoveByName

Remove a curve by a specified name.

```cpp
bool CurveRemoveByName(
    const string name // curve name
)
```

**Parameters**

- **name**
  
  [in] Name of the curve to be removed.

**Return Value**

- true — successful, otherwise — false.
CurvesTotal

Get the number of curves for the given chart.

```c
int CurvesTotal()
```

Return Value

Number of curves.

Note

All curves on the current chart are considered regardless of drawing and visibility style.
MarksToAxisAdd

Add a scale mark (ticks) to the specified chart axis.

```c
bool MarksToAxisAdd(
    const double &marks[], // tick coordinates
    const int mark_size,   // tick size
    ENUM_MARK_POSITION position, // tick location
    const int dimension=0   // dimension
)
```

**Parameters**

- `&marks[]`  
  [in] Tick coordinates

- `mark_size`  
  [in] Tick size

- `position`  
  [in] Tick location

- `dimension=0`  
  [in] 0 — adding to X axis,  
  1 — adding to Y axis

**Return Value**

- `true` - successful, otherwise - `false`.
**MajorMarkSize (Get method)**

Returns the size of the scale's ticks on the coordinate axes.

```c
int MajorMarkSize()
```

**MajorMarkSize (Set method)**

Returns the size of the scale's ticks on the coordinate axes.

```c
void MajorMarkSize(
    const int size  // tick size
)
```

**Parameters**

- `size`
  
FontSet

Sets the current font parameters.

```c
bool FontSet(
    const string name,    // name
    const int size,       // size
    const uint flags=0,   // flags
    const uint angle=0    // angle
)
```

**Parameters**

- **name**
  - [in] Name.

- **size**
  - [in] Size.

- **flags=0**

- **angle=0**

**Return Value**

- true - successful, otherwise - false.
FontGet

Gets the current font parameters.

```c
void FontGet(
    string &name,   // name
    int &size,     // size
    uint &flags,   // flags
    uint &angle   // angle
)
```

Parameters

- **&name**
  
  [out] Name.

- **&size**
  
  [out] Size.

- **&flags**
  
  [out] Flags.

- **&angle**
  
  [out] Angle.
Attach

The version for getting a graphical resource from the OBJ_BITMAP_LABEL object and binding it to the CGraphic class instance:

```cpp
bool Attach(
    const long chart_id,   // chart ID
    const string objname   // graphical object name
)
```

The version for creating a graphical resource for the OBJ_BITMAP_LABEL object and binding it to the CGraphic class instance:

```cpp
bool Attach(
    const long chart_id,   // chart ID
    const string objname,  // graphical object name
    const int width,       // image width
    const int height       // image height
)
```

Parameters

- `chart_id`  
  `[in]` Chart ID.

- `objname`  
  `[in]` Name of the graphical object.

- `width`  
  `[in]` Image width in the resource.

- `height`  
  `[in]` Image height in the resource.

Return Value

true — successful, false — failed to bind the object.
CalculateMaxMinValues

Calculate (re-calculate) minimum and maximum chart values on both axes.

```c
void CalculateMaxMinValues()
```
**Height**

Get a chart height in pixels.

```cpp
int Height()
```

**Return Value**

Chart height in pixels.
**IndentDown (Get method)**

Get a chart indent from the lower border.

```cpp
int IndentDown()
```

**Return Value**

Indent size in pixels.

**IndentDown (Set method)**

Set a chart indent from the lower border.

```cpp
void IndentDown(const int down = 0) // indent size
```

**Parameters**

*down*

[in] Indent size in pixels.
**IndentLeft (Get method)**

Get a chart indent from the left border.

```c
int IndentLeft()
```

**Return Value**

Indent size in pixels.

**IndentLeft (Set method)**

Set a chart indent from the left border.

```c
void IndentLeft(
    const int left  // indent size
)
```

**Parameters**

- `left`  
  [in] Indent size in pixels.
**IndentRight (Get method)**

Get a chart indent from the right border.

```cpp
int IndentRight()
```

**Return Value**

Indent size in pixels.

**IndentRight (Set method)**

Set a chart indent from the right border.

```cpp
void IndentRight(
    const int right  // indent size
)
```

**Parameters**

`right`

[in] Indent size in pixels.
**IndentUp (Get method)**

Get a chart indent from the upper border.

```c
int IndentUp()  
```

**Return Value**

Indent size in pixels.

**IndentUp (Set method)**

Set a chart indent from the upper border.

```c
void IndentUp(  
    const int up  // indent size  
)
```

**Parameters**

`up`

[in] Indent value in pixels.
**Redraw**

Redraw the chart.

```cpp
bool Redraw(
    const bool rescale=false  // flag value
)
```

**Parameters**

`rescale=false`

[in] The flag indicating if a chart should be re-scaled.

**Return Value**

true - successful, otherwise - false.
ResetParameters

Reset the chart redrawing parameters.

```c
void ResetParameters()
```
ScaleX

Scale the value by X axis.

```cpp
virtual int ScaleX(
    double x  // value by X axis
)
```

**Parameters**

x

[in] Real value by X axis.

**Return Value**

A value in pixels.

**Note**

Scale a real value to pixels for displaying on the chart.
**ScaleY**

Scale the value by Y axis.

```cpp
virtual int ScaleY(
    double y // value by Y axis
)
```

**Parameters**

`y`

[in] Real value by Y axis.

**Return Value**

A value in pixels.

**Note**

Scale a real value to pixels for displaying on the chart.
SetDefaultParameters

Set the chart parameters to default values.

```cpp
void SetDefaultParameters()
```
Width

Get the chart width in pixels.

```cpp
int Width()
```

Return Value

Chart width in pixels.
Technical Indicators and Timeseries

This section contains the technical details of the technical indicator and timeseries classes and description of the corresponding components of the standard MQL5 library.

The use of the technical indicator and timeseries classes will save time in developing applications (scripts, Expert Advisors).

The MQL5 Standard Library (in terms of technical indicators and timeseries) is located in the working directory of the terminal in the Include\Indicators folder.

CSpreadBuffer

CSpreadBuffer is a class for simplified access to spreads of the bars in the history.

Description

The CSpreadBuffer class provides a simplified access to spreads of the bars in the history.

Declaration

```cpp
class CSpreadBuffer: public CArrayInt
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CArrayInt
      - CSpreadBuffer

DeleteRange, CompareArray, CompareArray, InsertSort, Search, SearchGreat, SearchLess, SearchGreatOrEqual, SearchLessOrEqual, SearchFirst, SearchLast, SearchLinear
Size

Sets buffer size.

```cpp
void Size(
    const int size // size
)
```

**Parameters**

- `size`
SetSymbolPeriod

Sets symbol and period.

```cpp
void SetSymbolPeriod(
    const string symbol, // symbol
    const ENUM_TIMEFRAMES period // period
)
```

**Parameters**

- **symbol**
  

- **period**
  
At

Gets the buffer element.

```c
int At(
    const int index      // index
) const
```

Parameters

`index`

[in] Index of buffer element.

Return Value

Buffer element with the specified index.
Refresh

Updates the buffer.

```cpp
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.
**RefreshCurrent**

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

**Return Value**

- true - successful, false - cannot update the buffer.
CTimeBuffer

CTimeBuffer is a class for simplified access to opening times of the bars in the history.

Description

The CTimeBuffer class provides a simplified access to opening times of the bars in the history.

Declaration

```cpp
class CTimeBuffer: public CArrayLong
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CArrayLong
      - CTimeBuffer

Size

Sets buffer size.

```c
void Size(
    const int size    // size
)
```

Parameters

- `size`
SetSymbolPeriod

Sets symbol and period.

```c
void SetSymbolPeriod(
    const string symbol,  // symbol
    const ENUM_TIMEFRAMES period  // period
)
```

Parameters

**symbol**

**period**

At

Gets the buffer element.

```cpp
long At(
    const int index // index
) const
```

Parameters

- `index`  
  - [in] Index of buffer element.

Return Value

Buffer element with the specified index.
Refresh

Updates the buffer.

```cpp
virtual bool Refresh()
```

Return Value

- true - successful, false - cannot update the buffer.
**RefreshCurrent**

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

**Return Value**

- true - successful, false - cannot update the buffer.
CTickVolumeBuffer

CTickVolumeBuffer is a class for simplified access to tick volumes of bars in the history.

Description

The CTickVolumeBuffer class provides a simplified access to tick volumes of bars in the history.

Declaration

```cpp
class CTickVolumeBuffer: public CArrayLong
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CArrayLong
      - CTickVolumeBuffer

DeleteRange, CompareArray, CompareArray, InsertSort, Search, SearchGreat, SearchLess, SearchGreatOrEqual, SearchLessOrEqual, SearchFirst, SearchLast, SearchLinear
**Size**

Sets buffer size.

```c
void Size(
    const int size    // size
)
```

**Parameters**

- **size**
SetSymbolPeriod

Sets symbol and period.

```c
void SetSymbolPeriod(
    const string symbol,  // symbol
    const ENUM_TIMEFRAMES period  // period
)
```

**Parameters**

- **symbol**
  - [in] New symbol.

- **period**
At

Gets the buffer element.

```cpp
long At(
    const int index // index
) const
```

Parameters

- `index`
  - [in] Index of buffer element.

Return Value

- Buffer element with the specified index.
Refresh

Updates the buffer.

```cpp
virtual bool Refresh()
```

Return Value

- true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

Return Value

- true - successful, false - cannot update the buffer.
**CRealVolumeBuffer**

**Description**

`CTickVolumeBuffer` class provides a simplified access to real volumes of bars in the history.

**Declaration**

```cpp
class CRealVolumeBuffer: public CArrayLong
```

**Title**

```cpp
#include <Indicators\TimeSeries.mqh>
```

**Inheritance hierarchy**

Size

Sets buffer size.

```cpp
void Size(
    const int size        // size
)
```

Parameters

- `size`
**SetSymbolPeriod**

Sets symbol and period.

```c
void SetSymbolPeriod(
    const string    symbol,    // symbol
    const ENUM_TIMEFRAMES period   // period
)
```

**Parameters**

*symbol*

*period*

At

Gets the buffer element.

```cpp
long At(
    const int index  // index
) const
```

Parameters

- `index`  
  [in] Index of buffer element.

Return Value

Buffer element with the specified index.
Refresh

Updates the buffer.

```cpp
virtual bool Refresh()
```

Return Value

- true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

Return Value

- true - successful, false - cannot update the buffer.
**CDoubleBuffer**

CDoubleBuffer is a base class for simplified access to data buffers of double type.

**Description**

The CDoubleBuffer class provides a simplified access to the data of the buffer of double type.

**Declaration**

```c++
#include <Indicators\TimeSeries.mqh>

class CDoubleBuffer: public CArrayDouble
```

**Title**

Inheritance hierarchy

- **CObject**
- **CArray**
  - **CArrayDouble**
    - **CDoubleBuffer**

Size

Sets buffer size.

```c
void Size(
    const int size // size
)
```

Parameters

- `size`
SetSymbolPeriod

Sets symbol and period.

```cpp
void SetSymbolPeriod(
    const string symbol,  // symbol
    const ENUM_TIMEFRAMES period  // period
)
```

Parameters

symbol

period

At

Gets the buffer element.

```cpp
double At(
    const int index  // index
) const
```

Parameters

- `index` 
  
  [in] Index of buffer element.

Return Value

- Buffer element with the specified index.
Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

- true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

virtual bool RefreshCurrent()

Return Value

true - successful, false - cannot update the buffer.
COpenBuffer

COpenBuffer is a class for simplified access to open prices of bars in the history.

Description

COpenBuffer class provides a simplified access to open prices of bars in the history.

Declaration

class COpenBuffer: public CDoubleBuffer

#include <Indicators\TimeSeries.mqh>

Inheritance hierarchy

CObject
  CArray
    CArrayDouble
      CDoubleBuffer
        COpenBuffer

Methods inherited from class CDoubleBuffer

Size, At, SetSymbolPeriod
Refresh

Updates the buffer.

```cpp
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.
**CHighBuffer**

CHighBuffer is a class for simplified access to high prices of bars in the history.

**Description**

CHighBuffer class provides a simplified access to high prices of bars in the history.

**Declaration**

```cpp
class CHighBuffer: public CDoubleBuffer
```

**Title**

```cpp
#include <Indicators\TimeSeries.mqh>
```

**Inheritance hierarchy**

Refresh

Updates the buffer.

virtual bool Refresh()

Return Value

true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

Return Value

- true - successful, false - cannot update the buffer.
CLowBuffer

CLowBuffer is a class for simplified access to low prices of bars in the history.

Description

The CLowBuffer class provides a simplified access to low prices of bars in the history.

Declaration

```cpp
class CLowBuffer: public CDoubleBuffer
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

- Size, At, SetSymbolPeriod
Refresh

Updates the buffer.

```cpp
class Buffer {
public:
    virtual bool Refresh() = 0;
};
```

Return Value

- true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) element of the buffer.

```cpp
virtual bool RefreshCurrent()
```

Return Value

- true – successful, false – cannot update the buffer.
**CIndicatorBuffer**

CIndicatorBuffer is a class for simplified access to the data of the indicator's buffer.

**Description**

CIndicatorBuffer class provides the simplified access to the data buffer of technical indicator.

**Declaration**

```cpp
class CIndicatorBuffer: public CDoubleBuffer
```

**Title**

```cpp
#include <Indicators\Indicator.mqh>
```

**Inheritance hierarchy**

- **CObject**
  - **CArray**

Methods inherited from class CDoubleBuffer

- Size, At, SetSymbolPeriod
**Offset**

Gets offset of the buffer.

```c
int Offset() const
```

**Return Value**

Buffer offset.

**Offset**

Sets offset of the buffer.

```c
void Offset(
    const int offset // offset
);
```

**Parameters**

`offset`

Name

Gets the name of the buffer.

```cpp
string Name() const
```

Return Value

Name of the buffer.

Name

Sets the name of the buffer.

```cpp
void Name(
    const string name  // name
)
```

Parameters

name

[in] New name of the buffer.
At

Gets buffer element.

```cpp
double At(
    int index  // index
) const
```

Parameters

`index`

[in] Index of buffer element.

Return Value

Buffer element with the specified index.
Refresh

Updates the whole buffer.

```c
bool Refresh(
    const int handle,  // indicator handle
    const int num      // buffer number
);
```

Parameters

- **handle**
  - [in] Handle of the indicator.

- **num**
  - [in] Buffer index of the indicator.

Return Value

- true - successful, false - cannot update the buffer.
RefreshCurrent

Updates the current (zeroth) buffer element.

```cpp
bool RefreshCurrent(
    const int handle,  // handle of the indicator
    const int num      // buffer number
)
```

Parameters

- **handle**
  - [in] Handle of the indicator.

- **num**
  - [in] Indicator buffer number.

Return Value

- true - successful, false - cannot update the buffer.
CSeries

CSeries is a base class for an access to the timeseries data of the Standard Library.

Description

CSeries class provides the simplified access to all the MQL5 API general functions related to working with the series data for all its descendants (timeseries and indicator classes).

Declaration

```cpp
class CSeries: public CArrayObj
```

Title

```cpp
#include <Indicators\Series.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CArrayObj
      - CSeries

Direct descendants

- CIIndicator
  - CRealVolume
  - CISpread
  - CI TickVolume
  - CI Time
  - CPriceSeries

Data Access

- virtual BufferResize
  - Sets buffer size of timeseries or indicator

Data Update

- virtual Refresh
  - Update the data of timeseries or indicator
PeriodDescription | Transforms ENUM_TIMEFRAMES into a string

Methods inherited from class CObject
- Prev, Prev, Next, Next, Compare

Methods inherited from class CArray
- Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

Methods inherited from class CArrayObj
- FreeMode, FreeMode, Type, Save, Load, createElement, Reserve, Resize, Shutdown, Add, AddArray, Insert, InsertArray, AssignArray, At, Update, Shift, Detach, Delete, DeleteRange, Clear, CompareArray, InsertSort, Search, SearchGreat, SearchLess, SearchGreatOrEqual, SearchLessOrEqual, SearchFirst, SearchLast
Name

Gets the name of timeseries or indicator.

```
string Name() const
```

**Return Value**

The name of timeseries or indicator.
BuffersTotal

Gets the number of buffers of timeseries or indicator.

```cpp
int BuffersTotal() const
```

Return Value

The number of buffers of timeseries or indicator.

Note

The timeseries has only one buffer.
Timeframe

Gets the timeframe flag of timeseries or indicator.

```cpp
int Timeframe() const
```

Return Value

The timeframe flag of timeseries or indicator.

Note

It is generated as the object visibility flags.
Symbol

Gets the symbol of timeseries or indicator.

```cpp
string Symbol() const
```

Return Value

The symbol of timeseries or indicator.
Period

Gets the period of timeseries or indicator.

| ENUM_TIMEFRAMES | Period() const |

Return Value

The period (value of ENUM_TIMEFRAMES enumeration) of timeseries or indicator.
RefreshCurrent

Sets a flag to constantly update the current values of timeseries or indicator.

```csharp
string RefreshCurrent(
    const bool flag     // value
)
```

Parameters

*flag*

Return Value

None.
BufferSize

Returns the amount of data available in timeseries buffer or indicator buffer.

```c
int BufferSize() const
```

Return Value

*Amount of data available in timeseries buffer or indicator buffer.*
**BufferResize**

Sets buffer size of timeseries or indicator.

```cpp
virtual bool BufferResize(
    const int size // size
)
```

**Parameters**

- `size`
  - [in] New size of the buffers.

**Return Value**

- `true` - successful, otherwise - `false`.

**Note**

All the timeseries or indicator buffers have the same size.
Refresh

Updates the data of timeseries or indicator.

```cpp
virtual void Refresh(
    const int flags  // flags
)
```

Parameters

- `flags`
  
  [in] Timeframes to update (flag).
PeriodDescription

Gets the string representation of the specified ENUM TIMEFRAMES enumeration.

```c
string PeriodDescription(
    const int val=0       // value
)
```

**Parameters**

`val=0`

- [in] Value to convert.

**Return Value**

The string representation of the specified ENUM TIMEFRAMES enumeration.

**Note**

If the value is not specified or equal to zero, the timeframe of timeseries or indicator is transformed into a string.
# CPriceSeries

CPriceSeries is a base class for access to the price data.

## Description

CPriceSeries class provides the simplified access to MQL5 API general functions for working with price data to all its descendants.

## Declaration

```cpp
class CPriceSeries: public CSeries
```

## Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

## Inheritance hierarchy

- **CObject**
- **CArray**
  - **CArrayObj**
    - **CSeries**
      - **CPriceSeries**

## Direct descendants

- `CiClose`, `CiHigh`, `CiLow`, `CiOpen`

Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
**BufferResize**

Sets the series buffer size.

```cpp
virtual void BufferResize(  
    const int size   // size
)
```

**Parameters**

- `size`
  

**Return Value**

- `true` - successful, otherwise `false`.
**GetData**

Gets the specified series buffer element.

```cpp
double GetData(
    const int index       // index
) const
```

**Parameters**

`index`

[in] Index of a buffer element.

**Return Value**

The series buffer element, or `EMPTY_VALUE`. 
Refresh

Updates the timeseries data

```cpp
virtual void Refresh(
    const int flags=OBJ_ALL_PERIODS  // flags
)
```

Parameters

`flags=OBJ_ALL_PERIODS`

MinIndex

Gets the index of minimal value in the specified range.

```cpp
virtual int MinIndex(
    const int start,   // size
    const int count    // number
) const
```

**Parameters**

- **start**
  - [in] Search range initial index.

- **count**
  - [in] Search range size (number of elements).

**Return Value**

The index of minimal value of a series buffer in the specified range, or -1.
MinValue

Gets the minimal value in the specified range.

```cpp
virtual double MinValue(
    const int start,  // size
    const int count,  // number
    int& index       // reference
) const
```

Parameters

- **start**
  - [in] Search range initial index.

- **count**
  - [in] Search range size (number of elements).

- **index**
  - [out] Reference to the variable for placing the found element's index value.

Return Value

The minimal value of the series buffer in the specified range, or **EMPTY_VALUE**.

Note

The index of the found element is stored by index reference.
MaxIndex

Gets the index of maximal value in the specified range.

```cpp
virtual int MaxIndex(
    const int start,  // index
    const int count   // number
) const
```

**Parameters**

- `start`
  - [in] Search range initial index.

- `count`
  - [in] Search range size (number of elements).

**Return Value**

The index of the maximal value of the series buffer in the specified range, or -1.
MaxValue

Gets the maximal value in the specified range.

```cpp
virtual double MaxValue(
    const int start,  // size
    const int count,  // amount
    int& index        // reference
) const
```

Parameters

- `start`  
  [in] Search range initial index.

- `count`  
  [in] Search range size (number of elements).

- `index`  
  [out] Reference to the variable for placing the found element's index value.

Return Value

The maximal value of a series buffer in the specified range, or `EMPTY_VALUE`.

Note

The index of the found element is stored by index reference.
CIndicator

CIndicator is a base class for technical indicator classes of the MQL5 standard library.

Description

The CIndicator class provides the simplified access for all of its descendants to general MQL5 API technical indicator functions.

Declaration

```cpp
class CIndicator: public CSeries
```

Title

```
#include <Indicators\Indicator.mqh>
```

Inheritance hierarchy

- CObject
- CArray
  - CArrayObj
    - CSeries
      - CIndicator

Direct descendants

Finding Min/Max Values

**Minimum**
- Gets the index of minimal value in a specified range.

**MinValue**
- Gets the minimal value in a specified range.

**Maximum**
- Gets the index of maximal value in a specified range.

**MaxValue**
- Gets the maximal value in a specified range.

Conversion of Enumerations

**MethodDescription**
- Converts `ENUM_MA_METHOD` into a string

**PriceDescription**
- Converts `ENUM_APPLIED_PRICE` into a string

**VolumeDescription**
- Converts `ENUM_APPLIED_VOLUME` into a string

Working with chart

**AddToChart**
- Adds an indicator to the chart

**DeleteFromChart**
- Deletes an indicator from the chart

Methods inherited from class CObject

- Prev, Prev, Next, Next, Compare

Methods inherited from class CArray

- Step, Step, Total, Available, Max, IsSorted, SortMode, Clear, Sort

Methods inherited from class CArrayObj

- FreeMode, FreeMode, Type, Save, Load, CreateElement, Reserve, Resize, Shutdown, Add, AddArray, Insert, InsertArray, AssignArray, At, Update, Shift, Detach, Delete, DeleteRange, Clear, CompareArray, InsertSort, Search, SearchGreat, SearchLess, SearchGreatOrEqual, SearchLessOrEqual, SearchFirst, SearchLast

Methods inherited from class CSeries

- Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
Handle

Gets the indicator's handle.

```cpp
int Handle() const
```

Return Value

Handle of the indicator.
Status

Gets the status of the indicator.

```cpp
string Status() const
```

Return Value

The status of indicator creation.
FullRelease

Sets a flag to release the handle.

```cpp
void FullRelease(
    const bool flag=true // flag
)
```

Parameters

- **flag**
  
Create

Creates the indicator of the specified type with the specified parameters.

```cpp
bool Create(
    const string symbol, // symbol
    const ENUM_TIMEFRAMES period, // period
    const ENUM_INDICATOR type, // type
    const int num_params, // number of parameters
    const MqlParam& params[] // array of parameters
)
```

Parameters

- `symbol` [in] Indicator symbol.
- `period` [in] Indicator timeframe (ENUM_TIMEFRAMES enumeration).
- `type` [in] Indicator type (ENUM_INDICATOR enumeration).
- `num_params` [in] Number of indicator’s parameters.
- `params` [in] Reference to the parameters array for the indicator.

Return Value

- `true` - successful, `false` - cannot create the indicator.
BufferResize

Sets the sizes of the indicator buffers.

```cpp
virtual bool BufferResize(
    const int size  // size
)
```

Parameters

- `size`

Return Value

- `true` - successful, otherwise `false`.

Note

All the indicator buffers have the same size.
BarsCalculated

Returns the amount of calculated data for the indicator.

```cpp
int BarsCalculated() const;
```

Return Value

Returns the amount of calculated data in the indicator buffer, or -1 in the case of error (data is not calculated yet).
**GetData**

Gets the specified element of the specified buffer of the indicator. `Refresh()` should be called for working with recent data before using the method.

```cpp
double GetData(
    const int buffer_num,  // buffer number
    const int index        // index
) const
```

**Parameters**

- `buffer_num`  
  [in] Indicator buffer number.

- `index`  
  [in] Indicator buffer element index.

**Return Value**

- value - success, `EMPTY_VALUE` - cannot receive the data.

**GetData**

Gets the data from the indicator's buffer by starting position and number.

```cpp
int GetData(
    const int start_pos,   // position
    const int count,       // number
    const int buffer_num,  // buffer number
    double& buffer[]       // array
) const
```

**Parameters**

- `start_pos`  
  [in] Starting position of the indicator buffer.

- `count`  
  [in] Number of indicator buffer elements.

- `buffer_num`  
  [in] Number of the indicator buffer.

- `buffer`  
  [in] Reference to the array for storing data.

**Return Value**

- Number of the indicator values received from the specified indicator buffer - success, otherwise -1.

**GetData**

Gets the data from the indicator buffer by start time and number.
### GetData

```c
int GetData(
    const datetime start_time, // starting time
    const int count, // amount
    const int buffer_num, // buffer number
    double& buffer[] // array
) const
```

**Parameters**

- **start_time**
  - [in] Indicator buffer element starting time.

- **count**
  - [in] Number of indicator buffer elements.

- **buffer_num**
  - [in] Number of the indicator buffer.

- **buffer**
  - [in] Reference to the array for storing data.

**Return Value**

Number of the indicator values received from the specified buffer, otherwise -1.

### GetData

```c
int GetData(
    const datetime start_time, // start time
    const datetime stop_time, // end time
    const int buffer_num, // number of buffer
    double& buffer[] // array
) const
```

**Parameters**

- **start_time**
  - [in] Indicator buffer initial element time.

- **stop_time**
  - [in] Indicator buffer end element time.

- **buffer_num**
  - [in] Number of the indicator buffer.

- **buffer**
  - [in] Reference to the array for storing data.

**Return Value**

Number of the indicator values received from the specified buffer - success, otherwise -1.
Refresh

Updates the indicator data. It is recommended calling the method before using GetData().

```cpp
virtual void Refresh(
    int flags=OBJ_ALL_PERIODS  // flags
)
```

Parameters

- **flags=OBJ_ALL_PERIODS**
  - [in] Timeframe update flags.
Minimum

Returns the index of minimal element of the specified buffer in a specified range.

```int Minimum(
    const int buffer_num,  // buffer number
    const int start,      // starting index
    const int count       // number
) const```

**Parameters**

*buffer_num*

[in] Buffer number to search the value in.

*start*

[in] Search range initial index.

*count*

[in] Search range size (number of elements).

**Return Value**

Index of the minimal element of the specified buffer in a specified range.
MinValue

Returns the value of minimal element of the specified buffer in a specified range.

```cpp
double MinValue(
    const int buffer_num,  // buffer number
    const int start,       // starting index
    const int count,       // number
    int& index             // reference
) const
```

Parameters

- `buffer_num`
  - [in] Buffer number to search the value in.

- `start`
  - [in] Search range initial index.

- `count`
  - [in] Search range size (number of elements).

- `index`
  - [out] Reference to the variable for storing the found element index value.

Return Value

The value of the minimal element of the specified buffer in a specified range.

Note

The index of the found element is stored by index reference.
Maximum

Returns the index of maximal element of the specified buffer in a specified range.

```c
int Maximum(
    const int buffer_num,  // buffer number
    const int start,      // starting index
    const int count       // number
) const
```

Parameters

- `buffer_num`
  - [in] Buffer number to search the value in.
- `start`
  - [in] Search range initial index.
- `count`
  - [in] Search range size (number of elements).

Return Value

Index of the maximal element of the specified buffer in a specified range.
MaxValue

Returns the value of maximal element of the specified buffer in a specified range.

```cpp
double MaxValue(
    const int buffer_num,  // buffer number
    const int start,       // starting index
    const int count,       // number
    int& index             // reference
) const
```

Parameters

- `buffer_num` [in] Buffer number to search the value in.
- `start` [in] Search range initial index.
- `count` [in] Search range size (number of elements).
- `index` [out] Reference to the variable for storing the found element index value.

Return Value

The value of the maximal element of the specified buffer in a specified range.

Note

The index of maximal buffer element is stored by index reference.
MethodDescription

Converts `ENUM_MA_METHOD` enumeration value to a string.

```c
string MethodDescription(
    const int val  // value
) const
```

Parameters

`val`

[in] Conversion value.

Return Value

The string corresponding to `ENUM_MA_METHOD` enumeration value.
### PriceDescription

Converts `ENUM_APPLIED_PRICE` enumeration value to a string.

```cpp
string PriceDescription(
    const int val  // value
) const
```

**Parameters**

- `val`
  - [in] Conversion value.

**Return Value**

The string corresponding to `ENUM_APPLIED_PRICE` enumeration value.
**VolumeDescription**

Converts `ENUM_APPLIED_VOLUME` enumeration value to a string.

```c
string VolumeDescription(
    const int val  // value
) const
```

**Parameters**

`val`

[in] Conversion value.

**Return Value**

The string corresponding to `ENUM_APPLIED_VOLUME` enumeration value.
AddToChart

Adds the indicator to the chart.

```cpp
bool AddToChart(
    const long chart, // chart ID
    const int subwin  // subwindow index
)
```

**Parameters**

- `chart`  
  [in] Chart ID.

- `subwin`  
  [in] Chart subwindow index.

**Return Value**

- true - successful, false - cannot add the indicator to the chart.
DeleteFromChart

Deletes the indicator from the chart.

```cpp
bool DeleteFromChart(
    const long chart, // chart ID
    const int subwin  // subwindow index
)
```

Parameters

- `chart` [in] Chart ID.

Return Value

- `true` - successful, `false` - cannot remove the indicator from the chart.
**CIndicators**

The CIndicators is a class for collecting instances of timeseries and technical indicators classes.

**Description**

CIndicators class provides creation of the technical indicators class instances, their storage and management (data synchronization, handle and memory management).

**Declaration**

```cpp
class CIndicators: public CArrayObj
```

**Title**

```
#include <Indicators\Indicators.mqh>
```

**Class Methods by Groups**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create</td>
<td>Creates an indicator</td>
</tr>
<tr>
<td>Data Update</td>
<td>Updates indicator data</td>
</tr>
</tbody>
</table>
Create

Creates the indicator of the specified type with the specified parameters.

```c
CIndicator* Create(
    const string symbol, // symbol name
    const ENUM_TIMEFRAMES period, // period
    const ENUM_INDICATOR type, // type
    const int count, // number of parameters
    const MqlParam& params // parameters array
)
```

Parameters

- `symbol`  
  [in] Indicator symbol name.

- `period`  
  [in] Indicator timeframe (ENUM_TIMEFRAMES enumeration value).

- `type`  
  [in] Indicator type (ENUM_INDICATOR enumeration value).

- `count`  
  [in] Number of parameters for the indicator.

- `params`  
  [in] Reference to the parameters array for the indicator.

Return Value

Reference to the created indicator - successful, NULL - cannot create the indicator.
Refresh

Updates data for all timeseries and technical indicators in the collection.

```cpp
int Refresh()
```

Return Value

Updated timeframe flags (formed as object visibility flags).
# Timeseries classes

This group of chapters contains technical details of timeseries classes of the MQL5 Standard Library and descriptions of all its key components.

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CiSpread</td>
<td>Provides an access to spread historical data</td>

</tbody>
</table>
CiSpread

CiSpread is a class designed for access to spreads of the bars in the history.

Description

CiSpread class provides an access to spread historical data.

Declaration

```cpp
class CiSpread : public CSeries
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

- **CObject**
- **CArray**
- **CArrayObj**
  - **CSeries**
  - **CiSpread**

</tbody>
</table>
Methods inherited from class CSeries

Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
Create

Creates a timeseries with the specified parameters for access to the spreads history.

```csharp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period  // period
)
```

Parameters

symbol

period

Return Value

true - successful, false - cannot create the timeseries.
### BufferResize

Sets size of the buffer series.

```cpp
virtual void BufferResize(
    int size              // size
)
```

#### Parameters

- **size**
  
**GetData**

Gets the specified element of timeseries buffer.

```c
int GetData(
    int index // index
) const
```

**Parameters**

- `index`
  - [in] Index of the buffer element.

**Return Value**

The timeseries buffer element, or 0.

**GetData**

Gets the element of timeseries by starting position and number of elements.

```c
int GetData(
    int start_pos, // position
    int count, // number
    int& buffer // array
) const
```

**Parameters**

- `start_pos`
  - [in] Starting position of a timeseries buffer.
- `count`
  - [in] Number of timeseries buffer elements.
- `buffer`
  - [in] Reference to the array for storing the data.

**Return Value**

`>=0` - successful, `-1` - cannot receive the data.

**GetData**

Gets data from a timeseries buffer by initial time and number.

```c
int GetData(
    datetime start_time, // starting time
    int count, // number
    int& buffer // array
) const
```

**Parameters**

- `start_time`
**GetData**

Gets the data from a timeseries buffer by start and stop times.

```c
int GetData(
    datetime start_time,  // starting time
    datetime stop_time,   // stop time
    int* buffer            // array
) const
```

**Parameters**

- **start_time**
  
  [in] Starting time of a timeseries buffer element.

- **stop_time**
  
  [in] Stop time of a timeseries buffer element.

- **buffer**
  
  [in] Reference to the array for storing data.

**Return Value**

- $\geq 0$ - successful, $-1$ - cannot receive the data.
Refresh

Updates the data of timeseries.

```cpp
virtual void Refresh(
    int flags  // flags
);
```

Parameters

`flags`

CiTime

CiTime is a class designed for access to open times of the bars in the history.

Description

CiTime class provides an access to open times of the bars in the history.

Declaration

```cpp
class CiTime: public CSeries
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

```
CObject
   CArray
      CArrayObj
         CSeries
            CiTime
```

```
Methods inherited from class CSeries

Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
Create

Creates a timeseries with the specified parameters for access to the opening times of the bars in the history.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period  // period
)
```

Parameters

- **symbol**
  

- **period**
  

Return Value

true - successful, false - cannot create timeseries.
BufferResize

Sets series buffer sizes.

```cpp
virtual void BufferResize(
    int size     // size
)
```

Parameters

- `size`
  
**GetData**

Gets the specified element of a timeseries buffer.

```c
datetime GetData(
    int index // index
) const
```

**Parameters**

`index`

[in] Index of the buffer element.

**Return Value**

The timeseries buffer element, or 0.

**GetData**

Gets the data from a timeseries buffer by starting position and number.

```c
int GetData(
    int start_pos, // position
    int count, // number
    long& buffer // array
) const
```

**Parameters**

`start_pos`

[in] Starting position of timeseries.

`count`

[in] Number of timeseries buffer elements.

`buffer`

[in] Reference to the array for storing data.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

**GetData**

Gets the data from timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time, // starting time
    int count, // number
    long& buffer // array
) const
```

**Parameters**

`start_time`
**GetData**

Gets the data from a timeseries buffer by starting and stop times.

```mql
int GetData(
    datetime start_time, // starting time
    datetime stop_time,  // stop time
    long& buffer         // array
) const
```

**Parameters**

- **start_time**

- **stop_time**

- **buffer**
  - [in] Reference to the array for storing data.

**Return Value**

>=0 - successful, -1 - cannot receive data.
Refresh

Updates the data of timeseries.

```cpp
virtual void Refresh(
    int flags  // flags
)
```

Parameters

flags

CiTickVolume

CiTickVolume is a class designed for access to tick volumes of the bars in the history.

Description

CiTickVolume class provides an access to tick volumes of the bars in the history.

Declaration

```cpp
class CiTickVolume: public CSeries
```

Title

```cpp
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

© 2000-2019, MetaQuotes Software Corp.
Methods inherited from class CSeries

Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
Create

Creates a timeseries with the specified parameters for access to the tick volumes of the bars in the history.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period // period
)
```

Parameters

- `symbol`
  - [in] Timeseries symbol.

- `period`

Return Value

- `true` - successful, `false` - cannot create a timeseries.
BufferResize

Sets size of the series buffer.

```cpp
virtual void BufferResize(int size) // size
```

Parameters

- `size`
**GetData**

Gets the specified timeseries buffer element.

```cpp
long GetData(
    int index       // index
) const
```

**Parameters**

*index*

[in] Index of the buffer element.

**Return Value**

The timeseries buffer element, or 0.

**GetData**

Gets the data from the timeseries buffer by starting position and number.

```cpp
int GetData(
    int start_pos,     // position
    int count,         // number
    long& buffer       // array
) const
```

**Parameters**

*start_pos*

[in] Starting position of a timeseries buffer.

*count*

[in] Number of timeseries buffer elements.

*buffer*

[in] Reference to the array for storing the data.

**Return Value**

>=0 - successful, -1 - cannot receive data.

**GetData**

Gets the data from a timeseries buffer by starting time and number.

```cpp
int GetData(
    datetime start_time,   // starting time
    int count,             // number
    long& buffer           // array
) const
```

**Parameters**

*start_time*
GetData

Gets the data from a timeseries buffer by starting and stop times.

```c
int GetData(
    datetime start_time,   // starting time
    datetime stop_time,    // stop time
    long& buffer           // array
) const
```

**Parameters**

- `start_time`
  - [in] Time of the timeseries buffer initial element.
- `stop_time`
  - [in] Time of the timeseries buffer end element.
- `buffer`
  - [in] Reference to the array for storing data

**Return Value**

- `>=0` - successful, `-1` - cannot receive data.
Refresh

Updates the data of timeseries.

```cpp
virtual void Refresh(
    int flags       // flags
)
```

**Parameters**

`flags`

CiRealVolume

CiRealVolume is a class designed for access to real volumes of the bars in the history.

Description

CiRealVolume class provides an access to real volumes of the bars in the history.

Declaration

```
class CiRealVolume: public CSeries
```

Title

```#include <Indicators\TimeSeries.mqh>```

Inheritance hierarchy

- **CObject**
  - **CArray**
    - **CArrayObj**

Methods inherited from class CSeries

Name, BuffersTotal, BufferSize, Timeframe, Symbol, Period, PeriodDescription, RefreshCurrent
Create

Creates a timeseries with the specified parameters for access to the real volumes of the bars in the history.

```csharp
bool Create(
    string symbol,   // symbol
    ENUM_TIMEFRAMES period  // period
)
```

Parameters

- `symbol`:
  - [in] Timeseries symbol.

- `period`:

Return Value

- true - successful, false - cannot create a timeseries.
**BufferResize**

Sets a series buffer size.

```cpp
virtual void BufferResize(
    int size      // size
)
```

**Parameters**

- `size`
**GetData**

Gets the specified series buffer element.

```c
datetime GetData(
    int index  // index
) const
```

**Parameters**

- `index`
  - [in] Buffer element index.

**Return Value**

Series buffer element, or 0.

**GetData**

Gets the data from timeseries buffer by starting position and number.

```c
int GetData(
    int start_pos,  // position
    int count,      // number
    long& buffer    // array
) const
```

**Parameters**

- `start_pos`
  - [in] Starting position of timeseries buffer.

- `count`
  - [in] Number of timeseries buffer elements.

- `buffer`
  - [in] Reference to the data storage array.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

**GetData**

Gets the data from timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time,  // starting time
    int count,            // number
    long& buffer          // array
) const
```

**Parameters**

- `start_time`
**GetData**

Gets the element of timeseries by starting and stop times.

```cpp
int GetData(
    datetime start_time,  // starting time
    datetime stop_time,   // stop time
    long& buffer          // target array
) const
```

**Parameters**

- **start_time**
  - [in] Starting time.

- **stop_time**
  - [in] Stop time.

- **buffer**
  - [in] Reference to the target array for data

**Return Value**

- `>=0` if successful, `-1` in the case of error.
Refresh

Updates the data of timeseries.

```cpp
virtual void Refresh(
    int flags  // flags
)
```

**Parameters**

*flags*

CiOpen

CiOpen is a class designed for access to open prices of the bars in the history.

Description

CiOpen class provides an access to open prices of the bars in the history.

Declaration

Create

Creates a timeseries with the specified parameters for access to the open prices of the bars in the history.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period // period
)
```

Parameters

- **symbol**
  - [in] Timeseries symbol.
- **period**
  - [in] Timeseries timeframe ([ENUM_TIMEFRAMES](ENUM_TIMEFRAMES) enumeration value).

Return Value

- true - successful, false - cannot create a timeseries.
**GetData**

Gets the element of timeseries by starting position and number.

```c
int GetData(
    int start_pos, // starting position
    int count, // number
    double& buffer // array
) const
```

**Parameters**

- **start_pos**
  - [in] Starting position of timeseries buffer.

- **count**
  - [in] Number of timeseries buffer elements.

- **buffer**
  - [in] Reference to the data storage array.

**Return Value**

- \[\geq0\] successful, \[-1\] - cannot receive data.

**GetData**

Gets data from the timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time, // starting time
    int count, // number
    double& buffer // array
) const
```

**Parameters**

- **start_time**

- **count**
  - [in] Number of timeseries buffer elements.

- **buffer**
  - [in] Reference to the data storage array.

**Return Value**

- \[\geq0\] successful, \[-1\] - cannot receive data.

**GetData**

Gets the data from the timeseries buffer by starting and stop times.
int GetData(
    datetime start_time, // starting time
    datetime stop_time,   // stop time
    double& buffer        // array
) const

Parameters

start_time

stop_time

buffer
    [in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.
CiHigh

CiHigh is a class designed for access to high prices of the bars in the history.

Description

CiHigh class provides an access to high prices of the bars in the history.

Declaration

Create

Creates a timeseries with the specified parameters for access to the high prices of the bars in the history.

```cpp
bool Create(
    string symbol,    // symbol
    ENUM_TIMEFRAMES period    // period
)
```

Parameters

- **symbol**
  - [in] Timeseries symbol.

- **period**

Return Value

- true - successful, false - cannot create a timeseries.
**GetData**

Gets data from the timeseries buffer by starting position and number.

```c
int GetData(
    int start_pos, // position
    int count,     // number
    double& buffer // array
) const
```

**Parameters**

- `start_pos` - [in] Starting position of a timeseries buffer.
- `count` - [in] Number of timeseries buffer elements.
- `buffer` - [in] Reference to the data storage array.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

**GetData**

Gets data from the timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time, // starting time
    int count,           // number
    double& buffer       // array
) const
```

**Parameters**

- `count` - [in] Number of timeseries buffer elements.
- `buffer` - [in] Reference to the data storage array.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

**GetData**

Gets data from the timeseries buffer by starting and stop times.
### Standard Library

```c
int GetData(
    datetime start_time,  // starting time
    datetime stop_time,   // stop time
    double& buffer        // array
) const
```

**Parameters**

- **start_time**

- **stop_time**

- **buffer**
  - [in] Reference to the data storage array.

**Return Value**

- >=0 - successful, -1 - cannot receive data.
CiLow

CiLow is a class designed for access to low prices of the bars in the history.

Description

CiLow class provides an access to low prices of the bars in the history.

Declaration

```cpp

Create

Creates a timeseries with the specified parameters for access to the low prices of the bars in the history.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period  // period
)
```

Parameters

symbol

period

Return Value

true - successful, false - cannot create the timeseries.
**GetData**

Gets the element of timeseries by starting position and number of elements.

```c
int GetData(
    int start_pos, // position
    int count,     // number
    double* buffer  // array
) const
```

**Parameters**

- **start_pos**
  - [in] Starting position of a timeseries buffer.
- **count**
  - [in] Number of timeseries buffer elements.
- **buffer**
  - [in] Reference to the data storage array.

**Return Value**

- >=0 · successful, -1 · cannot receive data.

**GetData**

Gets the data from a timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time, // starting time
    int count,           // number
    double* buffer       // array
) const
```

**Parameters**

- **start_time**
- **count**
  - [in] Number of timeseries buffer elements.
- **buffer**
  - [in] Reference to the data storage array.

**Return Value**

- >=0 · successful, -1 · cannot receive data.

**GetData**

Gets data from the timeseries buffer by starting and stop times.
int GetData(
    datetime start_time,     // starting time
    datetime stop_time,      // stop time
    double& buffer          // array
) const

Parameters

start_time

stop_time

buffer

[in] Reference to the data storage array

Return Value

>=0 - successful, -1 - cannot receive data.
CiClose is a class designed for access to close prices of the bars in the history.

**Description**

CiClose class provides an access to close prices of the bars in the history.

**Declaration**

Create

Creates a timeseries with the specified parameters for access to the closing prices of the bars in the history.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period // period
)
```

Parameters

symbol

period

Return Value

true - successful, false - cannot create the timeseries.
GetData

Gets data from a timeseries buffer by starting position and number.

```c
int GetData(
    int start_pos,       // position
    int count,           // number
    double* buffer       // array
) const
```

**Parameters**

- `start_pos`
  - [in] Starting position of a timeseries buffer.
- `count`
  - [in] Number of timeseries buffer elements.
- `buffer`
  - [in] Reference to the data storage array.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

GetData

Gets data from a timeseries buffer by starting time and number.

```c
int GetData(
    datetime start_time,  // starting time
    int count,            // number
    double* buffer        // array

```

**Parameters**

- `start_time`
- `count`
  - [in] Number of a timeseries buffer element.
- `buffer`
  - [in] Reference to the data storage array.

**Return Value**

`>=0` - successful, `-1` - cannot receive data.

GetData

Gets data from a timeseries buffer by starting and stop times.
```c
int GetData(
    datetime start_time, // starting time
    datetime stop_time,   // stop time
    double& buffer        // array
) const
```

**Parameters**

- `start_time`
  

- `stop_time`
  

- `buffer`
  
  [in] Reference to the data storage array.

**Return Value**

- `>=0` - successful, `-1` - cannot receive data.
Main and Auxiliary Classes of Technical Indicators and Timeseries

This group of chapters contains technical details of the main and auxiliary classes of technical indicators and timeseries, as well as descriptions of the appropriate components of the MQL5 Standard Library.

MaPeriod

Returns the averaging period.

```c
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period   // averaging period
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element of the main line by the specified index.

```cpp
double Main(
    int index    // index
)
```

Parameters

- **index**
  - [in] Main line buffer element index.

Return Value

- Main line buffer element by the specified index, or \texttt{EMPTY\_VALUE} if there is no correct data.
Returns the buffer element of the +DI line by the specified index.

```c
double Plus(
    int index   // index
)
```

**Parameters**

*index*

[in] +DI line buffer element index.

**Return Value**

The buffer element of the +DI line by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Minus**

Returns the buffer element of the -DI line by the specified index.

```c
double Minus(
    int index  // index
)
```

**Parameters**

- `index`  
  [in]  -DI line buffer element index.

**Return Value**

The buffer element of the -DI line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_ADX for CiADX).
CiADXWilder

CiADXWilder is a class intended for using the technical indicator Average Directional Index by Welles Wilder.

Description

CiADXWilder class provides the creation, configuration, and access to the data of the Average Directional Index by Welles Wilder.

Declaration

```cpp
class CiADXWilder: public CIndicator
```

Title

```cpp
#include <Indicators/Trend.mqh>
```

Inheritance hierarchy

```
CObject
  CArray
    CArrayObj

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period  // averaging period
)
```

Parameters

- `symbol`
  - [in] Symbol.

- `period`

- `ma_period`

Return Value

- `true` - successful, `false` - cannot create the indicator.
Main

Returns the buffer element of the main line by the specified index.

```cpp
double Main(
    int  index  // index
)
```

Parameters

index

[in] Main line buffer element index.

Return Value

Main line buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Plus

Returns the buffer element of the +DI line by the specified index.

```c
double Plus(
    int index // index
)
```

**Parameters**

*index*

- [in] +DI line buffer element index.

**Return Value**

The buffer element of the +DI line by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Minus**

Returns the buffer element of the -DI line by the specified index.

```c
double Minus(
    int index  // index
);
```

**Parameters**

- `index`  
  [in] -DI line buffer element index.

**Return Value**

The buffer element of the -DI line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type (IND_ADWX for CiADXWilder).
CiBands

CiBands is a class intended for using the Bollinger Bands® technical indicator.

Description

CiBands class provides the creation, configuration, and access to the data of the Bollinger Bands indicator.

Declaration

```
class CiBands: public CIndicator
```

Title

```
# include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
MaShift

Returns the horizontal shift.

```c
int MaShift() const
```

**Return Value**

Returns the horizontal shift value, defined at the indicator creation.
Deviation

Returns the deviation.

```cpp
double Deviation() const
```

Return Value

Returns the deviation, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    int ma_period, // averaging period
    int ma_shift, // shift
    double deviation, // deviation
    int applied // applied price, handle
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **ma_shift**
  - [in] Horizontal shift of the indicator.

- **deviation**
  - [in] Deviation.

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Base

Returns the buffer element of the base line by the specified index.

```c
double Base(
    int index    // index
)
```

Parameters

index

[in]  Base line buffer element index.

Return Value

The buffer element of the base line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Upper

Returns the buffer element of the upper line by the specified index.

```c
double Upper(
    int index  // index
)
```

**Parameters**

- `index`
  - [in] Upper line buffer element index.

**Return Value**

The buffer element of the upper line of the specified index, or `EMPTY_VALUE` if there is no correct data.
Lower

Returns the buffer element of the lower line by the specified index.

```cpp
double Lower(
    int index // index
)
```

**Parameters**

*index*

[in] Lower line buffer element index.

**Return Value**

The buffer element of the lower line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_BANDS for CiBands).
CiEnvelopes

CiEnvelopes is a class intended for using the Envelopes technical indicator.

Description

CiEnvelopes class provides the creation, configuration, and access to the data of the Envelopes indicator.

Declaration

```cpp
class CiEnvelopes: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiEnvelopes

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
MaShift

Returns the horizontal shift of the indicator.

`int MaShift() const`

Return Value

Returns the horizontal shift value, defined at the indicator creation.
**MaMethod**

Returns the averaging method.

```c
const ENUM_MA_METHOD MaMethod()
```

**Return Value**

Returns the averaging method, defined at the indicator creation (enum `ENUM_MA_METHOD` enumeration value).
Deviation

Returns the value of deviation.

```c
double Deviation() const
```

Return Value

Returns the value of deviation, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

*Price type or handle to apply, defined at the indicator creation.*
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```csharp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    int ma_period, // averaging period
    int ma_shift, // shift
    ENUM_MA_METHOD ma_method, // averaging method
    int applied, // price type, handle
    double deviation // deviation
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**
  - [in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

- **ma_period**

- **ma_shift**
  - [in] Price axis shift.

- **ma_method**

- **applied**
  - [in] Object (price type or handle) to apply.

- **deviation**
  - [in] Deviation.

Return Value

- true - successful, false - cannot create the indicator.
Upper

Returns the buffer element of the upper line by the specified index.

def Upper(index)
    int index // index

Parameters
index
    [in] Upper line buffer element index.

Return Value
The buffer element of the upper line by the specified index, or EMPTY_VALUE if there is no correct data.
Lower

Returns the buffer element of the lower line by the specified index.

```c
double Lower(
    int index  // index
)
```

Parameters

- `index`
  - [in] Lower line buffer element index.

Return Value

The buffer element of the lower line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_ENVELOPES for CiEnvelopes).
CiIchimoku

CiIchimoku is a class intended for using the Ichimoku Kinko Hyo technical indicator.

Description

CiIchimoku class provides the creation, setup, and access to the data of the Ichimoku Kinko Hyo indicator.

Declaration

```cpp
class CiIchimoku: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

TenkanSenPeriod

Returns the TenkanSen period.

```cpp
int TenkanSenPeriod() const
```

Return Value

Returns the TenkanSen period, defined at the indicator creation.
KijunSenPeriod

Returns the KijunSen period.

```cpp
int KijunSenPeriod() const
```

Return Value

Returns the KijunSen period, defined at the indicator creation.
SensorSpanBPeriod

Returns the SensorSpanB period.

```cpp
int SensorSpanBPeriod() const
```

Return Value

Returns the SensorSpanB period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```mql5
bool Create(
    string symbol,       // symbol
    ENUM_TIMEFRAMES period,  // period
    int tenkan_sen,      // period of TenkanSen
    int kijun_sen,       // period of KijunSen
    int senkou_span_b    // period of SenkouSpanB
)
```

**Parameters**

- **symbol**
  

- **period**
  

- **tenkan_sen**
  
  [in] Period of TenkanSen.

- **kijun_sen**
  

- **senkou_span_b**
  
  [in] Period of SenkouSpanB.

**Return Value**

- true - successful, false - cannot create the indicator.
TenkanSen

Returns the buffer element of the TenkanSen line by the specified index.

```c
double TenkanSen(  
    int index // index
)
```

**Parameters**

index

**Return Value**

The buffer element of the TenkanSen line by the specified index, or `EMPTY_VALUE` if there is no correct data.
KijunSen

Returns the buffer element of the KijunSen line by the specified index.

```c
double KijunSen(
    int index  // index
)
```

**Parameters**

*index*

**Return Value**

The buffer element of the KijunSen line of the specified index, or `EMPTY VALUE` if there is no correct data.
SenkouSpanA

Returns the buffer element of the SenkouSpanA line by the specified index.

```cpp
double SenkouSpanA(
    int index    // index
)
```

**Parameters**

- `index`
  - `[in]` SenkouSpanA line buffer element index.

**Return Value**

- The buffer element of the SenkouSpanA line of the specified index, or `EMPTY_VALUE` if there is no correct data.
SenkouSpanB

Returns the buffer element of the SenkouSpanB line by the specified index.

```c
double SenkouSpanB(
    int index    // index
)
```

**Parameters**

`index`

[in] SenkouSpanB line buffer element index.

**Return Value**

The buffer element of the SenkouSpanB line of the specified index, or `EMPTY_VALUE` if there is no correct data.
ChinkouSpan

Returns the buffer element of the ChinkouSpan line by the specified index.

```cpp
double ChinkouSpan(int index) // index
```

**Parameters**

`index`

[in] ChinkouSpan line buffer element index.

**Return Value**

The buffer element of the ChinkouSpan line of the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_ICHIMOKU for Ichimoku).
CiMA

CiMA is a class intended for using the Moving Average technical indicator.

Description

CiMA class provides the creation, setup, and access to the data of the Moving Average indicator.

Declaration

```cpp
class CiMA: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
MaShift

Returns the horizontal shift of the indicator.

```cpp
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.
MaMethod

Returns the averaging method.

| ENUM_MA_METHOD | MaMethod() const |

Return Value

Returns the averaging method (value of ENUM_MA_METHOD enumeration), defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

*Price type or handle to apply, defined at the indicator creation.*
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES timeframe, // period
    int ma_period, // averaging period
    int ma_shift, // shift
    ENUM_MA_METHOD ma_method, // averaging method
    int applied // price type, handle
)
```

**Parameters**

- `applied` [in] Price type or handle to apply.

**Return Value**

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(  
    int index  // index  
)
```

Parameters

index

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (`IND_MA` for CiMA).
CiSAR

CiSAR is a class intended for using the Parabolic Stop And Reverse System technical indicator.

Description

CiSAR class provides the creation, setup, and access to the data of the Parabolic Stop And Reverse System indicator.

SarStep

Returns the step of price increment.

\[
\text{double \ } \text{SarStep()} \ \text{const}
\]

Return Value

The step of price increment, defined at the indicator creation.
Maximum

Returns the maximum value of the step.

def double Maximum() const

Return Value

The maximum value of the step, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```mql
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    double step, // step
    double maximum // coefficient
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **step**
  - [in] Step for the velocity increasing.

- **maximum**
  - [in] Price following coefficient.

Return Value

true - successful, false - cannot change the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

- `index`
  - [in] Buffer element index.

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (\texttt{IND\_SAR} for CiSAR).
CiStdDev

CiStdDev is a class intended for using the Standard Deviation technical indicator.

Description

CiStdDev class provides the creation, setup, and access to the data of the Standard Deviation indicator.

Declaration

```cpp
class CiStdDev: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

CObject
  CArray
    CArrayObj
      CSeries
        CIndicator
          CiStdDev
```

**MaPeriod**

Returns the averaging period.

```cpp
int MaPeriod() const
```

**Return Value**

Returns the averaging period, defined at the indicator creation.
MaShift

Returns the horizontal shift of the indicator.

```c
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.
MaMethod

Returns the averaging method.

| ENUM_MAMETHOD | MaMethod() const |

**Return Value**

Returns the averaging method (value of `ENUM_MAMETHOD` enumeration), defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```c++
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,  // averaging period
    int ma_shift,  // shift
    ENUM_MA_METHOD ma_method,  // averaging method
    int applied  // price type, handle
)
```

Parameters

symbol

period

ma_period

ma_shift

[in] Horizontal shift.

ma_method

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

def double Main(
    int index       // index
)

Parameters

index

Return Value

Buffer element by the specified index if successful, or EMPTY_VALUE if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (IND_STDDEV for CiStdDev).
CiDEMA

CiDEMA is a class intended for using the Double Exponential Moving Average technical indicator.

Description

CiDEMA class provides the creation, setup, and access to the data of the Double Exponential Moving Average indicator.

Declaration

```cpp
class CiDEMA: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

int MaPeriod() const

Return Value

Returns the averaging period, defined at the indicator creation.
**IndShift**

Returns the horizontal shift of the indicator.

```cpp
int IndShift() const
```

**Return Value**

Returns the horizontal shift value, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string string,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,  // averaging period
    int ind_shift,  // shift
    int applied // price type, handle
)
```

Parameters

- **string**
  - [in] Symbol.

- **period**

- **ma_period**

- **ind_shift**
  - [in] Horizontal shift.

- **applied**
  - [in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

Return Value

- Buffer element of the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_DEMA` for CiDEMA).
CiTEMA

CiTEMA is a class intended for using the Triple Exponential Moving Average technical indicator.

Description

CiTEMA class provides the creation, setup, and access to the data of the Triple Exponential Moving Average indicator.

Declaration

```cpp
class CiTEMA: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
IndShift

Returns the horizontal shift of the indicator.

```cpp
int IndShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```mql5
def Create(
    string symbol,      // symbol
    ENUM_TIMEFRAMES period,    // period
    int ma_period,     // averaging period
    int ma_shift,      // shift
    int applied       // price type, handle
)```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **ma_shift**
  - [in] Horizontal shift.

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

- `index`
  - [in] Buffer element index.

Return Value

Buffer element of the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_TEMA for CiTEMA).
CiFrAMA

CiFrAMA is a class intended for using the Fractal Adaptive Moving Average technical indicator.

Description

CiFrAMA class provides the creation, setup, and access to the data of the Fractal Adaptive Moving Average indicator.

Declaration

class CiFrAMA: public CIndicator

Title

**MaPeriod**

Returns the averaging period.

```cpp
int MaPeriod() const
```

**Return Value**

Returns the averaging period, defined at the indicator creation.
**IndShift**

Returns the horizontal shift of the indicator.

```
int IndShift() const
```

**Return Value**

Returns the horizontal shift value, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,  // averaging period
    int ma_shift,  // shift
    int applied  // price type, handle
)
```

**Parameters**

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **ma_shift**
  - [in] Horizontal shift.

- **applied**
  - [in] Price type or handle to apply.

**Return Value**

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index    // index
)
```

Parameters

- `index`:
  - [in] Buffer element index.

Return Value

Buffer element of the specified index if successful, or `EMPTY_VALUE` if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (IND.FRAMA for CiFrAMA).
CiAMA

CiAMA is a class intended for using the Adaptive Moving Average technical indicator.

Description

CiAMA class provides the creation, setup, and access to the data of the Adaptive Moving Average indicator.

Declaration

MaPeriod

Returns the averaging period.

```c
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
**FastEmaPeriod**

Returns the averaging period for the fast EMA.

```c
int FastEmaPeriod() const
```

**Return Value**

Returns the averaging period for the fast EMA, defined at the indicator creation.
SlowEmaPeriod

Returns the averaging period for the slow EMA.

```c
int SlowEmaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.
**IndShift**

Returns the horizontal shift of the indicator.

```c
int IndShift() const
```

**Return Value**

Returns the horizontal shift value, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```csharp
bool Create(
    string string,       // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,        // averaging period
    int fast_ema_period,  // fast EMA period
    int slow_ema_period,  // slow EMA period
    int ind_shift,        // shift
    int applied           // price type, handle
)
```

Parameters

- **string**
  - [in] Symbol.

- **period**

- **ma_period**

- **fast_ema_period**

- **slow_ema_period**
  - [in] Slow EMA averaging period.

- **ind_shift**
  - [in] Horizontal shift.

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index // index
)
```

Parameters

- `index`  

Return Value

- Buffer element of the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_AMA for CiAMA).
CiVIDyA

CiVIDyA is a class intended for using the Variable Index Dynamic Average technical indicator.

Description

CiVIDyA class provides the creation, setup, and access to the data of the Variable Index Dynamic Average indicator.

Declaration

```cpp
class CiVIDyA: public CIndicator
```

Title

```cpp
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

CmoPeriod

Closes the chart bound to the class instance.

```cpp
int CmoPeriod() const
```
EmaPeriod

Returns the chart symbol.

```cpp
int EmaPeriod() const
```

Return Value

Returns a chart symbol bound to a class instance. "" - no bound chart.
IndShift

Returns the horizontal shift of the indicator.

```
int IndShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```csharp
bool Create(
    string symbol,       // symbol
    ENUM_TIMEFRAMES period,   // period
    int cmo_period,        // momentum period
    int ema_period,        // averaging period
    int ind_shift,         // shift
    int applied            // price type, handle
)
```

**Parameters**

- `applied` [in] Price type or handle to apply.

**Return Value**

- true - successful, false - cannot create the indicator.
# Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

## Parameters

**index**

## Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_VIDYA` for CiVIDyA).
# Oscillator Classes

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```c
bool Create(
    string    symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int       ma_period    // averaging period
)
```

Parameters

|--------|--------------|

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

**Parameters**

- **index**
  - [in] Buffer element index.

**Return Value**

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type (IND_ATR for CiATR).
CiBearsPower

CiBearsPower is a class intended for using the Bears Power technical indicator.

Description

CiBearsPower class provides the creation, setup, and access to the data of the Bears Power indicator.

Declaration

```cpp
class CiBearsPower: public CIndicator
```

Title

```cpp
#include <Indicators/Oscilators.mqh>
```

Inheritance hierarchy

- CObject
- CArray

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```cpp
bool Create(
    string symbol,     // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period      // averaging period
)
```

Parameters

- `symbol`  

- `period`  
  [in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

- `ma_period`  

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index  // index
)
```

Parameters

- `index`
  - [in] Buffer element index.

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type (IND_BEARS for CiBearsPower).
CiBullsPower

CiBullsPower is a class intended for using the Bulls Power technical indicator.

Description

CiBullsPower class provides the creation, setup, and access to the data of the Bulls Power indicator.

Declaration

```cpp
class CiBullsPower: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

- CObject

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```csharp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period  // averaging period
)
```

Parameters

- `symbol`  

- `period`  

- `ma_period`  

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int  index  // index
)
```

Parameters

index

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

    virtual int Type() const

Return Value

Indicator type (IND_BULLS for CiBullsPower).
# CiCCI

CiCCI is a class intended for using the Commodity Channel Index technical indicator.

## Description

CiCCI class provides the creation, setup, and access to the data of the Commodity Channel Index indicator.

## Declaration

```cpp
class CiCCI: public CIndicator
```

## Title

```cpp
#include <Indicators\Oscilators.mqh>
```

## Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiCCI

MaPeriod

Returns the averaging period.

```cpp
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,  // averaging period
    int applied  // price type, handle
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
**Main**

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

**Parameters**

- `index`  
  

**Return Value**

- Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type ([IND_CCI] for CiCCI).
CiChaikin

CiChaikin is a class intended for using the Chaikin Oscillator technical indicator.

Description

CiChaikin class provides the creation, setup, and access to the data of the Chaikin Oscillator indicator.

Declaration

```cpp
class CiChaikin: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

FastMaPeriod

Returns the averaging period for the fast EMA.

```cpp
int FastMaPeriod() const
```

Return Value

Returns the averaging period for the fast EMA, defined at the indicator creation.
SlowMaPeriod

Returns the averaging period for the slow EMA.

```
int SlowMaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.
MaMethod

Returns the averaging method.

```c
ENUM_MA_METHOD MaMethod() const
```

**Return Value**

Returns the averaging method, defined at the indicator creation (`ENUM_MA_METHOD` enumeration value).
**Applied**

Returns the object (volume type) to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

**Return Value**

Object (volume type) to apply, defined at the indicator creation (**ENUM_APPLIED_VOLUME** enumeration value).
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int fast_ma_period,  // fast EMA period
    int slow_ma_period,  // slow EMA period
    ENUM_MA_METHOD ma_method,  // averaging method
    ENUM_APPLIED_VOLUME applied  // volume type
)
```

**Parameters**

- `fast_ma_period` [in] Period for fast EMA.
- `slow_ma_period` [in] Period for slow EMA.
- `applied` [in] Object (volume type) to apply (`ENUM_APPLIED_VOLUME` enumeration value).

**Return Value**

- `true` - successful, `false` - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index  // index
)
```

Parameters

`index`

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_CHAIKIN` for CiChaikin).
CiDeMarker

CiDeMarker is a class intended for using the DeMarker technical indicator.

Description

CiDeMarker class provides the creation, setup, and access to the data of the DeMarker indicator.

Declaration

```cpp
class CiDeMarker: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

```
CObject
  CArray
    CArrayObj
      CSeries

**MaPeriod**

Returns the averaging period.

```c
int MaPeriod() const
```

**Return Value**

Returns the averaging period, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```csharp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period  // averaging period
)
```

Parameters

- `symbol`
  - [in] Symbol.

- `period`

- `ma_period`

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

`index`

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_DEMARKER` for CiDeMarker).
CiForce

CiForce is a class intended for using the Force Index technical indicator.

Description

CiForce class provides the creation, setup, and access to the data of the Force Index indicator.

Declaration

```cpp
class CiForce : public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiForce

MaPeriod

Returns the averaging period.

\[
\text{int}\ \text{MaPeriod() const}
\]

Return Value

Returns the averaging period, defined at the indicator creation.
MaMethod

Returns the averaging method.

| ENUM_MA_METHOD | MaMethod() const |

Return Value

Returns the averaging method, defined at the indicator creation.
**Applied**

Returns the object (volume type) to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

**Return Value**

Object (volume type) to apply, defined at the indicator creation (**ENUM_APPLIED_VOLUME** enumeration value).
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```csharp
bool Create(
    string symbol,   // symbol
    ENUM_TIMEFRAMES period, // period
    int ma_period,   // averaging period
    ENUM_MA_METHOD ma_method, // averaging method
    ENUM_APPLIED_VOLUME applied // volume type
)
```

**Parameters**

- `symbol`  

- `period`  

- `ma_period`  

- `ma_method`  

- `applied`  
  `[in]` Object (volume type) to apply (`ENUM_APPLIED_VOLUME` enumeration value).

**Return Value**

- `true` - successful, `false` - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

- `index`  
  - [in] Buffer element index.

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_FORCE` for CiForce).
CiMACD

CiMACD is a class intended for using the Moving Averages Convergence-Divergence technical indicator.

Description

CiMACD class provides the creation, setup, and access to the data of the Moving Averages Convergence-Divergence indicator.

Declaration

```cpp
class CiMACD: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

**FastEmaPeriod**

Returns the averaging period for the fast EMA.

```cpp
int FastEmaPeriod() const
```

**Return Value**

Returns the averaging period for the fast EMA, defined at the indicator creation.
### SlowEmaPeriod

Returns the averaging period for the slow EMA.

```cpp
int SlowEmaPeriod() const
```

**Return Value**

Returns the averaging period for the slow EMA, defined at the indicator creation.
**SignalPeriod**

Returns the averaging period for the signal line.

```
int SignalPeriod() const
```

**Return Value**

Returns the averaging period for the signal line, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```csharp
bool Create(
    string symbol,             // symbol
    ENUM_TIMEFRAMES period,    // period
    int fast_ema_period,       // fast EMA period
    int slow_ema_period,       // slow EMA period
    int signal_period,         // signal period
    int applied                // price type, handle
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **fast_ema_period**

- **slow_ema_period**
  - [in] Slow EMA averaging period.

- **signal_period**
  - [in] Signal line averaging period.

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the main line buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

*index*

Return Value

Main line buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Signal

Returns the buffer element of the signal line by the specified index.

```c
double Signal(
    int index  // index
)
```

Parameters

- `index`  
  - [in] Buffer element index.

Return Value

- The buffer element of the signal line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_MACD` for CiMACD).
CiMomentum

CiMomentum is a class intended for using the Momentum technical indicator.

Description

CiMomentum class provides the creation, setup, and access to the data of the Momentum indicator.

Declaration

```cpp
class CiMomentum: public CIndicator
```

Title

```cpp
#include <Indicators/Oscillators.mqh>
```

Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiMomentum

MaPeriod

Returns the averaging period.

```
ing  MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
**Applied**

Returns the price type or handle to apply.

```cpp
int Applied() const
```

**Return Value**

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    int ma_period, // averaging period
    int applied // price type, handle
)
```

**Parameters**

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **applied**
  - [in] Price type or handle to apply.

**Return Value**

true - successful, false - cannot create the indicator.
**Main**

Returns the buffer element by the specified index.

```c
double Main(
    int index       // index
)
```

**Parameters**

- `index`
  - [in] Buffer element index.

**Return Value**

- Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_MOMENTUM` for CiMomentum).
CiOsMA

CiOsMA is a class intended for using the Moving Average of Oscillator (MACD histogram) technical indicator.

Description

CiOsMA class provides the creation, setup, and access to the data of the Moving Average of Oscillator (MACD histogram) indicator.

Declaration

```
class CiOsMA: public CIndicator
```

  Handle, Status, FullRelease, Redrawer, Create, BufferResize, BarsCalculated, GetData, GetData,
  GetData, GetData, Minimum, MinValue, Maximum, MaxValue, Refresh, AddToChart,
  DeleteFromChart, MethodDescription, PriceDescription, VolumeDescription
FastEmaPeriod

Returns the averaging period for the fast EMA.

```c
int FastEmaPeriod() const
```

**Return Value**

Returns the averaging period for the fast EMA, defined at the indicator creation.
**SlowEmaPeriod**

Returns the averaging period for the slow EMA.

```cpp
int SlowEmaPeriod() const
```

**Return Value**

Returns the averaging period for the slow EMA, defined at the indicator creation.
SignalPeriod

Returns the averaging period for the signal line.

```c
int SignalPeriod() const
```

Return Value

Returns the averaging period for the signal line, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```cpp
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,       // symbol
    ENUM_TIMEFRAMES period,  // period
    int fast_ema_period,  // fast EMA period
    int slow_ema_period,  // slow EMA period
    int signal_period,    // signal line period
    int applied           // price type, handle
)
```

Parameters

- **symbol**: [in] Symbol.
- **period**: [in] Timeframe (ENUM_TIMEFRAMES enumeration value).
- **fast_ema_period**: [in] Fast EMA averaging period.
- **slow_ema_period**: [in] Slow EMA averaging period.
- **signal_period**: [in] Signal line averaging period.
- **applied**: [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index // index
)
```

Parameters

- `index`
  - [in] Buffer element index.

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (IND_OSMA for CiOsMA).
CiRSI

CiRSI is a class intended for using the Relative Strength Index technical indicator.

Description

CiRSI class provides the creation, setup, and access to the data of the Relative Strength Index indicator.

Declaration

```cpp
class CiRSI: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

```
CObject
    CArray
        CArrayObj
            CSeries
                CIndicator
                    CiRSI
```

MaPeriod

Returns the averaging period.

```c
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```c++
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    int ma_period, // averaging period
    int applied // price type, handle
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **applied**
  - [in] Price type or handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

index

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_RSI for CiRSI).
CiRVI

CiRVI is a class intended for using the Relative Vigor Index technical indicator.

Description

CiRVI class provides the creation, setup, and access to the data of the Relative Vigor Index indicator.

Declaration

```cpp
class CiRVI: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

```

Parameters

symbol

period

ma_period

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the main line buffer element by the specified index.

```cpp
double Main(
    int index  // index
)
```

Parameters

index

Return Value

Main line buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Signal

Returns the buffer element of the signal line by the specified index.

```c
double Signal(int index) // index
```

Parameters

index

Return Value

The buffer element of the signal line by the specified index, or **EMPTY_VALUE** if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_RVI for CiRVI).
CiStochastic

CiStochastic is a class intended for using the Stochastic Oscillator technical indicator.

Description

CiStochastic class provides the creation, setup, and access to the data of the Stochastic Oscillator indicator.

Declaration

```cpp
class CiStochastic: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

Kperiod

Returns the averaging period for the %K line.

```c
int Kperiod() const
```

Return Value

Returns the averaging period for the %K line, defined at the indicator creation.
Dperiod

Returns the averaging period for the %D line.

```c
int Dperiod() const
```

Return Value

Returns the averaging period for the %D line, defined at the indicator creation.
Slowing

Returns the period of slowing.

```
int Slowing() const
```

Return Value

Returns the period of slowing, defined at the indicator creation.
MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation (ENUM_MA_METHOD enumeration value).
PriceField

Returns the object (Low/High or Close/Close) to apply.

```cpp
ENUM_STO_PRICE PriceField() const
```

Return Value

The object (Low/High or Close/Close) to apply, defined at the indicator creation (`ENUM_STOPRICE` enumeration value).
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```c
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    int Kperiod, // %K period
    int Dperiod, // %D period
    int slowing, // slowing period
    ENUM_MA_METHOD ma_method, // averaging method
    ENUM_STO_PRICE price_field // application
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **Kperiod**
  - [in] Averaging period of %K indicator.

- **Dperiod**
  - [in] Averaging period of %D indicator.

- **slowing**
  - [in] Slowing period.

- **ma_method**

- **price_field**
  - [in] Object (Low/High or Close/Close) to apply (ENUM_STO_PRICE enumeration value).

Return Value

- true - successful, false - cannot create the indicator.
### Main

Returns the main line buffer element by the specified index.

```cpp
double Main(
    int  index  // index
)
```

**Parameters**

- `index`  

**Return Value**

Main line buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Signal

Returns the buffer element of the signal line by the specified index.

```c
double Signal(
    int index  // index
)
```

Parameters

- `index`
  - `[in]` Buffer element index.

Return Value

The buffer element of the signal line by the specified index, or `EMPTY_VALUE` if there is no correct data.
### Type

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (IND_STOCHASTIC for CiStochastic).
CiTriX

CiTriX is a class intended for using the Triple Exponential Moving Averages Oscillator technical indicator.

Description

CiTriX class provides the creation, setup, and access to the data of the Triple Exponential Moving Averages Oscillator indicator.

Declaration

```cpp
class CiTriX: public CIndicator
```

Title

```cpp
#include <Indicators\Oscilators.mqh>
```

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```c
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,    // symbol
    ENUM_TIMEFRAMES period,    // period
    int ma_period,    // averaging period
    int applied     // price type, handle
)
```

Parameters

- `symbol`:
  - [in] Symbol.

- `period`:

- `ma_period`:

- `applied`:
  - [in] Price type of handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int  index  // index
)
```

**Parameters**

- **index**
  - [in] Buffer element index.

**Return Value**

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_TRI for CiTriX).
**CiWPR**

CiWPR is a class intended for using the Williams' Percent Range technical indicator.

**Description**

CiWPR class provides the creation, setup, and access to the data of the Williams' Percent Range indicator.

**Declaration**

```cpp
class CiWPR: public CIndicator
```

CalcPeriod

Returns the period for calculation.

```cpp
int CalcPeriod() const
```

Return Value

Returns the period for calculation, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int calc_period  // calculation period
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **calc_period**
  - [in] Period for calculation.

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index    // index
)
```

Parameters

index

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (`IND_WPR` for CiWPR).
Volume Indicators

Applied

Returns the volume type to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

Return Value

Volume type to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
  string symbol, // symbol
  ENUM_TIMEFRAMES period, // period
  ENUM_APPLIED_VOLUME applied // volume type
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **applied**
  - [in] Volume type to apply (ENUM_APPLIED_VOLUME enumeration value).

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

- `index`
  

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_AD` for CiAD).
CiMFI

CiMFI is a class intended for using the Money Flow Index technical indicator.

Description

CiMFI class provides the creation, setup, and access to the data of the Money Flow Index indicator.

Declaration

```cpp
class CiMFI: public CIndicator
```

Title

```cpp
#include <Indicators\Volumes.mqh>
```

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.
Applied

Returns the volume type to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

Return Value

Volume type to apply, defined at the indicator creation (ENUM_APPLIED_VOLUME enumeration value).
Create

Creates the indicator with specified parameters. Use `Refresh()` and `GetData()` to update and get the indicator values.

```cpp
bool Create(
    string symbol,   // symbol
    ENUM_TIMEFRAMES period,  // period
    int ma_period,   // averaging period
    ENUM_APPLIED_VOLUME applied  // volume type
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **ma_period**

- **applied**
  - [in] Volume type to apply (`ENUM_APPLIED_VOLUME` enumeration value).

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type (IND_MFI for CiMFI).
CiOBV

CiOBV is a class intended for using the On Balance Volume technical indicator.

Description

CiOBV class provides the creation, setup, and access to the data of the On Balance Volume indicator.

Declaration

```
class CiOBV: public CIndicator
```

Title

```
#include <Indicators/Volumes.mqh>
```

Inheritance hierarchy

Applied

Returns the volume type to apply.

** ENUM_APPLIED_VOLUME  Applied() const

Return Value

Volume type to apply, defined at the indicator creation (ENUM_APPLIED_VOLUME enumeration value).
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    ENUM_APPLIED_VOLUME applied // volume type
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **applied**
  - [in] Volume type to apply (ENUM_APPLIED_VOLUME enumeration value).

Return Value

true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index    // index
);
```

Parameters

`index`

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_OBV` for CiOBV).
CiVolumes

CiVolumes is a class intended for using the Volumes technical indicator.

Description

CiVolumes class provides the creation, setup, and access to the data of the Volumes indicator.

Declaration

```cpp
class CiVolumes: public CIndicator
```

Title

```cpp
#include <Indicators\Volumes.mqh>
```

Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiVolumes

Applied

Returns the volume type to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

Return Value

Volume type to apply, defined at the indicator creation (ENUM_APPLIED_VOLUME enumeration value).
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```csharp
bool Create(
    string symbol, // symbol
    ENUM_TIMEFRAMES period, // period
    ENUM_APPLIED_VOLUME applied // volume type
)
```

Parameters

- `symbol`  

- `period`  

- `applied`  
  [in] Volume type to apply (ENUM_APPLIED_VOLUME enumeration value).

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(int index) // index
```

Parameters

index

Return Value

Buffer element by the specified index, or EMPTY_VALUE if there is no correct data.
Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type (IND_VOLUMES for CiVolumes).
Bill Williams Indicators

This group of chapters contains technical details of Bill Williams indicator classes and descriptions of all the appropriate components of the MQL5 Standard Library.

Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(  
    string symbol, // symbol  
    ENUM_TIMEFRAMES period // period
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index // index
)
```

Parameters

- `index`  
  

Return Value

- Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
def Type() const
```

Return Value

Indicator type (IND_AC for CiAC).
CiAlligator

CiAlligator is a class intended for using the Alligator technical indicator.

Description

CiAlligator class provides the creation, setup, and access to the data of the Alligator indicator.

Declaration

```cpp
class CiAlligator: public CIndicator
```

Title

```cpp
#include <Indicators\BillWilliams.mqh>
```

Methods inherited from class CIndicator

JawPeriod

Returns the averaging period for the Jaw line.

```
int JawPeriod() const
```

Return Value

Returns the averaging period for the Jaw line, defined at the indicator creation.

JawShift

Returns the horizontal shift of the Jaws line.

```cpp
int JawShift() const
```

Return Value

Horizontal shift of the Jaws line, defined at the indicator creation.
TeethPeriod

Returns the averaging period for the Teeth line.

```c
int TeethPeriod() const
```

Return Value

Returns the averaging period for the Teeth line, defined at the indicator creation.
TeethShift

Returns the horizontal shift of the Teeth line.

```cpp
int TeethShift() const
```

Return Value

Horizontal shift of the Teeth line, defined at the indicator creation.
LipsPeriod

Returns the averaging period for the Lips line.

```
int LipsPeriod() const
```

**Return Value**

Returns the averaging period for the Lips line, defined at the indicator creation.
**LipsShift**

Returns the horizontal shift of the Lips line.

```cpp
int LipsShift() const
```

**Return Value**

Horizontal shift of the Lips line, defined at the indicator creation.
MaMethod

Returns the averaging method.

```
enum MaMethod
```

Return Value

Returns the averaging method, defined at the indicator creation.
**Applied**

Returns the price type or handle to apply.

```cpp
int Applied() const
```

**Return Value**

Price type or handle to apply, defined at the indicator creation.
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```csharp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period,  // period
    int jaw_period,  // jaws period
    int jaw_shift,  // jaws shift
    int teeth_period,  // teeth period
    int teeth_shift,  // teeth shift
    int lips_period,  // lips period
    int lips_shift,  // lips shift
    ENUM_MA_METHOD ma_method,  // averaging method
    int applied  // price type, handle
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **jaw_period**

- **jaw_shift**

- **teeth_period**

- **teeth_shift**

- **lips_period**
  - [in] Lips averaging period.

- **lips_shift**
  - [in] Lips horizontal shift.

- **ma_method**

- **applied**
  - [in] Price type, handle to apply.

Return Value

- true - successful, false - cannot create the indicator.
Jaw

Returns the buffer element of the Jaws line by the specified index.

```c
double Jaw(
    int index // index
)
```

**Parameters**

- `index`  

**Return Value**

The buffer element of the Jaws line by the specified index, or `EMPTY_VALUE` if there is no correct data.
**Teeth**

Returns the buffer element of the Teeth line by the specified index.

```c
double Teeth(
    int index  // index
)
```

**Parameters**

`index`

**Return Value**

The buffer element of the Teeth line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Lips

Returns the buffer element of the Lips line by the specified index.

```c
double Lips(
    int index  // index
)
```

**Parameters**

- `index`  
  - [in] Lips line buffer element index.

**Return Value**

- The buffer element of the Lips line by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (IND_ALLIGATOR for CiAlligator).
CiAO

CiAO is a class intended for using the Awesome Oscillator technical indicator.

Description

CiAO class provides the creation, setup, and access to the data of the Awesome Oscillator indicator.

Declaration

```cpp
class CiAO: public CIndicator
```

Title

```cpp
#include <Indicators\BillWilliams.mqh>
```

Inheritance hierarchy

- CObject
  - CArray
    - CActive
      - CSeries
        - CIndicator
  - CIao

Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period  // period
)
```

Parameters

symbol

- [in] Symbol.

period

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```cpp
double Main(
    int index  // index
)
```

Parameters

- `index`  
  

Return Value

- Buffer element of the specified index, or `EMPTY_VALUE` if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (`IND_AO` for CiAO).
CiFractals

CiFractals is a class intended for using the Fractals technical indicator.

Description

CiFractals class provides the creation, setup, and access to the data of the Fractals indicator.

Declaration

```cpp
class CiFractals: public CIndicator
```

Title

```cpp
#include <Indicators\BillWilliams.mqh>
```

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```
bool Create(
    string symbol,  // symbol
    ENUM_TIMEFRAMES period  // period
}
```

**Parameters**

symbol

period

**Return Value**

true - successful, false - cannot create the indicator.
Upper

Returns the element of the upper buffer by the specified index.

```c
double Upper(
    int index  // index
)
```

**Parameters**

- `index`  
  [in] Upper buffer element index.

**Return Value**

The element of the upper buffer by the specified index, or `EMPTY_VALUE` if there is no correct data.
Lower

Returns the element of the lower buffer by the specified index.

```c
double Lower(int index) // index
```

**Parameters**

index

[in] Lower buffer element index.

**Return Value**

The element of the lower buffer by the specified index, or **EMPTY_VALUE** if there is no correct data.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type ([IND_FRACTALS](#) for CiFractals).
CiGator

CiGator is a class intended for using the Gator Oscillator technical indicator.

Description

CiGator class provides the creation, setup, and access to the data of the Gator Oscillator indicator.

Declaration

```cpp
class CiGator: public CIndicator
```

Title

```cpp
#include <Indicators\BillWilliams.mqh>
```

Inheritance hierarchy

- CObject
- CArray
- CArrayObj
- CSeries
- CIndicator
- CiGator

JawPeriod

Returns the averaging period for the Jaws line.

```c
int JawPeriod() const
```

Return Value

Returns the averaging period for the Jaws line, defined at the indicator creation.
**JawShift**

Returns the horizontal shift of the Jaws line.

```cpp
int JawShift() const
```

**Return Value**

Horizontal shift of the Jaws line, defined at the indicator creation.
TeethPeriod

Returns the averaging period for the Teeth line.

```
int TeethPeriod() const
```

Return Value

Returns the averaging period for the Teeth line, defined at the indicator creation.
TeethShift

Returns the horizontal shift of the Teeth line.

```cpp
int TeethShift() const
```

Return Value

Horizontal shift of the Teeth line, defined at the indicator creation.
LipsPeriod

Returns the averaging period for the Lips line.

```cpp
int LipsPeriod() const
```

Return Value

Returns the averaging period for the Lips line, defined at the indicator creation.
LipsShift

Returns the horizontal shift of the Lips line.

```c
int LipsShift() const
```

Return Value

Horizontal shift of the Lips line, defined at the indicator creation.
MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation.
Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

*Price type or handle to apply, defined at the indicator creation.*
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,       // symbol
    ENUM_TIMEFRAMES period, // period
    int jaw_period,      // jaws period
    int jaw_shift,       // jaws shift
    int teeth_period,    // teeth period
    int teeth_shift,     // teeth shift
    int lips_period,     // lips period
    int lips_shift,      // lips shift
    ENUM_MA_METHOD ma_method, // averaging method
    int applied         // price type, handle
)
```

Parameters

- `symbol`  

- `period`  

- `jaw_period`  

- `jaw_shift`  

- `teeth_period`  

- `teeth_shift`  

- `lips_period`  
  [in] Lips averaging period.

- `lips_shift`  
  [in] Lips horizontal shift.

- `ma_method`  

- `applied`  
  [in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.
Upper

Returns the element of the upper buffer by the specified index.

```c
double Upper(
    int index  // index
)
```

Parameters

- **index**
  - [in] Upper buffer element index.

Return Value

The upper buffer element by the specified index, or **EMPTY_VALUE** if there is no correct data.
Lower

Returns the element of the lower buffer by the specified index.

```c
double Upper(
    int index  // index
)
```

**Parameters**

`index`

[in] Lower buffer element index.

**Return Value**

The element of the lower buffer by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (\texttt{IND\_GATOR} for CiGator).
CiBWMFI

CiBWMFI is a class intended for using the Market Facilitation Index by Bill Williams technical indicator.

Description

CiBWMFI class provides the creation, setup, and access to the data of the Market Facilitation Index by Bill Williams indicator.

Declaration

```cpp
class CiBWMFI: public CIndicator
```

Title

```cpp
#include <Indicators\BillWilliams.mqh>
```

Inheritance hierarchy

```
CObject
  CArray
    CArrayObj
      CSeries
        CIndicator
          CiBWMFI
```

**Applied**

Returns the volume type to apply.

| ENUM_APPLIED_VOLUME | Applied() const |

**Return Value**

Volume type to apply, defined at the indicator creation (ENUM_APPLIED_VOLUME enumeration value).
Create

Creates the indicator with specified parameters. Use Refresh() and GetData() to update and get the indicator values.

```cpp
bool Create(
    string symbol,    // symbol
    ENUM_TIMEFRAMES period,  // period
    ENUM_APPLIED_VOLUME applied  // volume type
)
```

Parameters

- **symbol**
  - [in] Symbol.

- **period**

- **applied**
  - [in] Volume type to apply (ENUM_APPLIED_VOLUME enumeration value).

Return Value

- true - successful, false - cannot create the indicator.
Main

Returns the buffer element by the specified index.

```c
double Main(
    int index  // index
)
```

Parameters

`index`

Return Value

Buffer element by the specified index, or `EMPTY_VALUE` if there is no correct data.
Type

Virtual identification method.

```cpp
virtual int Type() const
```

Return Value

Indicator type (`IND_BWMFI` for CiBWMFI).
CiCustom

CiCustom is a class intended for using the custom technical indicators.

Description

CiCustom class provides the creation, setup, and access to the data of a custom indicator.

Declaration

```cpp
#include <Indicators\Custom.mqh>
```

</tbody>
</table>
**NumBuffers**

Sets the number of buffers.

```c
bool NumBuffers;
```

**Return Value**

true - successful, false - cannot set the necessary number of buffers.
NumParams

Gets the number of parameters used when creating an indicator.

```cpp
int NumParams() const
```

Return Value

Number of parameters, used in creation of the indicator.
**ParamType**

Gets a type of the parameter.

```cpp
enum DATATYPE ParamType(  
    int index // index  
) const
```

**Parameters**

- `index`
  - [in] Parameter index.

**Return Value**

Returns the data type of the specified parameter, used in indicator creation.

**Note**

If parameter index is invalid, it returns `WRONG_VALUE`. 
ParamLong

Gets the value of specified parameter of long type.

```c
long ParamLong(
    int index    // index
) const
```

**Parameters**

*index*

[in] Parameter index.

**Return Value**

The value of specified parameter of long type, used in creation of the indicator.

**Note**

If the parameter index is invalid or the parameter is not of long type, it returns 0.
**ParamDouble**

Gets the value of specified parameter of double type.

```c
double ParamDouble(
    int index  // index
) const
```

**Parameters**

- `index`
  - [in] Parameter index.

**Return Value**

- The value of specified parameter of double type, used in creation of the indicator.

**Note**

- If the parameter index is invalid or the parameter type is not of double type, it returns `EMPTY_VALUE`. 
### ParamString

**Gets the value of specified parameter of string type.**

```cpp
string ParamString(
    int index  // index
) const
```

#### Parameters

- **index**
  - [in] Parameter index.

#### Return Value

The value of specified string parameter, used in creation of the indicator.

#### Note

If the number is invalid or the parameter is not of string type, it returns an empty string.
**Type**

Virtual identification method.

```cpp
virtual int Type() const
```

**Return Value**

Indicator type (`IND_CUSTOM` for CiCustom).
Trade Classes

This section contains technical details of working with trade classes and description of the relevant components of the MQL5 standard library.

Using trade classes will save time when creating custom programs (Expert Advisors).

MQL5 Standard Library (in terms of trade classes) is placed in the terminal working directory, in the `Include\Trade` folder.

CAccountInfo

CAccountInfo is a class for easy access to the currently opened trade account properties.

Description

CAccountInfo class provides easy access to the currently opened trade account properties.

Declaration

```c
class CAccountInfo : public CObject
```

Title

```c
#include <Trade\AccountInfo.mqh>
```

Inheritance hierarchy

CObject

</table>

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare
Login

Gets the account number.

```cpp
long Login() const
```

Return Value

Account number.
TradeMode

Gets the trade mode.

```cpp
ENUM_ACCOUNT_TRADE_MODE TradeMode() const
```

Return Value

Trade mode from the `ENUM_ACCOUNT_TRADE_MODE` enumeration.
TradeModeDescription

Gets the trade mode as a string.

```cpp
string TradeModeDescription() const
```

Return Value

Trade mode as a string.
Leverage

Gets the amount of given leverage.

```cpp
long Leverage() const
```

Return Value

Amount of given leverage.
StopoutMode

Gets the mode of the Stop Out level specification.

```
ENUM_ACCOUNT_STOPOUT_MODE StopoutMode() const
```

Return Value

The stop out setting mode from the `ENUM_ACCOUNT_STOPOUT_MODE` enumeration.
StopoutModeDescription

Gets the mode of the Stop Out level specification as a string.

```
string StopoutModeDescription() const
```

Return Value

The stop out setting mode as a string.
**MarginMode**

Gets the margin calculation mode.

```cpp
EBOR_ENUM_ACCOUNT_MARGIN_MODE MarginMode() const
```

**Return Value**

The margin calculation mode from the `ENUM_ACCOUNT_MARGIN_MODE` enumeration.
**MarginModeDescription**

Gets the margin calculation mode as a string.

```cpp
string MarginModeDescription() const
```

**Return Value**

Margin calculation mode as a string.
TradeAllowed

Gets the flag of trade allowance.

```cpp
bool TradeAllowed() const
```

Return Value

Flag of trade allowance.
TradeExpert

Gets the flag of automated trade allowance.

```cpp
bool TradeExpert() const
```

Return Value

Flag of automated trade allowance.
**LimitOrders**

Gets the maximal number of allowed pending orders

```cpp
int LimitOrders() const
```

**Return Value**

The maximal number of allowed pending orders.

**Note**

0 - no limits.
Balance

Gets the balance of account.

```cpp
double Balance() const
```

Return Value

The balance of account (in deposit currency).
Credit

Gets the amount of given credit.

    double Credit() const

Return Value

    Amount of given credit (in deposit currency).
Profit

Gets the amount of current profit on account.

```cpp
double Profit() const
```

Return Value

Amount of current profit on account (in deposit currency).
**Equity**

Gets the amount of current equity on account.

```cpp
double Equity() const
```

**Return Value**

Amount of current equity on account (in deposit currency).
**Margin**

Gets the amount of reserved margin.

```cpp
double Margin() const
```

**Return Value**

Amount of reserved margin (in deposit currency).
FreeMargin

Gets the amount of free margin.

```plaintext
double FreeMargin() const
```

Return Value

Amount of free margin (in deposit currency).
MarginLevel

Gets the level of margin.

```cpp
double MarginLevel() const
```

Return Value

Level of margin.
MarginCall

Gets the level of margin for a deposit.

```cpp
double MarginCall() const
```

Return Value

Level of margin for a deposit.
**MarginStopOut**

Gets the level of margin for Stop Out.

```cpp
double MarginStopOut() const
```

**Return Value**

Level of margin for Stop Out.
Name

Gets the client name.

```
string Name() const
```

Return Value

Client name.
Server

Gets the trade server name.

```cpp
string Server() const
```

Return Value

Trade server name.
Currency

Gets the deposit currency name.

```
string Currency() const
```

Return Value

Deposit currency name.
Company

Gets the company name, that serves an account.

```
string Company() const
```

Return Value

Company name that serves an account.
InfoInteger

Gets the value of specified integer type property.

```c
long InfoInteger(
    ENUM_ACCOUNT_INFO_INTEGER prop_id  // property ID
) const
```

**Parameters**

*prop_id*

[in] Identifier of the property. The value can be one of the values of `ENUM_ACCOUNT_INFO_INTEGER` enumeration.

**Return Value**

Value of `long` type.
InfoDouble

Gets the value of specified double type property.

```cpp
double InfoDouble(
    ENUM_ACCOUNT_INFO_DOUBLE  prop_id  // property ID
) const
```

**Parameters**

- **prop_id**
  
  [in] Identifier of the property. The value can be one of the values of `ENUM_ACCOUNT_INFO_DOUBLE` enumeration.

**Return Value**

Value of `double` type.
**InfoString**

Gets the value of specified string type property.

```cpp
string InfoString(
    ENUM_ACCOUNT_INFO_STRING prop_id  // property ID
) const
```

**Parameters**

- `prop_id`  
  [in] Identifier of the property. The value can be one of the values of `ENUM_ACCOUNT_INFO_STRING` enumeration.

**Return Value**

Value of `string` type.
OrderProfitCheck

The function calculates the profit for the current account, based on the parameters passed. The function is used for pre-evaluation of the result of a trade operation. The value is returned in the account currency.

```c
double OrderProfitCheck(
    const string symbol, // symbol
    ENUM_ORDER_TYPE trade_operation, // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
    double volume, // volume
    double price_open, // position open price
    double price_close // position close price
) const
```

Parameters

- `symbol` [in] Symbol for trade operation.
- `trade_operation` [in] Type of trade operation from `ENUM_ORDER_TYPE` enumeration.

Return Value

If successful, it returns amount of profit or `EMPTY_VALUE` in the case of error.
## MarginCheck

Gets the amount of margin, required for trade operation.

```cpp
double MarginCheck(
    const string symbol, // symbol
    ENUM_ORDER_TYPE trade_operation, // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
    double volume, // volume
    double price // price
) const
```

### Parameters

- `symbol` - Symbol for trade operation.
- `trade_operation` - Type of trade operation from `ENUM_ORDER_TYPE` enumeration.
- `volume` - Volume of trade operation.
- `price` - Price of trade operation.

### Return Value

Amount of margin required for trade operation.
FreeMarginCheck

Gets the amount of free margin left after trade operation.

```cpp
double FreeMarginCheck(
    const string symbol, // symbol
    ENUM_ORDER_TYPE trade_operation, // order type (ORDER_TYPEBUY or ORDER_TYI
    double volume, // volume
    double price // price
) const
```

Parameters

- `symbol`  
  [in] Symbol for trade operation.

- `trade_operation`  
  [in] Type of trade operation from ENUM_ORDER_TYPE enumeration.

- `volume`  
  [in] Volume of trade operation.

- `price`  
  [in] Price of trade operation.

Return Value

- Amount of free margin left after trade operation.
MaxLotCheck

Gets the maximum possible volume of trade operation.

```cpp
double MaxLotCheck(
    const string symbol,       // symbol
    ENUM_ORDER_TYPE trade_operation,  // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)
    double price,             // price
    double percent=100        // percent of available margin (default is 100%)
) const
```

**Parameters**

- `symbol`
  - [in] Symbol for trade operation.

- `trade_operation`
  - [in] Type of trade operation from ENUM_ORDER_TYPE enumeration.

- `price`
  - [in] Price of trade operation.

- `percent=100`
  - [in] Percent of available margin (in %) to be used for trade operation.

**Return Value**

Maximum possible volume of trade operation.
**CSymbolInfo**

CSymbolInfo is a class for easy access to the symbol properties.

**Description**

CSymbolInfo class provides access to the symbol properties.

**Declaration**

```cpp
class CSymbolInfo : public CObject
```

**Title**

```cpp
#include <Trade\SymbolInfo.mqh>
```

**Inheritance hierarchy**

**CObject**

CSymbolInfo

Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare
Refresh

Refreshes the symbol data.

```cpp
void Refresh()
```

Return Value

None.

Note

The symbol should be selected by `Name` method.
**RefreshRates**

Refreshes the symbol quotes data.

```cpp
bool RefreshRates()
```

**Return Value**

- true - success, false - unable to refresh quotes.

**Note**

The symbol should be selected by `Name` method.
Name

Gets symbol name.

```cpp
string Name() const
```

Return Value

Symbol name.

Name

Sets symbol name.

```cpp
bool Name(string name)
```

Return Value

None.
Select

Gets the “Market Watch” symbol flag.

```cpp
bool Select() const
```

Return Value

“Market Watch” symbol flag.

Select

Sets the “Market Watch” symbol flag.

```cpp
bool Select()
```

Return Value

true - success, false - unable to change flag.

Note

The symbol should be selected by Name method.
IsSynchronized

Checks the symbol synchronization with server.

```cpp
bool IsSynchronized() const
```

Return Value

- true - if the symbol is synchronized with server, false - if not.

Note

The symbol should be selected by `Name` method.
**Volume**

Gets the volume of last deal.

```c
long Volume() const
```

**Return Value**

Volume of last deal.

**Note**

The symbol should be selected by `Name` method.
**VolumeHigh**

Gets the maximal volume of the day.

```cpp
long VolumeHigh() const
```

**Return Value**

Maximal volume of the day.

**Note**

The symbol should be selected by `Name` method.
VolumeLow

Gets the minimal volume of the day.

```cpp
long VolumeLow() const
```

Return Value

Minimal volume of the day.

Note

The symbol should be selected by `Name` method.
**Time**

Gets the time of last quote.

```cpp
datetime Time() const
```

Return Value

Time of last quote.

**Note**

The symbol should be selected by `Name` method.
**Spread**

Gets the amount of spread (in points).

```cpp
int Spread() const
```

**Return Value**

Gets the amount of spread (in points).

**Note**

The symbol should be selected by `Name` method.
SpreadFloat

Gets the flag of floating spread.

```cpp
bool SpreadFloat() const
```

Return Value

Flag of floating spread.

Note

The symbol should be selected by Name method.
**TicksBookDepth**

Gets the depth of ticks saving.

```cpp
int TicksBookDepth() const
```

**Return Value**

Depth of ticks saving.

**Note**

The symbol should be selected by `Name` method.
StopsLevel

Gets the minimal stop level for orders (in points).

```
int StopsLevel() const
```

Return Value

Minimal stop level for orders (in points).

Note

The symbol should be selected by Name method.
FreezeLevel

Gets the freeze level (in points).

```cpp
int FreezeLevel() const
```

Return Value

Distance of freeze level (in points).

Note

The symbol should be selected by Name method.
Bid

Gets the current Bid price.

\[
\text{double Bid()} \text{ const}
\]

Return Value

Current Bid price.

Note

The symbol should be selected by \text{Name} method.
BidHigh

Gets the maximal Bid price of the day.

```cpp
double BidHigh() const
```

Return Value

Maximal Bid price of the day.

Note

The symbol should be selected by Name method.
BidLow

Gets the minimal Bid price of the day.

```cpp
double BidLow() const
```

Return Value

Minimal Bid price of the day.

Note

The symbol should be selected by Name method.
Ask

Gets the current Ask price.

```cpp
double Ask() const
```

Return Value

Current Ask price.

Note

The symbol should be selected by `Name` method.
AskHigh

Gets the maximal Ask price for a day.

```
    double AskHigh() const
```

Return Value

Maximal Ask price of the day.

Note

The symbol should be selected by Name method.
AskLow

Gets the minimal Ask price for a day.

```cpp
  double  AskLow() const
```

Return Value

Minimal Ask price of the day.

Note

The symbol should be selected by Name method.
Last

Gets the current Last price.

```cpp
double Last() const
```

Return Value

Current Last price.
**LastHigh**

Gets the maximal Last price of the day.

```cpp
double LastHigh() const
```

**Return Value**

Maximal Last price of the day.

**Note**

The symbol should be selected by `Name` method.
LastLow

Gets the minimal Last price of the day.

\[
\text{double LastLow()} \text{ const}
\]

Return Value

Minimal Last price of the day.

Note

The symbol should be selected by Name method.
TradeCalcMode

Gets the mode of contract cost calculation.

`enum TradeCalcMode;` const

Return Value

Mode of contract cost calculation from `ENUM_SYMBOL_CALC_MODE` enumeration.

Note

The symbol should be selected by `Name` method.
TradeCalcModeDescription

Gets the mode of contract cost calculation as a string.

```cpp
string TradeCalcModeDescription() const
```

Return Value

Mode of contract cost calculation as a string.

Note

The symbol should be selected by `Name` method.
**TradeMode**

Gets the order execution type.

```cpp
ENUM_SYMBOL_TRADE_MODE TradeMode() const
```

**Return Value**

Order execution type from `ENUM_SYMBOL_TRADE_MODE` enumeration.

**Note**

The symbol should be selected by `Name` method.
TradeModeDescription

Gets the trade mode as a string.

```cpp
string TradeModeDescription() const
```

Return Value

Trade mode as a string.

Note

The symbol should be selected by Name method.
TradeExecution

Gets the trade execution mode.

```
ENUM_SYMBOL_TRADE_EXECUTION TradeExecution() const
```

Return Value

Trade execution mode from `ENUM_SYMBOL_TRADE_EXECUTION` enumeration.

Note

The symbol should be selected by `Name` method.
TradeExecutionDescription

Gets the description of trade execution mode as a string.

```cpp
string TradeExecutionDescription() const
```

Return Value

Trade execution mode as a string.

Note

The symbol should be selected by `Name` method.
SwapMode

Gets the swap calculation mode.

### Return Value

Swap calculation mode from `ENUM_SYMBOL_SWAP_MODE` enumeration.

### Note

The symbol should be selected by `Name` method.
SwapModeDescription

Gets the swap mode description as a string.

```
string SwapModeDescription() const
```

Return Value

Swap mode description as a string.

Note

The symbol should be selected by Name method.
SwapRollover3days

Gets the swap rollover day.

```c
ENUM_DAY_OF_WEEK SwapRollover3days() const
```

Return Value

Swap rollover day from `ENUM_DAY_OF_WEEK` enumeration.

Note

The symbol should be selected by `Name` method.
SwapRollover3daysDescription

Gets the swap rollover day as a string.

```
string SwapRollover3daysDescription() const
```

**Return Value**

Swap rollover day as a string.

**Note**

The symbol should be selected by `Name` method.
**MarginInitial**

Gets the value of initial margin.

```cpp
double MarginInitial()
```

**Return Value**

Value of initial margin.

**Note**

It returns the amount of margin (in margin currency of instrument) that is charged from one lot. Used to check client's equity, when they enter the market.

The symbol should be selected by Name method.
MarginMaintenance

Gets the value of maintenance margin.

```
double MarginMaintenance()
```

Return Value

Value of maintenance margin.

Note

It returns the amount of margin (in margin currency of instrument) that is charged from one lot. Used to check client’s equity, when the account state is changed. If the maintenance margin is equal to 0, then the initial margin is used.

The symbol should be selected by Name method.
**MarginLong**

Gets the rate of margin charging on long positions.

```cpp
double MarginLong() const
```

**Return Value**

Rate of margin charging on long positions.

**Note**

The symbol should be selected by `Name` method.
**MarginShort**

Gets the rate of margin charging on short positions.

```c
double MarginShort() const
```

**Return Value**

Rate of margin charging on short positions.

**Note**

The symbol should be selected by `Name` method.
MarginLimit

Gets the rate of margin charging on Limit orders.

```c
double MarginLimit() const
```

Return Value

Rate of margin charging on Limit orders.

Note

The symbol should be selected by `Name` method.
**MarginStop**

Gets the rate of margin charging on Stop orders.

```c
double MarginStop() const
```

**Return Value**

Rate of margin charging on Stop orders.

**Note**

The symbol should be selected by [Name](#) method.
**MarginStopLimit**

 Gets the rate of margin charging on Stop Limit orders.

```cpp
    double MarginStopLimit() const
```

**Return Value**

Rate of margin charging on Stop Limit orders.

**Note**

The symbol should be selected by `Name` method.
TradeTimeFlags

Gets the flags of allowed expiration modes.

```cpp
int TradeTimeFlags() const
```

Return Value

Flags of allowed expiration modes.

Note

The symbol should be selected by Name method.
TradeFillFlags

Gets the flags of allowed filling modes.

```cpp
int TradeFillFlags() const
```

Return Value

Flags of allowed filling modes.

Note

The symbol should be selected by Name method.
**Digits**

Gets the number of digits after period.

```cpp
int Digits() const
```

**Return Value**

The number of digits after period.

**Note**

The symbol should be selected by Name method.
Point

Gets the value of one point.

```cpp
double Point() const
```

Return Value

Value of one point.

Note

The symbol should be selected by `Name` method.
TickValue

Gets the tick value (minimal change of price).

```
    double TickValue() const
```

Return Value

Tick value (minimal change of price).

Note

The symbol should be selected by Name method.
TickValueProfit

Gets the calculated tick price for a profitable position.

```cpp
double TickValueProfit() const
```

Return Value

The calculated tick price for a profitable position.

Note

The symbol should be selected by `Name` method.
**TickValueLoss**

Gets the calculated tick price for a losing position.

```cpp
double TickValueLoss() const
```

**Return Value**

The calculated tick price for a losing position.

**Note**

The symbol should be selected by `Name` method.
**TickSize**

Gets the minimal change of price.

```cpp
double TickSize() const
```

**Return Value**

Minimal change of price.

**Note**

The symbol should be selected by `Name` method.
**ContractSize**

Gets the amount of trade contract.

```cpp
double ContractSize() const
```

**Return Value**

Amount of trade contract.

**Note**

The symbol should be selected by `Name` method.
**LotsMin**

GETS the minimal volume to close a deal.

```cpp
double LotsMin() const
```

**Return Value**

Minimal volume to close a deal.

**Note**

The symbol should be selected by `Name` method.
LotsMax

Gets the maximal volume to close a deal.

```cpp
double LotsMax() const
```

**Return Value**

*Maximal volume to close a deal.*

**Note**

The symbol should be selected by `Name` method.
**LotsStep**

Gets the minimal step of volume change to close a deal.

```cpp
double LotsStep() const
```

**Return Value**

**Minimal step of volume change to close a deal.**

**Note**

The symbol should be selected by Name method.
**LotsLimit**

Gets the maximal allowed volume of opened position and pending orders (direction insensitive) for one symbol.

```cpp
double LotsLimit() const
```

**Return Value**

The maximal allowed volume of opened position and pending orders (direction insensitive) for one symbol.

**Note**

The symbol should be selected by `Name` method.
SwapLong

Gets the value of long position swap.

```c
double SwapLong() const
```

Return Value

Value of long position swap.

Note

The symbol should be selected by `Name` method.
SwapShort

Gets the value of short position swap.

```cpp
double SwapShort() const
```

Return Value

Value of short position swap.

Note

The symbol should be selected by `Name` method.
CurrencyBase

Gets the name of symbol base currency.

```cpp
string CurrencyBase() const
```

Return Value

Name of symbol base currency.

Note

The symbol should be selected by `Name` method.
**CurrencyProfit**

Gets the profit currency name.

```cpp
string CurrencyProfit() const
```

**Return Value**

Profit currency name.

**Note**

The symbol should be selected by `Name` method.
**CurrencyMargin**

Gets the margin currency name.

```plaintext
string CurrencyMargin() const
```

**Return Value**

Margin currency name.

**Note**

The symbol should be selected by `Name` method.
**Bank**

Gets the name of current quote source.

```
string Bank() const
```

**Return Value**

Name of current quote source.

**Note**

The symbol should be selected by `Name` method.
Description

Gets the string description of symbol.

```cpp
string Description() const
```

Return Value

String description of symbol.

Note

The symbol should be selected by `Name` method.
Path

Gets the path in symbols tree.

`string Path() const`

Return Value

- Gets the path in symbols tree.

Note

The symbol should be selected by `Name` method.
SessionDeals

Gets the number of deals in the current session.

```cpp
long SessionDeals() const
```

Return Value

Number of deals in the current session.

Note

The symbol should be selected by `Name` method.
**SessionBuyOrders**

**Gets the number of Buy orders at the moment.**

```cpp
long SessionBuyOrders() const
```

**Return Value**

Number of Buy orders at the moment.

**Note**

The symbol should be selected by `Name` method.
SessionSellOrders

Gets then number of Sell orders at the moment.

```c
long SessionSellOrders() const
```

Return Value

Number of Sell orders at the moment.

Note

The symbol should be selected by `Name` method.
### SessionTurnover

**Gets summary turnover of the current session.**

```cpp
    double SessionTurnover() const
```

#### Return Value

Summary turnover of the current session.

#### Note

The symbol should be selected by `Name` method.
SessionInterest

Gets the summary of open interest of the current session.

```cpp
double SessionInterest() const
```

Return Value

Summary open interest of the current session.

Note

The symbol should be selected by Name method.
SessionBuyOrdersVolume

Gets the current volume of Buy orders.

```cpp
double SessionBuyOrdersVolume() const
```

Return Value

Current volume of Buy orders.

Note

The symbol should be selected by `Name` method.
SessionSellOrdersVolume

Gets the current volume of Sell orders.

```cpp
    double SessionSellOrdersVolume() const
```

Return Value

Current volume of Sell orders.

Note

The symbol should be selected by `Name` method.
SessionOpen

Gets the open price of the current session.

```c
double SessionOpen() const
```

Return Value

Open price of the current session.

Note

The symbol should be selected by `Name` method.
SessionClose

Gets the close price of the current session.

```cpp
double SessionClose() const
```

Return Value

Close price of the current session.

Note

The symbol should be selected by `Name` method.
**SessionAW**

Gets the average weighted price of the current session.

```c
double SessionAW() const
```

**Return Value**

Average weighted price of the current session.

**Note**

The symbol should be selected by `Name` method.
**SessionPriceSettlement**

Gets the settlement price of the current session.

```cpp
double SessionPriceSettlement() const
```

**Return Value**

Settlement price of the current session.

**Note**

The symbol should be selected by `Name` method.
SessionPriceLimitMin

Gets the minimal price of the current session.

```cpp
double SessionPriceLimitMin() const
```

**Return Value**

Minimal price of the current session.

**Note**

The symbol should be selected by Name method.
SessionPriceLimitMax

Gets the maximal price of the current session.

```
double SessionPriceLimitMax() const
```

Return Value

Maximal price of the current session.

Note

The symbol should be selected by Name method.
**InfoInteger**

Gets the value of specified integer type property.

```cpp
bool InfoInteger(
   ENUM_SYMBOL_INFO_INTEGER prop_id, // property ID
   long& var // reference to variable

) const
```

**Parameters**

*prop_id*

[in] ID of integer type property from `ENUM_SYMBOL_INFO_INTEGER` enumeration.

*var*

[out] Reference to `long` type variable to place result.

**Return Value**

true - success, false - unable to get property value.

**Note**

The symbol should be selected by `Name` method.
**InfoDouble**

Gets the value of specified double type property.

```cpp
bool InfoDouble(
    ENUM_SYMBOL_INFO_DOUBLE prop_id,  // property ID
    double& var                      // reference to variable
) const
```

**Parameters**

- **prop_id**
  - [in] ID of double type property from `ENUM_SYMBOL_INFO_DOUBLE` enumeration.

- **var**
  - [out] Reference to `double` type variable to place result.

**Return Value**

- `true` - success, `false` - unable to get property value.

**Note**

The symbol should be selected by `Name` method.
InfoString

Gets the value of specified string type property.

```cpp
bool InfoString(
    ENUM_SYMBOL_INFO_STRING prop_id, // property ID
    string& var // reference to variable
) const
```

**Parameters**

*prop_id*

[in] ID of text property.

*var*

[ou] Reference to string type variable to place result.

**Return Value**

true - success, false - unable to get property value.

**Note**

The symbol should be selected by Name method.
**NormalizePrice**

Returns the value of price normalized using the symbol properties.

```cpp
double NormalizePrice(
    double price  // price
) const
```

**Parameters**

- `price`
  - [in] Price.

**Return Value**

- Normalized price.

**Note**

The symbol should be selected by `Name` method.
COrderInfo

COrderInfo is a class for easy access to the pending order properties.

Description

COrderInfo class provides access to the pending order properties.

Declaration

```cpp
class COrderInfo : public CObject
```

Title

```cpp
#include <Trade\OrderInfo.mqh>
```

Inheritance hierarchy

CObject

  COrderInfo

### Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare
Ticket

Gets the ticket of an order.

`ulong Ticket() const`

Return Value

Order ticket if successful, otherwise - `ULONG_MAX`.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
TimeSetup

Gets the time of order placement.

```cpp
.datetime  TimeSetup() const
```

Return Value

Time of order placement.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TimeSetupMsc**

Receives the time of placing an order for execution in milliseconds since 01.01.1970.

```cpp
ulong TimeSetupMsc() const
```

**Return Value**

The time of placing an order for execution in milliseconds since 01.01.1970.

**Note**

Order should be preliminarily selected for access using `Select` (by ticket) or `SelectByIndex` (by index) method.
**OrderType**

Gets the order type.

```c
ENUM_ORDER_TYPE OrderType();
```

**Return Value**

Order type from `ENUM_ORDER_TYPE` enumeration.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TypeDescription**

Gets the order type as a string.

```cpp
string TypeDescription() const
```

**Return Value**

Order type as a string.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
State

Gets the order state.

```c
enum ORDER_STATE State() const
```

**Return Value**

Order state from `ENUM_ORDER_STATE` enumeration.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
StateDescription

Gets the order state as a string.

```cpp
string StateDescription() const
```

Return Value

Order state as a string.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
TimeExpiration

Gets the order expiration time.

```cpp
    datetime   TimeExpiration() const
```

Return Value

Order expiration time, set on its placement.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TimeDone**

Gets the time of order execution or cancellation.

```cpp
datetime TimeDone() const
```

**Return Value**

Time of order execution or cancellation.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TimeDoneMsc**

Receives order execution or cancellation time in milliseconds since 01.01.1970.

```cpp
ulong TimeDoneMsc() const
```

**Return Value**

Order execution or cancellation time in milliseconds since 01.01.1970.

**Note**

Order should be preliminarily selected for access using `Select` (by ticket) or `SelectByIndex` (by index) method.
TypeFilling

Gets the order filling type.

```
ENUM_ORDER_TYPE_FILLING TypeFilling() const
```

Return Value

Order filling type from `ENUM_ORDER_TYPE_FILLING` enumeration.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TypeFillingDescription**

Gets the order filling type as a string.

```
string TypeFillingDescription() const
```

**Return Value**

Order filling type as a string.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
TypeTime

Gets the type of order at the time of the expiration.

```cpp
enum ORDER_TYPE_TIME TypeTime() const
```

**Return Value**

Type of order at the time of the expiration from `ENUM_ORDER_TYPE_TIME` enumeration.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TypeTimeDescription**

Gets the order type by expiration time as a string.

```cpp
string TypeTimeDescription() const
```

**Return Value**

Order type by expiration time as a string.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.

**Magic**

 Gets the ID of an Expert Advisor that placed the order.

```cpp
long Magic() const
```

**Return Value**

- ID of an Expert Advisor that placed the order.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
PositionId

Gets the ID of position.

```cpp
long PositionId() const
```

**Return Value**

ID of position, in which the order was involved.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**VolumeInitial**

Gets the initial volume of order.

```c
double VolumeInitial() const
```

**Return Value**

Initial volume of order.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**VolumeCurrent**

Gets the unfilled volume of order.

```cpp
    double VolumeCurrent() const
```

**Return Value**

Unfilled volume of order.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
PriceOpen

Gets the order price.

```cpp
double PriceOpen() const
```

**Return Value**

*Price of order placement.*

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
StopLoss

Gets the order's Stop Loss.

```cpp
    double StopLoss() const
```

Return Value

Order's Stop Loss.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TakeProfit**

Gets the order's Take Profit.

```cpp
double TakeProfit() const
```

**Return Value**

Order's Take Profit.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
PriceCurrent

Gets the current price by order symbol.

```cpp
double PriceCurrent() const
```

Return Value

Current price by order symbol.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
PriceStopLimit

Gets the price of a pending order.

```cpp
double PriceStopLimit() const
```

Return Value

Pending order price.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**Symbol**

Gets the name of order symbol.

```cpp
string Symbol() const
```

**Return Value**

Name of order symbol.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Comment

Gets the order comment.

```c++
string Comment() const
```

Return Value

Order comment.

Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**InfoInteger**

Gets the value of specified integer type property.

```cpp
bool InfoInteger(
    ENUM_ORDER_PROPERTY_INTEGER prop_id,  // property ID
    long& var                               // reference to variable
) const
```

**Parameters**

- **prop_id**
  - [in] ID of integer type property from **ENUM_ORDER_PROPERTY_INTEGER** enumeration.

- **var**
  - [out] Reference to **long** type variable to place result.

**Return Value**

- true - success, false - unable to get property value.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
InfoDouble

Gets the value of specified double type property.

```cpp
bool InfoDouble(
    ENUM_ORDER_PROPERTY_DOUBLE prop_id,  // property ID
    double& var  // reference to variable
) const
```

**Parameters**

*prop_id*

[in] ID of double type property from `ENUM_ORDER_PROPERTY_DOUBLE` enumeration.

*var*

[out] Reference to `double` type variable to place result.

**Return Value**

true - success, false - unable to get property value.

**Note**

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
### InfoString

Gets the value of specified string type property.

```cpp
bool InfoString(
    ENUM_ORDERPROPERTY_STRING prop_id,  // property ID
    string& var                              // reference to variable
) const
```

#### Parameters

- **prop_id**
  - [in] ID of string property from `ENUM_ORDERPROPERTY_STRING` enumeration.

- **var**
  - [out] Reference to `string` type variable to place result.

#### Return Value

- `true` - success, `false` - unable to get property value.

#### Note

The order should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
StoreState

Saves the order parameters.

```c
void StoreState()
```

Return Value

None.
CheckState

Checks the current parameters against the saved parameters.

```cpp
bool CheckState()
```

Return Value

- true - if the order parameters have changed since the last call of the `StoreState()` method, otherwise
- false.
Select

Selects an order by ticket for further access to its properties.

```cpp
bool Select(
    ulong ticket  // order ticket
)
```

Return Value

true - success, false - unable to select order.
SelectByIndex

Selects an order by index.

```cpp
bool SelectByIndex(
    int index  // order index
)
```

Parameters

`index`

[in] Order index.

Return Value

true - success, false - unable to select order.
**CHistoryOrderInfo**

CHistoryOrderInfo is a class for easy access to the history order properties.

**Description**

CHistoryOrderInfo class provides easy access to the history order properties.

**Declaration**

```cpp
class CHistoryOrderInfo : public CObject
```

**Title**

```cpp
#include <Trade\HistoryOrderInfo.mqh>
```

**Inheritance hierarchy**

- CObject
  - CHistoryOrderInfo

### Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare
**TimeSetup**

Gets the time of order placement.

```cpp
    datetime TimeSetup() const
```

**Return Value**

Time of order placement.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
TimeSetupMsc

Receives the time of placing an order for execution in milliseconds since 01.01.1970.

```c
ulong TimeSetupMsc() const
```

Return Value

The time of placing an order for execution in milliseconds since 01.01.1970.

Note

Historical order should be preliminarily selected for access using `Ticket` (by ticket) or `SelectByIndex` (by index) method.
**OrderType**

Gets the order type.

```cpp
    ENUM_ORDER_TYPE OrderType() const
```

**Return Value**

Order type from `ENUM_ORDER_TYPE` enumeration.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
TypeDescription

Gets the order type as a string.

```cpp
string TypeDescription() const
```

Return Value

Order type as a string.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
State

Gets the order state.

```cpp
ENUM_ORDER_STATE State() const
```

Return Value

Order state from `ENUM_ORDER_STATE` enumeration.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
StateDescription

Gets the order state as a string.

```
string StateDescription() const
```

Return Value

Order state as a string.

Note

The historical order should be selected using the Ticket (by ticket) or SelectByIndex (by index) methods.
TimeExpiration

Gets the time of order expiration.

```cpp
datetime TimeExpiration() const
```

Return Value

Time of order expiration, set on its placement.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
TimeDone

Gets the time of order execution or cancellation.

```cpp
datetime TimeDone() const
```

**Return Value**

Time of order execution or cancellation.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**TimeDoneMsc**

Receives order execution or cancellation time in milliseconds since 01.01.1970.

```c
ulong TimeDoneMsc() const
```

**Return Value**

Order execution or cancellation time in milliseconds since 01.01.1970.

**Note**

Historical order should be preliminarily selected for access using `Ticket` (by ticket) or `SelectByIndex` (by index) method.
TypeFilling

Gets the type of order execution by remainder.

```c
ENUM_ORDER_TYPE_FILLING TypeFilling() const
```

Return Value

Type of order execution by remainder from `ENUM_ORDER_TYPE_FILLING` enumeration.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
TypeFillingDescription

Gets the type of order execution by remainder as a string.

```
string TypeFillingDescription() const
```

Return Value

Type order of execution by remainder as a string.

Note

The historical order should be selected using the Ticket (by ticket) or SelectByIndex (by index) methods.
**TypeTime**

Gets the type of order at the time of the expiration.

```cpp
ENUM_ORDER_TYPE_TIME TypeTime() const
```

**Return Value**

Type of order at the time of the expiration from `ENUM_ORDER_TYPE_TIME` enumeration.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**TypeTimeDescription**

Gets the order type by expiration time as a string.

```cpp
string TypeTimeDescription() const
```

**Return Value**

Order type by expiration time as a string.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Magic

Gets the ID of the Expert Advisor, that placed the order.

```cpp
long Magic() const
```

Return Value

ID of the Expert Advisor, that placed the order.

Note

The historical order should be selected using the Ticket (by ticket) or SelectByIndex (by index) methods.
PositionId

Gets the ID of position.

```cpp
long PositionId() const
```

Return Value

ID of position, in which the order was involved.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
VolumeInitial

Gets the initial volume of order.

```cpp
double VolumeInitial() const
```

Return Value

Initial volume of order.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**VolumeCurrent**

Gets the unfilled volume of order.

```
double VolumeCurrent() const
```

**Return Value**

Unfilled volume of order.

**Note**

The historical order should be selected using the Ticket (by ticket) or SelectByIndex (by index) methods.
**PriceOpen**

Gets the order price.

```cpp
double PriceOpen() const
```

**Return Value**

*Price of order placement.*

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**StopLoss**

Gets the Stop Loss price of the order.

```cpp
double StopLoss() const
```

**Return Value**

Stop Loss price of the order.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
TakeProfit

Gets the Take Profit price of the order.

```cpp
double TakeProfit() const
```

**Return Value**

The Take Profit price of the order.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**PriceCurrent**

Gets the current price of the order’s symbol.

```cpp
double PriceCurrent() const
```

**Return Value**

The current price of order’s symbol.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
PriceStopLimit

Gets the pending order price.

```cpp
double PriceStopLimit() const
```

Return Value

Pending orders price.

Note

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Symbol**

Gets the name of order symbol.

```cpp
string Symbol() const
```

**Return Value**

Name of order symbol.

**Note**

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.
**Comment**

Gets the order comment.

```cpp
string Comment() const
```

**Return Value**

Order comment.

**Note**

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.
**InfoInteger**

Gets the value of specified integer type property.

```cpp
bool InfoInteger(
    ENUM_ORDER_PROPERTY_INTEGER prop_id,  // property ID
    long& var  // reference to variable
) const
```

**Parameters**

- **prop_id**
  
  [in] ID of integer type property from **ENUM_ORDER_PROPERTY_INTEGER** enumeration.

- **var**
  
  [out] Reference to `long` type variable to place result.

**Return Value**

- `true` - success, `false` - unable to get property value.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
InfoDouble

Gets the value of specified double type property.

```cpp
bool InfoDouble(
    ENUM_ORDER_PROPERTY_DOUBLE prop_id,  // property ID
    double& var                         // reference to variable
) const
```

Parameters

prop_id

[in] ID of double type property from ENUM_ORDER_PROPERTY_DOUBLE enumeration.

var

[out] Reference to double type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The historical order should be selected using the Ticket (by ticket) or SelectByIndex (by index) methods.
InfoString

Gets the value of specified string type property.

```cpp
bool InfoString(
    ENUM_ORDERPROPERTYSTRING prop_id, // property ID
    string& var, // reference to variable
) const
```

**Parameters**

*prop_id*

[in] ID of text property from `ENUM_ORDERPROPERTYSTRING` enumeration.

*var*

[ out] Reference to `string` type variable to place result.

**Return Value**

true - success, false - unable to get property value.

**Note**

The historical order should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Ticket (Get method)

Gets the order ticket.

```c
ulong Ticket() const
```

Return Value

Order ticket.

Ticket (Set method)

Select the order for further work.

```c
void Ticket(
    ulong ticket // ticket
)
```

Parameters

ticket

SelectByIndex

Selects a historical order by index.

```cpp
bool SelectByIndex(
    int index  // order index
)
```

Parameters

`index`

[in] Historical order index.

Return Value

true - success, false - unable to select order.
CPositionInfo

CPositionInfo is a class for easy access to the open position properties.

Description

CPositionInfo class provides easy access to the open position properties.

Declaration

```cpp
class CPositionInfo : public CObject
```

Title

```cpp
#include <Trade\PositionInfo.mqh>
```

Inheritance hierarchy

- CObject
  - CPositionInfo

**Methods inherited from class CObject**
- Prev, Prev, Next, Next, **Save**, **Load**, **Type**, **Compare**
Time

Gets the time of position opening.

```cpp
datetime Time() const
```

**Return Value**

Time of position opening.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
TimeMsc

Receives position opening time in milliseconds since 01.01.1970.

```c
ulong TimeMsc() const
```

Return Value

Position opening time in milliseconds since 01.01.1970.

Note

Position should be preliminarily selected for access using `Select` (by symbol) or `SelectByIndex` (by index) method.
TimeUpdate

Receives the time of position changing in seconds since 01.01.1970.

```cpp
  datetime  TimeUpdate() const
```

**Return Value**

Time of position changing in seconds since 01.01.1970.

**Note**

Position should be preliminarily selected for access using `Select` (by symbol) or `SelectByIndex` (by index) method.
TimeUpdateMsc

Receives the time of position changing in milliseconds since 01.01.1970.

```cpp
ulong TimeUpdateMsc() const
```

Return Value

The time of position changing in milliseconds since 01.01.1970.

Note

Position should be preliminarily selected for access using `Select` (by symbol) or `SelectByIndex` (by index) method.
PositionType

Gets the position type.

\texttt{\textit{ENUM\_POSITION\_TYPE} \ PositionType() const}

Return Value

Position type from \texttt{ENUM\_POSITION\_TYPE} enumeration.

Note

The position should be selected using the \texttt{Select} (by ticket) or \texttt{SelectByIndex} (by index) methods.
**TypeDescription**

Gets the position type as a string.

```
string TypeDescription() const
```

**Return Value**

Position type as a string.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**Magic**

Gets the ID of Expert Advisor that opened the position.

```cpp
long Magic() const
```

**Return Value**

ID of the Expert Advisor that opened the position.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**Identifier**

Gets the ID of position.

```cpp
long Identifier() const
```

**Return Value**

ID of position.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Volume

Gets the volume of position.

```
   double Volume() const
```

**Return Value**

Volume of position.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**PriceOpen**

Gets the price of position opening.

```cpp
double PriceOpen() const
```

**Return Value**

Position open price.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**StopLoss**

Gets the Stop Loss price of the position.

```cpp
double StopLoss() const
```

**Return Value**

The Stop Loss price of the position.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**TakeProfit**

Gets the Take Profit price of the position.

```cpp
    double TakeProfit() const
```

**Return Value**

The Take Profit price of the position.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**PriceCurrent**

Gets the current price by position symbol.

```cpp
double PriceCurrent() const
```

**Return Value**

Current price by position symbol.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Commission

Gets the amount of commission of the position.

```cpp
double Commission() const
```

Return Value

Amount of commission of the position (in deposit currency).

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Swap

Gets the amount of swap of the position.

```cpp
double Swap() const
```

Return Value

Amount of swap of the position (in deposit currency).

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Profit

Gets the amount of current profit of the position.

```cpp
double Profit() const
```

Return Value

Amount of current profit of the position (in deposit currency).

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Symbol

Gets the name of position symbol.

```csharp
string Symbol() const
```

Return Value

Name of position symbol.

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Comment

Gets the comment of the position.

```cpp
string Comment() const
```

Return Value

Comment of the position.

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**InfoInteger**

Gets the value of specified integer type property.

```cpp
bool InfoInteger(
    ENUM_POSITION_PROPERTY_INTEGER prop_id, // property ID
    long& var // reference to variable
) const
```

**Parameters**

- `prop_id`
  - [in] ID of integer type property from `ENUM_POSITION_PROPERTY_INTEGER` enumeration.

- `var`
  - [out] Reference to `long` type variable to place result.

**Return Value**

- `true` - success, `false` - unable to get property value.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
InfoDouble

Gets the value of specified double type property.

```cpp
bool InfoDouble(
    ENUM_POSITION_PROPERTY_DOUBLE prop_id, // property ID
    double& var // reference to variable
) const
```

Parameters

`prop_id`

[in] ID of double type property from `ENUM_POSITION_PROPERTY_DOUBLE` enumeration.

`var`

[in] Reference to `double` type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
**InfoString**

Gets the value of specified string type property.

```cpp
bool InfoString(
    ENUM_POSITIONPROPERTY_STRING prop_id, // property ID
    string& var // reference to variable
) const
```

**Parameters**

- `prop_id`  
  [in] ID of text property from `ENUM_POSITIONPROPERTY_STRING` enumeration.

- `var`  
  [out] Reference to `string` type variable to place result.

**Return Value**

- `true` - success, `false` - unable to get property value.

**Note**

The position should be selected using the `Select` (by ticket) or `SelectByIndex` (by index) methods.
Select

Select the position for further work.

```cpp
bool Select(
    const string symbol // symbol
)
```

Parameters
symbol

SelectByIndex

Selects the position by index for further access to its properties.

```cpp
bool SelectByIndex(
    int index  // position index
);
```

Return Value

ture - success, false - unable to select position.
**SelectByMagic**

Select a position based on the name of a financial instrument and magic number to further work with.

```csharp
bool SelectByMagic(
    const string symbol, // symbol name
    const ulong magic    // magic number
);
```

**Parameters**

- `symbol`
  - `[in]` Symbol name.

- `magic`
  - `[in]` Magic number of the position.

**Return Value**

- true - successful, false - unable to select position.
SelectByTicket

Selects position by ticket for further operation.

```mql5
bool SelectByTicket(
    ulong ticket // position ticket
);
```

Parameters

- `ticket`
  - [in] Position ticket.

Return value

- true - success, false - no position selected.
StoreState

Saves the position parameters.

```cpp
void StoreState()
```

Return Value

None.
CheckState

Checks the current parameters against the saved parameters.

```cpp
bool CheckState()
```

Return Value

true - the position parameters have changed since the last call of the `StoreState()` method, otherwise - false.
CDealInfo

CDealInfo is a class for easy access to the deal properties.

Description

CDealInfo class provides access to the deal properties.

Declaration

```cpp
class CDealInfo : public CObject
```

Title

```cpp
#include <Trade\DealInfo.mqh>
```

Inheritance hierarchy

- CObject
- CDealInfo

### Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare
Order

Gets the order by which the deal is executed.

```cpp
long Order() const
```

**Return Value**

Order by which the deal is executed.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Time

Gets the time of deal execution.

```cpp
datetime Time() const
```

Return Value

Time of deal execution.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**TimeMsc**

Receives the time of a deal execution in milliseconds since 01.01.1970.

```c++
ulong TimeMsc() const
```

**Return Value**

The time of a deal execution in milliseconds since 01.01.1970.

**Note**

Deal should be preliminarily selected for access using `Ticket` (by ticket) or `SelectByIndex` (by index) method.
DealType

Gets the deal type.

```cpp
enum DealType;
```

Return Value

Deal type from `ENUM_DEAL_TYPE` enumeration.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**TypeDescription**

Gets the deal type as a string.

```cpp
string TypeDescription() const
```

**Return Value**

Deal type as a string.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Entry

Compares the deal direction.

```cpp
enum DEAL_ENTRY Entry() const
```

Return Value

Deal direction (value of `ENUM DEAL_ENTRY` enumeration).

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
EntryDescription

Gets the deal direction as a string.

```cpp
string EntryDescription() const
```

Return Value

Deal direction as a string.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Magic**

Gets the ID of the Expert Advisor, that executed the deal.

```cpp
long Magic() const
```

**Return Value**

ID of the Expert Advisor, that executed the deal.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**PositionId**

Gets the ID of position, in which the deal was involved.

```cpp
long PositionId() const
```

**Return Value**

ID of position, in which the deal was involved.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Volume**

Gets the volume of deal.

```cpp
  double Volume() const
```

**Return Value**

Volume of deal.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Price

Gets the deal price.

```cpp
double Price() const
```

Return Value

Deal price.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Commission

Gets the amount of commission of the deal.

```cpp
    double Commission() const
```

**Return Value**

Amount of commission of the deal.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Swap

Gets the amount of swap when position is closed.

```cpp
double Swap() const
```

Return Value

Amount of swap when position is closed.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Profit**

Gets the financial result of the deal.

```cpp
double Profit() const
```

Return Value

Financial result of the deal (in deposit currency).

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
Symbol

Gets the name of the deal symbol.

```
string Symbol() const
```

Return Value

Name of the deal symbol.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Comment**

Gets the deal comment.

```c++
string Comment() const
```

**Return Value**

Deal comment.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
InfoInteger

Gets the value of specified integer type property.

```cpp
bool InfoInteger(
    ENUM DEAL_PROPERTY_INTEGER prop_id,  // property ID
    long& var                           // reference to variable
) const
```

Parameters

`prop_id`

[in] ID of integer type property from `ENUM DEAL_PROPERTY_INTEGER` enumeration.

`var`

[out] Reference to `long` type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
InfoDouble

Gets the value of specified double type property.

```c
bool InfoDouble(
    ENUM_DEAL_PROPERTY_DOUBLE prop_id,  // property ID
    double& var                       // reference to variable
) const
```

Parameters

- `prop_id`
  - [in] ID of double type property from `ENUM_DEAL_PROPERTY_DOUBLE` enumeration.

- `var`
  - [out] Reference to `double` type variable to place result.

Return Value

- true - success, false - unable to get property value.

Note

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**InfoString**

Gets the value of specified string type property.

```c
bool InfoString(
    ENUM_DEAL_PROPERTY_STRING prop_id, // property ID
    string& var // reference to variable
) const
```

**Parameters**

- `prop_id`
  - [in] ID of text property from `ENUM_DEAL_PROPERTY_STRING` enumeration.
- `var`
  - [out] Reference to `string` type variable to place result.

**Return Value**

- `true` - success, `false` - unable to get property value.

**Note**

The deal should be selected using the `Ticket` (by ticket) or `SelectByIndex` (by index) methods.
**Ticket (Get method)**

Gets the deal ticket.

```cpp
ulong Ticket() const
```

**Return Value**

Deal ticket.

**Ticket (Set method)**

Select the position for further work.

```cpp
void Ticket(
    ulong ticket // ticket
)
```

**Parameters**

`ticket`

[in] Deal ticket.
SelectByIndex

Selects the deal by index for further access to its properties.

```cpp
bool SelectByIndex(
    int index  // order index
)
```

Return Value

true - success, false - unable to select the deal.
CTrade

CTrade is a class for easy access to the trade functions.

Description

CTrade class provides easy access to the trade functions.

Declaration

```cpp
class CTrade : public CObject
```

Title

```cpp
#include <Trade\Trade.mqh>
```

Inheritance hierarchy

- CObject
- CTrade

Direct descendants

- CExpertTrade

Class methods by groups

Operations with orders

- OrderOpen: Places a pending order with specified parameters
- OrderModify: Modifies the pending order parameters
- OrderDelete: Deletes a pending order

Operations with positions

- PositionOpen: Opens a position with specified parameters
### PositionModify
Modifies position parameters by the specified symbol or position ticket

### PositionClose
Closes a position for the specified symbol

### PositionClosePartial
Partially closes a position on a specified symbol or having a specified ticket

### PositionCloseBy
Closes a position with the specified ticket by an opposite position

#### Additional methods

<table>

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare
**LogLevel**

Sets logging level for messages.

```c
void LogLevel(
    ENUM_LOG_LEVELS log_level  // level
)
```

**Parameters**

- `log_level`
  - [in] New logging level.

**Return Value**

None.

**Note**

LOG_LEVEL_NO and less disables displaying any messages (set up automatically in the optimization mode). LOG_LEVEL_ERRORS enables displaying only error messages (value by default). LOG_LEVEL_ALL and greater enables displaying any messages (set up automatically in the test mode).

**ENUM_LOG_LEVELS**

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOG_LEVEL_NO</td>
<td>Displaying messages disabled</td>
<td>0</td>
</tr>
<tr>
<td>LOG_LEVEL_ERRORS</td>
<td>Only error messages are displayed</td>
<td>1</td>
</tr>
<tr>
<td>LOG_LEVEL_ALL</td>
<td>All messages are displayed</td>
<td>2</td>
</tr>
</tbody>
</table>
### SetExpertMagicNumber

Sets the expert ID.

```c
void SetExpertMagicNumber(
    ulong magic  // ID
)
```

**Parameters**

- `magic`

**Return Value**

- None.
SetDeviationInPoints

Sets the allowed deviation.

```c
void SetDeviationInPoints(
    ulong deviation // deviation
)
```

Parameters

deviation

[in] Allowed deviation in points.

Return Value

None.
**SetTypeFilling**

Sets filling type of the order.

```c
void SetTypeFilling(
    ENUM_ORDER_TYPE_FILLING filling  // order filling type
)
```

**Parameters**

- `filling`
  
  [in] Order filling type from `ENUM_ORDER_TYPE_FILLING` enumeration.

**Return Value**

None.
SetTypeFillingBySymbol

Sets filling type of the order according to the specified symbol settings.

```cpp
bool SetTypeFillingBySymbol(
    const string symbol // symbol name
)
```

**Parameters**

`symbol`

[in] Name of the symbol, in which SYMBOL_FILLING_MODE contains allowed order filling policies.

**Return Value**

true - successful execution, false - failed to define the filling policy.

**Note**

If SYMBOL_FILLING_FOK and SYMBOL_FILLING_IOC filling policies are allowed for a symbol simultaneously, the ORDER_FILLING_FOK value is set for the order.
SetAsyncMode

Sets asynchronous mode for trade operations.

```cpp
void SetAsyncMode(
    bool mode  // asynchronous mode flag
);```

Parameters

- **mode**

Return Value

- None.

Note

This mode is used for asynchronous (without waiting for the trade server's response to a sent request) trade operations (see `OrderSendAsync`).
SetMarginMode

Sets margin calculation mode in accordance with the current account settings.

```c
void SetMarginMode()
```

Return Value

No.

Note

The margin calculation mode is specified in `ENUM_ACCOUNT_MARGIN_MODE`.
OrderOpen

Places the pending order with set parameters.

```c++
bool OrderOpen(
    const string symbol,     // symbol
    ENUM_ORDER_TYPE order_type, // order type
    double volume,          // order volume
    double limit_price,     // StopLimit price
    double price,           // execution price
    double sl,              // Stop Loss price
    double tp,              // Take Profit price
    ENUM_ORDER_TYPE_TIME type_time, // type by expiration
    datetime expiration,    // expiration
    const string comment=""  // comment
)
```

**Parameters**

*symbol*
- [in] Name of trade instrument.

*order_type*
- [in] Type of order trade operation from `ENUM_ORDER_TYPE` enumeration.

*volume*
- [in] Requested order volume.

*limit_price*
- [in] Price at which the StopLimit order will be placed.

*price*
- [in] Price at which the order must be executed.

*sl*
- [in] Price at which the Stop Loss will trigger.

*tp*
- [in] Price at which the Take Profit will trigger.

*type_time*
- [in] Order type by execution from `ENUM_ORDER_TYPE_TIME` enumeration.

*expiration*
- [in] Expiration date of pending order.

*comment=""
- [in] Order comment.

**Return Value**

true - successful check of the basic structures, otherwise - false.
Note

Successful completion of the OrderSend(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of a trade request (trade server return code) using ResultRetcode() and value returned by ResultOrder().
**OrderModify**

Modifies the pending order parameters.

```c
bool OrderModify(
    ulong ticket,  // order ticket
    double price,   // execution price
    double sl,      // Stop Loss price
    double tp,      // Take Profit price
    ENUM_ORDER_TYPE_TIME type_time,  // type by expiration
    datetime expiration,  // expiration
    double stoplimit  // Limit order price
)
```

**Parameters**

- `ticket`  

- `price`  
  `[in]` The new price by which the order must be executed (or the previous value, if the change is not necessary).

- `sl`  
  `[in]` The new price by which the Stop Loss will trigger (or the previous value, if the change is not necessary).

- `tp`  
  `[in]` The new price by which the Take Profit will trigger (or the previous value, if the change is not necessary).

- `type_time`  
  `[in]` The new type of order by expiration from `ENUM_ORDER_TYPE_TIME` enumeration (or the previous value, if the change is not necessary).

- `expiration`  
  `[in]` The new expiration date of pending order (or the previous value, if the change is not necessary).

- `stoplimit`  
  `[in]` New price used for setting a Limit order when the price reaches `price` value. It is specified only for StopLimit orders.

**Return Value**

- `true` - successful check of the basic structures, otherwise - `false`.

**Note**

Successful completion of the `OrderModify(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()`.
**OrderDelete**

Deletes the pending order.

```csharp
bool OrderDelete(
    ulong ticket // order ticket
)
```

**Parameters**

**Return Value**

- `true` - successful check of the basic structures, otherwise - `false`.

**Note**

Successful completion of the `OrderDelete(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()`.
PositionOpen

Opens a position with the specified parameters.

```cpp
bool PositionOpen(
    const string symbol, // symbol
    const ENUM_ORDER_TYPE order_type, // order type to open position
    double volume, // position volume
    double price, // execution price
    double sl, // Stop Loss price
    double tp, // Take Profit price
    const string comment="" // comment
)
```

### Parameters

**symbol**
- [in] Name of trade instrument, by which it is intended to open position.

**order_type**
- [in] Order type (trade operation) to open position from `ENUM_ORDER_TYPE` enumeration.

**volume**
- [in] Requested position volume.

**price**
- [in] Price at which the position must be opened.

**sl**
- [in] Price at which the Stop Loss will trigger.

**tp**
- [in] Price at which the Take Profit will trigger.

**comment=""**
- [in] Position comment.

### Return Value

- `true` - successful check of the basic structures, otherwise - `false`.

### Note

Successful completion of the `PositionOpen(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()` and value returned by `ResultDeal()`.
**PositionModify**

Modifies the position parameters by specified symbol.

```cpp
bool PositionModify(
    const string symbol,  // symbol
    double sl,            // Stop Loss price
    double tp             // Take Profit price
)
```

Modifies position parameters by the specified ticket.

```cpp
bool PositionModify(
    const ulong ticket, // position ticket
    double sl,         // Stop Loss price
    double tp          // Take Profit price
)
```

**Parameters**

- `symbol`  
  [in] Name of trade instrument, by which it is intended to modify position.

- `ticket`  
  [in] Ticket of the position to be modified.

- `sl`  
  [in] The new price by which the Stop Loss will trigger (or the previous value, if the change is not necessary).

- `tp`  
  [in] The new price by which the Take Profit will trigger (or the previous value, if the change is not necessary).

**Return Value**

- `true` - successful check of the basic structures, otherwise - `false`.

**Note**

Successful completion of the `PositionModify(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()`.

For the "netting" interpretation of positions (**ACCOUNT_MARGIN_MODE_RETAIL_NETTING** and **ACCOUNT_MARGIN_MODE_EXCHANGE**), only one position can exist for a symbol at any moment of time. This position is a result of one or more **deals**. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (**ACCOUNT_MARGIN_MODE_RETAIL_HEDGING**), multiple positions can be open for one symbol. In this case, `PositionModify` will modify the position with the lowest ticket.
PositionClose

Closes a position by the specified symbol.

```cpp
bool PositionClose(  
    const string symbol,  // symbol  
    ulong deviation=ULONG_MAX  // deviation
);
```

Closes a position with the specified ticket.

```cpp
bool PositionClose(  
    const ulong ticket,  // position ticket  
    ulong deviation=ULONG_MAX  // deviation
);
```

Parameters

symbol
- [in] Name of trade instrument, by which it is intended to close position.

ticket

deviation=ULONG_MAX
- [in] Maximal deviation from the current price (in points).

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the PositionClose(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using ResultRetcode().

For the "netting" interpretation of positions (ACCOUNT_MARGIN_MODE_RETAIL_NETTING and ACCOUNT_MARGIN_MODE_EXCHANGE), only one position can exist for a symbol at any moment of time. This position is a result of one or more deals. Do not confuse positions with valid pending orders, which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be open for one symbol. In this case, PositionClose will close a position with the lowest ticket.
PositionClosePartial

Partially closes a position on a specified symbol in case of a “hedging” accounting.

```plaintext
bool PositionClosePartial{
    const string symbol, // symbol
    const double volume, // volume
    ulong deviation=ULONG_MAX // deviation
}
```

Partially closes a position having a specified ticket in case of a “hedging” accounting.

```plaintext
bool PositionClosePartial{
    const ulong ticket, // position ticket
    const double volume, // volume
    ulong deviation=ULONG_MAX // deviation
}
```

**Parameters**

**symbol**

[in] Name of a trading instrument, on which a position is closed partially. If a symbol (not a ticket) is specified for a position partial closing, the first detected position having a specified MagicNumber (Expert Advisor ID) on the symbol is selected. Therefore, it is sometimes better to use PositionClosePartial() with a specified position ticket.

**volume**

[in] Volume, by which a position should be decreased. If the value exceeds the volume of a partially closed position, it is closed in full. No position in the opposite direction is opened.

**ticket**

[in] Closed position ticket.

**deviation=ULONG_MAX**

[in] The maximum deviation from the current price (in points).

**Return Value**

true if the basic check of structures is successful, otherwise false.

**Note**

A successful completion of the PositionClosePartial(...) method does not always mean a successful execution of a trading operation. You should call the ResultRetcode() method to check the result of a trade request (trade server return code).

In the “netting” system (ACCOUNT_MARGIND_MODE_RETAIL_NETTING and ACCOUNT_MARGIND_MODE_EXCHANGE), for each symbol, at any given moment of time, only one position can be open, which is the result of one or more deals. Do not confuse the current pending orders with positions that are also displayed on the "Trade" tab of the client terminal's "Toolbox" panel.
In case of the position representation (ACCOUNT_MARGIN_MODE_RETAIL_HEDGING), multiple positions can be opened on each symbol simultaneously. In this case, PositionClose closes a position having a least ticket.
PositionCloseBy

Closes a position with the specified ticket by an opposite position.

```cpp
bool PositionCloseBy(
    const ulong ticket, // position ticket
    const ulong ticket_by // opposite position ticket
)
```

Parameters

ticket

ticket_by
  [in] Ticket of the opposite position used for closing.

Returned value

true - the basic check of structures is successful, otherwise - false.

Note

A successful completion of the PositionCloseBy(...) method does not always mean a successful execution of a trading operation. You should call the ResultRetcode() method to check the result of a trade request (trade server return code).
Buy

Opens a long position with specified parameters.

```cpp
bool Buy(
    double volume, // position volume
    const string symbol=NULL, // symbol
    double price=0.0, // execution price
    double sl=0.0, // stop loss price
    double tp=0.0, // take profit price
    const string comment="" // comment
)
```

Parameters

- **volume**
  - [in] Requested position volume.

- **symbol=NULL**
  - [in] Position symbol. If it is not specified, the current symbol will be used.

- **price=0.0**
  - [in] Price. If the price is not specified, the current market Ask price will be used.

- **sl=0.0**
  - [in] Stop Loss price.

- **tp=0.0**
  - [in] Take Profit price.

- **comment=""**
  - [in] Comment.

Return Value

- true - successful check of the structures, otherwise - false.

Note

Successful completion of the Buy(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()` and value returned by `ResultDeal()`.
Sell

Opens a short position with specified parameters.

```cpp
bool    Sell(
    double    volume, // position volume
    const string symbol=NULL, // symbol
    double    price=0.0, // execution price
    double    sl=0.0, // stop loss price
    double    tp=0.0, // take profit price
    const string comment="" // comment
)
```

Parameters

- `volume`
  - [in] Requested position volume.

- `symbol=NULL`
  - [in] Position symbol. If the symbol is not specified, the current symbol will be used.

- `price=0.0`
  - [in] Price. If the price is not specified, the current market Bid price will be used.

- `sl=0.0`
  - [in] Stop Loss price.

- `tp=0.0`
  - [in] Take Profit price.

- `comment=""`
  - [in] Comment.

Return Value

- true - successful check of the structures, otherwise - false.

Note

Successful completion of the Sell(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using ResultRetcode() and value returned by ResultDeal().
BuyLimit

Places the pending order of Buy Limit type (buy at the price lower than current market price) with specified parameters.

```cpp
bool BuyLimit(
    double volume,  // order volume
    double price,   // order price
    const string symbol=NULL,  // symbol
    double sl=0.0,    // stop loss price
    double tp=0.0,    // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC,  // order lifetime
    datetime expiration=0,  // order expiration time
    const string comment=""  // comment
)
```

Parameters

- **volume**
  - [in] Requested order volume.
- **price**
- **symbol=NULL**
  - [in] Order symbol. If the symbol is not specified, the current symbol will be used.
- **sl=0.0**
  - [in] Stop Loss price.
- **tp=0.0**
  - [in] Take Profit price.
- **type_time=ORDER_TIME_GTC**
  - [in] Order lifetime from `ENUM_ORDER_TYPE_TIME` enumeration.
- **expiration=0**
  - [in] Order expiration time (used only if `type_time=ORDER_TIME_SPECIFIED`).
- **comment=""**
  - [in] Order comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the `BuyLimit(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server `return code`) using `ResultRetcode()` and value returned by `ResultOrder()`.
BuyStop

Places the pending order of Buy Stop type (buy at the price higher than current market price) with specified parameters.

```cpp
bool BuyStop(
    double volume, // order volume
    double price,  // order price
    const string symbol=NULL, // symbol
    double sl=0.0,  // stop loss price
    double tp=0.0,  // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime expiration=0, // order expiration time
    const string comment="" // comment
)
```

**Parameters**

- **volume**

- **price**

- **symbol=NULL**

  [in] Order symbol. If the symbol isn't specified, the current symbol will be used.

- **sl=0.0**

  [in] Stop Loss price.

- **tp=0.0**

  [in] Take Profit price.

- **type_time=ORDER_TIME_GTC**

  [in] Order lifetime from ENUM_ORDER_TYPE_TIME enumeration.

- **expiration=0**

  [in] Order expiration time (used only if type_time=ORDER_TIME_SPECIFIED).

- **comment=""**

  [in] Order comment.

**Return Value**

- true - successful check of the structures, otherwise - false.

**Note**

Successful completion of the BuyStop(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using ResultRetcode() and value returned by ResultOrder().
SellLimit

Places the pending order of Sell Limit type (sell at the price higher than current market price) with specified parameters.

```cpp
bool SellLimit(
    double volume, // order volume
    double price,  // order price
    const string symbol=NULL, // symbol
    double sl=0.0, // stop loss price
    double tp=0.0, // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime expiration=0, // order expiration time
    const string comment="" // comment
)
```

**Parameters**

- `volume`  

- `price`  

- `symbol=NULL`  
  [in] Order symbol. If the symbol is not specified, the current symbol will be used.

- `sl=0.0`  
  [in] Stop Loss price.

- `tp=0.0`  
  [in] Take Profit price.

- `type_time=ORDER_TIME_GTC`  
  [in] Order lifetime from `ENUM_ORDER_TYPE_TIME` enumeration.

- `expiration=0`  
  [in] Order expiration time (used only if `type_time=ORDER_TIME_SPECIFIED`).

- `comment=""`  
  [in] Order comment.

**Return Value**

- `true` - successful check of the structures, otherwise - `false`.

**Note**

Successful completion of the `SellLimit(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server `return code`) using `ResultRetcode()` and value returned by `ResultOrder()`.
SellStop

Places the pending order of Sell Stop type (sell at the price lower than current market price) with specified parameters.

```cpp
bool SellStop(
    double volume, // order volume
    double price, // order price
    const string symbol=NULL, // symbol
    double sl=0.0, // stop loss price
    double tp=0.0, // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime expiration=0, // order expiration time
    const string comment="" // comment
)
```

### Parameters

- **volume**
  - [in] Requested order volume.
- **price**
- **symbol=NULL**
  - [in] Order symbol. If the symbol is not specified, the current symbol will be used.
- **sl=0.0**
  - [in] Stop Loss price.
- **tp=0.0**
  - [in] Take Profit price.
- **type_time=ORDER_TIME_GTC**
  - [in] Order lifetime from `ENUM_ORDER_TYPE_TIME` enumeration.
- **expiration=0**
  - [in] Order expiration time (used only if type_time=ORDER_TIME_SPECIFIED).
- **comment=""**
  - [in] Order comment.

### Return Value

- `true` - successful check of the structures, otherwise - `false`.

### Note

Successful completion of the SellStop(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using `ResultRetcode()` and value returned by `ResultOrder()`.
Request

Gets the copy of the last request structure.

```c
void Request(
    MqlTradeRequest& request  // reference
) const
```

Parameters

request

[out] Reference to the copied structure.

Return Value

None.
# RequestAction

Gets the trade operation type.

| ENUM_TRADE_REQUEST_ACTIONS | RequestAction() const |

**Return Value**

Trade operation type used in the last request from `ENUM_TRADE_REQUEST_ACTIONS` enumeration.
RequestActionDescription

Gets the trade operation type as string.

```cpp
string RequestActionDescription() const
```

**Return Value**

Trade operation type (as string) used in the last request.
**RequestMagic**

Gets the magic number of the Expert Advisor.

```cpp
ulong RequestMagic() const
```

**Return Value**

The magic number (ID) of the Expert Advisor, used in the last request.
**RequestOrder**

Gets the order ticket.

```c++
ulong RequestOrder() const
```

**Return Value**

Order ticket of the last request.
RequestSymbol

Gets the name of the symbol.

```cpp
string RequestSymbol() const
```

**Return Value**

The name of the symbol used in the last request.
RequestVolume

Gets the trade volume (in lots).

```cpp
double RequestVolume() const
```

Return Value

The requested trade volume (in lots) used in the last request.
**RequestPrice**

Gets the order execution price.

```cpp
double RequestPrice() const
```

**Return Value**

Order execution price used in the last request.
RequestStopLimit

Gets the price of pending order of Stop Limit type.

```cpp
double RequestStopLimit() const
```

Return Value

The price of pending order of Stop Limit type used in the last request.
**RequestSL**

Gets the Stop Loss price of an order.

```cpp
double RequestSL() const
```

**Return Value**

The Stop Loss price used in the last request.
RequestTP

Gets the Take Profit price of the order.

```cpp
double RequestTP() const
```

Return Value

The Take Profit price used in the last request.
RequestDeviation

Gets the maximum price deviation from a requested price.

ulong RequestDeviation() const

Return Value

The maximum allowable price deviation from a requested price used in the last request.
**RequestType**

Gets the type of the order.

```
enum RequestType { ORDER_TYPE_ENUM
```

**Return Value**

Order type used in the last request from `ENUM_ORDER_TYPE` enumeration.
**RequestTypeDescription**

Gets the type of the order (as string).

```
string RequestTypeDescription() const
```

Return Value

The order type (as string) used in the last request.
**RequestTypeFilling**

Gets the filling type of the order.

```cpp
ENUM_ORDER_TYPE_FILLING RequestTypeFilling() const
```

**Return Value**

The filling type of the order from `ENUM_ORDER_TYPE_FILLING` used in the last request.
**RequestTypeFillingDescription**

Gets the filling type of the order (as string).

```cpp
string RequestTypeFillingDescription() const
```

**Return Value**

The filling type (as string) of the order used in the last request.
RequestTypeTime

Gets the validity period of the order.

```
enum RequestTypeTime
```

Return Value

The validity period of the order from `ENUM_ORDER_TYPE_TIME` enumeration used in the last request.
**RequestTypeTimeDescription**

Gets the validity period of the order (as string).

```
string RequestTypeTimeDescription() const
```

**Return Value**

The validity period of the order (as string) used in the last request.
RequestExpiration

Gets the expiration time of a pending order.

```cpp
datetime RequestExpiration() const
```

Return Value

The expiration time of a pending order used in the last request.
RequestComment

Gets the comment of the order.

```cpp
string RequestComment() const
```

Return Value

The comment of the order used in the last request.
**RequestPosition**

Gets position ticket.

```plaintext
ulong RequestPosition() const
```

**Return value**

Position ticket used in the last request.
RequestPositionBy

Gets opposite position ticket.

ulong RequestPositionBy() const

Return value

Opposite position ticket used in the last request.
Result

Gets the copy of the structure of the last request result.

```c
void Result(
    MqlTradeResult& result // reference
) const
```

Parameters

result

[out] Reference to the structure of MqlTradeResult type for copying.

Return Value

None.
ResultRetcode

Gets the code of request execution result.

```
uint ResultRetcode() const
```

Return Value

The code of request result.
**ResultRetcodeDescription**

Gets the code of request execution result as a string.

```cpp
string ResultRetcodeDescription() const
```

**Return Value**

`Code of the last request` result as a string.
ResultDeal

Gets the deal ticket.

```cpp
ulong ResultDeal() const
```

Return Value

Deal ticket if the deal is executed.
ResultOrder

Gets the order ticket.

`ulong ResultOrder() const`

Return Value

Order ticket if the order is placed.
**ResultVolume**

Gets the volume of deal or order.

```cpp
    double ResultVolume() const
```

**Return Value**

Volume of deal or order confirmed by a broker.
**ResultPrice**

Gets the price confirmed by a broker.

```cpp
double ResultPrice() const
```

**Return Value**

Price confirmed by a broker.
ResultBid

Gets the current bid price (the requote).

```cpp
double ResultBid() const
```

Return Value

Current bid price (the requote).
ResultAsk

Gets the current ask price (the requote).

```cpp
double ResultAsk() const
```

Return Value

Current ask price (the requote).
**ResultComment**

Gets the broker comment.

```
string ResultComment() const
```

**Return Value**

Broker comment to the operation.
CheckResult

Gets the copy of the structure of the last request check result.

```cpp
void CheckResult(MqlTradeCheckResult& check_result) const
```

**Parameters**

- `check_result`  
  `[out]` Reference to the target structure of the `MqlTradeCheckResult` type for copying.

**Return Value**

None.
CheckResultRetcode

Gets the value of the retcode field of *MqlTradeCheckResult* type, filled while checking the request correctness.

```c
uint CheckResultRetcode() const
```

Return Value

The value of the retcode field (error code) of *MqlTradeCheckResult* type filled while checking the request correctness.
CheckResultRetcodeDescription

Gets the string description of the retcode field of `MqlTradeCheckResult` type filled while checking the request correctness.

```cpp
string ResultRetcodeDescription() const
```

Return Value

The string description of the retcode field (Error code) of `MqlTradeCheckResult` type filled while checking the request correctness.
CheckResultBalance

Gets the value of the balance field of `MqlTradeCheckResult` type filled while checking the request correctness.

```cpp
double CheckResultBalance() const
```

**Return Value**

The value of the balance field (balance value that will be after the execution of the trade operation) of `MqlTradeCheckResult` type filled while checking the request correctness.
CheckResultEquity

Gets the value of the equity field of MqlTradeCheckResult type filled while checking the request correctness.

```cpp
double CheckResultEquity() const
```

**Return Value**

The value of the equity field (equity value that will be after the execution of the trade operation) of MqlTradeCheckResult type filled while checking the request correctness.
CheckResultProfit

Gets the value of a floating profit.

double CheckResultProfit() const

Return Value

The value of a floating profit after executing a trading operation.
CheckResultMargin

Gets the value of the margin field of `MqlTradeCheckResult` type filled while checking the request correctness.

```c
double CheckResultMargin() const
```

**Return Value**

The value of the margin field (margin required for the trade operation) of `MqlTradeCheckResult` type filled while checking the request correctness.
CheckResultMarginFree

Gets the value of the margin_free field of `MqlTradeCheckResult` type filled while checking the request correctness.

```c
double CheckResultMarginFree() const
```

Return Value

The value of the margin_free field (free margin that will be left after the execution of the trade operation) of `MqlTradeCheckResult` type filled while checking the request correctness.
CheckResultMarginLevel

Gets the value of the margin_level field of MqlTradeCheckResult type filled while checking the request correctness.

```cpp
double CheckResultMarginLevel() const
```

Return Value

The value of the margin_level field (margin level that will be set after the execution of the trade operation) of MqlTradeCheckResult type filled while checking the request correctness.
CheckResultComment

The value of the comment field of `MqlTradeCheckResult` type filled while checking the request correctness.

```cpp
string CheckResultComment() const
```

**Return Value**

The value of the comment field (comment to the reply code, error description) of `MqlTradeCheckResult` type filled while checking the request correctness.
PrintRequest

Prints the last request parameters into journal.

```cpp
void PrintRequest() const
```

Return Value

None.
# PrintResult

Prints the results of the last request into journal.

```cpp
void PrintResult() const
```

## Return Value

None.
FormatRequest

 Prepares the formatted string with last request parameters.

 ```cpp
 string FormatRequest(
     string& str,       // string
     const MqlTradeRequest& request,   // request
 ) const
 ```

 **Parameters**

 str

 request

 [in] A structure of MqlTradeRequest type with parameters of the last request.

 **Return Value**

 None.
FormatRequestResult

 Prepares the formatted string with results of the last request execution.

 ```
 string FormatRequestResult(
     string& str,      // string
     const MqlTradeRequest& request, // request
     const MqlTradeResult& result // result
 ) const
 ```

Parameters

- `str`

- `request`
  - [in] A structure of `MqlTradeRequest` type with parameters of the last request.

- `result`
  - [in] A structure of `MqlTradeResult` type with results of the last request.

Return Value

None.
CTerminalInfo

CTerminalInfo is a class for simplified access to the properties of mql5 program environment.

Description

CTerminalInfo class provides access to the properties of mql5 program environment.

Declaration

```cpp
class CTerminalInfo : public CObject
```

Title

```cpp
#include <Trade\TerminalInfo.mqh>
```

Inheritance hierarchy

- CObject
  - CTerminalInfo

Class methods by groups

<table>
<thead>
<tr>
<th>Methods for access to the properties of integer type</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>
### MemoryTotal
- Gets the information about the total memory available for the terminal/agent process (in Mb)

### MemoryAvailable
- Gets the information about the free memory available for the terminal/agent process (in Mb)

### MemoryUsed
- Gets the information about the memory used by the terminal/agent process (in Mb)

### IsX64
- Gets the information about the type of the client terminal

### OpenCLSupport
- Gets the information about the version of OpenCL supported by the video card

### DiskSpace
- Gets the information about free disk space (in Mb)

### Methods for access to the properties of string type
- **Language**: Gets the language of the client terminal
- **Name**: Gets the name of the client terminal
- **Company**: Gets the company name of the client terminal
- **Path**: Gets the folder of the client terminal
- **DataPath**: Gets the data folder of the client terminal
- **CommonDataPath**: Gets the common data folder of all client terminals, installed on the computer

### Access to MQL5 API functions
- **InfoInteger**: Gets the value of the property of integer type
- **InfoString**: Gets the value of property of string type

### Methods inherited from class CObject
- Prev, Prev, Next, Next, Save, Load, Type, Compare
Build

Gets the build number of the client terminal.

```c
int CBuild() const
```

**Return Value**

Build number of the client terminal

**Note**

The terminal build number is defined by `TerminalInfoInteger()` function (`TERMINAL_BUILD` property).
**IsConnected**

Gets the information about connection to trade server.

```cpp
bool IsConnected() const
```

**Return Value**

true - the terminal is connected to a trade server, otherwise - false.

**Note**

Connection status is defined by `TerminalInfoInteger()` function (`TERMINAL_CONNECTED` property).
IsDLLsAllowed

Gets the information about permission of DLL usage.

```cpp
bool IsDLLsAllowed() const
```

**Return Value**

true - DLL usage is allowed, otherwise - false.

**Note**

Permission of DLL usage is defined by `TerminalInfoInteger()` function (`TERMINAL_DLLS_ALLOWED` property).
IsTradeAllowed

Gets the information about permission to trade.

```cpp
bool IsTradeAllowed() const
```

**Return Value**

- `true` - trade allowed, otherwise - `false`.

**Note**

Permission to trade is defined by `TerminalInfoInteger()` function (`TERMINAL_TRADE_ALLOWED` property).
IsEmailEnabled

Gets the information about permission to send e-mails to SMTP server and login specified in the terminal settings.

```cpp
bool IsEmailEnabled() const
```

Return Value

true - sending e-mails is allowed, otherwise - false.

Note

Permission to send e-mails is defined by `TerminalInfoInteger()` function (TERMINAL_EMAIL_ENABLED property).
IsFtpEnabled

Gets the information about permission to send trade reports to FTP server and login specified in the terminal settings.

```cpp
bool IsFtpEnabled() const
```

**Return Value**

true - sending trade reports to FTP server is allowed, otherwise - false.

**Note**

Permission to send trade reports is defined `TerminalInfoInteger()` function (TERMINAL_FTP_ENABLED property).
MaxBars

Gets the maximum number of bars on chart specified in the terminal settings.

```cpp
int MaxBars() const
```

Return Value

Maximum number of bars on the chart.

Note

The maximum number of bars on chart is defined by `TerminalInfoInteger()` function (TERMINAL_MAXBARS property).
**CodePage**

Gets the information about code page of the language in the terminal.

```
int CodePage() const
```

**Return Value**

Code page of the language in the client terminal.

**Note**

Code page of the language is defined by `TerminalInfoInteger()` function `(TERMINAL_CODEPAGE` property).
**CPUCores**

Gets the information about the number of CPU cores in the system.

```cpp
int CPUCores() const
```

**Return Value**

Number of CPU cores in the system.

**Note**

The number of CPU cores is defined by `TerminalInfoInteger()` function (`TERMINAL_CPU_CORES` property).
MemoryPhysical

Gets the information about the physical memory (in Mb).

```c
int MemoryPhysical() const
```

Return Value

Physical memory (in Mb).

Note

The physical memory is defined by `TerminalInfoInteger()` function (`TERMINAL_MEMORY_PHYSICAL` property).
MemoryTotal

Gets the information about the total memory available to the terminal/agent (in Mb).

```cpp
int MemoryTotal() const
```

Return Value

Total memory (in Mb) available to the terminal/agent.

Note

The total memory available to the terminal/agent is defined by `TerminalInfoInteger()` function (`TERMINAL_MEMORY_TOTAL` property).
MemoryAvailable

Gets the information about the free memory available to the client terminal/agent (in Mb).

```c
int MemoryTotal() const
```

Return Value

Free memory (in Mb) available to the terminal/agent.

Note

The free memory available to the client terminal/agent is defined by `TerminalInfInteger()` function (TERMINAL_MEMORY_TOTAL property).
MemoryUsed

Gets the information about the memory used by the client terminal/agent (in Mb).

```cpp
int MemoryUsed() const
```

Return Value

The memory used by the client terminal/agent (in Mb).

Note

The memory used by the client terminal/agent is defined by `TerminalInfoInteger()` function (`TERMINAL_MEMORY_USED` property).
**IsX64**

Gets the information about the type of the client terminal.

```c
bool IsX64() const
```

**Return Value**

true - 64-bit version is used, otherwise - false.

**Note**

The type of the terminal is defined by `TerminalInfoInteger()` function (`TERMINAL_X64` property).
OpenCLSupport

Gets the information about the version of OpenCL supported by video card.

```c
int OpenCLSupport() const
```

**Return Value**

OpenCL version having the following form: 0x00010002 = "1.2". 0 means that OpenCL is not supported.

**Note**

OpenCL version is defined by `TerminalInfolnTEGER()` function `TERMINAL_OPENCL_SUPPORT` property).
DiskSpace

Gets the information about free disk space available for MQL5\Files folder of the terminal/agent (in Mb).

```cpp
int MDiskSpace() const
```

**Return Value**

Free disk space.

**Note**

Free disk space is defined by `TerminalInfInteger()` function (`TERMINAL_DISK_SPACE` property).
Language

Gets the information about the language of the client terminal.

```cpp
string Language() const
```

Return Value

Language used in the client terminal.

Note

The terminal language is defined by `TerminalInfoString()` function (`TERMINAL_LANGUAGE` property).
Name

Gets the information on the name of the client terminal.

```c
string Name() const
```

Return Value

Name of the client terminal.

Note

The name of the terminal is defined by `TerminalInfoString()` function (`TERMINAL_NAME` property).
Company

Gets the information about the name of the company.

```cpp
string Company() const
```

Return Value

The name of the company.

Note

The company name is defined by `TerminalInfoString()` function (`TERMINAL_COMPANY` property).
Path

Gets the client terminal folder.

```cpp
string Path() const
```

Return Value

The client terminal folder.

Note

The client terminal folder is used by `TerminalInfoString()` function (`TERMINAL_PATH` property).
### DataPath

Gets the information about the terminal data folder.

```cpp
string DataPath() const
```

**Return Value**

Data folder of the client terminal.

**Note**

Client terminal data folder is defined by `TerminalInfoString()` function (`TERMINAL_DATA_PATH` property).
CommonDataPath

Gets the common data folder of all client terminals installed on the computer.

```cpp
string CommonDataPath() const
```

Return Value

Common data folder of all installed terminals.

Note

The common data folder of all installed terminals is defined by `TerminalInfoString()` function (`COMMON_DATA_PATH` property).
InfoInteger

Returns the value of a corresponding integer property of the mql5 program environment.

```c
int TerminalInfoInteger(
    int property_id  // identifier of a property
);
```

Parameters

property_id

[in] Identifier of a property. It can be one of the values of the enumeration `ENUM_TERMINAL_INFO_INTEGER`.

Return Value

Value of int type.

Note

The property value is defined by `TerminalInfoInteger()` function.
InfoString

The function returns the value of a corresponding property of the mql5 program environment. The property must be of string type.

```c
string TerminalInfoString(
    int property_id       // property ID
);
```

Parameters

property_id

[in] Identifier of a property. It can be one the values of the enumeration `ENUM_TERMINAL_INFO_STRING`.

Return Value

Value of string type.

Note

The property value is defined by `TerminalInfoString()` function.
Classes for Creating and Testing Trading Strategies

This section contains technical details of working with classes for creation and testing of trading strategies and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and especially testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies) is placed in the terminal directory, in the Include\Expert folder.

Base classes for Expert Advisors

This section contains technical details of working with classes for creation and testing of trading strategies and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and especially testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies classes) is placed in the terminal directory, in the Include\Expert folder.

CExpertBase

CExpertBase is a base class for the CExpert class and all auxiliary trading strategy classes.

Description

CExpertBase provides the data and methods, which are common to all objects of the Expert Advisor.

Declaration

```cpp
class CExpertBase : public CObject
```

Title

```cpp
#include <Expert\ExpertBase.mqh>
```

Inheritance hierarchy

CObject
   CExpertBase

Direct descendants
   CExpert, CExpertMoney, CExpertSignal, CExpertTrailing

Class Methods by Groups

Public Methods:

<table>
<thead>
<tr>
<th>Initialization</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>virtual Init</td>
<td>Initializes the object</td>
</tr>
<tr>
<td>virtual ValidationSettings</td>
<td>Checks the settings</td>
</tr>
</tbody>
</table>

Parameters

Symbol
   Sets the symbol

Period
   Sets the timeframe

Magic
   Sets the Expert Advisor ID

Indicators and Timeseries

virtual SetPriceSeries
   Sets pointers to external timeseries (price series)

virtual SetOtherSeries
   Sets pointers to external timeseries (non-price series)

virtual InitIndicators
   Initializes the indicators and timeseries

Access to Protected Data

InitPhase
   Gets the current phase of object initialization
### Standard Library

Methods inherited from class `CObject`:
- Prev, Prev, Next, Next, `Save`, `Load`, `Type`, `Compare`
InitPhase

Gets the current phase of the object initialization.

<table>
<thead>
<tr>
<th>ENUM_INIT_PHASE</th>
<th>InitPhase()</th>
</tr>
</thead>
</table>

**Return Value**

Current phase of the object initialization.

**Note**

The object initialization consist of several phases:

1. Start initialization.
   - start - after finish of the constructor
   - finish - after successful completion of the Init(...) method.
   - allowed - call of the Init(...) method
   - not allowed - call of the ValidationSettings() method and other initialization methods

2. Parameters setting phase. In this phase you need to set all the object parameters, used for creation of indicators.
   - start - after successful completion of the Init(...) method
   - finish - after successful completion of the ValidationSettings() method
   - allowed - call of the Symbol(...), SetPriceSeries(...), SetOtherSeries(...) and InitIndicators(...) methods
   - not allowed - call of any other initialization methods

3. Checking of parameters.
   - start - after successful completion of the ValidationSettings() method
   - finish - after successful completion of the InitIndicators(...) method
   - allowed - call of the Symbol(...), Period(...) and InitIndicators(...) methods
   - not allowed - call of any other initialization methods

4. Finish of initialization.
   - start - after successful completion of the InitIndicators(...) method
   - not allowed - call of initialization methods
**TrendType**

Sets trend type.

```c
void TrendType( 
    M_TYPE_TREND value     // value
);
```

**Parameters**

- `value`
  
  `[in]` New value of trend type.

**Return Value**

None.
UsedSeries

Gets the bitmask of timeseries used.

```c
int UsedSeries()
```

Return Value

The list of used timeseries as bitmask.

Note

If the bit is set, the corresponding timeseries is used, if it is not set, the timeseries is not used.

The bit-timeseries correspondence:

- bit 0 - Open timeseries,
- bit 1 - High timeseries,
- bit 2 - Low timeseries,
- bit 3 - Close timeseries,
- bit 4 - Spread timeseries,
- bit 5 - Time timeseries,
- bit 6 - TickVolume timeseries,
- bit 7 - RealVolume timeseries.
EveryTick

Sets the “Every tick” flag.

```c
void EveryTick(
    bool value // flag
)
```

**Parameters**

`value`

**Return Value**

None.

**Note**

If the flag is set, each price (tick) change at a working symbol is processed.

If the flag is not set, the processing method is called only at a new bar on the working timeframe and symbol.
Open

Gets the element of the Open timeseries by index.

```c
double Open(
    int ind // index
);
```

Parameters

- `ind`
  - [in] Element index.

Return Value

If successful, it returns the numerical value of the Open timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
High

Gets the element of the High timeseries by index.

```c
double High(
    int  ind  // index
)
```

Parameters

- `ind`
  - [in] Element index.

Return Value

If successful, it returns the numerical value of the High timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
Low

Gets the element of the Low timeseries by index.

```c
double Low(
    int ind // index
)
```

**Parameters**

`ind`

[in] Element index.

**Return Value**

If successful, it returns the numerical value of the Low timeseries element with specified index, otherwise it returns EMPTY_VALUE.

**Note**

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
Close

Gets the element of the Close timeseries by index.

```c
double Close(
    int ind // index
)
```

**Parameters**

- `ind`
  - [in] Element index.

**Return Value**

If successful, it returns the numerical value of the Close timeseries element with specified index, otherwise it returns EMPTY_VALUE.

**Note**

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
Spread

Gets the element of the Spread timeseries by index.

```c
double Spread(
    int ind // index
)
```

**Parameters**

`ind`

[in] Element index.

**Return Value**

If successful, it returns the numerical value of the Spread timeseries element with specified index, otherwise it returns EMPTY_VALUE.

**Note**

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
Time

Gets the element of the Time timeseries by index.

```cpp
datetime Time(
    int ind // index
)
```

Parameters

`ind`

[in] Element index.

Return Value

If successful, it returns the numerical value of the Time timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
TickVolume

Gets the element of the TickVolume timeseries by index.

```c
long TickVolume(
    int ind // index
)
```

**Parameters**

`ind`

[in] Element index.

**Return Value**

If successful, it returns the numerical value of the TickVolume timeseries element with specified index, otherwise it returns EMPTY_VALUE.

**Note**

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.
RealVolume

Gets the element of the RealVolume timeseries by index.

```c
long RealVolume(
    int    ind    // index
)
```

Parameters

- `ind`
  - [in] Element index.

Return Value

- If successful, it returns the numerical value of the RealVolume timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

- The EMPTY_VALUE is returned in two cases:
  1. Timeseries is not used (the corresponding bit is not set).
  2. Element index is out of range.
**Init**

Initializes the object.

```cpp
bool Init(
    CSymbolInfo symbol, // symbol
    ENUM_TIMEFRAMES period, // timeframe
    double point // point
)
```

**Parameters**

- **symbol**
  - [in] Pointer to the object of `CSymbolInfo` type for access to symbol information.

- **period**

- **point**
  - [in] The "weight" of 2/4-digit point.

**Return Value**

- `true` - successful completion, otherwise - `false`. 
Symbol

Sets the object symbol.

```cpp
bool Symbol(
    string name    // symbol
)
```

**Parameters**

- `name`:
  - [in] Symbol.

**Return Value**

- `true` - successful, otherwise - `false`.

**Note**

The setting of working symbol is necessary if the object uses the symbol different from symbol defined at the first initialization.
Period

Sets the object timeframe.

```c
bool Period
    ENUM_TIMEFRAMES value  // timeframe
```

Parameters

- `value`:
  - [in] Timeframe.

Return Value

- true - successful, otherwise - false.

Note

The setting of working timeframe is necessary if the object uses the timeframe different from timeframe defined at the initialization.
**Magic**

Sets the Expert Advisor ID.

```c
void Magic(
    ulong value  // magic
)
```

**Parameters**

- `value`
  - `[in]` Expert Advisor ID.

**Return Value**

- None.
ValidationSettings

Checks the settings.

virtual bool ValidationSettings()

Return Value

ture - successful, otherwise - false.
SetPriceSeries

Sets pointers to external price series.

```cpp
virtual bool SetPriceSeries(
    CiOpen* open, // pointer
    CiHigh* high, // pointer
    CiLow* low,   // pointer
    CiClose* close // pointer
)
```

**Parameters**

- **open**
  
  `[in]` Pointer to Open timeseries.

- **high**
  
  `[in]` Pointer to High timeseries.

- **low**
  
  `[in]` Pointer to Low timeseries.

- **close**
  
  `[in]` Pointer to Close timeseries.

**Return Value**

- `true` - successful, otherwise - `false`.

**Note**

The setting of pointers to external timeseries (price series) is necessary if the object uses the symbol and timeframe (set during the first initialization) and price timeseries necessary for further work.
SetOtherSeries

Sets pointers to external non-price series.

```c
virtual bool SetOtherSeries(
    CiSpread* spread,     // pointer
    CiTime* time,         // pointer
    CiTickVolume* tick_volume,  // pointer
    CiRealVolume* real_volume   // pointer
)
```

**Parameters**

- **spread**
  - [in] Pointer to Spread timeseries.

- **time**
  - [in] Pointer to Time timeseries.

- **tick_volume**
  - [in] Pointer to TickVolume timeseries.

- **real_volume**
  - [in] Pointer to RealVolume timeseries.

**Return Value**

- true - successful, otherwise - false.

**Note**

The setting of pointers to external timeseries (price series) is necessary if the object uses the symbol and timeframe (set during the first initialization) and price timeseries necessary for further work.
InitIndicators

Initializes all indicators and time series.

```cpp
class Indicators:
    virtual bool InitIndicators(CIndicators* indicators=NULL) { // pointer
    }
```

Parameters

- `indicators` [in] Pointer to collection of indicators and timeseries.

Return Value

- true - successful, otherwise - false.

Note

The timeseries are initialized only if the object uses the symbol or timeframe different from the symbol or timeframe defined at initialization.
**InitOpen**

Initializes the Open timeseries.

```c
bool InitOpen(
    CIndicators* indicators // pointer
)
```

**Parameters**

`indicators`

[in] Pointer to collection of indicators and timeseries.

**Return Value**

true - successful, otherwise - false.

**Note**

The Open timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
**InitHigh**

Initializes the High timeseries.

```cpp
bool InitHigh(
    CIndicators* indicators  // pointer
)
```

**Parameters**

`indicators`

[in] Pointer to collection of indicators and timeseries.

**Return Value**

true - successful, otherwise - false.

**Note**

The High timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
InitLow

Initializes the Low timeseries.

```c
bool InitLow(
    CIndicators* indicators  // pointer
)
```

Parameters

`indicators`

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Low timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
**InitClose**

Initializes the Close timeseries.

```c
bool InitClose(
    CIndicators* indicators  // pointer
)
```

**Parameters**

`indicators`

[in] Pointer to collection of indicators and timeseries.

**Return Value**

true - successful, otherwise - false.

**Note**

The Close timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
InitSpread

Initializes the Spread timeseries.

```cpp
bool InitSpread(
    CIndicators* indicators  // pointer
)
```

**Parameters**

`indicators`

[in] Pointer to collection of indicators and timeseries.

**Return Value**

true - successful, otherwise - false.

**Note**

The Spread timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
**InitTime**

Initializes the Time timeseries.

```cpp
bool InitTime(
    CIndicators* indicators  // pointer
)
```

**Parameters**

- **indicators**
  - [in] Pointer to collection of indicators and timeseries.

**Return Value**

- true - successful, otherwise - false.

**Note**

The Time timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
InitTickVolume

Initializes the TickVolume timeseries.

```cpp
bool InitTickVolume(
    CIndicators* indicators  // pointer
)
```

Parameters

`indicators`

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The TickVolume timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
InitRealVolume

Initializes the RealVolume timeseries.

```c
bool InitRealVolume(
    CIndicators* indicators  // pointer
)
```

Parameters

`indicators`

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The RealVolume timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).
PriceLevelUnit

Gets the price level unit.

virtual double PriceLevelUnit() 

Return Value

The value of price level unit.

Note

The method of a base class returns the “weight” of the 2/4 digits point.
StartIndex

Gets the index of starting bar to analyze.

```cpp
virtual int StartIndex()
```

Return Value

The index of starting bar to analyze.

Note

The method returns 0 if the flag to analyze current bar is set to true (analysis from the current bar). If the flag is not set, it returns 1 (analysis from the last completed bar).
**CompareMagic**

Compares the Expert Advisor ID (magic) with the specified value.

```cpp
virtual bool CompareMagic(
    ulong magic  // identifier
)
```

**Parameters**

- `magic`  
  [in] Identifier value to compare.

**Return Value**

- `true` - identifier matches the specified one, otherwise - `false`. 
CExpert

CExpert is a base class for trading strategies.

It already has some elementary trading "skills". It has built-in algorithms for working with time series and indicators and a set of virtual methods for trading strategy.

How to use it:

1. Prepare an algorithm of the strategy;
2. Create your own class, inherited from CExpert class;
3. Override the virtual methods in your class with your own algorithms.

Description

The CExpert class is a set of virtual methods for implementation of trading strategies.

Note

A position is recognized as belonging to an Expert Advisor and managed by it based on the pair of properties m_symbol and m_magic. In the "hedging" mode, multiple positions can be opened for the same symbol, therefore the m_magic value is important.

Declaration

```cpp
class CExpert : public CExpertBase
```

Title

```cpp
#include <Expert\Expert.mqh>
```

Inheritance hierarchy

```
CObject
  CExpertBase
  CExpert
```

### Magic

Sets the Expert Advisor ID

### MaxOrders

Gets/sets the maximum amount of allowed orders

### OnTickProcess

Sets a flag to proceed the "OnTick" event

### OnTradeProcess

Sets a flag to proceed the "OnTrade" event

### OnTimerProcess

Sets a flag to proceed the "OnTimer" event

### OnChartEventProcess

Sets a flag to proceed the "OnChartEvent" event

### OnBookEventProcess

Sets a flag to proceed the "OnBookEvent" event

### Event Processing Methods

<table>

Methods inherited from class CObject

Prev, Prev, Next, Next, **Save**, **Load**, **Type**, **Compare**

Methods inherited from class CExpertBase

Init

Class instance initialization method.

```cpp
bool Init(
    string symbol,    // symbol
    ENUM_TIMEFRAMES period,   // timeframe
    bool every_tick,     // flag
    ulong magic          // Expert Advisor identifier
)
```

**Parameters**

- `symbol`  

- `period`  
  [in] Timeframe from `ENUM_TIMEFRAMES` enumeration.

- `every_tick`  

- `magic`  

**Return Value**

None.

**Note**

If `every_tick` is set to true, the `Processing()` method is called at each tick of the working symbol. Otherwise, the `Processing()` is called only when a new bar is formed on the working timeframe of the EA's working symbol.
Magic

Sets the Expert Advisor ID (magic).

```c
void Magic(
    ulong value  // new value
)
```

Parameters

**value**

[in] New value of Expert Advisor ID.

Return Value

None.

Note

If EA's identifier is changed, the same identifier is assigned to all auxiliary objects.

Implementation

```c
//+------------------------------------------------------------------+
//| Sets magic number for object and its dependent objects           |
//| INP            | OUTPUT: value - new value of magic number.                     |
//| O              | REMARK: no.                                                      |
//|                 |
//+------------------------------------------------------------------+
void CExpert::Magic(ulong value)
{
    if(m_trade!=NULL)   m_trade.SetExpertMagicNumber(value);
    if(m_signal!=NULL)  m_signal.Magic(value);
    if(m_money!=NULL)   m_money.Magic(value);
    if(m_trailing!=NULL)  m_trailing.Magic(value);
    //---
    CExpertBase::Magic(value);
}
```
InitSignal

Initializes trading signal object.

```cpp
virtual bool InitSignal(
    CExpertSignal* signal=NULL,  // pointer
)
```

**Parameters**

*signal*

[in] Pointer to `CExpertSignal` class object (or its descendant).

**Return Value**

true - successful, otherwise - false.

**Note**

If signal is NULL, the `CExpertSignal` class will be used for initialization (it does nothing).
InitTrailing

Initializes trailing stop object.

```cpp
virtual bool InitTrailing(
    CExpertTrailing* trailing=NULL, // pointer
)
```

Parameters

- `trailing` [in] Pointer to `CExpertTrailing` class object (or its descendant).

Return Value

- true - successful, otherwise - false.

Note

- If trailing is NULL, the `ExpertTrailing` class will be used for initialization (it does nothing).
**InitMoney**

Initializes the money management object.

```cpp
virtual bool InitMoney(
    CExpertMoney* money=NULL,  // pointer
)
```

**Parameters**

*money*

[in] Pointer to `CExpertMoney` class object (or its descendant).

**Return Value**

true - successful, otherwise - false.

**Note**

If `money` is NULL, the `CExpertMoney` class will be used for initialization (it uses the minimum lot).
InitTrade

Initializes the trade object.

```cpp
virtual bool InitTrade(
    ulong magic,    // identifier
    CExpertTrade* trade=NULL   // pointer
)
```

Parameters

- **magic**
  - [in] Expert Advisor ID (will be used in trade requests).

- **trade**
  - [in] Pointer to trade object.

Return Value

- true - successful, otherwise - false.
**Deinit**

Class instance deinitialization method.

```cpp
virtual void Deinit()
```

**Return Value**

None.
OnTickProcess

Sets the OnTick event handling flag.

```cpp
void OnTickOProcess(
    bool value     // flag
)
```

Parameters

value

[in] OnTick event handling flag.

Return Value

None.

Note

If the flag is true, the OnTick event is handled. By default, the flag is set to true.
**OnTradeProcess**

Sets the **OnTrade** event handling flag.

```cpp
void OnTradeProcess(
    bool value  // flag
)
```

**Parameters**

- **value**

  [in] **OnTrade** event handling flag.

**Return Value**

None.

**Note**

If the flag is true, the **OnTrade** event is handled. By default, the flag is set to false.
OnTimerProcess

Sets the OnTimer event handling flag.

```cpp
void OnTimerProcess(
    bool value  // flag
)
```

Parameters

- `value`

  [in] OnTimer event handling flag.

Return Value

- None.

Note

If the flag is true, the OnTimer event is handled. By default, the flag is set to false.
OnChartEventProcess

Sets a flag to handle the `OnChartEvent` event.

```c
void OnChartEventProcess(
    bool value   // flag
)
```

**Parameters**

`value`

> [in] Flag to handle the `OnChartEvent` event.

**Return Value**

None.

**Note**

If the flag is true, the `OnChartEvent` event is handled. By default, the flag is set to false.
OnBookEventProcess

Sets a flag to handle the OnBookEvent event.

```cpp
void OnBookEventProcess(
    bool value  // flag
)
```

**Parameters**

- `value`  
  [in] Flag to handle the OnBookEvent event.

**Return Value**

- None.

**Note**

If the flag is true, the OnBookEvent event is handled. By default, the flag is set to false.
MaxOrders (Get Method)

Gets the maximum amount of allowed orders.

```c
int MaxOrders()
```

Return Value

Maximum amount of allowed orders.

MaxOrders (Set Method)

Sets the maximum amount of allowed orders.

```c
void MaxOrders(
    int max_orders  // amount of orders
)
```

Parameters

`max_orders`

[in] New value of maximum amount of allowed orders.

Return Value

None.

Note

By default, the maximum amount of allowed orders is equal to 1.
Signal

Gets the pointer to the trade signal object.

```c
CExpertSignal* Signal() const
```

Return Value

Pointer to the trade signal object.
**ValidationSettings**

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

**Return Value**

true - successful, otherwise - false.

**Note**

It also checks the settings of all the Expert Advisor objects.
InitIndicators

Initializes necessary indicators and timeseries.

```
virtual bool InitIndicators(
    CIndicators* indicators=NULL    // pointer
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful completion, otherwise - false.

Note

The timeseries are initialized if the object uses a symbol or timeframe other than the one defined in the initialization.

Indicators and timeseries of all auxiliary EA objects are initialized.
OnTick

OnTick event handler.

```cpp
virtual void OnTick()
```

Return Value

None.
OnTrade

OnTrade event handler.

```cpp
virtual void OnTrade()
```

Return Value

None.
OnTimer

**OnTimer** event handler.

```c
virtual void OnTimer()
```

Return Value

None.
OnChartEvent

OnChartEvent event handler.

```cpp
virtual void OnChartEvent(
    const int id,       // event id
    const long lparam,  // long type event parameter
    const double dparam, // double type event parameter
    const string sparam  // string type event parameter
)
```

Parameters

- **id**
  - [in] Event ID.

- **lparam**
  - [in] Event parameter of long type.

- **dparam**
  - [in] Event parameter of double type.

- **sparam**
  - [in] Event parameter of string type.

Return Value

None.
OnBookEvent

OnBookEvent event handler.

```cpp
virtual void OnBookEvent(
    const string& symbol // symbol
)
```

Parameters
symbol

Return Value
None.
**InitParameters**

Initializes parameters of Expert Advisor.

```cpp
virtual bool InitParameters()
```

**Return Value**

true - successful, otherwise - false.

**Note**

The InitParameters() function of `CExpert` base class does nothing and always returns true.
**DeinitTrade**

Deinitializes trade object.

```
virtual void DeinitTrade()
```

**Return Value**

None.
DeinitSignal

Deinitializes trade signal object.

```c++
virtual void DeinitSignal()
```

Return Value

None.
DeinitTrailing

Deinitializes trailing object.

virtual void DeinitTrailing() 

Return Value

None.
DeinitMoney

Deinitializes money management object.

```
virtual void DeinitMoney()
```

Return Value

None.
DeinitIndicators

Deinitializes indicators and timeseries.

virtual void DeinitIndicators();

Return Value

None.

Note

Indicators and timeseries of all auxiliary EA objects are deinitialized.
Refresh

Updates all necessary data.

```
virtual bool Refresh()
```

Return Value

true - further tick processing is needed, otherwise - false.

Note

It allows to determine the need of tick processing. If it is needed, it updates all quotes and timeseries and indicators data and returns true.

Implementation

```
bool CExpert::Refresh()
{
    MqlDateTime time;
    //--- refresh rates
    if (!m_symbol.RefreshRates()) return(false);
    //--- check need processing
    TimeToStruct(m_symbol.Time(),time);
    if (m_period_flags!=WRONG_VALUE && m_period_flags!=0)
        if (((m_period_flags & TimeframesFlags(time))==0) return(false);
    m_last_tick_time=time;
    //--- refresh indicators
    m_indicators.Refresh();
    //--- ok
    return(true);
}
```
Processing

Main processing algorithm.

```cpp
virtual bool Processing()
```

Return Value

- true - trade operation has been executed, otherwise - false.

Note

It does the following steps:

1. Checks the presence of the opened position on the symbol. If there is no opened position, skip steps 2, 3, and 4.
2. Checks conditions to reverse opened position (`CheckReverse()` method). If position has been "reversed", exit.
3. Checks conditions to close position (`CheckClose()` method). If position has been closed, skip step 4.
4. Checks conditions to modify position parameters (`CheckTrailingStop()` method). If position parameters have been modified, exit.
5. Check the presence of pending orders on the symbol. If there is no any pending order, go to step 9.
6. Checks condition to delete order (`CheckDeleteOrderLong()` for buy pending orders or `CheckDeleteOrderShort()` for sell pending orders). If the order has been deleted, go to step 9.
7. Check conditions to modify pending order parameters (`CheckTrailingOrderLong()` for buy orders or `CheckTrailingOrderShort()` for sell orders). If the order parameters have been modified, exit.
8. Exit.
9. Checks conditions to open position (`CheckOpen()` method).

If you want to implement your own algorithm, you need to override the `Processing()` method of the descendant class.

Implementation
//+------------------------------------------------------------------+
//| Main function                                                      |
//| INPUT: no.                                                         |
//| OUTPUT: true-if any trade operation processed, false otherwise.   |
//| REMARK: no.                                                       |
//+------------------------------------------------------------------+

bool CExpert::Processing()
{
    //--- check if open positions
    if(m_position.Select(m_symbol.Name()))
    {
        //--- open position is available
        //--- check the possibility of reverse the position
        if(CheckReverse()) return(true);
        //--- check the possibility of closing the position/delete pending orders
        if(!CheckClose())
        {
            //--- check the possibility of modifying the position
            if(CheckTrailingStop()) return(true);
            //--- return without operations
            return(false);
        }
    }
    //--- check if placed pending orders
    int total=OrdersTotal();
    if(total!=0)
    {
        for(int i=total-1;i>=0;i--)
        {
            m_order.SelectByIndex(i);
            if(m_order.Symbol()!=m_symbol.Name()) continue;
            if(m_order.OrderType()==ORDER_TYPE_BUY_LIMIT || m_order.OrderType()==ORDER_TYPE_BUY_STOP)
            {
                //--- check the ability to delete a pending order to buy
                if(CheckDeleteOrderLong()) return(true);
                //--- check the possibility of modifying a pending order to buy
                if(CheckTrailingOrderLong()) return(true);
            }
            else
            {
                //--- check the ability to delete a pending order to sell
                if(CheckDeleteOrderShort()) return(true);
                //--- check the possibility of modifying a pending order to sell
                if(CheckTrailingOrderShort()) return(true);
            }
            //--- return without operations
            return(false);
        }
    }
    //--- check the possibility of opening a position/setting pending order
    if(CheckOpen()) return(true);
    //--- return without operations
    return(false);
}
**SelectPosition**

Selects a position to work with.

```cpp
void SelectPosition()
```

**Return Value**

No.

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Position select                                                  |
//| INPUT:  no.                                                      |
//| OUTPUT: no.                                                      |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+

bool CExpert::SelectPosition(void)
{
    bool res=false;
    //---
    if(m_margin_mode==ACCOUNT_MARGIN_MODE RETAIL HEDGING)
    res=m_position.SelectByMagic(m_symbol.Name(),m_magic);
    else
    res=m_position.Select(m_symbol.Name());
    //---
    return(res);
}"
CheckOpen

Checks conditions to open a position.

virtual bool CheckOpen()

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open long (CheckOpenLong()) and short (CheckOpenShort()) positions.

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for position open or limit/stop order set                  |
//| INP                                                                  |
//| OUTPUT: true-if trade operation processed, false otherwise.       |
//| REMARK: no.                                                        |
//+------------------------------------------------------------------+
bool CExpert::CheckOpen()
{
    if (CheckOpenLong()) return (true);
    if (CheckOpenShort()) return (true);
    //--- return without operations
    return (false);
} 
```
CheckOpenLong

Checks necessity and conditions to open long position.

```
virtual bool CheckOpenLong()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open a long position (CheckOpenLong() method of Signal object) and does that with the parameters set by Signal object (OpenLong() method) if the conditions are met.

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for long position open or limit/stop order set             |
//| INP                                                                 |
//| O                                                                 |
//| U                                                                 |
//| T:  no.                                                      |
//| O                                                                 |
//| U                                                                 |
//| T: true-if trade operation processed, false otherwise.         |
//| R                                                                 |
//| E                                                                 |
//| M                                                                 |
//| R: no.                                                      |
//+------------------------------------------------------------------+

bool CExpert::CheckOpenLong()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //--- check signal for long enter operations
    if(m_signal.CheckOpenLong(price,sl,tp,expiration))
    {
        if(!m_trade.SetOrderExpiration(expiration))
        {
            m_expiration=expiration;
            return (OpenLong(price,sl,tp));
        }
        //--- return without operations
        return (false);
    }
}
```
CheckOpenShort

Checks necessity and conditions to open a short position.

virtual bool CheckOpenShort()

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open a short position (CheckOpenShort() method of Signal object) and does that with the parameters set by Signal object (OpenShort() method) if the conditions are met.

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for short position open or limit/stop order set            |
//| INP                                                          |
//| O|T:  no.                                                      |
//| U|P: true-if trade operation processed, false otherwise.        |
//| T: no.                                                      |
//| REMARK: no.                                                  |
//+------------------------------------------------------------------+
bool CExpert::CheckOpenShort()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //--- check signal for short enter operations
    if(m_signal.CheckOpenShort(price,sl,tp,expiration))
    {
        if(!m_trade.SetOrderExpiration(expiration))
        {
            m_expiration=expiration;
        }
        return(OpenShort(price,sl,tp));
    }
    //--- return without operations
    return(false);
}
```
OpenLong

Opens a long position.

```cpp
virtual bool OpenLong(
    double price,  // price
    double sl,     // Stop Loss
    double tp      // Take Profit
)
```

**Parameters**

- `price`
- `sl`
  - [in] Stop Loss price.
- `tp`
  - [in] Take Profit price.

**Return Value**

- `true` - trade operation has been executed, otherwise - `false`.

**Note**

It gets trading volume (LotOpenLong(...) method) and opens a long position (Buy() method of Trade object) if trading volume is not equal to 0.

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Long position open or limit/stop order set                      |
//| INPUT:  price - price,                                           |
//|         sl    - stop loss,                                       |
//|         tp    - take profit.                                     |
//| OUTPUT: true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::OpenLong(double price, double sl, double tp)
{
    if (price==EMPTY_VALUE) return(false);
    //--- get lot for open
    double lot=LotOpenLong(price,sl);
    //--- check lot for open
    if (lot==0.0) return(false);
    //---
    return(m_trade.Buy(lot,price,sl,tp));
}
```
OpenShort

Opens a short position.

```cpp
virtual bool OpenShort(
    double price,  // price
    double sl,  // Stop Loss
    double tp  // Take Profit
)
```

Parameters

- **price**

- **sl**
  - [in] Stop Loss price.

- **tp**
  - [in] Take Profit price.

Return Value

- true - trade operation has been executed, otherwise - false.

Note

It gets trading volume (LotOpenShort() method) and opens a short position (by calling Sell method of Trade object) if trading volume is not equal to 0.

Implementation

```cpp
bool CExpert::OpenShort(double price, double sl, double tp)
{
    if (price==EMPTY_VALUE) return(false);
    //--- get lot for open
    double lot=LotOpenShort(price,sl);
    //--- check lot for open
    if (lot==0.0) return(false);
    //---
    return(m_trade.Sell(lot,price,sl,tp));
}
```
CheckReverse

Checks necessity and conditions to reverse an open position.

```cpp
virtual bool CheckReverse()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to reverse long (CheckReverseLong()) and short (CheckReverseShort()) positions.

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for position reverse                                       |
//| INPU    no.                                                      |
//| OUP    true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::CheckReverse()
{
    if(m_position.PositionType()==POSITION_TYPE_BUY)
    {
        //--- check the possibility of reverse the long position
        if(CheckReverseLong()) return(true);
    }
    else
    //--- check the possibility of reverse the short position
    if(CheckReverseShort()) return(true);
    //--- return without operations
    return(false);
}
```
CheckReverseLong

Checks necessity and conditions to reverse a long position.

```cpp
virtual bool CheckReverseLong()
```

**Return Value**

- `true` - a trade operation has been executed, otherwise - `false`.

**Note**

It checks the necessity to reverse a long position (CheckReverseLong() method of Signal object) and perform reverse operation of the current long position with the parameters set by Signal object (ReverseLong(...) method) if the conditions are met.

**Implementation**

```cpp
bool CExpert::CheckReverseLong()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //--- check signal for long reverse operations
    if(m_signal.CheckReverseLong(price,sl,tp,expiration)) return (ReverseLong(price,sl,;
    //--- return without operations
    return (false);
}
```
CheckReverseShort

Checks necessity and conditions to reverse a short position.

virtual bool CheckReverseLong()

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to reverse a short position (CheckReverseShort() method of Signal object) and perform reverse operation of the current short position with the parameters set by Signal object (ReverseShort() method) if the conditions are met.

Implementation

```cpp
#include "CExpert.h"

bool CExpert::CheckReverseShort()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();

    //--- check signal for short reverse operations
    if(m_signal.CheckReverseShort(price,sl,tp,expiration)) return (ReverseShort(price,s.
    //--- return without operations
    return(false);
}
```
ReverseLong

Performs reverse operation of a long position.

```cpp
virtual bool ReverseLong(
    double price,   // price
    double sl,      // Stop Loss
    double tp       // Take Profit
)
```

Parameters

- `price`
- `sl`
  - [in] Stop Loss price.
- `tp`
  - [in] Take Profit price.

Return Value

- `true` - trade operation has been executed, otherwise - `false`.

Note

- It gets the position reverse volume (`LotReverse()`) method and reverses a long position (`Sell()` method of Trade object) if trading volume is not equal to 0.

- In the “hedging” mode of position accounting, position reversal is performed as the closure of the existing position and opening of a new opposite one with the remaining volume.

Implementation
//+------------------------------------------------------------------+
//| Long position reverse                                            |
//| INPUT: price - price,                                           |
//|        sl  - stop loss,                                         |
//|        tp  - take profit.                                       |
//| OUTPUT: true-if trade operation processed, false otherwise.     |
//| REMARK: no.                                                     |
//+------------------------------------------------------------------+

bool CExpert::ReverseLong(double price, double sl, double tp)
{
    if (price == EMPTY_VALUE)
        return (false);
    //--- get lot for reverse
    double lot = LotReverse(sl);
    //--- check lot
    if (lot == 0.0)
        return (false);
    //---
    bool result = true;
    if (m_margin_mode == ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
    {
        //--- first close existing position
        lot = m_position.Volume();
        result = m_trade.PositionCloseByTicket(m_position.Identifier());
    }
    if (result)
        result = m_trade.Sell(lot, price, sl, tp);
    //---
    return (result);
}
ReverseShort

Performs reverse operation of a short position.

```cpp
virtual bool ReverseShort(
    double price,  // price
    double sl,    // Stop Loss
    double tp     // Take Profit
)
```

Parameters

`price`

`sl`
- [in] Stop Loss price.

`tp`
- [in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It gets position reverse volume (`LotReverse(...)` method) and perform trade operation of the short position reverse (Buy() method of Trade object) if trading volume is not equal to 0.

In the "hedging" mode of position accounting, position reversal is performed as the closure of the existing position and opening of a new opposite one with the remaining volume.

Implementation
```cpp
// Short position reverse |
// INPUT:  price - price,     |
//        sl    - stop loss,  |
//        tp    - take profit.|
// OUTPUT: true-if trade operation processed, false otherwise. |
// REMARK: no.             |
//----------------------------------------------------------------------------

bool CExpert::ReverseLong(double price, double sl, double tp)
{
    if (price == EMPTY_VALUE)
        return false;
    //--- get lot for reverse
double lot = LotReverse(sl);
    //--- check lot
    if (lot == 0.0)
        return false;
    //---
    bool result = true;
    if (m_margin_mode == ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
    {
        //--- first close existing position
        lot -= m_position.Volume();
        result = m_trade.PositionCloseByTicket(m_position.Identifier());
    }
    if (result)
        result = m_trade.Sell(lot, price, sl, tp);
    //---
    return result;
}
**CheckClose**

Checks conditions to close position.

```cpp
virtual bool CheckClose()
```

**Return Value**

true - trade operation has been executed, otherwise - false.

**Note**

1. It checks Expert Advisor Stop Out conditions (CheckClose() method of money management object). If condition is satisfied, it closes the position, deletes all orders (CloseAll()), and exits.

2. It checks conditions to close long or short position (CheckCloseLong() or CheckCloseShort() methods) and if position is closed, it deletes all orders (DeleteOrders() method).

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Check for position close or limit/stop order delete              |
//| INP                                                            |
//| UTP:  no.                                                      |
//| OUTF: true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                    |
//+------------------------------------------------------------------+
bool CExpert::CheckClose()
{
  double lot;
  //--- position must be selected before call
  if((lot=m_money.CheckClose(GetPointer(m_position)))!=0.0)
    return(CloseAll(lot));
  //--- check for position type
  if(m_position.PositionType()==POSITION_TYPE_BUY)
  {
    //--- check the possibility of closing the long position / delete pending orders:
    if(CheckCloseLong())
    {
      DeleteOrders();
      return(true);
    }
  }
  else
  {
    //--- check the possibility of closing the short position / delete pending orders:
    if(CheckCloseShort())
    {
      DeleteOrders();
      return(true);
    }
  }
  //--- return without operations
  return(false);
}
```
CheckCloseLong

Checks conditions to close a long position.

```cpp
virtual bool CheckCloseLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks conditions to close a long position (CheckCloseLong() method of Signal object) and if they are satisfied, it closes the open position (CloseLong(...) method).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for long position close or limit/stop order delete         |
//| INP                                                          |
//| OUTPUT: true-if trade operation processed, false otherwise.   |
//| REMARK: no.                                                  |
//+------------------------------------------------------------------+
bool CExpert::CheckCloseLong()
{
    double price=EMPTY_VALUE;
    //--- check for long close operations
    if(m_signal.CheckCloseLong(price))
        return(CloseLong(price));
    //--- return without operations
    return(false);
}
```
CheckCloseShort

Checks conditions to close a short position.

```cpp
virtual bool CheckCloseShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks conditions to close a short position (CheckCloseShort() method of Signal object) and if they are satisfied, it closes the position (CloseShort() method).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for short position close or limit/stop order delete        |
//| INPUT:  no.                                                      |
//| OUTPUT: true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::CheckCloseShort()
{
    double price=EMPTY_VALUE;
    //--- check for short close operations
    if(m_signal.CheckCloseShort(price))
        return(CloseShort(price));
    //--- return without operations
    return(false);
}
```
CloseAll

It performs partial or full position closing.

```cpp
virtual bool CloseAll(
    double  lot    // lot
)
```

**Parameters**

```
lot
[in] Number of lots to reduce the position.
```

**Return Value**

true - trade operation has been executed, otherwise - false.

**Note**

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionClose method is used, which can also be used on accounts with the netting mode. The `DeleteOrders()` method is used to delete orders.

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Position close and orders delete                                |
//| INPUT: lot - volume for close.                                  |
//| OUTPUT: true-if trade operation processed, false otherwise.     |
//| REMARK: no.                                                     |
//+------------------------------------------------------------------+
bool CExpert::CloseAll(double lot)
{
    bool result=false;
    //--- check for close operations
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    else
    {
        if(m_position.PositionType()==POSITION_TYPE_BUY)
            result=m_trade.Sell(lot,0,0,0);
        else
            result=m_trade.Buy(lot,0,0,0);
    }
    result|=DeleteOrders();
    //---
    return(result);
}
```
Close

Closes the opened position.

```cpp
virtual bool Close()
```

Return Value

- `true` - trade operation has been executed, otherwise - `false`.

Note

Closes the position (PositionClose() method of CTrade class object).

Implementation

```cpp
bool CExpert::Close()
{
    return m_trade.PositionClose(m_symbol.Name());
}
```
**CloseLong**

Closes the long position.

```cpp
virtual bool CloseLong(
    double price    // price
)
```

**Parameters**

- `price`
  

**Return Value**

- `true` - trade operation has been executed, otherwise - `false`.

**Note**

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionCloseByTicket method is used.

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Long position close                                              |
//| INPU:  price - price for close.                                  |
//| OUTPU: true-if trade operation processed, false otherwise.       |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::CloseLong(double price)
{
    bool result=false;
    //---
    if(price==EMPTY_VALUE)
        return(false);
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    else
        result=m_trade.Sell(m_position.Volume(),price,0,0);
    //---
    return(result);
}
```
CloseShort

Closes the short position.

```cpp
virtual bool CloseShort(
    double price  // price
)
```

Parameters

- **price**

Return Value

- true - trade operation has been executed, otherwise - false.

Note

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionCloseByTicket method is used.

Implementation

```cpp
//+------------------------------------------------------------------+
//| Short position close                                             |
//| INP U T:  price - price for close.                              |
//| O U TP T: true-if trade operation successful, false otherwise.  |
//| REMARK: no.                                                     |
//+------------------------------------------------------------------+
bool CExpert::CloseShort(double price)
{
    bool result=false;
    //---
    if(price==EMPTY_VALUE)
        return(false);
    if(m_margin_mode==ACCOUNT_MARGIN_MODERetail_HEDGING)
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    else
        result=m_trade.Buy(m_position.Volume(),price,0,0);
    //---
    return(result);
}
```
CheckTrailingStop

It checks Trailing Stop conditions of the opened position.

```
virtual bool CheckTrailingStop()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions of the opened position (CheckTrailingStopLong() or CheckTrailingStopShort()) for long and short positions.

Implementation

```
//+------------------------------------------------------------------+
//| Check for trailing stop/profit position                          |
//| INP                                                                 |
//| UTT: no.                                                      |
//| OUtUPTU: true-if trade operation processed, false otherwise. |
//| REMARK: no.                                                   |
//+------------------------------------------------------------------+
bool CExpert::CheckTrailingStop()
{
    //--- position must be selected before call
    if(m_position.PositionType()==POSITION_TYPE_BUY)
    {
        //--- check the possibility of modifying the long position
        if(CheckTrailingStopLong()) return(true);
    }
    else
    {
        //--- check the possibility of modifying the short position
        if(CheckTrailingStopShort()) return(true);
    }
    //--- return without operations
    return(false);
}
```
CheckTrailingStopLong

It checks Trailing Stop conditions of the opened long position.

```
virtual bool CheckTrailingStopLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions of the opened long position (CheckTrailingStopLong(...) method of Expert Trailing object). If conditions are satisfied, it modifies the position parameters (TrailingStopLong(...) method).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for trailing stop/profit long position                     |
//| INP                                                                 |
//| OUTPUT: true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                       |
//+------------------------------------------------------------------+
bool CExpert::CheckTrailingStopLong()
{
    double sl=EMPTY_VALUE;
    double tp=EMPTY_VALUE;
    //--- check for long trailing stop operations
    if(m_trailing.CheckTrailingStopLong(GetPointer(m_position),sl,tp))
    {
        if(sl==EMPTY_VALUE) sl=m_position.StopLoss();
        if(tp==EMPTY_VALUE) tp=m_position.TakeProfit();
        //--- long trailing stop operations
        return(TrailingStopLong(sl,tp));
    }
    //--- return without operations
    return(false);
}
```
CheckTrailingStopShort

It checks Trailing Stop conditions of the opened short position.

```
virtual bool CheckTrailingStopShort()
```

**Return Value**

true - trade operation has been executed, otherwise - false.

**Note**

It checks Trailing Stop conditions of the opened short position (CheckTrailingStopShort(...) method of Expert Trailing object). If conditions are satisfied, it modifies the position parameters (TrailingStopShort(...) method).

**Implementation**

```c++
//+------------------------------------------------------------------+
//| Check for trailing stop/profit short position                    |
//| INP                                                      |
//| O                  U: true-if trade operation processed, false otherwise. |
//| R                  EMA RK: no.                                   |
//+------------------------------------------------------------------+
bool CExpert::CheckTrailingStopShort()
{
    double sl=EMPTY_VALUE;
    double tp=EMPTY_VALUE;
    //--- check for short trailing stop operations
    if(m_trailing.CheckTrailingStopShort(GetPointer(m_position),sl,tp))
    {
        if(sl==EMPTY_VALUE) sl=m_position.StopLoss();
        if(tp==EMPTY_VALUE) tp=m_position.TakeProfit();
        //--- short trailing stop operations
        return(TrailingStopShort(sl,tp));
    }
    //--- return without operations
    return(false);
}
```
**TrailingStopLong**

It modifies parameters of the opened long position.

```cpp
virtual bool TrailingStopLong(
    double sl,    // Stop Loss
    double tp,    // Take Profit
)
```

**Parameters**

- `sl`
  - [in] Stop Loss price.
- `tp`
  - [in] Take Profit price.

**Return Value**

- `true` - trade operation has been executed, otherwise - `false`.

**Note**

The function modifies parameters of the opened long position (PositionModify(...) method of CTrade class object).

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Trailing stop/profit long position                               |
//| INPUJT:  sl - new stop loss,                                    |
//|         tp - new take profit.                                    |
//| OUTPUT: true-if trade operation successful, false otherwise.     |
//| REMARK: no.                                                     |
//+------------------------------------------------------------------+
bool CExpert::TrailingStopLong(double sl, double tp)
{
    return (m_trade.PositionModify(m_symbol.Name(), sl, tp));
}
```
**TrailingStopShort**

It modifies parameters of the opened short position.

```cpp
virtual bool TrailingStopLong(
    double sl, // Stop Loss
    double tp, // Take Profit
)
```

**Parameters**

- `sl`  
  [in] Stop Loss price.

- `tp`  
  [in] Take Profit price.

**Return Value**

- `true` - trade operation has been executed, otherwise - `false`.

**Note**

The function modifies parameters of the opened short position (PositionModify(...) method of CTrade class object).

**Implementation**

```cpp
//+------------------------------------------------------------------+
// | Trailing stop/profit short position                             |
// | INPUUT: sl - new stop loss,                                    |
// |         tp - new take profit.                                    |
// | O UTPUT: true-if trade operation successful, false otherwise.  |
// | REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::TrailingStopShort(double sl, double tp)
{
    return (m_trade.PositionModify(m_symbol.Name(), sl, tp));
}
```
CheckTrailingOrderLong

Checks Trailing Stop conditions of Buy Limit/Stop trailing order.

```cpp
virtual bool CheckTrailingOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions for buy limit/stop trailing order (CheckTrailingOrderLong() method of Trade Signals object) and modifies the order parameters if necessary (TrailingOrderLong(...) method).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for trailing long limit/stop order                        |
//| INPU: no.                                                      |
//| OUTPU: true-if trade operation processed, false otherwise.      |
//| REMARK: no.                                                    |
//+------------------------------------------------------------------+
bool CExpert::CheckTrailingOrderLong()
{
  double price;
  //--- check the possibility of modifying the long order
  if(m_signal.CheckTrailingOrderLong(GetPointer(m_order),price))
    return(TrailingOrderLong(m_order.PriceOpen()-price));
  //--- return without operations
  return(false);
}
```
CheckTrailingOrderShort

It checks Trailing Stop conditions of Sell Limit/Stop trailing order.

```cpp
virtual bool CheckTrailingOrderShort()
```

**Return Value**

true - trade operation has been executed, otherwise - false.

**Note**

It checks Trailing Stop conditions for sell limit/stop trailing order (CheckTrailingOrderShort() method of Trade Signals object) and modifies the order parameters if necessary (TrailingOrderShort() method).

**Implementation**

```cpp
bool CExpert::CheckTrailingOrderShort()
{
    double price;
    //--- check the possibility of modifying the short order
    if(m_signal.CheckTrailingOrderShort(GetPointer(m_order),price))
        return(TrailingOrderShort(m_order.PriceOpen()-price));
    //--- return without operations
    return(false);
}
```
TrailingOrderLong

It modifies parameters of Buy Limit/Stop trailing order.

```cpp
virtual bool TrailingOrderLong(
    double delta  // delta
)
```

Parameters

delta

[in] Price delta.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It modifies parameters of Buy Limit/Stop trailing order (OrderModify(...) method of CTrade class object).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Trailing long limit/stop order                                   |
//| INP  U T:  delta - price change.                                |
//| O U TP T: true-if trade operation successful, false otherwise. |
//| R EMARK: no.                                                    |
//+------------------------------------------------------------------+
bool CExpert::TrailingOrderLong(double delta)
{
    ulong ticket=m_order.Ticket();
    double price =m_order.PriceOpen()-delta;
    double sl    =m_order.StopLoss()-delta;
    double tp    =m_order.TakeProfit()-delta;
    //--- modifying the long order
    return(m_trade.OrderModify(ticket,price,sl,tp,m_order.TypeTime(),m_order.TimeExpiration()));
}
```
TrailingOrderShort

It modifies parameters of Sell Limit/Stop trailing order.

```cpp
virtual bool TrailingOrderShort(
    double delta  // delta
)
```

**Parameters**

*delta*

[in] Price delta.

**Return Value**

true - trade operation has been executed, otherwise - false.

**Note**

It modifies parameters of Sell Limit/Stop trailing order (OrderModify(...) method of CTrade class object).

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Trailing short limit/stop order                                  |
//| INPU: delta - price change.                                      |
//| OUTPUT: true-if trade operation successful, false otherwise.     |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::TrailingOrderShort(double delta)
{
    ulong ticket=m_order.Ticket();
    double price =m_order.PriceOpen()-delta;
    double sl   =m_order.StopLoss()-delta;
    double tp   =m_order.TakeProfit()-delta;
    //--- modifying the short order
    return(m_trade.OrderModify(ticket,price,sl,tp,m_order.TypeTime(),m_order.TimeExpiration()));
}
```
CheckDeleteOrderLong

It checks conditions to delete Buy Limit/Stop order.

```cpp
virtual bool CheckDeleteOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks the order expiration time. It checks conditions to delete the Buy Limit/Stop order (CheckCloseLong(...) method of Signal class object) and deletes the order if condition is satisfied (DeleteOrderLong() method).

Implementation

```cpp
bool CExpert::CheckDeleteOrderLong()
{
    double price;
    //--- check the possibility of deleting the long order
    if(m_expiration!=0 && TimeCurrent()>m_expiration)
    {
        m_expiration=0;
        return(DeleteOrderLong());
    }
    if(m_signal.CheckCloseLong(price))
        return(DeleteOrderLong());
    //--- return without operations
    return(false);
}
```
CheckDeleteOrderShort

It checks conditions to delete Sell Limit/Stop order.

```cpp
virtual bool CheckDeleteOrderShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

1. It checks the order expiration time.

2. It checks conditions to delete the Sell Limit/Stop order (CheckCloseShort(...) method of Signal class object) and deletes the order if one of the conditions is satisfied (DeleteOrderShort() method).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Check for delete short limit/stop order                          |
//| INP| no.                                                      |
//| O| UT: true-if trade operation processed, false otherwise.      |
//| R| EMA RK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::CheckDeleteOrderShort()
{
    double price;
    //--- check the possibility of deleting the short order
    if(m_expiration!=0 && TimeCurrent()>m_expiration)
    {
        m_expiration=0;
        return(DeleteOrderShort());
    }
    if(m_signal.CheckCloseShort(price))
        return(DeleteOrderShort());
    //--- return without operations
    return(false);
}
```
DeleteOrders

Deletes all orders.

```
virtual bool DeleteOrders()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes all orders (DeleteOrder() for all orders).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Delete all limit/stop orders                                     |
//| INPUUT: no.                                                      |
//| OUTPUT: true-if trade operation successful, false otherwise.     |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::DeleteOrders()
{
  bool result=false;
  int total=OrdersTotal();
  //---
  for(int i=total-1;i>=0;i--)
  {
    if(m_order.Select(OrderGetTicket(i)))
    {
      if(m_order.Symbol()!=m_symbol.Name()) continue;
      result|=DeleteOrder();
    }
  }
  //---
  return(result);
}
```
DeleteOrder

Deletes the Limit/Stop order.

```cpp
virtual bool DeleteOrder()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes the Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```cpp
//+------------------------------------------------------------------+
//|                     Delete limit/stop order                          |
//|         INPUUT: no.                                               |
//|         OUTPUT: true-if trade operation successful, false otherwise.|
//|         REMARK: no.                                               |
//+------------------------------------------------------------------+
bool CExpert::DeleteOrder()
{
    return m_trade.OrderDelete(m_order.Ticket());
}
```
DeleteOrderLong

Deletes the Buy Limit/Stop order.

```cpp
virtual bool DeleteOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes Buy Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```cpp
bool CExpert::DeleteOrderLong()
{
    return m_trade.OrderDelete(m_order.Ticket());
}
```
DeleteOrderShort

Deletes the Sell Limit/Stop order.

```cpp
virtual bool DeleteOrderShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes the Sell Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```cpp
//+------------------------------------------------------------------+
//| Delete short limit/stop order                                    |
//| INPUT:  no.                                                      |
//| OUTPUT: true-if trade operation successful, false otherwise.     |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+
bool CExpert::DeleteOrderShort()
{
    return m_trade.OrderDelete(m_order.Ticket());
}
```
LotOpenLong

Gets trade volume for buy operation.

double LotOpenLong(
    double price,  // price
    double sl      // Stop Loss
)

Parameters

price

sl
    [in] Stop Loss price.

Return Value

Trade volume (in lots) for buy operation.

Note

It gets trade volume for buy operation (CheckOpenLong(...) method of money management object).

Implementation

    //+------------------------------------------------------------------+
    //| Method of getting the lot for open long position.                |
    //| INPUT:  price - price,                                         |
    //|         sl    - stop loss.                                       |
    //| OUTPUT: lot for open.                                           |
    //| REMARK: no.                                                    |
    //+------------------------------------------------------------------+

double CExpert::LotOpenLong(double price, double sl)
{
    return _money.CheckOpenLong(price, sl);
}
**LotOpenShort**

Gets trade volume for sell operation.

```cpp
double LotOpenShort(
    double price,  // price
    double sl       // Stop Loss
)
```

**Parameters**

*price*

*sl*

[in] Stop Loss price.

**Return Value**

Trade volume (in lots) for sell operation.

**Note**

It gets trade volume for sell operation (CheckOpenShort(...) method of money management object).

**Implementation**

```cpp
//+------------------------------------------------------------------+
//| Method of getting the lot for open short position.              |
//| INPUT:  price - price,                                         |
//|         sl    - stop loss.                                       |
//| OUTPUT: lot for open.                                           |
//| REMARK: no.                                                      |
//+------------------------------------------------------------------+

double CExpert::LotOpenShort(double price, double sl)
{
    return (_money.CheckOpenShort(price,sl));
}
```
LotReverse

Gets trade volume for position reverse.

```c
double LotReverse(
    double sl // Stop Loss
)
```

Parameters

- **sl**
  - [in] Stop Loss price.

Return Value

Trade volume (in lots) for position reverse operation.

Note

It gets trade volume for position reverse operation (CheckReverse(...) method of money management object).

Implementation

```c
//+------------------------------------------------------------------+
//| Method of getting the lot for reverse position.                  |
//| INPUT:  sl - stop loss.                                         |
//| OUTPUT: lot for open.                                           |
//| REMARK: no.                                                     |
//+------------------------------------------------------------------+

double CExpert::LotReverse(double sl)
{
    return (m_money.CheckReverse(GetPointer(m_position),sl));
}
```
PrepareHistoryDate

Sets starting date for tracking of trade history.

```cpp
void PrepareHistoryDate()
```

Note

The trade history tracking period is set from the beginning of the month (but not less than one day).
**HistoryPoint**

Creates a checkpoint of trade history.

```cpp
void HistoryPoint(
    bool from_check_trade=false  // flag
)
```

**Parameters**

`from_check_trade=false`

[in] Flag to avoid recursion.

**Note**

It saves the amount of positions, orders, deals, and historical orders.
CheckTradeState

Compares the current state with the saved one and calls the corresponding event handler.

```cpp
bool CheckTradeState()
```

**Return Value**

true - event has been handled, otherwise - false.

**Note**

It checks the number of positions, orders, deals, and historical orders by comparing with the values saved by **HistoryPoint()** method. If trade history has changed, it calls the corresponding virtual event handler.
**WaitEvent**

Sets the event waiting flag.

```c
void WaitEvent(
    ENUM_TRADE_EVENTS event   // flag
)
```

**Parameters**

*event*

[in] Flag of waiting for an event (from ENUM_TRADE_EVENTS enumeration) to set.

**Return Value**

None.

**Event flags**

```c
//--- flags of expected events
enum ENUM_TRADE_EVENTS {
    TRADE_EVENT_NO_EVENT =0,         // no expected events
    TRADE_EVENT_POSITION_OPEN =0x1,  // flag of expecting the "opening of
    TRADE_EVENT_POSITION_VOLUME_CHANGE=0x2,  // flag of expecting of the "modify:
    TRADE_EVENT_POSITION_MODIFY =0x4,   // flag of expecting of the "modify:
    TRADE_EVENT_POSITION_CLOSE =0x8,    // flag of expecting of the "closing
    TRADE_EVENT_POSITION_STOP_TAKE =0x10,   // flag of expecting of the "trigger:
    TRADE_EVENT_ORDER_PLACE =0x20,     // flag of expecting of the "placing
    TRADE_EVENT_ORDER_MODIFY =0x40,    // flag of expecting of the "modify:
    TRADE_EVENT_ORDER_DELETE =0x80,    // flag of expecting of the "deletion
    TRADE_EVENT_ORDER_TRIGGER =0x100   // flag of expecting of the "trigger:
};
```
NoWaitEvent

Resets the event waiting flag.

```c
void NoWaitEvent(
    ENUM_TRADE_EVENTS event  // flag
);
```

Parameters

`event`

[in] Flag with events (from ENUM_TRADE_EVENTS enumeration) to reset.

Return Value

None.

Event flags

```c
//--- flags of expected events
enum ENUM_TRADE_EVENTS
{
    TRADE_EVENT_NO_EVENT =0,       // no expected events
    TRADE_EVENT_POSITION_OPEN =0x1, // flag of expecting the "opening of
    TRADE_EVENT_POSITION_VOLUME_CHANGE=0x2, // flag of expecting of the "modification
    TRADE_EVENT_POSITION_MODIFY =0x4,  // flag of expecting of the "modification
    TRADE_EVENT_POSITION_CLOSE =0x8,   // flag of expecting of the "closing
    TRADE_EVENT_POSITION_STOP_TAKE =0x10,  // flag of expecting of the "triggering
    TRADE_EVENT_ORDER_PLACE =0x20,     // flag of expecting of the "placing
    TRADE_EVENT_ORDER_MODIFY =0x40,    // flag of expecting of the "modification
    TRADE_EVENT_ORDER_DELETE =0x80,    // flag of expecting of the "deletion
    TRADE_EVENT_ORDER_TRIGGER =0x100   // flag of expecting of the "triggering
};
```
TradeEventPositionStopTake

Event handler of the "Position Stop Loss/Take Profit triggered" event.

virtual bool TradeEventPositionStopTake() 

Return Value

The CExpert class method does nothing and always returns true.
TradeEventOrderTriggered

Event handler of the "Pending Order triggered" event.

```cpp
virtual bool TradeEventOrderTriggered()
```

Return Value

The **CExpert** class method does nothing and always returns true.
TradeEventPositionOpened

Event handler of the "Position opened" event.

```cpp
virtual bool TradeEventPositionOpened()
```

Return Value

The **CExpert** class method does nothing and always returns true.
TradeEventPositionVolumeChanged

Event handler of the "Position volume changed" event.

```cpp
virtual bool TradeEventPositionVolumeChanged()
```

Return Value

The **CExpert** class method does nothing and always returns true.
**TradeEventPositionModified**

Event handler of the "Position modified" event.

```cpp
virtual bool TradeEventPositionModified()
```

**Return Value**

The **CExpert** class method does nothing and always returns true.
**TradeEventPositionClosed**

Event handler of the "Position closed" event.

```
virtual bool TradeEventPositionClosed()
```

**Return Value**

The [CExpert](#) class method does nothing and always returns true.
**TradeEventOrderPlaced**

Event handler of the "Pending order placed" event.

```cpp
virtual bool TradeEventOrderPlaced()
```

**Return Value**

The `CExpert` class method does nothing and always returns true.
TradeEventOrderModified

Event handler of the "Pending order modified" event.

```cpp
virtual bool TradeEventOrderModified()
```

Return Value

The `CExpert` class method does nothing and always returns true.
TradeEventOrderDeleted

Event handler of the "Pending order deleted" event.

```cpp
virtual bool TradeEventOrderDeleted()
```

Return Value

The `CExpert` class method does nothing and always returns true.
TradeEventNotIdentified

Event handler of the non-identified event.

```cpp
virtual bool TradeEventNotIdentified()
```

Return Value

The **CExpert** class method does nothing and always returns true.

Note

Note that several trade events can arrive, in such cases it is difficult to identify them.
TimeframeAdd

Add a timeframe for tracking.

```c
void TimeframeAdd(
    ENUM_TIMEFRAMES     period    // timeframe
)
```

Parameters

- `period` [in] Timeframe (from `ENUM_TIMEFRAMES` enumeration) to be tracked.

Return Value

None.
TimeframesFlags

Forms the timeframe flags.

```c
int TimeframesFlags(
    MqlDateTime& time    // reference
)
```

Parameters

time

[in] Reference to `MqlDateTime` type structure containing a new time.

Return Value

It returns the flag that indicates timeframes with a new bar.
CExpertSignal

CExpertSignal is a base class for trading signals, it does nothing (except CheckReverseLong() and CheckReverseShort() methods) but provides the interfaces.

How to use it:
1. Prepare an algorithm for trading signals;
2. Create your own trading signal class, inherited from CExpertSignal class;
3. Override the virtual methods in your class with your own algorithms.

You can find an examples of trading signal classes in the Expert\Signal\ folder.

Description

CExpertSignal is a base class for implementation of trading signal algorithms.

Declaration

```cpp
class CExpertSignal : public CExpertBase
```

Title

`#include <Expert\ExpertSignal.mqh>`

Inheritance hierarchy

```
CObject
    CExpertBase
        CExpertSignal
```

Checking Trading Conditions

virtual **CheckOpenLong** Checks conditions to open long position

virtual **CheckCloseLong** Checks conditions to close long position

virtual **CheckOpenShort** Checks conditions to open short position

virtual **CheckCloseShort** Checks conditions to close short position

virtual **CheckReverseLong** Checks conditions of long position reversal

virtual **CheckReverseShort** Checks conditions of short position reversal

Trade Parameters Setting

virtual **OpenLongParams** Sets parameters for long position opening

virtual **OpenShortParams** Sets parameters for short position opening

virtual **CloseLongParams** Sets parameters for long position closing

virtual **CloseShortParams** Sets parameters for short position closing

Checking of Order Trailing Conditions

virtual **CheckTrailingOrderLong** Checks conditions to modify parameters of Buy Pending order

virtual **CheckTrailingOrderShort** Checks conditions to modify parameters of Sell Pending order

Methods to Check Formation of Market Orders

virtual **LongCondition** Gets the result of checking buy conditions
virtual `ShortCondition` Gets the result of checking sell conditions

virtual `Direction` Gets the "weighted" direction of price

Methods inherited from class `CObject`

Prev, Prev, Next, Next, `Save`, `Load`, `Type`, `Compare`

Methods inherited from class `CExpertBase`

`InitPhase`, `TrendType`, `UsedSeries`, `EveryTick`, `Open`, `High`, `Low`, `Close`, `Spread`, `Time`, `TickVolume`, `RealVolume`, `Init`, `Symbol`, `Period`, `Magic`, `SetMarginMode`, `SetPriceSeries`, `SetOtherSeries`
BasePrice

Sets base price level.

```cpp
void BasePrice(
    double value // value
)
```

Parameters

value

Return Value

None.
**UsedSeries**

Gets the flags of the timeseries used.

```c
int UsedSeries()
```

**Return Value**

Flags of the used timeseries (if the symbol/timeframe corresponds to the working symbol/timeframe), otherwise 0.
Weight

Sets new value of "Weight" parameter.

```c
void Weight(
    double value // value
)
```

Parameters

value

[in] "Weight" parameter.

Return Value

None.
**PatternUsage**

Sets new value of "PatternsUsage" parameter.

```c
void PatternUsage(
    double value  // value
);```

**Parameters**

*value*

[\emph{in]} New value of "PatternsUsage".

**Return Value**

None.
**General**

Sets new value of "General" parameter.

```cpp
void General(
    int  value  // value
)
```

**Parameters**

value

[in] New value of "General".

**Return Value**

None.
Ignore

Sets new value of "Ignore" parameter.

```c
void Ignore(
    long value    // value
)
```

Parameters

- `value`
  - [in] New value of "Ignore".

Return Value

None.
**Invert**

Sets new value of "Invert" parameter.

```c
void Invert(
    long value // value
);
```

**Parameters**

- **value**
  
  [in] New value of "Invert".

**Return Value**

- None.
ThresholdOpen

Sets new value of "ThresholdOpen" parameter.

```c
void ThresholdOpen(
    long value             // value
)
```

Parameters

value

[in] New value of "ThresholdOpen".

Return Value

None.

Note

The range of "ThresholdOpen" parameter is from 0 to 100. Used when "voting" to open position.
ThresholdClose

Sets new value of “ThresholdClose” parameter.

```c
void ThresholdOpen(
    long value // value
)
```

Parameters

`value`

[in] New value of “ThresholdClose”.

Return Value

None.

Note

The range of “ThresholdClose” parameter is from 0 to 100. Used when “voting” to close position.
PriceLevel

Sets new value of “PriceLevel” parameter.

```c
void PriceLevel(
    double value  // value
)
```

Parameters

- `value`
  
  [in] New value of “PriceLevel”.

Return Value

None.

Note

The value of “PriceLevel” is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The “PriceLevel” is used to define the open price relative to the base price.
### StopLevel

Sets new value of "StopLevel" parameter.

```c
void StopLevel(
    double value // value
)
```

**Parameters**

- `value`
  - [in] New value of "StopLevel".

**Return Value**

- None.

**Note**

The value of "StopLevel" is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The "StopLevel" is used to define the Stop Loss price relative to the open price.
TakeLevel

Sets new value of "TakeLevel" parameter.

```cpp
void TakeLevel(
    double value    // value
)
```

Parameters

value

[in] New value of "TakeLevel".

Return Value

None.

Note

The value of "TakeLevel" is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The "TakeLevel" is used to define the Take Profit price relative to the open price.
Expiration

Sets the value of “Expiration” parameter.

```c
void Expiration(
    int value    // value
)
```

Parameters

- `value`
  
  [in] New value of “Expiration”.

Return Value

- None.

Note

The value of “Expiration” parameter is defined in bars. It is used as Expiration time for Pending Orders (when trading using pending orders).
**Magic**

Sets the value of "Magic" parameter.

```c
void Magic(
    int value // value
)
```

**Parameters**

- `value`

**Return Value**

None.
**ValidationSettings**

Checks the object settings.

```cpp
virtual bool ValidationSettings()
```

**Return Value**

- **true** - object settings are correct, otherwise - **false**.
**InitIndicators**

Initializes all necessary indicators and timeseries.

```cpp
virtual bool InitIndicators(
    CIndicators* indicators    // pointer
)
```

**Parameters**

`indicators`  
[in] Pointer to collection of indicators and timeseries.

**Return Value**

true - successful completion, otherwise - false.

**Note**

The necessary timeseries are initialized only if the object uses the symbol or timeframe different from the one defined at initialization.
AddFilter

Adds a filter to the composite signal.

```cpp
virtual bool AddFilter(
    CExpertSignal* filter // pointer
)
```

Parameters

- `indicators`:
  - `[in]` Pointer to filter object.

Return Value

- `true` - successful, otherwise `false`. 
**CheckOpenLong**

Checks conditions to open a long position.

```cpp
virtual bool CheckOpenLong(
    double& price,  // price
    double& sl,     // Stop Loss
    double& tp,     // Take Profit
    datetime& expiration // expiration
)
```

**Parameters**

- **price**
  - [in][out] Variable for open price, passed by reference.

- **sl**
  - [in][out] Variable for Stop Loss price, passed by reference.

- **tp**
  - [in][out] Variable for Take Profit price, passed by reference.

- **expiration**
  - [in][out] Variable for expiration time, passed by reference (if necessary).

**Return Value**

- true - condition is satisfied, otherwise - false.
CheckOpenShort

Checks conditions to open a short position.

```cpp
virtual bool CheckOpenShort(
    double& price,      // price
    double& sl,         // Stop Loss
    double& tp,         // Take Profit
    datetime& expiration // expiration
)
```

**Parameters**

- **price**
  - [in][out] Variable for open price, passed by reference.

- **sl**
  - [in][out] Variable for Stop Loss price, passed by reference.

- **tp**
  - [in][out] Variable for Take Profit price, passed by reference.

- **expiration**
  - [in][out] Variable for expiration time, passed by reference (if necessary).

**Return Value**

- true - condition is satisfied, otherwise - false.
**OpenLongParams**

Sets parameters to open a long position.

```cpp
virtual bool OpenLongParams(
    double& price, // price
    double& sl, // Stop Loss
    double& tp, // Take Profit
    datetime& expiration // expiration
);
```

**Parameters**

*price*

[in][out] Variable for open price, passed by reference.

*sl*

[in][out] Variable for Stop Loss price, passed by reference.

*tp*

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

**Return Value**

true - successful, otherwise - false.
OpenShortParams

Sets parameters to open a short position.

```cpp
virtual bool OpenShortParams(
    double& price,     // price
    double& sl,        // Stop Loss
    double& tp,        // Take Profit
    datetime& expiration // expiration
)
```

Parameters

- **price**
  

- **sl**
  
  [in][out] Variable for Stop Loss price, passed by reference.

- **tp**
  
  [in][out] Variable for Take Profit price, passed by reference.

- **expiration**
  
  [in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

- true - successful, otherwise - false.
CheckCloseLong

Checks conditions to close a long position.

```cpp
virtual bool CheckCloseLong(
    double& price // price
)
```

Parameters

*price*

[in][out] Variable for close price, passed by reference.

Return Value

true - condition is satisfied, otherwise - false.
CheckCloseShort

Checks conditions to close a short position.

```cpp
virtual bool CheckCloseShort(
    double& price    // price
)
```

**Parameters**

- `price`  
  `[in][out]` Variable for close price, passed by reference.

**Return Value**

- `true` - condition is satisfied, otherwise - `false`. 
**CloseLongParams**

Sets parameters to close a long position.

```cpp
virtual bool CloseLongParams(
    double& price // price
)
```

**Parameters**

`price`

[in][out] Variable for close price, passed by reference.

**Return Value**

true - successful, otherwise - false.
**CloseShortParams**

Sets parameters to close a short position.

```cpp
virtual bool CloseShortParams(
    double& price// price
)
```

**Parameters**

- **price**
  
  [in][out] Variable for close price, passed by reference.

**Return Value**

- true - successful, otherwise - false.
CheckReverseLong

Checks conditions of a long position reversal.

```cpp
virtual bool CheckReverseLong(
    double& price,   // price
    double& sl,      // Stop Loss
    double& tp,      // Take Profit
    datetime& expiration // expiration
)
```

**Parameters**

- `price`  

- `sl`  
  [in][out] Variable for Stop Loss price, passed by reference.

- `tp`  
  [in][out] Variable for Take Profit price, passed by reference.

- `expiration`  
  [in][out] Variable for expiration time, passed by reference (if necessary).

**Return Value**

- `true` - condition is satisfied, otherwise - `false`. 
CheckReverseShort

Checks conditions of a short position reversal.

```cpp
virtual bool CheckReverseShort(
    double& price,  // price
    double& sl,     // Stop Loss
    double& tp,     // Take Profit
    datetime& expiration // expiration
)
```

Parameters

- **price**
  - [in][out] Variable for reversal price, passed by reference.

- **sl**
  - [in][out] Variable for Stop Loss price, passed by reference.

- **tp**
  - [in][out] Variable for Take Profit price, passed by reference.

- **expiration**
  - [in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

- true - condition is satisfied, otherwise - false.
CheckTrailingOrderLong

Checks conditions to modify parameters of Buy Pending order.

```cpp
virtual bool CheckTrailingOrderLong(
    COrderInfo* order, // order
    double& price    // price
)
```

Parameters

order

[in] Pointer to COrderInfo class object.

price

[in][out] Variable for Stop Loss price.

Return Value

true - condition is satisfied, otherwise - false.
CheckTrailingOrderShort

Checks conditions to modify parameters of Sell Pending order.

```cpp
virtual bool CheckTrailingOrderShort(
    COrderInfo* order,  // order
    double& price       // price
)
```

**Parameters**

`order`

[in] Pointer to `COrderInfo` class object.

`price`

[in][out] Variable for Stop Loss price.

**Return Value**

`true` - condition is satisfied, otherwise - `false`.
LongCondition

Checks conditions to open a long position.

virtual int LongCondition() {

Return Value

If the conditions are satisfied, it returns the value from 1 to 100 (depending on “strength” of a signal). If there is no signal to open a long position, it returns 0.

Note

The base class has no implementation of checking conditions to open a long position and always returns 0.
ShortCondition

Checks conditions to open a short position.

```
virtual int ShortCondition()
```

**Return Value**

If the conditions are satisfied, it returns the value from 1 to 100 (depending on “strength” of a signal). If there isn’t a signal to open short position, it returns 0.

**Note**

The base class has no implementation of checking conditions to open a short position and always returns 0.
Direction

Returns the value of "weighted" price direction.

```c
virtual double Direction()
```

Return Value

It returns the value > 0 when upward direction is most probable and < 0 in case of a downward direction. The absolute value depends on the "strength" of a signal.

Note

If the built-in filters are used, their results are considered when defining the general direction.
**CExpertTrailing**

CExpertTrailing is a base class for trailing algorithms, it does nothing but provides the interfaces.

How to use it:

1. Prepare an algorithm for trailing;
2. Create your own trailing class inherited from CExpertTrailing class;
3. Override the virtual methods in your class with your own algorithms.

You can find an examples of trailing classes in the Expert\Trailing\ folder.

**Description**

CExpertTrailing is a base class for implementation of trailing stop algorithms.

**Declaration**

```cpp
class CExpertTrailing : public CExpertBase
```

**Title**

```cpp
#include <Expert\ExpertTrailing.mqh>
```

**Inheritance hierarchy**

- `CObject`
- `CExpertBase`
- `CExpertTrailing`

**Direct descendants**

- `CTrailingFixedPips`, `CTrailingMA`, `CTrailingNone`, `CTrailingPSAR`

CheckTrailingStopLong checks conditions to modify parameters of a long position.

```cpp
virtual bool CheckTrailingStopLong(
    CPositionInfo* position, // pointer
doUBLE& sl, // Stop Loss
doUBLE& tp // Take Profit
)
```

**Parameters**

- `position`  
  [in]  Pointer to `CPositionInfo` class object.

- `sl`  
  [in][out] Variable for Stop Loss price, passed by reference.

- `tp`  
  [in][out] Variable for Take Profit price, passed by reference.

**Return Value**

- `true` - condition is satisfied, otherwise - `false`.

**Note**

Base class method always returns `false`.
# CheckTrailingStopShort

Checks conditions to modify parameters of a short position.

```cpp
virtual bool CheckTrailingStopShort(
    CPositionInfo* position,  // pointer
    double& sl,               // Stop Loss
    double& tp                 // Take Profit
)
```

## Parameters

- **position**
  - [in] Pointer to `CPositionInfo` class object.

- **sl**
  - [in][out] Variable for Stop Loss price, passed by reference.

- **tp**
  - [in][out] Variable for Take Profit price, passed by reference.

## Return Value

- `true` - condition is satisfied, otherwise `false`.

## Note

Base class method always returns `false`. 
CExpertMoney

CExpertMoney is a base class for money and risk management algorithms.

Description

CExpertMoney is a base class for implementation of money and risk management classes.

Declaration

```cpp
class CExpertMoney : public CObject
```

Title

```cpp
#include <Expert\ExpertMoney.mqh>
```

Inheritance hierarchy

CObject
    CExpertBase
        CExpertMoney

Methods inherited from class CExpertBase

InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries, InitIndicators
Percent

Sets the value of “Risk percent” parameter.

```cpp
void Percent(
    double percent  // risk percent
)
```

Parameters

percent

[in] Risk percent.

Return Value

None.
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

Base class method always returns true.
CheckOpenLong

Gets the volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,    // price
    double sl        // Stop Loss
)
```

**Parameters**

- `sl` [in] Stop Loss price of a long position.

**Return Value**

Trade volume for a long position.
CheckOpenShort

Gets the volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,     // price
    double sl         // Stop Loss
)
```

**Parameters**

- `price`

- `sl`

**Return Value**

Trade volume for a short position.
CheckReverse

Gets the volume for reverse of the position.

```cpp
virtual double CheckReverse(
    CPositionInfo* position,    // pointer
    double sl                    // Stop Loss
)
```

**Parameters**

- `position`
  - [in] Pointer to `CPositionInfo` class object.
- `sl`
  - [in] Stop Loss price.

**Return Value**

Volume for reverse of the position.
CheckClose

Checks conditions to close the opened position.

```cpp
virtual double CheckClose()
```

**Return Value**

- `true` - condition is satisfied, otherwise - `false`. 
Modules of Trade Signals

The standard delivery of the client terminal includes a set of ready-made modules of trade signals for "MQL5 Wizard". When creating an Expert Advisor in MQL5 Wizard, you can use any combination of the modules of trade signals (up to 64). The final decision on a trade operation is made on the basis of complex analysis of signals obtained from all included modules. The detailed description of the mechanism of making trade decisions is given below.

The standard delivery includes the following modules of signals:

- Signals of the Indicator Accelerator Oscillator
- Signals of the Indicator Adaptive Moving Average
- Signals of the Indicator Awesome Oscillator
- Signals of the Oscillator Bears Power
- Signals of the Oscillator Bulls Power
- Signals of the Oscillator Commodity Channel Index
- Signals of the Oscillator DeMarker
- Signals of the Indicator Double Exponential Moving Average
- Signals of the Indicator Envelopes
- Signals of the Indicator Fractal Adaptive Moving Average
- Signals of the Intraday Time Filter
- Signals of the Oscillator MACD
- Signals of the Indicator Moving Average
- Signals of the Indicator Parabolic SAR
- Signals of the Oscillator Relative Strength Index
- Signals of the Oscillator Relative Vigor Index
- Signals of the Oscillator Stochastic
- Signals of the Oscillator Triple Exponential Average
- Signals of the Indicator Triple Exponential Moving Average
- Signals of the Oscillator Williams Percent Range

The Mechanism of Making Trade Decisions on the Basis of Signal Modules

The mechanism of making trade decisions can be represented as the following list of basic principles:

- Each of the modules of signals has its set of market modules (certain combination of prices and values of an indicator).
- Each market model has a significance that may vary with the range of 1 to 100. The higher is the significance, the stronger the model is.
- Each of the models generates a forecast of direction of the price movement.
- A forecast of a module is the result of search for embedded models, and it is outputted as a number within the range of -100 to 100. The sign determines the direction of forecast movement (negative
sign means the price will fall, positive sign means the price will rise). The absolute value corresponds to the strength of the best found model.

- The forecast of each module is sent to the final "voting" with a weight coefficient of 0 to 1 specified in its settings ("Weight").
- The result of voting is a number within the range of -100 to 100, where the sign determines direction of the forecast movement, and the absolute value characterizes the strength of the signal. It is calculated as the Arithmetic mean of weighted forecasts of all the modules of signals. The absolute value is used by an Expert Advisor to make trade decisions.

Each generated Expert Advisor has two adjustable settings — threshold levels of opening and closing a position (ThresholdOpen and ThresholdClose) that can be equal to a value in the range of 0 to 100. If the strength of final signal exceeds a threshold level, a trade operation that corresponds to the sign of the signal is performed.

**Examples**

Consider an Expert Advisor with the following threshold levels: ThresholdOpen=20 and ThresholdClose=90. Two modules of signals participate in making decisions on trade operations: the MA module with weight 0.4 and the Stochastic module with weight 0.8. Let's analyze two variants of obtained trade signals:

**Variant 1**

The price crossed the rising MA upwards. This case corresponds to one of the market models implemented in the **MA module**. This model implies a rise of price. Its significance is equal to 100. At the same time, the Stochastic oscillator turned down and formed a divergence with price. This case corresponds to one of the models implemented in the **Stochastic module**. This model implies a fall of price. The weight of this model is 80.

Let's calculate the result of final "voting". The rate obtained from the MA module is calculated as 0.4 * 100 = 40. The value from the Stochastic module is calculated as 0.8 * (-80) = -64. The final value is calculated as the Arithmetic mean of these two rates: (40 - 64)/2 = -12. The result of voting is the signal for selling with relative strength equal to 12. The threshold level that is equal to 20 is not reached. Thus a trade operation is not performed.

**Variant 2**

The price crossed the rising MA downwards. This case corresponds to one of the models implemented in the **MA module**. This model implies a rise of price. Its significance is equal to 10. At the same time, the Stochastic oscillator turned down and formed a divergence with price. This case corresponds to one of the models implemented in the **Stochastic module**. This model implies a fall of price. The weight of this model is 80.

Let's calculate the result of final "voting". The rate obtained from the MA module is calculated as 0.4 * 10 = 4. The value from the Stochastic module is calculated as 0.8 * (-80) = -64. The final value is calculated as the Arithmetic mean of these two rates: (4 - 64)/2 = -30. The result of voting is the signal for selling with relative strength equal to 30. The threshold level that is equal to 20 is reached. Thus the result is the signal for opening a short position.
a) Divergence of the price and the Stochastic oscillator (variants 1 and 2).
b) The price crossed the MA indicator upwards (variant 1).
c) The price crossed the MA indicator downwards (variant 2).
# Signals of the Indicator Accelerator Oscillator

This module is based on the market models of the indicator [Accelerator Oscillator](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

## Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Trailing Stop classes

This section contains technical details of working with trailing stop classes and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies) is placed in the terminal directory, in the `Include\Expert\Trailing` folder.

CTrailingFixedPips

CTrailingFixedPips is a class with implementation of Trailing Stop algorithm based on fixed points trailing.

CTrailingFixedPips class implements the following algorithm of trailing open positions: If Stop Loss level is equal to zero, Stop Loss order modification condition is considered unfulfilled, therefore there is no suggestion to change a position's Stop Loss. Otherwise, the check of whether the price has moved in favorable direction is performed.

If a position has a Stop Loss order, it checks the minimal allowed Stop Loss distance to the current price. If the position has no Stop Loss level, the distance between the current and open prices is checked. If the distance exceeds Stop Loss level, the system suggests to set a new Stop Loss price.

If Stop Loss modification condition is fulfilled and Take Profit is not equal to zero, the system suggests setting a new Take Profit price.

If Expert Advisor class has been initialized with the flag every_tick=false, it will perform all operations (trading, trailing, etc) only at the new bar on a working symbol and timeframe. In this case, setting Take Profit order allows you to close position when the price moves in the position direction before a new bar appears.

Description

CTrailingFixedPips implements the Trailing Stop algorithm at a specified "distance" from the current price (in points).

Declaration

class CTrailingFixedPips: public CExpertTrailing

Title

#include <Expert\Trailing\CTrailingFixedPips.mqh>

Inheritance hierarchy

CObject
  CExpertBase
    CExpertTrailing
      CTrailingFixedPips

</tbody>
</table>
virtual `CheckTrailingStopLong` | Check Trailing Stop conditions of a long position
---|---
virtual `CheckTrailingStopShort` | Check Trailing Stop conditions of a short position

Methods inherited from class `CObject`  
Prev, Prev, Next, Next, `Save`, `Load`, `Type`, `Compare`

Methods inherited from class `CExpertBase`  
`InitPhase`, `TrendType`, `UsedSeries`, `EveryTick`, `Open`, `High`, `Low`, `Close`, `Spread`, `Time`, `TickVolume`, `RealVolume`, `Init`, `Symbol`, `Period`, `Magic`, `SetMarginMode`, `SetPriceSeries`, `SetOtherSeries`, `InitIndicators`
StopLevel

Sets the value of Stop Loss level.

```c
void StopLevel(
    int stop_level  // level
);
```

**Parameters**

`stop_loss`

[in] The value of Stop Loss level (in conventional 2/4-digit points).

**Note**

If Stop Loss level is equal to 0, the Trailing Stop is not used.
ProfitLevel

Sets the value of Take Profit level.

```cpp
void ProfitLevel(
    int profit_level // level
)
```

Parameters

`profit_level`

[in] The value of Take Profit level (in conventional 2/4-digit points).

Note

If profit level is equal to 0, the Trailing Stop is not used.
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

The function checks Take Profit and Stop Loss levels. The correct values are 0 and values greater than the minimal indentation in points from the current close price to place Stop orders.
CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```cpp
virtual bool CheckTrailingStopLong(
    CPositionInfo* position,  // pointer
    double& sl,               // reference to Stop Loss
    double& tp                 // reference to Take Profit
)
```

**Parameters**

- `position`  
  [in] Pointer to `CPositionInfo` object.

- `sl`  
  [in][out] Reference to variable for Stop Loss price.

- `tp`  
  [in][out] Reference to variable for Take Profit price.

**Return Value**

true - conditions are satisfied, otherwise - false.

**Note**

If Stop Loss level is equal to 0, the condition is not fulfilled (exit). If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the current Bid price is higher than base price+stop loss level, it suggests to set new Stop Loss price. In this case, if position already has Take Profit price, it suggests to set new Take Profit price equal to Bid price+take profit level.
CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```cpp
class CPositionInfo

virtual bool CheckTrailingStopShort(
    CPositionInfo* position,  // pointer
    double& sl,               // reference to Stop Loss
    double& tp                // reference to Take Profit
)
```

Parameters

- **position**
  - [in] Pointer to `CPositionInfo` object.

- **sl**
  - [in][out] Reference to variable for Stop Loss price.

- **tp**
  - [in][out] Reference to variable for Take Profit price.

Return Value

- `true` - conditions are satisfied, otherwise - `false`.

Note

If Stop Loss level is equal to 0, the condition is not fulfilled (exit). If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the current Ask price is lower than base price - stop loss level, it suggests to set new Stop Loss price. In this case, if position already has Take Profit price, it suggests to set new Take Profit price equal to Ask price - take profit level.
CTrailingMA

CTrailingMA is a class with implementation of Trailing Stop algorithm based on the values of moving average indicator.

Description

CTrailingMA class implements Trailing Stop algorithm based on the values of moving average indicator of the previous (completed) bar.

Declaration

```cpp
class CTrailingMA: public CExpertTrailing
```

Title

```
#include <Expert\Trailing\TrailingMA.mqh>
```

Inheritance hierarchy

- CObject
  - CExpertBase
    - CExpertTrailing
      - CTrailingMA

</table>

Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CExpertBase
InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries
**Period**

Sets period of a moving average.

```c
void Period(
    int period  // period
)
```

**Parameters**

- `period`
  - **[in]** Period of a moving average.
Shift

Sets shift of a moving average.

```c
void Shift(
    int shift  // parameter
)
```

Parameters

- `shift`
  
  [in] Shift of a moving average.
Method

Sets smoothing method of a moving average.

```c
void Method(
    ENUM_MA_METHOD method // parameter
)
```

Parameters

`method`

[in] Smoothing method (from `ENUM_MA_METHOD` enumeration) of a moving average.
Applied

Sets applied price of a moving average.

```c
void Applied(
    ENUM_APPLIED_PRICE applied // parameter
)
```

Parameters

- **applied**
  
InitIndicators

Initializes indicators and timeseries.

```cpp
virtual bool InitIndicators(
    CIndicators* indicators  // pointer
)
```

**Parameters**

*indicators*

[in] Pointer to indicators and timeseries collection (CExpert class member).

**Return Value**

true - successful, otherwise - false.
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

The function checks the period of moving average, the correct values are positive.
CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```cpp
virtual bool CheckTrailingStopLong(
    CPositionInfo* position,  // pointer
    double& sl,              // reference
    double& tp                // reference
)
```

Parameters

- **position**
  - [in] Pointer to `CPositionInfo` object.
- **sl**
  - [in][out] Reference to variable for Stop Loss price.
- **tp**
  - [in][out] Reference to variable for Take Profit price.

Return Value

- `true` - conditions are satisfied, otherwise - `false`.

Note

First it calculates the maximal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of moving average indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the base price is the open price of the position. If the calculated Stop Loss price is higher than base price and lower than maximal allowed Stop Loss price, it suggests to set new Stop Loss price.
**CheckTrailingStopShort**

Checks Trailing Stop conditions of a short position.

```cpp
virtual bool CheckTrailingStopShort(
    CPositionInfo* position,   // pointer
    double& sl,               // reference
    double& tp                 // reference
)
```

**Parameters**

- `position`
  - `[in]` Pointer to `CPositionInfo` object.
- `sl`
  - `[in][out]` Reference to variable for Stop Loss price.
- `tp`
  - `[in][out]` Reference to variable for Take Profit price.

**Return Value**

- `true` - conditions are satisfied, otherwise - `false`.

**Note**

First it calculates the minimal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of moving average indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the base price is the open price of the position. If the calculated Stop Loss price is lower than base price and higher than minimal allowed Stop Loss price, it suggests to set new Stop Loss price.
CTrailingNone

CTrailingNone is a stub class. This class should be used at initialization of trailing object in CExpert class if your strategy does not use Trailing Stop.

Description

CTrailingNone class does not implement any Trailing Stop algorithm. The methods of checking Trailing Stop conditions always return false.

Declaration

```cpp
class CTrailingNone: public CExpertTrailing
```

Title

```cpp
#include <Expert\Trailing\TrailingNone.mqh>
```

Inheritance hierarchy

- CObject
  - CExpertBase
    - CExpertTrailing
      - CTrailingNone

Methods inherited from class CExpertTrailing

- CheckTrailingStopLong, CheckTrailingStopShort
CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```cpp
virtual bool CheckTrailingStopLong(
    CPositionInfo* position,   // pointer
    double&  sl,              // reference
    double&  tp                // reference
)
```

Parameters

- **position**
  - [in] Pointer to `CPositionInfo` object.

- **sl**
  - [in][out] Reference to variable for Stop Loss price.

- **tp**
  - [in][out] Reference to variable for Take Profit price.

Return Value

- `true` - conditions are satisfied, otherwise - `false`.

Note

The function always returns `false`. 
CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```cpp
virtual bool CheckTrailingStopShort(
    CPositionInfo* position,  // pointer
    double& sl,              // reference
    double& tp                // reference
)
```

Parameters

- `position` 
  
  [in] Pointer to `CPositionInfo` object.

- `sl` 
  
  [in][out] Reference to variable for Stop Loss price.

- `tp` 
  
  [in][out] Reference to variable for Take Profit price.

Return Value

- `true` - conditions are satisfied, otherwise - `false`.

Note

The function always returns `false`. 
CTrailingPSAR

CTrailingPSAR is a class with implementation of Trailing Stop algorithm based on the values of Parabolic SAR indicator.

**Description**

CTrailingPSAR class implements the Trailing Stop algorithm based on the values of Parabolic SAR indicator of the previous (completed) bar.

**Declaration**

```cpp
class CTrailingPSAR: public CExpertTrailing
```

**Title**

```cpp
#include <Expert\Trailing\TrailingParabolicSAR.mqh>
```

**Inheritance hierarchy**

```
CObject
  CExpertBase
    CExpertTrailing
      CTrailingPSAR
```

**Class Methods by Groups**

<table>
<thead>
<tr>
<th>Initialization</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step</strong></td>
<td>Sets the value of step of Parabolic SAR indicator</td>
</tr>
<tr>
<td><strong>Maximum</strong></td>
<td>Sets the value of maximum of Parabolic SAR indicator</td>
</tr>
<tr>
<td>virtual <strong>InitIndicators</strong></td>
<td>Initializes indicators and timeseries</td>
</tr>
</tbody>
</table>

**Check Trailing Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>virtual <strong>CheckTrailingStopLong</strong></td>
<td>Check conditions of trailing stop of a long position</td>
</tr>
<tr>
<td>virtual <strong>CheckTrailingStopShort</strong></td>
<td>Check conditions of trailing stop of a short position</td>
</tr>
</tbody>
</table>

**Methods inherited from class CObject**

```
Prev, Prev, Next, Next, Save, Load, Type, Compare
```

**Methods inherited from class CExpertBase**

```
InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, ValidationSettings, SetPriceSeries, SetOtherSeries
```
Step

Sets the value of step of Parabolic SAR indicator.

```c
void Step(
    double step   // parameter
)
```

Parameters

`step`

**Maximum**

Sets the value of maximum of Parabolic SAR indicator.

```cpp
void Maximum(
    double maximum  // parameter
)
```

**Parameters**

`maximum`

- `[in]` The value of maximum of Parabolic SAR indicator.
**InitIndicators**

Initializes indicators and timeseries.

```cpp
virtual bool InitIndicators(
    CIndicators* indicators    // pointer
)
```

**Parameters**

- `indicators`
  - [in] Pointer to indicators and timeseries collection (**CExpert** class member).

**Return Value**

- `true` - successful, otherwise - `false`. 
CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```
virtual bool CheckTrailingStopLong(
    CPositionInfo* position,  // pointer
    double& sl,               // reference
    double& tp                 // reference
)
```

Parameters

`position`

[in] Pointer to `CPositionInfo` object.

`sl`

[in][out] Reference to variable for Stop Loss price.

`tp`

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

First it calculates the maximal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of Parabolic SAR indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the calculated Stop Loss price is higher than base price and lower than maximal allowed Stop Loss price, it suggests to set new Stop Loss price.
CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```cpp
virtual bool CheckTrailingStopShort(
    CPositionInfo* position,  // pointer
    double& sl,              // reference
    double& tp                // reference
)
```

**Parameters**

- `position`  
  [in] Pointer to `CPositionInfo` object.

- `sl`  
  [in][out] Reference to variable for Stop Loss price.

- `tp`  
  [in][out] Reference to variable for Take Profit price.

**Return Value**

- `true` - conditions are satisfied, otherwise - `false`.

**Note**

First it calculates the minimal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of Parabolic SAR indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the calculated Stop Loss price is lower than base price and higher than minimal allowed Stop Loss price, it suggests to set new Stop Loss price.
Money Management classes

This section contains technical details of working with money and risk management classes and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and testing) trading strategies.

MQL5 Standard Library (in terms of money and risk management classes) is placed in the terminal directory, in the Include\Expert\Money\ folder.

<table>

CMoneyFixedLot

CMoneyFixedLot is the class designed to implement money management algorithm based on trading with predefined fixed lot size.

Description

CMoneyFixedLot implements money management algorithm based on trading with predefined fixed lot size.

Declaration

```cpp
class CMoneyFixedLot: public CExpertMoney
```

Inheritance hierarchy

```
CObject
  CExpertBase
    CExpertMoney
      CMoneyFixedLot
```

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CExpertBase

InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries, InitIndicators

Methods inherited from class CExpertMoney

Percent, CheckReverse, CheckClose
Lots

Sets trading volume (in lots).

```c
void Lots(
    double lots // number of lots
)
```

**Parameters**

- `lots`
  
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

Return Value

- true - successful, otherwise - false.

Note

Checks if the predefined fixed lot falls within the range of allowed values and is multiple of change step.
CheckOpenLong

Gets trade volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,   // price
    double sl       // Stop Loss price
)
```

**Parameters**

- `price`
  - [in] Estimated open price.

- `sl`
  - [in] Estimated Stop Loss order price.

**Return Value**

Trade volume for a long position.

**Note**

The function always returns the predefined fixed trade volume.
CheckOpenShort

Gets trade volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,   // price
    double sl       // Stop Loss price
)
```

Parameters

- **price**
  - [in] Estimated open price.
- **sl**
  - [in] Estimated Stop Loss order price.

Return Value

Trade volume for a short position.

Note

The function always returns the predefined fixed trade volume.
CMoneyFixedMargin

CMoneyFixedMargin is the class designed to implement money management algorithm based on trading with predefined fixed margin.

**Description**

CMoneyFixedMargin implements money management algorithm based on trading with predefined fixed margin.

**Declaration**

```cpp
class CMoneyFixedMargin: public CExpertMoney
```

**Title**

```cpp
#include <Expert\Money\MoneyFixedMargin.mqh>
```

**Inheritance hierarchy**

- CObject
  - CExpertBase
    - CExpertMoney
      - CMoneyFixedMargin

**Class Methods by Groups**

<table>
<thead>
<tr>

- Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CExpertBase

- InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries, InitIndicators

Methods inherited from class CExpertMoney

- Percent, ValidationSettings, CheckReverse, CheckClose
CheckOpenLong

Gets trade volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,    // price
    double sl        // Stop Loss price
)
```

**Parameters**

- `price`
  - [in] Estimated open price.

- `sl`
  - [in] Estimated Stop Loss price.

**Return Value**

Trade volume for a long position.

**Note**

The function returns trade volume for a long position with a fixed predefined margin. The margin is defined by Percent parameter of `CExpertMoney` base class.
**CheckOpenShort**

Gets trade volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,      // price
    double sl          // Stop Loss price
)
```

**Parameters**

- `price`  

- `sl`  
  [in] Estimated Stop Loss price.

**Return Value**

Trade volume for a short position.

**Note**

The function returns trade volume for a short position with a predefined fixed margin. The margin is defined by Percent parameter of `CExpertMoney` base class.
CMoneyFixedRisk

CMoneyFixedRisk is a class with implementation of money management algorithm with fixed predefined risk.

Description

CMoneyFixedRisk class implements the money management algorithm with fixed predefined risk.

Declaration

```cpp
class CMoneyFixedRisk : public CExpertMoney
```

Title

```cpp
#include <Expert\Money\MoneyFixedRisk.mqh>
```

Inheritance hierarchy

- CObject
  - CExpertBase
    - CExpertMoney
      - CMoneyFixedRisk

Methods inherited from class CExpertMoney

Percent, ValidationSettings, CheckReverse
CheckOpenLong

Gets trade volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,       // price
    double sl           // Stop Loss price
)
```

Parameters

- **price**
  - [in] Estimated open price.

- **sl**
  - [in] Estimated Stop Loss price.

Return Value

- Trade volume for a long position.

Note

The function returns trade volume for a long position with a fixed predefined risk level. The risk is defined by Percent parameter of `CExpertMoney` base class.
CheckOpenShort

Gets trade volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,       // price
    double sl           // Stop Loss price
)
```

**Parameters**

*price*

*sl*

[in] Estimated Stop Loss price.

**Return Value**

Trade volume for a short position.

**Note**

The function returns trade volume for a short position with a fixed predefined risk level. The risk is defined by Percent parameter of [CExpertMoney](#) base class.
CMoneyNone

CMoneyNone is a class with implementation of the "absence" of money and risk management.

Description

CMoneyNone class implements trading with minimal allowed lot.

Declaration

```cpp
class CMoneyNone: public CExpertMoney
```

Title

```cpp
#include <Expert\Money\MoneyNone.mqh>
```

Inheritance hierarchy

- CObject
  - CExpertBase
    - CExpertMoney
      - CMoneyNone

Class Methods by Groups

Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CExpertBase

- InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries, InitIndicators

Methods inherited from class CExpertMoney

- Percent, CheckReverse, CheckClose
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

**Return Value**

true - successful, otherwise - false.

**Note**

The function always returns true.
CheckOpenLong

Gets trade volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,     // price
    double sl         // Stop Loss price
)
```

**Parameters**

- **price**
  - [in] Estimated open price.

- **sl**
  - [in] Estimated Stop Loss price.

**Return Value**

Trade volume for a long position.

**Note**

The function always returns the minimal lot size.
CheckOpenShort

Gets trade volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,  // price
    double sl      // Stop Loss price
)
```

Parameters

- `price`
  - [in] Estimated open price.

- `sl`
  - [in] Estimated Stop Loss price.

Return Value

Trade volume for a short position.

Note

The function always returns the minimal lot size.
**CMoneySizeOptimized**

CMoneySizeOptimized is a class with implementation of money and risk management algorithm depending on results of the previous deals.

**Description**

CMoneySizeOptimized implements the market entry algorithm with the lot size depending on results of the previous deals.

**Declaration**

```cpp
class CMoneySizeOptimized: public CExpertMoney
```

**Title**

```
#include <Expert\Money\MoneySizeOptimized.mqh>
```

**Inheritance hierarchy**

- **CMoneySizeOptimized**
- **CExpertMoney**
- **CExpertBase**
- **CObject**

**Methods inherited from class CExpertBase**

- InitPhase, TrendType, UsedSeries, EveryTick, Open, High, Low, Close, Spread, Time, TickVolume, RealVolume, Init, Symbol, Period, Magic, SetMarginMode, SetPriceSeries, SetOtherSeries, InitIndicators

**Methods inherited from class CExpertMoney**

- Percent, CheckReverse, CheckClose
DecreaseFactor

Sets the value of decrease factor.

```c
void DecreaseFactor(
    double decrease_factor // decrease factor
);
```

Parameters

- `decrease_factor`
  - [in] Decrease factor.

Note

The `DecreaseFactor` defines the open position volume decreasing coefficient (compared with the volume of a previous position) for the case of consecutive loss trades.
ValidationSettings

Checks the settings.

```cpp
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

If the value of decrease factor is negative, it returns false, otherwise it returns true.
CheckOpenLong

Gets trade volume for a long position.

```cpp
virtual double CheckOpenLong(
    double price,  // price
    double sl      // Stop Loss price
)
```

Parameters

- `price`
  - [in] Estimated open price.
- `sl`
  - [in] Estimated Stop Loss price.

Return Value

- Trade volume for long position.

Note

- The function returns trade volume for a long position considering results of previous deals.
CheckOpenShort

Gets trade volume for a short position.

```cpp
virtual double CheckOpenShort(
    double price,  // price
    double sl      // Stop Loss price
)
```

Parameters

- `price`
  - [in] Estimated open price.

- `sl`
  - [in] Estimated Stop Loss price.

Return Value

Trade volume for a long position.

Note

The function returns trade volume for a short position considering results of previous deals.
Classes for Creating Control Panels and Dialogs

This section contains technical details of working with classes for creation of controls panels and dialogs, as well as description of the relevant components of the MQL5 standard library.

The use of these classes will save time when developing custom interactive MQL5 applications, including Expert Advisors and indicators.

MQL5 Standard Library (in terms of classes for creation of control panels and dialogs) is placed in the terminal data folder, in the MQL5\Include\Controls.

The sample Expert Advisor, which illustrates the operation of these classes, can be found in MQL5\Expert\Examples\Controls.

CRect

CRect is a class of the rectangular area of the chart.

Description

CRect is a class of the area, it is defined by both coordinates of the upper-left and lower-right corners of a rectangle in Cartesian coordinates.

Declaration

```cpp
class CRect
```

Title

```cpp
#include <Controls\Rect.mqh>
```

</tr>
</tbody>
</table>
**Left (Get Method)**

Gets the X coordinate of the upper-left corner.

```cpp
int Left()
```

**Return Value**

X coordinate of the upper-left corner.

---

**Left (Set Method)**

Sets the X coordinate of the upper-left corner.

```cpp
void Left(
    const int x  // x coordinate
)
```

**Parameters**

x

[in] New X coordinate of the upper-left corner.

**Return Value**

None.
Top (Get Method)

Gets the Y coordinate of the upper-left corner.

```cpp
int Top()
```

Return Value

Y coordinate of the upper-left corner.

Top (Set Method)

Sets the Y coordinate of the upper-left corner.

```cpp
void Top(const int y // y coordinate)
```

Parameters

y

[in] New Y coordinate of the upper-left corner.

Return Value

None.
Right (Get Method)

Gets the X coordinate of the lower-right corner.

```cpp
int Right()
```

**Return Value**

X coordinate of the lower-right corner.

Right (Set Method)

Sets the X coordinate of the lower-right corner.

```cpp
void Right(
    const int x // x coordinate
)
```

**Parameters**

x

[in] New X coordinate of the lower-right corner.

**Return Value**

None.
**Bottom (Get Method)**

Gets the Y coordinate of the lower-right corner.

```cpp
int Bottom()
```

**Return Value**

Y coordinate of the lower-right corner.

**Bottom (Set Method)**

Sets the Y coordinate of the lower-right corner.

```cpp
void Bottom(
    const int y  // y coordinate
)
```

**Parameters**

`y`

[in] New Y coordinate of the lower-right corner.

**Return Value**

None.
**Width (Get Method)**

Gets the width of the area.

```cpp
int Width()
```

**Return Value**

Width of the area.

**Width (Set Method)**

Sets new width of the area.

```cpp
virtual bool Width(
    const int w  // width
)
```

**Parameters**

- `w`

**Return Value**

true - successful, otherwise - false.
Height (Get Method)

Gets the height of the area.

```cpp
int Height()
```

Return Value

Height of the area.

Height (Set Method)

Sets new height of the area.

```cpp
virtual bool Height(
    const int h  // height
)
```

Parameters

- **h**
  

Return Value

true - successful, otherwise - false.
### SetBound

Sets new coordinates of the area using CRect class coordinates.

```cpp
void SetBound(
    const &CRect rect  // CRect class
);
```

#### Return Value

None.

### SetBound

Sets new coordinates of the area.

```cpp
void SetBound(
    const int l  // left
    const int t  // top
    const int r  // right
    const int b  // bottom
);
```

#### Parameters

- `l`
  - [in] X coordinate of the upper-left corner.
- `t`
  - [in] Y coordinate of the upper-left corner.
- `r`
  - [in] X coordinate of the lower-right corner.
- `b`
  - [in] Y coordinate of the lower-right corner.

#### Return Value

None.
**Move**

Performs the absolute displacement of the area coordinates.

```cpp
void Move(
    const int x,  // X coordinate
    const int y   // Y coordinate
)
```

**Parameters**

- **x**
  - [in] New X coordinate.

- **y**
  - [in] New Y coordinate.

**Return Value**

None.
Shift

Performs the relative displacement (shift) of the area coordinates.

```cpp
void Shift(
    const int dx,    // delta X
    const int dy     // delta Y
)
```

Parameters

dx

[in] Delta X.

dy

[in] Delta Y.

Return Value

None.
Contains

Checks if the point is inside the CRect class area.

```cpp
bool Contains(const int x, // X coordinate
              const int y) // Y coordinate
```

Parameters

- `x` [in] X coordinate.

Return Value

`true` - the point is inside the area (including borders), otherwise - `false`.
Format

Gets the area coordinates as a string.

```cpp
string Format(
    string & fmt, // format
) const
```

**Parameters**

- `fmt`
  
  [in] String with format.

**Return Value**

String with the area coordinates.
**CDateTime**

CDateTime is a structure for working with date and time.

**Description**

CDateTime is a structure derived from `MqlDateTime`, it is used for operation with date and time in controls.

**Declaration**

```c
struct CDateTime
```

**Title**

```c
#include <Tools\DateTime.mqh>
```

**Methods**

</tbody>
</table>
MonthName

Gets month name.

```cpp
string MonthName() const
```

Gets month name by index.

```cpp
string MonthName(
    const int num // month index
) const
```

**Parameters**

`num`

[in] Month index (1-12).

**Return Value**

Full month name.
**ShortMonthName**

Gets short month name.

```
string ShortMonthName() const
```

Gets short month name by index.

```
string ShortMonthName(
    const int num // month index
) const
```

**Parameters**

`num`

[in] Month index (1-12).

**Return Value**

Short month name.
# DayName

**Gets full name of the day in a week.**

```cpp
string DayName() const
```

**Gets full name of the day in a week by index.**

```cpp
string DayName(
    const int num // day index
) const
```

## Parameters

**num**

[in] Day index (0-6).

## Return Value

Full name of the day.
ShortDayName

Gets short name of the day in a week.

```cpp
string ShortDayName() const
```

Gets short name of the day in a week by index.

```cpp
string ShortDayName(const int num) const
```

**Parameters**

- `num`
  
  [in]  Day index (0-6).

**Return Value**

Short name of the day.
DaysInMonth

Gets number of days in month.

```
int DaysInMonth() const
```

Return Value

Number of days in month.
**DateTime (Get Method)**

Gets date and time.

```cpp
datetime DateTime()
```

**Return Value**

Value of `datetime` type.

**DateTime (Set Method dateTime)**

Sets date and time with `datetime` type.

```cpp
void DateTime(
    const datetime value  // date and time
)
```

**Parameters**

- `value`
  

**Return Value**

None.

**DateTime (Set Method MqlDateTime)**

Sets date and time with `MqlDateTime` type.

```cpp
void DateTime(
    const MqlDateTime &value  // date and time
)
```

**Parameters**

- `value`
  
  `[in]` Value of `MqlDateTime` type.

**Return Value**

None.
Date (Set Method datetime)

Sets date with `datetime` type.

```cpp
void Date(
    const datetime value // date
)
```

Parameters

`value`

Return Value

None.

Date (Set Method MqlDateTime)

Sets date with `MqlDateTime` type.

```cpp
void Date(
    const MqlDateTime &value // date
)
```

Parameters

`value`

[in] Value of `MqlDateTime` type.

Return Value

None.
Time (Set Method datetime)

Sets time with datetime type.

```cpp
void Time(
    const datetime value // time
)
```

Parameters

value

Return Value

None.

Time (Set Method MqlDateTime)

Sets time with MqlDateTime type.

```cpp
void Time(
    const MqlDateTime &value // time
)
```

Parameters

value

[in] Value of MqlDateTime type.

Return Value

None.
Sec

Sets seconds.

```c
void Sec(
    const int value // seconds
)
```

Parameters

- `value`
  - [in] Seconds.

Return Value

None.
Min

Sets minutes.

```cpp
void Min(
    const int value // minutes
)
```

Parameters

- `value`
  

Return Value

None.
**Hour**

Sets hour.

```cpp
void Hour(
    const int value  // hour
)
```

**Parameters**

- `value`
  - `[in]` Hour.

**Return Value**

None.
Day

Sets day of the month.

```c
void Day(
    const int value     // day of month
)
```

Parameters

- `value` [in] Day of month.

Return Value

None.
**Mon**

Sets month.

```c
void Mon(
    const int value  // month
)
```

**Parameters**

- **value**
  - [in] Month.

**Return Value**

None.
Year

Sets year.

```cpp
void Day(
    const int value  // year
)
```

Parameters

value

[in] Year.

Return Value

None.
SecDec

Subtracts specified number of seconds.

```cpp
void SecDec(
    int delta=1  // seconds
)
```

**Parameters**

delta

[in] Seconds to subtract.

**Return Value**

None.
SecInc

Adds specified number of seconds.

```cpp
void SecInc(
    int delta=1  // seconds
)
```

Parameters

- `delta`

  [in] Seconds to add.

Return Value

None.
MinDec

Subtracts specified number of minutes.

```c
void MinDec(
    int delta=1 // minutes
)
```

Parameters

delta

[in] Minutes to subtract.

Return Value

None.
**MinInc**

Adds specified number of minutes.

```c
void MinInc(
    int delta=1    // minutes
)
```

**Parameters**

*delta*  
[in] Minutes to add.

**Return Value**

None.
HourDec

Subtracts specified number of hours.

```c
void HourDec(
    int delta=1    // hours
)
```

Parameters

- `delta`
  - [in] Hours to subtract.

Return Value

- None.
HourInc

Adds specified number of hours.

```c
void HourInc(
    int delta=1  // hours
)
```

Parameters

delta

[in] Hours to add.

Return Value

None.
DayDec

Subtracts specified number of days.

```c
void DayDec(
    int delta=1  // days
)
```

Parameters

delta

[in] Days to subtract.

Return Value

None.
DayInc

Adds specified number of days.

```c
void DayInc(
    int delta=1    // days
)
```

Parameters

delta

[in] Days to add.

Return Value

None.
MonDec

Subtracts specified number of months.

```c
void MonDec(
    int delta=1    // months
)
```

**Parameters**

*delta*

  [in] Months to subtract.

**Return Value**

None.
MonInc

Adds specified number of months.

```c
void MonInc(
    int delta=1 // months
)
```

Parameters

delta
    [in] Months to add.

Return Value

None.
**YearDec**

Subtracts specified number of years.

```c
void YearDec(
    int  delta=1  // years
)
```

**Parameters**

- `delta`
  - [in] Years to subtract.

**Return Value**

- None.
YearInc

Adds specified number of years.

```c
void YearInc(
    int delta=1  // years
)
```

Parameters

- `delta` [in] Years to add.

Return Value

None.
CWnd

CWnd is a base class for all Standard Library controls.

Description

CWnd class is the implementation of the base control class.

Declaration

```cpp
class CWnd : public CObject
```

Title

```cpp
#include <Controls\Wnd.mqh>
```

Inheritance hierarchy

- CObject
- CWnd

Direct descendants

- CDragWnd, CWndContainer, CWndObj

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare
Create

Creates a control.

```cpp
virtual bool Create(
    const long chart,       // chart ID
    const string name,      // name
    const int subwin,       // chart subwindow
    const int x1,           // x1 coordinate
    const int y1,           // y1 coordinate
    const int x2,           // x2 coordinate
    const int y2            // y2 coordinate
)
```

**Parameters**

- **chart**
  - [in] ID of the chart, at which the control is created.

- **name**
  - [in] Unique name of the control.

- **subwin**
  - [in] Chart subwindow, at which the control is created.

- **x1**
  - [in] X coordinate of the upper-left corner.

- **y1**
  - [in] Y coordinate of the upper-left corner.

- **x2**
  - [in] X coordinate of the lower-right corner.

- **y2**
  - [in] Y coordinate of the lower-right corner.

**Return Value**

- `true` - successful, otherwise - `false`.

**Note**

Base class method only saves the creation parameters and always returns `true`. 
Destroy

Destroys a control.

```cpp
virtual bool Destroy()
```

Return Value

true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id, // ID
    const long& lparam, // event parameter
    const double& dparam, // event parameter
    const string& sparam // event parameter
)
```

Parameters

- **id**
  - [in] Event ID.

- **lparam**
  - [in] Event parameter of `long` type, passed by reference.

- **dparam**
  - [in] Event parameter of `double` type, passed by reference.

- **sparam**
  - [in] Event parameter of `string` type, passed by reference.

Return Value

- `true` - event has been processed, otherwise - `false`. 
OnMouseEvent

Mouse event handler (the CHARTEVENT_MOUSE_MOVE chart event).

```cpp
virtual bool OnMouseEvent(const int x, // x coordinate
                         const int y, // y coordinate
                         const int flags // flags
)
```

Parameters

- **x**
  - [in] X coordinate of the mouse cursor relative to the upper-left corner of the chart.

- **y**
  - [in] Y coordinate of the mouse cursor relative to the upper-left corner of the chart.

- **flags**
  - [in] Flag of mouse buttons states.

Return Value

- true - event has been processed, otherwise - false.
Name

Gets control name.

```
string Name() const
```

Return Value

Control name.
**ControlsTotal**

Gets the number of controls in the container.

```cpp
int ControlsTotal() const
```

**Return Value**

Number of controls in container.

**Note**

The base class method does not have the container, it provides the access to container for its heirs and always returns 0.
Control

Gets the control from the container by index.

```cpp
CWnd* Control(const int ind) // index
```

**Parameters**

- `ind`
  - [in] Control index.

**Return Value**

A pointer to the control.

**Note**

The base class method does not have the container, it provides the access to container for its heirs and always returns NULL.
ControlFind

Gets the control from container by specified ID.

```cpp
virtual CWnd* ControlFind(
    const long id // ID
)
```

**Parameters**

- `id`  
  [in] Identifier of the control to find.

**Return Value**

- Pointer to the control from the container.

**Note**

The base class method does not have the container, it provides the access to container for its heirs. If the specified ID matches the container's one, it returns a pointer to itself (this).
**Rect**

*Gets the pointer to the CRect class object.*

```c
const CRect* Rect() const
```

**Return Value**

*Pointer to the CRect class object.*
**Left (Get Method)**

Gets the X coordinate of the upper-left corner of the control.

```cpp
int Left()
```

**Return Value**

X coordinate of the upper-left corner of the control.

---

**Left (Set Method)**

Sets the X coordinate of the upper-left corner of the control.

```cpp
void Left(
    const int x  // coordinate
)
```

**Parameters**

- `x`

  [in] New X coordinate of the upper-left corner.

**Return Value**

None.
**Top (Get Method)**

Gets the Y coordinate of the upper-left corner of the control.

```c
int Top()
```

**Return Value**

Y coordinate of the upper-left corner of the control.

---

**Top (Set Method)**

Sets the Y coordinate of the upper-left corner of the control.

```c
void Top(
    const int y // y coordinate
)
```

**Parameters**

- `y`

  [in] New Y coordinate of the upper-left corner.

**Return Value**

None.
Right (Get Method)

Gets the X coordinate of the lower-right corner of the control.

```cpp
int Right()
```

Return Value

X coordinate of the lower-right corner.

Right (Set Method)

Sets the X coordinate of the lower-right corner of the control.

```cpp
void Right(
    const int x // x coordinate
)
```

Parameters

x

[in] New X coordinate of the lower-right corner.

Return Value

None.
Bottom (Get Method)

Gets the Y coordinate of the lower-right corner of the control.

```cpp
int Bottom()
```

Return Value

Y coordinate of the lower-right corner of the control.

Bottom (Set Method)

Sets the Y coordinate of the lower-right corner of the control.

```cpp
void Bottom(
    const int y   // y coordinate
)
```

Parameters

- `y`: [in] New Y coordinate of the lower-right corner.

Return Value

None.
**Width (Get Method)**

Gets the control width.

```c
int Width()
```

**Return Value**

Width of the control.

---

**Width (Set Method)**

Sets the width of the control.

```c
virtual bool Width(
    const int w  // width
)
```

**Parameters**

- `w`
  

**Return Value**

true - successful, otherwise - false.
**Height (Get Method)**

Gets the control height.

```cpp
int Height()
```

**Return Value**

Height of the control.

**Height (Set Method)**

Sets new height of the control.

```cpp
virtual bool Height(
    const int h  // height
)
```

**Parameters**

- `h`
  

**Return Value**

- true - successful, otherwise - false.
**Move**

Performs absolute displacement of a control.

```cpp
void Move(
    const int x,  // x coordinate
    const int y   // y coordinate
)
```

**Parameters**

- `x`
  - [in] New X coordinate of the upper-left point.
- `y`
  - [in] New Y coordinate of the upper-left point.

**Return Value**

- `true` - successful, otherwise - `false`. 
## Shift

Performs the relative shift of a control.

```cpp
void Shift(
    const int dx,  // delta X
    const int dy   // delta Y
)
```

**Parameters**

- `dx`
  - [in] Delta X.

- `dy`
  - [in] Delta Y.

**Return Value**

- `true` - successful, otherwise - `false`. 
**Resize**

Sets a size of the control.

```cpp
virtual bool Resize(
    const int w,
    const int h
)
```

**Parameters**

**Return Value**

- true - successful, otherwise - false.
Contains

Checks if the point is inside the control area of the chart.

```cpp
bool Contains(
    const int x, // X coordinate
    const int y // Y coordinate
)
```

Parameters

- `x`
  - [in] X coordinate.
- `y`
  - [in] Y coordinate.

Return Value

- `true` - the point is inside the area (including borders), otherwise - `false`.

Contains

Checks if the specified control is inside the control area of the chart.

```cpp
bool Contains(
    const CWnd* control // pointer
)
```

Parameters

- `control`
  - [in] Object pointer.

Return Value

- `true` - the specified control is inside the area (including borders), otherwise - `false`.
**Alignment**

Sets alignment parameters of the control.

```c
void Alignment(
    const int flags, // flags
    const int left,  // offset
    const int top,   // offset
    const int right, // offset
    const int bottom // offset
)
```

**Parameters**

flags

left

[in] Fixed offset from the left border.

top

[in] Fixed offset from the top border.

right

[in] Fixed offset from the right border.

bottom

[in] Fixed offset from the bottom border.

**Return Value**

None.

**Note**

Alignement flags:

```c
enum WND_ALIGN_FLAGS
{
    WND_ALIGN_NONE=0,         // no align
    WND_ALIGN_LEFT=1,         // align left
    WND_ALIGN_TOP=2,          // align top
    WND_ALIGN_RIGHT=4,        // align right
    WND_ALIGN_BOTTOM=8,       // align bottom
    WND_ALIGN_WIDTH = WND_ALIGN_LEFT|WND_ALIGN_RIGHT, // align width
    WND_ALIGN_HEIGHT = WND_ALIGN_TOP|WND_ALIGN_BOTTOM, // align height
    WND_ALIGN_CLIENT = WND_ALIGN_WIDTH|WND_ALIGN_HEIGHT, // align height and width
}
```
Align

Performs control alignment in the specified chart area.

```cpp
virtual bool Align(
    const CRect* rect  // pointer
)
```

**Parameters**

- `rect`  
  [in] Pointer to the object with chart area coordinates.

**Return Value**

- true - successful, otherwise - false.

**Note**

The alignment parameters must be specified (no alignment by default).
**Id (Get Method)**

Gets the control ID.

```cpp
long Id() const
```

**Return Value**

The control identifier.

**Id (Set Method)**

Sets the value of the control ID.

```cpp
virtual long Id(
    const long id     // identifier
)
```

**Parameters**

- `id`
  

**Return Value**

None.
**IsEnabled**

Checks the control ability to respond to user's actions.

```cpp
bool IsEnabled() const
```

**Return Value**

- true - control is enabled, otherwise - false.
Enable

Enables the control ability to respond to user's actions.

```
virtual bool Enable()
```

Return Value

true - successful, otherwise - false.

Note

If the control is enabled, it is able to process the external events.
Disable

Disables the control ability to respond to user’s actions.

```cpp
virtual bool Disable()
```

Return Value

- true - successful, otherwise - false.

Note

The disabled control is not able to process the external events.
**IsVisible**

Checks whether the control is visible.

```cpp
bool IsVisible() const
```

**Return Value**

- true - control is shown on the chart, otherwise - false.
Visible

Sets the visibility flag.

```cpp
virtual bool Visible{
    const bool flag  // flag
}
```

**Parameters**

*flag*

**Return Value**

true - successful, otherwise - false.
Show

Shows the control.

```cpp
template<class T>
virtual bool Show() = 0;
```

Return Value

- true - successful, otherwise - false.
**Hide**

Hides the control.

```cpp
virtual bool Hide()
```

**Return Value**

- `true` - successful, otherwise - `false`. 

© 2000-2019, MetaQuotes Software Corp.
IsActive

Gets a value indicating whether the control is active.

    bool IsActive() const

Return Value

    true - control is active, otherwise - false.
Activate

Activates the control.

```cpp
virtual bool Activate()
```

Return Value

- `true` - successful, otherwise - `false`.

Note

The control becomes active when the mouse cursor is hovering over it.
Deactivate

Deactivates the control.

```cpp
virtual bool Deactivate()
```

Return Value

true - successful, otherwise - false.

Note

The control becomes inactive when the mouse cursor is out off the control.
**StateFlags (Get Method)**

Gets the control state flags.

```cpp
int StateFlags()
```

**Return Value**

The control state flags.

**StateFlags (Set Method)**

Sets the control state flags.

```cpp
virtual void StateFlags(
    const int flags  // flags
)
```

**Parameters**

- `flags`
  - `[in]` New control state flags.

**Return Value**

None.
StateFlagsSet

Sets the control state flags.

```c
virtual void StateFlagsSet(
    const int flags  // flags
)
```

**Parameters**

*flags*

[in] Flags to set.

**Return Value**

None.
**StateFlagsReset**

Resets the control state flags.

```
virtual void StateFlagsReset(
    const int flags  // flags
);
```

**Parameters**

*flags*

[in] Flags to reset.

**Return Value**

None.
PropFlags (Get Method)

Gets the control properties flags.

```cpp
void PropFlags(
    const int flags // flags
)
```

Return Value

The control properties flags.

PropFlags (Set Method)

Sets the control properties flags.

```cpp
virtual void PropFlags(
    const int flags // flags
)
```

Parameters

flags

Return Value

None.
**PropFlagsSet**

Sets the control properties flags.

```cpp
virtual void PropFlagsSet(
    const int flags    // flags
)
```

**Parameters**

*flags*

[in] Flags to set.

**Return Value**

None.
PropFlagsReset

Resets the control properties flags.

```cpp
virtual void PropFlagsReset(
    const int flags // flags
)
```

Parameters

- `flags`
  - [in] Flags to reset.

Return Value

- None.
**MouseX (Set Method)**

Saves the mouse X coordinate.

```cpp
void MouseX(
    const int value     // coordinate
)
```

**Parameters**

- `value`
  - `[in]` The X coordinate of the mouse.

**Return Value**

- None.

---

**MouseX (Get Method)**

Gets the saved X coordinate of the mouse.

```cpp
int MouseX()
```

**Return Value**

- The X coordinate of the mouse.
MouseY (Set Method)

Saves the mouse Y coordinate.

```cpp
void MouseY(
    const int value   // coordinate
)
```

Parameters

- `value`
  

Return Value

None.

MouseY (Get Method)

Gets the saved Y coordinate of the mouse.

```cpp
int MouseY()
```

Return Value

The Y coordinate of the mouse.
MouseFlags (Set Method)

Saves the state of mouse buttons.

```cpp
virtual void MouseFlags(
    const int value // state
)
```

**Parameters**

- `value`

**Return Value**

None.

MouseFlags (Get Method)

Gets the saved state of mouse buttons.

```cpp
int MouseFlags()
```

**Return Value**

State of mouse buttons.
MouseFocusKill

Clears the saved state of mouse buttons and deactivates the control.

```cpp
bool MouseFocusKill(
    const long id=CONTROLS_INVALID_ID  // id
)
```

Parameters

- `id=CONTROLS_INVALID_ID`
  - [in] Identifier of the control, that received mouse focus.

Return Value

The control deactivation result.
OnCreate

The virtual handler of the internal "Create" event.

```cpp
virtual bool OnCreate()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnDestroy

The virtual handler of the internal "Destroy" event.

```cpp
virtual bool OnDestroy()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnMove

The virtual handler of the internal "Move" event.

```cpp
virtual bool OnMove() { }
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnResize

The virtual handler of the internal "Resize" event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnEnable

The virtual handler of the internal “Enable” event (if enabled, it can respond to user interaction).

```cpp
virtual bool OnEnable()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
**OnDisable**

The virtual handler of the internal “Disable” event (if disabled, it cannot respond to user interaction).

```cpp
virtual bool OnDisable()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnShow

The virtual handler of the internal "Show" event.

```cpp
virtual bool OnShow()
```

**Return Value**

true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnHide

The virtual handler of the internal "Hide" event.

```cpp
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnActivate

The virtual handler of the internal "Activate" event.

```cpp
virtual bool OnActivate()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnDeactivate

The virtual handler of the internal "Deactivate" event.

```cpp
virtual bool OnDeactivate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnClick

The virtual handler of the internal "Click" event (mouse click).

```cpp
virtual bool OnClick()
```

Return Value

- true - event processed, otherwise - false.
OnChange

The virtual handler of the internal "Change" event.

```cpp
virtual bool OnChange()
```

Return Value

- `true` - event processed, otherwise - `false`.

Note

The base class method does nothing and always returns `true`. 
OnMouseDown

The virtual handler of the "MouseDown" (mouse click) event.

```cpp
virtual bool OnMouseDown()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseDown" event occurs when left mouse button is pressed on the control.
OnMouseUp

The virtual handler of the “MouseUp” (mouse button release) event.

```
virtual bool OnMouseUp()
```

Return Value

true - event processed, otherwise - false.

Note

The “MouseUp” event occurs when left mouse button is released on the control.
OnDragStart

The virtual handler of the "DragStart" (start dragging) event.

```cpp
virtual bool OnDragStart()
```

Return Value

- true - event processed, otherwise - false.

Note

The "DragStart" event occurs at the start of control dragging operation.
OnDragProcess

The virtual handler of the "DragProcess" (dragging) event.

```cpp
virtual bool OnDragProcess(
    const int x,  // x coordinate
    const int y   // y coordinate
) {
}
```

Parameters

- **x**
  - [in] Current X coordinate of mouse cursor.

- **y**

Return Value

- true - event processed, otherwise - false.

Note

The "DragProcess" event occurs when the control is dragged.
OnDragEnd

The virtual handler of the "DragEnd" event.

```cpp
virtual bool OnDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "DragEnd" event occurs when control drag process is finished.
DragObjectCreate

Creates drag object.

virtual bool DragObjectCreate()  

Return Value

true - successful, otherwise - false.

Note

true - event processed, otherwise - false.
DragObjectDestroy

Destroys drag object.

virtual bool DragObjectDestroy()

Return Value

true - successful, otherwise - false.
**CWndObj**

CWndObj is a base class for simple controls (based on chart objects) of the Standard Library.

**Description**

CWndObj class implements base methods of the simple control.

**Declaration**

```cpp
class CWndObj : public CWnd
```

**Title**

```cpp
#include <Controls\WndObj.mqh>
```

**Inheritance hierarchy**

- CObject
  - CWnd
  - CWndObj

**Direct descendants**

- CBmpButton, CButton, CEdit, CLabel, CPanel, CPicture

### Methods inherited from class CObject

- Prev, Prev, Next, Next, Save, Load, Type, Compare

### Methods inherited from class CWnd

- Create, Destroy, OnMouseDown, Name, ControlsTotal, Control, ControlFind, Rect, Left, Left, Top, Top, Right, Right, Bottom, Bottom, Width, Width, Height, Height, Size, Size, Size, Move, Move, Shift, Contains, Contains, Alignment, Align, Id, Id, IsEnabled, Enable, Disable, IsVisible, Visible, Show, Hide, IsActive, Activate, Deactivate, StateFlags, StateFlags, StateFlagsSet, StateFlagsReset, PropFlags, PropFlags, PropFlagsSet, PropFlagsReset, MouseX, MouseX, MouseY, MouseY, MouseFlags, MouseFlags, MouseFocusKill, BringToTop
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,  // ID
    const long& lparam,  // parameter
    const double& dparam,  // parameter
    const string& sparam  // parameter
)
```

Parameters

id

[in] Event ID.

lparam

dparam

[in] Event parameter of double type, passed by reference.

sparam

[in] Event parameter of string type, passed by reference.

Return Value

true - event processed, otherwise - false.
Text (Get method)

Gets the OBJPROP_TEXT (text) property of the chart object.

```cpp
string Text();
```

Return Value

The value of the OBJPROP_TEXT property.

Text (Set method)

Sets the OBJPROP_TEXT (text) property of the chart object.

```cpp
bool Text(
    const string value  // value
);
```

Parameters

value

Return Value

true - successful, otherwise - false.
**Color (Get method)**

Gets the `OBJPROP_COLOR` (color) property of the chart object.

```plaintext
    color Color();
```

**Return Value**

The value of the `OBJPROP_COLOR` property.

**Color (Set method)**

Sets the `OBJPROP_COLOR` (color) property of the chart object.

```plaintext
    bool Color(
        const color value  // value
    )
```

**Parameters**

`value`

- `[in]` New value of the `OBJPROP_COLOR` property.

**Return Value**

- `true` - successful, otherwise - `false`.
ColorBackground (Get method)

Gets the OBJPROP_BGCOLOR (background color) of the chart object.

```cpp
color ColorBackground()
```

Return Value

The value of the OBJPROP_BGCOLOR property.

ColorBackground (Set method)

Sets the OBJPROP_BGCOLOR (background color) property of the chart object.

```cpp
bool ColorBackground(
    const color value  // value
)
```

Parameters

- `value`
  - `[in]` New value of the OBJPROP_BGCOLOR property.

Return Value

- `true` - successful, otherwise - false.
**ColorBorder (Get method)**

Gets the `OBJPROP_BORDER_COLOR` (border color) property of the chart object.

```csharp
color ColorBorder()
```

**Return Value**

The value of the `OBJPROP_BORDER_COLOR` property.

---

**ColorBorder (Set method)**

Sets the `OBJPROP_BORDER_COLOR` (border color) property of the chart object.

```csharp
bool ColorBorder(
    const color value  // value
)
```

**Parameters**

`value`

- `[in]` New value of the `OBJPROP_BORDER_COLOR` property.

**Return Value**

true - successful, otherwise - false.
Font (Get method)

Gets the OBJPROP_FONT (font) property of the chart object.

```
string Font()
```

Return Value

The value of the OBJPROP_FONT property.

Font (Set method)

Sets the OBJPROP_FONT (font) property of the chart object.

```
bool Font(
    const string value // value
)
```

Parameters

value

Return Value

true - successful, otherwise - false.
FontSize (Get method)

Gets the OBJPROP_FONTSIZE (font size) property of the chart object.

```c
int FontSize()
```

Return Value

The value of the OBJPROP_FONTSIZE property.

FontSize (Set method)

Sets the OBJPROP_FONTSIZE (font size) property of the chart object.

```c
bool FontSize(
    const int value   // value
)
```

Parameters

value

[in] New value of the OBJPROP_FONTSIZE property.

Return Value

true - successful, otherwise - false.
ZOrder (Get method)

Gets the OBJPROP_ZORDER property of the chart object.

```c
long ZOrder()
```

**Return Value**

The value of the OBJPROP_ZORDER property.

ZOrder (Set method)

Sets the OBJPROP_ZORDER property of the chart object.

```c
bool ZOrder(
    const long value // value
)
```

**Parameters**

- `value`
  - `[in]` New value of the OBJPROP_ZORDER property.

**Return Value**

- `true` - successful, otherwise - `false`. 

OnObjectCreate

The virtual handler of chart object `CHARTEVENT_OBJECT_CREATE` event.

```
virtual bool OnObjectCreate()
```

**Return Value**

true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnObjectChange

The virtual handler of chart object \texttt{CHARTEVENT\_OBJECT\_CHANGE} event.

\begin{verbatim}
virtual bool OnObjectChange()
\end{verbatim}

Return Value

true - event processed, otherwise - false.
OnObjectDelete

The virtual handler of chart object `CHARTEVENT_OBJECT_DELETE` event.

```cpp
virtual bool OnObjectDelete()
```

Return Value

true - event processed, otherwise - false.
OnObjectDrag

The virtual handler of chart object CHARTEVENT_OBJECT_DRAG event.

```cpp
virtual bool OnObjectDrag()
```

Return Value

true - event processed, otherwise - false.
OnSetText

The virtual handler of control "SetText" (change of the \texttt{OBJPROP\_TEXT} property) event.

```cpp
virtual bool OnSetText()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnSetColor

The virtual handler of control "SetColor" (change of the OBJPROP_COLOR property) event.

```cpp
virtual bool OnSetColor()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnSetColorBackground

The virtual handler of control “SetColorBackground” (change of the OBJPROP_BGCOLOR property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnSetFont

The virtual handler of “SetFont” (change of the OBJPROP_FONT property) event.

```cpp
virtual bool OnSetFont()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
**OnSetFontSize**

The virtual handler of “SetFontSize” (change of the **OBJPROP_FontSize** property) event.

```
virtual bool OnSetFontSize()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnSetZOrder

The virtual handler of “SetZOrder” (change of the OBJPROP_ZORDER property) event.

```cpp
virtual bool OnSetZOrder()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
**OnDestroy**

The virtual handler of control "Destroy" internal event.

```cpp
virtual bool OnDestroy()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
**OnChange**

The virtual handler of control “Change” internal event.

```cpp
virtual boolOnChange()
```

**Return Value**

true - event processed, otherwise - false.
CWndContainer

CWndContainer is a base class for a complex control (containing dependent controls) of the Standard library.

Description

CWndContainer class implements base methods of the complex control.

Declaration

```cpp
class CWndContainer : public CWnd
```

Title

```cpp
#include <Controls\WndContainer.mqh>
```

Inheritance hierarchy

- CObject
  - CWnd
    - CWndContainer

Direct descendants

- CCheckBox, CComboBox, CDateDropList, CDatePicker, CDialog, CRadioButton, CScroll, CSpinEdit, CWndClient

**Methods inherited from class CWnd**
- **Create**, Name, ControlsTotal, Control, Rect, Left, Left, Top, Top, Right, Right, Bottom, Bottom, Width, Width, Height, Height, Size, Size, Size, Contains, Contains, Alignment, Align, Id, IsEnabled, IsVisible, Visible, IsActive, Activate, Deactivate, StateFlags, StateFlags, StateFlagsSet, StateFlagsReset, PropFlags, PropFlags, PropFlagsSet, PropFlagsReset, MouseX, MouseX, MouseY, MouseY, MouseFlags, MouseFlags, MouseFlags, MouseFocusKill, BringToTop
Destroy

Destroys all the container controls.

virtual bool Destroy()

Return Value

   true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lpam,   // parameter
    const double& dpam, // parameter
    const string& spam  // parameter
)
```

Parameters

`id`

[in] Event ID.

`lpam`

`dpam`

[in] Event parameter of `double` type, passed by reference.

`spam`

[in] Event parameter of `string` type, passed by reference.

Return Value

true - event processed, otherwise - false.
OnMouseEvent

Mouse event handler.

```cpp
virtual bool OnMouseEvent(
    const int x,       // x coordinate
    const int y,       // y coordinate
    const int flags    // flags
)
```

### Parameters

- `x`
  - [in] X coordinate of the mouse cursor relative to the upper-left corner of the chart.

- `y`
  - [in] Y coordinate of the mouse cursor relative to the upper-left corner of the chart.

- `flags`
  - [in] Flag of mouse buttons states.

### Return Value

- `true` - event processed, otherwise - `false`.
ControlsTotal

Gets the number of controls in the container.

```cpp
int ControlsTotal() const
```

Return Value

Number of controls in the container.
Control

Gets control from the container by index.

```cpp
CWnd* Control(
    const int ind // index
) const
```

Parameters

`ind`

[in] Index of the control needed.

Return Value

Pointer to the control, otherwise NULL if the control is not found.
ControlFind

Gets control from the container by identifier.

```cpp
virtual CWnd* ControlFind(
    const long id // id
)
```

**Parameters**

*id*

[in] Control ID.

**Return Value**

Pointer to the control, otherwise NULL if the control is not found.
Add

Adds a control to a group (container).

```cpp
bool Add(
    CWnd& control  // reference
)
```

Parameters

control

[in] Control to add, passed by reference.

Return Value

true - successful, otherwise - false.
Delete

Deletes control from a group (container).

```cpp
bool Delete(
    CWnd& control   // reference
)
```

Parameters

`control`

[in] Control to delete, passed by reference.

Return Value

true - successful, otherwise - false.
Move

Performs an absolute displacement of all controls of the container.

```cpp
virtual bool Move(
    const int x,  // X coordinate
    const int y   // Y coordinate
)
```

Parameters

- **x**
  - [in] New X coordinate of the upper-left corner.

- **y**
  - [in] New Y coordinate of the upper-left corner.

Return Value

- true - successful, otherwise - false.
Shift

Performs the relative shift of the coordinates for all controls of the container.

```cpp
virtual bool Shift(
    const int dx,   // delta X
    const int dy    // delta Y
)
```

Parameters

dx
    [in] Delta X.

dy
    [in] Delta Y.

Return Value

true - successful, otherwise - false.
Id

Sets the ID for all controls of the container.

```cpp
virtual long Id(
    const long id // identifier
)
```

Parameters

`id`

[in] Base group identifier.

Return Value

Number of identifiers used by container controls.
Enable

Enables all the controls of the container.

```cpp
virtual bool Enable()
```

Return Value

true - successful, otherwise - false.
Disable

Disables all controls of the container.

```cpp
virtual bool Disable()
```

Return Value

- true - successful, otherwise - false.
Show

Shows all controls of the container.

```cpp
virtual bool Show()
```

Return Value

true - successful, otherwise - false.
Hide

Hides all controls of the container.

```cpp
virtual bool Hide()
```

Return Value

- true - successful, otherwise - false.
MouseFocusKill

Clears the saved state of mouse buttons and deactivates all controls in the container.

```cpp
bool MouseFocusKill(
    const long id=CONTROLS_INVALID_ID  // id
)
```

Parameters

`id=CONTROLS_INVALID_ID`

[in] Identifier of the control, that received mouse focus.

Return Value

The controls deactivation result.
Save

Saves container information to file.

```cpp
virtual bool Save(
    const int file_handle // handle
)
```

**Parameters**

`file_handle`

[in] Handle of the binary file previously opened for writing.

**Return Value**

true - successful, otherwise - false.
Load

Loads container information from file

```
virtual bool Load(
    const int file_handle // handle
)
```

Parameters

- `file_handle`
  - [in] Handle of the binary file previously opened for reading.

Return Value

- `true` - successful, otherwise - `false`. 
OnResize

The virtual handler of control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnActivate

The virtual handler of control "Activate" internal event.

```cpp
virtual bool OnActivate()
```

Return Value

- true - event processed, otherwise - false.

Note

- The base class method does nothing and always returns true.
OnDeactivate

The virtual handler of control "Deactivate" internal event.

```cpp
virtual bool OnDeactivate()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
CLabel

CLabel is class of the simple control based on "Text label" chart object.

Description

CLabel is intended for creation of simple non-editable text labels.

Declaration

```cpp
class CLabel : public CWndObj
```

Title

```cpp
#include <Controls\Label.mqh>
```

Inheritance hierarchy

- CObject
  - CWnd
    - CWndObj
      - CLabel

Methods inherited from class CObject

Prev, Prev, Next, Next, Save, Load, Type, Compare

Methods inherited from class CWnd

Destroy, OnMouseEvent, Name, ControlsTotal, Control, ControlFind, Rect, Left, Left, Top, Top, Right, Right, Bottom, Bottom, Width, Width, Height, Height, Size, Size, Size, Move, Move, Move, Shift, Contains, Contains, Alignment, Align, Id, Id, IsEnabled, Enable, Disable, IsVisible, Visible, Show, Hide, IsActive, Activate, Deactivate, StateFlags, StateFlags, StateFlagsSet, StateFlagsReset, PropFlags, PropFlags, PropFlagsSet, PropFlagsReset, MouseX, MouseX, MouseY, MouseY, MouseFlags, MouseFlags, MouseFocusKill, BringToTop

Methods inherited from class CWndObj

OnEvent, Text, Text, Color, Color, ColorBackground, ColorBackground, ColorBorder, ColorBorder, Font, Font, FontSize, FontSize, ZOrder, ZOrder

Example of creating a panel with text label:

```
//+------------------------------------------------------------------+
//|                                                Controls

{
  ExtDialog.ChartEvent(id, lparam, dparam, sparam);
}
Create

Creates new CLabel control.

```cpp
virtual bool Create(
    const long chart,       // chart ID
    const string name,      // name
    const int subwin,       // chart subwindow
    const int x1,           // x1 coordinate
    const int y1,           // y1 coordinate
    const int x2,           // x2 coordinate
    const int y2           // y2 coordinate
)
```

Parameters

**chart**
- [in] ID of the chart, at which the control is created.

**name**
- [in] Unique name of the control.

**subwin**
- [in] Subwindow of the chart, at which the control is created.

**x1**
- [in] X coordinate of the upper left corner.

**y1**
- [in] Y coordinate of the upper left corner.

**x2**
- [in] X coordinate of the lower right corner.

**y2**
- [in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
**OnSetText**

The virtual handler of control "SetText" (change of the `OBJPROP_TEXT` property) event.

```cpp
virtual bool OnSetText()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnSetColor

The virtual handler of control “SetColor” (change of the OBJPROP_COLOR property) event.

```cpp
virtual bool OnSetColor()
```

Return Value

- `true` - event processed, otherwise - `false`. 
OnSetFont

The virtual handler of control "SetFont" (change of the OBJPROP_FONT property) event.

```cpp
virtual bool OnSetFont()
```

Return Value

- true - event processed, otherwise - false.
OnSetFontSi

The virtual handler of control “SetFontSize” (change of the OBJPROP_FONTSIZE property) event.

```cpp
virtual bool OnSetFontSize()
```

Return Value

true - event processed, otherwise - false.
OnCreate

The virtual handler of control "Create" internal event.

```cpp
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.
OnShow

The virtual handler of control "Show" internal event.

```cpp
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.
OnHide

The virtual handler of control "Hide" internal event.

virtual bool OnHide()

Return Value

true - event processed, otherwise - false.
**OnMove**

The virtual handler of control "Move" internal event.

```cpp
virtual bool OnMove()
```

**Return Value**

true - event processed, otherwise - false.
CBmpButton

CBmpButton is class of the simple control based on “Bitmap label” chart object.

Description

CBmpButton is intended for creation of buttons with graphic image.

Declaration

```cpp
class CBmpButton : public CWndObj
```

Title

```c
#include <Controls\BmpButton.mqh>
```

{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates new CBmpButton control.

```cpp
virtual bool Create(
    const long chart,  // chart ID
    const string name,  // name
    const int subwin,   // chart subwindow
    const int x1,       // x1 coordinate
    const int y1,       // y1 coordinate
    const int x2,       // x2 coordinate
    const int y2)       // y2 coordinate
)
```

**Parameters**

- **chart**
  
  [in] ID of the chart, at which the control is created.

- **name**
  
  [in] Unique name of the control.

- **subwin**
  
  [in] Subwindow of the chart, at which the control is created.

- **x1**
  
  [in] X coordinate of the upper left corner.

- **y1**
  
  [in] Y coordinate of the upper left corner.

- **x2**
  
  [in] X coordinate of the lower right corner.

- **y2**
  
  [in] Y coordinate of the lower right corner.

**Return Value**

true - successful, otherwise - false.
**Border (Get method)**

Gets the "Border" (border width) property of the control.

```cpp
int Border() const
```

**Return Value**

The "Border" property.

**Border (Set method)**

Sets the "Border" (border width) property of the control.

```cpp
bool Border(
    const int value  // value
)
```

**Parameters**

- `value`
  - [in] New value of the "Border" property.

**Return Value**

- true - successful, otherwise - false.
BmpNames

Sets the name of bmp files of the control

```cpp
bool BmpNames(
    const string off="", // file name
    const string on=""   // file name
)
```

**Parameters**

- `off=""`
  - [in] Name of bmp file for OFF state.

- `on=""`
  - [in] Name of bmp file for ON state.

**Return Value**

- `true` - successful, otherwise `false`. 
BmpOffName (Get method)

Gets the name of bmp file for OFF state.

```cpp
string BmpOffName() const
```

Return Value

Name of bmp file for OFF state.

BmpOffName (Set method)

Sets the name of bmp file for OFF state.

```cpp
bool BmpOffName(const string name) // file name
```

Parameters

name

[in] Name of bmp file for OFF state.

Return Value

true - successful, otherwise - false.
BmpOnName (Get method)

Gets the name of bmp file for ON state.

```
string BmpOnName() const
```

Return Value

Name of bmp file for ON state.

BmpOnName (Set method)

Sets the name of bmp file for ON state.

```
bool BmpOnName(
    const string name // file name
)
```

Parameters

name

[in] Name of bmp file for ON state.

Return Value

true - successful, otherwise - false.
**BmpPassiveName (Get method)**

Gets the name of bmp file for the control passive state.

```
string BmpPassiveName() const
```

**Return Value**

Name of bmp file for the control passive state.

**BmpPassiveName (Set method)**

Sets the name of bmp file for the passive state.

```
bool BmpPassiveName(const string name); // file name
```

**Parameters**

- `name`
  
  [in] Name of bmp file for the control passive state.

**Return Value**

true - successful, otherwise - false.
BmpActiveName (Get method)

Gets the name of bmp file for the active state.

```cpp
string BmpActiveName() const
```

Return Value

Name of bmp file for the active state.

Note

The control becomes active when the mouse cursor is hovering over it.

BmpActiveName (Set method)

Sets the name of bmp file for the active state.

```cpp
bool BmpActiveName(
    const string name // file name
)
```

Parameters

name

[in] Name of bmp file for the active state.

Return Value

true - successful, otherwise - false.
**Pressed (Get method)**

Gets the state ("Pressed" property) of the control.

```cpp
bool Pressed() const
```

**Return Value**

Control state.

**Pressed (Set method)**

Sets the state ("Pressed" property) of the control.

```cpp
bool Pressed(
    const bool pressed // state
)
```

**Parameters**

- `pressed`
  
  [in] New control state.

**Return Value**

- `true` - successful, otherwise - `false`. 
Locking (Get method)

Gets the "Locking" property of the control.

```cpp
bool Locking() const
```

Return Value

The value of "Locking" property.

Locking (Set method)

Sets new value of the "Locking" property of the control.

```cpp
void Locking(
    const bool locking // value
)
```

Parameters

`locking`

[In] New value of "Locking" property.

Return Value

None.
OnSetZOrder

The virtual handler of control "SetZOrder" (change of the OBJPROP_ZORDER property) event.

```cpp
virtual bool OnSetZOrder()
```

Return Value

- true - event processed, otherwise - false.
OnCreate

The virtual handler of control "Create" internal event.

virtual bool OnCreate() 

Return Value

true - event processed, otherwise - false.
**OnShow**

The virtual handler of control “Show” internal event.

```cpp
virtual bool OnShow()
```

**Return Value**

- true - event processed, otherwise - false.
OnHide

The virtual handler of control “Hide” internal event.

```cpp
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.
**OnMove**

The virtual handler of control "Move" internal event.

```cpp
virtual bool OnMove()
```

**Return Value**

true - event processed, otherwise - false.
OnChange

The virtual handler of control "Change" internal event.

```cpp
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.
OnActivate

The virtual handler of control "Activate" internal event.

```cpp
virtual bool OnActivate()
```

Return Value

true - event processed, otherwise - false.
OnDeactivate

The virtual handler of control “Deactivate” internal event.

```
virtual bool OnDeactivate()
```

Return Value

true - event processed, otherwise - false.
OnMouseDown

The virtual handler of control "MouseDown" event.

```cpp
virtual bool OnMouseDown()
```

Return Value

true - event processed, otherwise - false.
OnMouseUp

The virtual handler of control "MouseUp" (mouse button release) event.

```cpp
virtual bool OnMouseUp()
```

Return Value

- true - event processed, otherwise - false.
CButton

CButton is a class of a simple control based on "Button" chart object.

Description

CButton class is intended for creation of simple buttons.

Declaration

```cpp
class CButton : public CWndObj
```

Title

```cpp
#include <Controls\Button.mqh>
```

Inheritance hierarchy

```
CObject
  CWnd
    CWndObj
      CButton
```

                  const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates new CButton control.

```cpp
virtual bool Create(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
    const int x1, // coordinate
    const int y1, // coordinate
    const int x2, // coordinate
    const int y2 // coordinate
)
```

**Parameters**

**chart**

- [in] ID of the chart, at which the control is created.

**name**

- [in] Unique name of the control.

**subwin**

- [in] Subwindow of the chart, at which the control is created.

**x1**

- [in] X coordinate of the upper left corner.

**y1**

- [in] Y coordinate of the upper left corner.

**x2**

- [in] X coordinate of the lower right corner.

**y2**

- [in] Y coordinate of the lower right corner.

**Return Value**

- true - successful, otherwise - false.
Pressed (Get method)

Gets the state ("Pressed" property) of the control.

```cpp
bool Pressed() const
```

Return Value

"Pressed" property of the control.

Pressed (Set method)

Sets the state ("Pressed" property) of the control.

```cpp
bool Pressed(
    const bool pressed // state
)
```

Parameters

`pressed`

- **[in]** New control state.

Return Value

- `true` - successful, otherwise - `false`.
Locking (Get method)

Gets the "Locking" property of the control.

```cpp
bool Locking() const
```

Return Value

The value of "Locking" property.

Locking (Set method)

Sets the value of "Locking" property of the control.

```cpp
void Locking(
    const bool locking // value
)
```

Parameters

- `locking`
  - [in] New value of "Locking" property of the control.

Return Value

None.
OnSetText

The virtual handler of control “SetText” (change of the OBJPROP_TEXT property) event.

```cpp
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.
OnSetColor

The virtual handler of control "SetColor" (change of the OBJPROP_COLOR property) event.

```cpp
virtual bool OnSetColor()
```

Return Value

- true - event processed, otherwise - false.
OnSetColorBackground

The virtual handler of control “SetColorBackground” (change of the OBJPROP_BGCOLOR property) event.

```cpp
virtual bool OnSetColorBackground()
```

Return Value

- true - event processed, otherwise - false.
OnSetColorBorder

The virtual handler of control "SetColorBorder" (change of the OBJPROP_BORDER_COLOR property) event.

```
virtual bool OnSetColorBorder()
```

**Return Value**

true - event processed, otherwise - false.
OnSetFont

The virtual handler of control "SetFont" (change of the OBJPROP_FONT property) event.

```cpp
virtual bool OnSetFont()
```

Return Value

- `true` - event processed, otherwise - `false`. 
OnSetFontSi

The virtual handler of control "SetFontSize" (change of the OBJPROP.FONTSIZE property) event.

```
virtual bool OnSetFontSi()
```

Return Value

true - event processed, otherwise - false.
**OnCreate**

The virtual handler of control "Create" internal event.

```c
virtual bool OnCreate()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnShow

The virtual handler of control "Show" internal event.

```cpp
virtual bool OnShow()
```

**Return Value**

- true - event processed, otherwise - false.
OnHide

The virtual handler of control “Hide” internal event.

```cpp
virtual bool OnHide()
```

Return Value

- true - event processed, otherwise - false.
OnMove

The virtual handler of control “Move” internal event.

```c++
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.
OnResize

The virtual handler of control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.
OnMouseDown

The virtual handler of control "MouseDown" event handler.

```cpp
virtual bool OnMouseDown()
```

Return Value

- true - event processed, otherwise - false.

Note

The "MouseDown" event occurs when left mouse button is pressed on the control.
OnMouseUp

The virtual handler of control "MouseUp" (left mouse button release) event.

```cpp
virtual bool OnMouseUp()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseUp" event occurs when left mouse button is released on the control.
CEdit

CEdit is class of the simple control based on “Edit” chart object.

Description

CEdit class in intended for creation of controls, in which the user can enter text.

Declaration

```cpp
class CEdit : public CWndObj
```

Title

```cpp
#include <Controls\Edit.mqh>
```

Inheritance hierarchy

```
CObject
  CWnd
    CWndObj
      CEdit
```

        return(INIT_FAILED);
    //--- run application
    ExtDialog.Run();
    //--- succeed
    return(INIT_SUCCEEDED);
}

void OnDeinit(const int reason)
{
    //--- clear comments
    Comment("");
    //--- destroy dialog
    ExtDialog.Destroy(reason);
}

void OnChartEvent(const int id, // event ID
                const long lparam, // event parameter of the long type
                const double dparam, // event parameter of the double type
                const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates CEdit control

```cpp
virtual bool Create(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
    const int x1,     // coordinate
    const int y1,     // coordinate
    const int x2,     // coordinate
    const int y2      // coordinate
)
```

**Parameters**

- **chart**
  - [in] ID of the chart, at which the control is created.

- **name**
  - [in] Unique name of the control.

- **subwin**
  - [in] Subwindow of the chart, at which the control is created.

- **x1**
  - [in] X coordinate of the upper left corner.

- **y1**
  - [in] Y coordinate of the upper left corner.

- **x2**
  - [in] X coordinate of the lower right corner.

- **y2**
  - [in] Y coordinate of the lower right corner.

**Return Value**

- true - successful, otherwise - false.
**ReadOnly (Get Method)**

Gets the "ReadOnly" property of the control.

```cpp
bool ReadOnly()
```

**Return Value**

The value of "ReadOnly" property.

**ReadOnly (Set Method)**

Sets the value of "ReadOnly" property of the control.

```cpp
bool ReadOnly(
    const bool flag  // value
)
```

**Parameters**

- `flag`
  - [in] New value of "ReadOnly" property.

**Return Value**

true - successful, otherwise - false.
** TextAlign (Get method)**

Gets the value of "TextAlign" property (text alignment mode) of the control.

```cpp
ENUM_ALIGN_MODE TextAlign() const
```

**Return Value**

Value of "TextAlign" property of the control.

---

** TextAlign (Set method)**

Sets new value of "TextAlign" property (text alignment mode) of the control.

```cpp
bool TextAlign(
    ENUM_ALIGN_MODE align // property value
)
```

**Parameters**

`align`

[in] New value of "TextAlign" property.

**Return Value**

true - successful, false - cannot change the property.
OnObjectEndEdit

The virtual handler of CHARTEVENT_OBJECT_ENDEDIT chart object event.

```
virtual bool OnObjectEndEdit()
```

Return Value

- true - event processed, otherwise - false.
OnSetText

The virtual handler of control "SetText" (change of the OBJPROP_TEXT property) event.

```cpp
virtual bool OnSetText()
```

Return Value

- true - event processed, otherwise - false.
OnSetColor

The virtual handler of control "SetColor" (change of the `OBJPROP_COLOR` property) event.

```cpp
virtual bool OnSetColor()
```

Return Value

- true - event processed, otherwise - false.
**OnSetColorBackground**

The virtual handler of control "SetColorBackground" (change of the `OBJPROP_BGCOLOR` property) event.

```cpp
virtual bool OnSetColorBackground()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnSetColorBorder

The virtual handler of control "SetColorBorder" (change of the OBJPROP_BORDER_COLOR property) event.

```cpp
virtual bool OnSetColorBackground()
```

**Return Value**

true - event processed, otherwise - false.
OnSetFont

The virtual handler of control "SetFont" (change of the `OBJPROP_FONT` property) event.

```cpp
virtual bool OnSetFont()
```

Return Value

- `true` - event processed, otherwise - `false`. 
OnSetFontSize

The virtual handler of control "SetFontSize" (change of the OBJPROP_FONTSIZE property) event.

```cpp
virtual bool OnSetFontSize()
```

**Return Value**

- true - event processed, otherwise - false.
OnSetZOrder

The virtual handler of control "SetZOrder" (change of the `OBJPROP_ZORDER` property) event.

```
virtual bool OnSetZOrder()
```

**Return Value**

- true - event processed, otherwise - false.
OnCreate

The virtual handler of control “Create” internal event.

```cpp
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.
OnShow

The virtual handler of control "Show" internal event.

```cpp
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.
OnHide

The virtual handler of control "Hide" internal event.

```cpp
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.
OnMove

The virtual handler of control "Move" internal event.

```cpp
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.
OnResize

The virtual handler of control "Resize" internal event.

```cpp
virtual bool OnResiz() //virtual bool OnResiz()
```

Return Value

- true - event processed, otherwise - false.
OnChange

The virtual handler of control "Change" internal event.

virtual bool OnChange()

Return Value

true - event processed, otherwise - false.
**OnClick**

The virtual handler of control “Click” (mouse button click) internal event.

```cpp
virtual bool OnClick()
```

**Return Value**

true - event processed, otherwise - false.
CPanel

CPanel is a class of the simple control based on "Rectangle label" chart object.

Description

CPanel class is intended to combine the controls with similar functions in the group.

Declaration

```cpp
class CPanel : public CWndObj
```

Title

```cpp
#include <Controls\Panel.mqh>
```

Inheritance hierarchy

```
CObject
 CWnd
 CWndObj
  CPanel
```

{
    pause=!pause;
}
Create

Creates new CPanel control.

```cpp
virtual bool Create(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
    const int x1,     // coordinate
    const int y1,     // coordinate
    const int x2,     // coordinate
    const int y2      // coordinate
)
```

Parameters

- **chart**
  - [in] ID of the chart, at which the control is created.

- **name**
  - [in] Unique name of the control.

- **subwin**
  - [in] Subwindow of the chart, at which the control is created.

- **x1**
  - [in] X coordinate of the upper left corner.

- **y1**
  - [in] Y coordinate of the upper left corner.

- **x2**
  - [in] X coordinate of the lower right corner.

- **y2**
  - [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
BorderType (Get method)

Gets the “BorderType” property of the chart object.

```cpp
ENUM_BORDER_TYPE BorderType()
```

Return Value

The value of “BorderType” property.

BorderType (Set method)

Sets new value of “BorderType” property of the chart object.

```cpp
bool BorderType(
    const ENUM_BORDER_TYPE type // value
)
```

Parameters

`type`

[in] New value of “BorderType” property.

Return Value

true - successful, otherwise - false.
OnSetText

The virtual handler of control "SetText" (change of the OBJPROP_TEXT property) event.

```cpp
virtual bool OnSetText()
```

Return Value

- true - event processed, otherwise - false.
OnSetColorBackground

The virtual handler of control "SetColorBackground" (change of the OBJPROP_BGCOLOR property) event.

```cpp
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.
OnSetColorBorder

The virtual handler of control “SetColorBorder” (change of the `OBJPROP_BORDER_COLOR` property) event.

```cpp
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.
OnCreate

The virtual handler of control "Create" internal event.

```cpp
virtual bool OnCreate()
```

Return Value

- true - event processed, otherwise - false.
**OnShow**

The virtual handler of control "Show" internal event.

```cpp
virtual bool OnShow()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnHide

The virtual handler of control "Hide" internal event.

```cpp
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.
OnMove

The virtual handler of control "Move" internal event.

```cpp
virtual bool OnMove()
```

Return Value

- true - event processed, otherwise - false.
OnResize

The virtual handler of control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.
OnChange

The virtual handler of control "Change" internal event.

```cpp
virtual bool OnChange()
```

Return Value

- true - event processed, otherwise - false.
CPicture

CPicture is a class of the simple control based on "Bitmap Label" object.

Description

CPicture class is intended for creation of simple graphic images.

Declaration

```cpp
class CPicture : public CWndObj
```

Title

```cpp
#include <Controls\Picture.mqh>
```

Inheritance hierarchy

```
CObject
  CWnd
    CWndObj
      CPicture
```

Create

Creates new CPicture control.

```cpp
virtual bool Create(
    const long chart,  // chart ID
    const string name,  // name
    const int subwin,  // chart subwindow
    const int x1,     // coordinate
    const int y1,     // coordinate
    const int x2,     // coordinate
    const int y2)    // coordinate
)
```

Parameters

- **chart**
  
  [in] ID of the chart, at which the control is created.

- **name**
  
  [in] Unique name of the control.

- **subwin**
  
  [in] Subwindow of the chart, at which the control is created.

- **x1**
  
  [in] X coordinate of the upper left corner.

- **y1**
  
  [in] Y coordinate of the upper left corner.

- **x2**
  
  [in] X coordinate of the lower right corner.

- **y2**
  
  [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
Border (Get method)

Gets the “Border” (border width) property of the control.

```cpp
int Border() const
```

Return Value

The “Border” property.

Border (Set method)

Sets the “Border” (border width) property of the control.

```cpp
bool Border(  
    const int value  // value
)
```

Parameters

`value`

Return Value

true - successful, otherwise - false.
**BmpName (Get method)**

Gets the name of bmp file of the control.

```cpp
string BmpName() const
```

**Return Value**

Name of bmp file of the control.

**BmpName (Set method)**

Sets the name of bmp file of the control.

```cpp
bool BmpName(const string name) // file name
```

**Parameters**

`name`

[in] Name of bmp file of the control.

**Return Value**

true - successful, otherwise - false.
OnCreate

The virtual handler of control "Create" internal event.

```cpp
virtual bool OnCreate()
```

Return Value

- true - event processed, otherwise - false.
OnShow

The virtual handler of control "Show" internal event.

```cpp
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.
OnHide

The virtual handler of control "Hide" internal event.

virtual bool OnHide() 

Return Value

true - event processed, otherwise - false.
**OnMove**

The virtual handler of control "Move" internal event.

```cpp
virtual bool OnMove()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnChange

The virtual handler of control "Change" internal event.

virtual boolOnChange()

Return Value

true - event processed, otherwise - false.
CScroll

CScroll is a base class for creation of scroll bars.

Description

CScroll is a complex control (with dependent controls), it contains the base functionality for creation of scroll bars. The base class itself is not used as a separate control, two of its heirs (CScrollV and CScrollH classes) are used as controls.

Declaration

```cpp
class CScroll : public CWndContainer
```

Title

```cpp
#include <Controls\Scrolls.mqh>
```

Inheritance hierarchy

- CObject
  - CWnd
    - CWndContainer
      - CScroll

Direct descendants

- CScrollH, CScrollV

© 2000-2019, MetaQuotes Software Corp.
Create

Creates new CScroll control.

```cpp
virtual bool Create(
  const long chart, // chart ID
  const string name, // name
  const int subwin, // chart subwindow
  const int x1,     // coordinate
  const int y1,     // coordinate
  const int x2,     // coordinate
  const int y2);    // coordinate
```

**Parameters**

- **chart**
  - [in] ID of the chart, at which the control is created.

- **name**
  - [in] Unique name of the control.

- **subwin**
  - [in] Subwindow of the chart, at which the control is created.

- **x1**
  - [in] X coordinate of the upper left corner.

- **y1**
  - [in] Y coordinate of the upper left corner.

- **x2**
  - [in] X coordinate of the lower right corner.

- **y2**
  - [in] Y coordinate of the lower right corner.

**Return Value**

- true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id, // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

Parameters

**id**

[in] Event ID.

**lparam**

**dparam**

**sparam**

Return Value

true - event processed, otherwise - false.
**MinPos (Get method)**

Gets the value of "MinPos" (minimal position) of the CScroll control.

```cpp
int MinPos() const
```

**Return Value**

New value of "MinPos" property.

**MinPos (Set method)**

Sets the value of "MinPos" (minimal position) of the CScroll control.

```cpp
void MinPos(
    const int value // value
)
```

**Parameters**

- `value`
  

**Return Value**

None.
MaxPos (Get method)

Gets the value of “MaxPos” (maximal position) of the CScroll control.

```c
int MaxPos() const
```

Return Value

New value of “MaxPos” property.

MaxPos (Set method)

Sets the value of “MaxPos” (maximal position) of the CScroll control.

```c
void MaxPos(
    const int value // value
)
```

Parameters

value

Return Value

None.
**CurrPos (Get method)**

Gets the value of “CurrPos” (current position) of the CScroll control.

```c
int CurrPos() const
```

**Return Value**

New value of “CurrPos” property.

**CurrPos (Set method)**

Sets the value of “CurrPos” (current position) of the CScroll control.

```c
void CurrPos(
    const int value // value
)
```

**Parameters**

`value`

**Return Value**

None.
CreateBack

Creates background button of the CScroll control.

```cpp
virtual bool CreateBack()
```

**Return Value**

true - successful, otherwise - false.
CreateInc

Creates increment button of CScroll control.

```
virtual bool CreateInc()
```

Return Value

- true - successful, otherwise - false.
CreateDec

Creates decrement button of CScroll control.

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.
CreateThumb

Creates thumb button (can be dragged) of CScroll control.

```cpp
virtual bool CreateThumb()
```

Return Value

- true - successful, otherwise - false.
OnClickInc

The virtual handler of the control "ClickInc" (left mouse button click on the increment button) internal event.

```cpp
virtual bool OnClickInc()
```

Return Value

true - event processed, otherwise - false.
**OnClickDec**

The virtual handler of the control "ClickDec" (left mouse button click on the decrement button) internal event.

```cpp
virtual bool OnClickDec()
```

**Return Value**

true - event processed, otherwise - false.
**OnShow**

The virtual handler of the control "Show" event.

```cpp
virtual bool OnShow()
```

**Return Value**

- true - event processed, otherwise - false.
OnHide

The virtual handler of the control "Hide" internal event.

```cpp
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.
OnChangePos

The virtual handler of the control “ChangePos” (position change) internal event.

```cpp
virtual bool OnChangePos()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnThumbDragStart

The virtual handler of the control “ThumbDragStart” (drag start) event.

```cpp
virtual bool OnThumbDragStart()
```

**Return Value**

true - event processed, otherwise - false.

**Note**

The “ThumbDragStart” event occurs at start of the drag operation.
OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```cpp
virtual bool OnThumbDragProcess(
    const int x,    // x coordinate
    const int y     // y coordinate
)
```

Parameters

- `x` [in] Current X coordinate of mouse cursor.

Return Value

- `true` - event processed, otherwise - `false`.

Note

The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.
OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```cpp
virtual bool OnThumbDragEnd()
```

Return Value

- true - event processed, otherwise - false.

Note

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.
CalcPos

Gets the control scroll bar position by coordinate.

```cpp
virtual int CalcPos(
    const int coord  // coordinate
)
```

**Parameters**

`coord`

[in] Scroll bar coordinate.

**Return Value**

Scroll bar position.
CScrollV

CScrollV is a class of the “Vertical scroll bar” complex control.

Description

CScrollV class is intended for creation of vertical scroll bars.

Declaration

```
class CScrollV : public CScroll
```

Title

```
#include <Controls\Scrolls.mqh>
```

Inheritance hierarchy

```
CObject
  CWnd
    CWndContainer
      CScroll
        CScrollV
```

}
CreateInc

Creates increment button of the control.

```cpp
virtual bool CreateInc()
```

**Return Value**

- `true` - successful, otherwise - `false`. 
CreateDec

Creates decrement button of the control.

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.
CreateThumb

Creates thumb button (can be dragged) of the control.

```cpp
virtual bool CreateThumb()
```

Return Value

- true - successful, otherwise - false.
OnResize

The virtual handler of the control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.
OnChangePos

The virtual handler of the control "ChangePos" (position change) internal event.

```cpp
virtual bool OnChangePos()
```

Return Value

true - event processed, otherwise - false.
OnThumbDragStart

The virtual handler of the control "ThumbDragStart" (drag start) event.

```cpp
virtual bool OnThumbDragStart()
```

Return Value

- true - event processed, otherwise - false.

Note

The "ThumbDragStart" event occurs at start of the drag operation.
OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```cpp
virtual bool OnThumbDragProcess(
    const int x,    // x coordinate
    const int y     // y coordinate
)
```

Parameters

- `x`  
  

- `y`  
  

Return Value

- true - event processed, otherwise - false.

Note

- The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.
OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```cpp
virtual bool OnThumbDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.
CalcPos

Gets the control scroll bar position by coordinate.

```cpp
virtual int CalcPos(
    const int coord    // coordinate
)
```

**Parameters**

*coord*  
  [in] Scroll bar coordinate.

**Return Value**

Scroll bar position.
**CScrollH**

CScrollH is a class of the "Horizontal scroll bar" complex control.

**Description**

CScrollH is intended for creation of horizontal scroll bars.

**Declaration**

```cpp
class CScrollH : public CScroll
```

**Title**

```cpp
#include <Controls Scrolls.mqh>
```

**Inheritance hierarchy**

```
CObject
   CWnd
      CWndContainer
         CScroll
            CScrollH
```

{
    ExtDialog.ChartEvent(id, lparam, dparam, sparam);
}
```
CreateInc

Creates increment button of the control.

```cpp
virtual bool CreateInc()
```

**Return Value**

true - successful, otherwise - false.
CreateDec

Creates decrement button of the control.

```cpp
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.
CreateThumb

Creates thumb button (can be dragged) of the control.

```cpp
virtual bool CreateThumb()
```

**Return Value**

- true - successful, otherwise - false.
OnResize

The virtual handler of the control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.
**OnChangePos**

The virtual handler of the control "ChangePos" (position change) internal event.

```cpp
virtual bool OnChangePos()
```

**Return Value**

true - event processed, otherwise - false.
OnThumbDragStart

The virtual handler of the control "ThumbDragStart" (drag start) event.

```cpp
virtual bool OnThumbDragStart()
```

Return Value

- true - event processed, otherwise - false.

Note

The "ThumbDragStart" event occurs at start of the drag operation.
OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```cpp
virtual bool OnThumbDragProcess(const int x, // x coordinate
                                      const int y // y coordinate
)
```

Parameters

- `x`
  - [in] Current X coordinate of mouse cursor.
- `y`

Return Value

- true - event processed, otherwise - false.

Note

The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.
OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```
virtual bool OnThumbDragEnd()
```

**Return Value**

- true - event processed, otherwise - false.

**Note**

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.
CalcPos

Gets the control scroll bar position by coordinate.

```cpp
virtual int CalcPos(
    const int coord  // coordinate
)
```

Parameters

- `coord`
  
  [in] Scroll bar coordinate.

Return Value

- Scroll bar position.
CWndClient

CWndClient is a class of the "Client area" complex control (with dependent controls). It is a base class for creation of scroll bars area.

Description

CWndClient implements the functionality for creation of client area with scroll bars.

Declaration

```cpp
class CWndClient : public CWndContainer
```

Title

```cpp
#include <Controls/WndClient.mqh>
```

Inheritance hierarchy

- CObject
- CWnd
- CWndContainer
- CWndClient

Direct descendants

- CCheckGroup, CListView, CRadioGroup

### CreateBack
- Creates background for scroll bar

### CreateScrollV
- Creates vertical scroll bar

### CreateScrollH
- Creates horizontal scroll bar

#### Internal event handlers

**OnResize**
- "Resize" internal event handler

#### Dependent controls event handlers

**OnVScrollShow**
- "Show" internal event handler (virtual) of VScroll dependent control

**OnVScrollHide**
- "Hide" internal event handler (virtual) of VScroll dependent control

**OnHScrollShow**
- "Show" internal event handler (virtual) of HScroll dependent control

**OnHScrollHide**
- "Hide" internal event handler (virtual) of HScroll dependent control

**OnScrollLineDown**
- "ScrollLineDown" internal event handler (virtual) of VScroll dependent control

**OnScrollLineUp**
- "ScrollLineUp" internal event handler (virtual) of VScroll dependent control

**OnScrollLineLeft**
- "ScrollLineLeft" internal event handler (virtual) of HScroll dependent control

**OnScrollLineRight**
- "ScrollLineRight" internal event handler (virtual) of HScroll dependent control

**Resize**

**Rebound**
- Sets new parameters of the control using CRect class coordinates

#### Methods inherited from class CObject
- Prev, Prev, Next, Next, Type, Compare

#### Methods inherited from class CWnd

- Name, ControlsTotal, Control, Rect, Left, Left, Top, Top, Right, Right, Bottom, Bottom, Width, Width, Height, Height, Size, Size, Size, Contains, Contains, Alignment, Align, Id, IsEnabled, IsVisible, Visible, IsActive, Activate, Deactivate, StateFlags, StateFlags, StateFlagsSet, StateFlagsReset, PropFlags, PropFlags, PropFlagsSet, PropFlagsReset, MouseX, MouseX, MouseY, MouseY, MouseFlags, MouseFlags, MouseFlags, MouseFocusKill, BringToTop

#### Methods inherited from class CWndContainer
- Destroy, OnMouseEvent, ControlsTotal, Control, ControlFind, MouseFocusKill, Add, Add, Delete, Delete, Move, Move, Shift, Enable, Disable, Hide, Save, Load
Create

Creates new CWndClient control.

```cpp
virtual bool Create(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
    const int x1,     // coordinate
    const int y1,     // coordinate
    const int x2,     // coordinate
    const int y2)     // coordinate
)
```

Parameters

`chart`  
[in] ID of the chart, at which the control is created.

`name`  
[in] Unique name of the control.

`subwin`  
[in] Subwindow of the chart, at which the control is created.

`x1`  
[in] X coordinate of the upper left corner.

`y1`  
[in] Y coordinate of the upper left corner.

`x2`  
[in] X coordinate of the lower right corner.

`y2`  
[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent
Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,     // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam  // parameter
)
```

**Parameters**

- `id`
  - [in] Event ID.

- `lparam`

- `dparam`
  - [in] Event parameter of `double` type passed by reference.

- `sparam`
  - [in] Event parameter of `string` type passed by reference.

**Return Value**

- `true` - event processed, otherwise `false`.
ColorBackground

Sets background color of the control.

```c
bool ColorBackground(
    const color value // background color
)
```

Parameters

 value

    [in] Background color of the control.

Return Value

    true - successful, otherwise - false.
ColorBorder

Set border color of the control.

```cpp
bool ColorBorder(
    const color value    // color
)
```

Parameters

- `value`
  - [in] Border color of the control

Return Value

- true - successful, otherwise - false.
BorderType

Sets border type of the control.

```cpp
bool BorderType(  
    const ENUM_BORDER_TYPE type  // value
)
```

Parameters

- `type`
  - [in] Border type of the control.

Return Value

- `true` - successful, otherwise - `false`.
**VScrolled (Get method)**

Gets the flag indicating that vertical scroll bar is used.

```cpp
bool VScrolled()
```

**Return Value**

true - vertical scroll bar is used, otherwise - false.

**VScrolled (Set method)**

Sets the flag indicating that vertical scroll bar is used.

```cpp
bool VScrolled(const bool flag) // flag
```

**Parameters**

*flag*

**Return Value**

true - successful, otherwise - false.
**HScrolled (Get method)**

Gets the flag indicating that horizontal scroll bar is used.

```c++
bool HScrolled()
```

Return Value

true - horizontal scroll bar is used, otherwise - false.

**HScrolled (Set method)**

Sets the flag indicating that horizontal scroll bar is used.

```c++
bool HScrolled(
    const bool flag // flag
)
```

Parameters

*flag*

Return Value

true - successful, otherwise - false.
CreateBack

Creates background button of the control.

```cpp
virtual bool CreateBack()
```

Return Value

true - successful, otherwise - false.
CreateScrollV

Creates vertical scroll bar.

```
virtual bool CreateScrollV()
```

Return Value

true - successful, otherwise - false.
CreateScrollH

Creates horizontal scroll bar.

```cpp
virtual bool CreateScrollH()
```

Return Value

true - successful, otherwise - false.
OnResize

The virtual handler of the control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.
OnVScrollShow

The virtual handler of the VScroll (vertical scroll) dependent control “Show” (vertical scroll bar show) internal event.

```cpp
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
**OnVScrollHide**

The virtual handler of the VScroll (vertical scroll) dependent control "Hide" (vertical scroll bar hide) internal event.

```cpp
virtual bool OnVScrollHide()
```

**Return Value**

true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnHScrollShow

The virtual handler of the HScroll (horizontal scroll) dependent control “Show” (horizontal scroll bar show) internal event.

    virtual bool OnHScrollShow()

Return Value

    true - event processed, otherwise - false.

Note

    The base class method does nothing and always returns true.
OnHScrollHide

The virtual handler of the HScroll (horizontal scroll) dependent control “Hide” (horizontal scroll bar hide) internal event.

```cpp
virtual bool OnHScrollHide()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnScrollLineDown

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineDown" (vertical scroll line down) internal event.

```cpp
virtual bool OnScrollLineDown()
```

**Return Value**

true - event processed, otherwise - false.

**Note**

The base class method does nothing and always returns true.
OnScrollLineUp

The virtual handler of the VScroll (vertical scroll) dependent control “ScrollLineUp” (vertical scroll line up) internal event.

```cpp
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnScrollLineLeft

The virtual handler of the HScroll (horizontal scroll) dependent control "ScrollLineLeft" (horizontal scroll line left) internal event.

```cpp
virtual bool OnScrollLineLeft()
```

Return Value

- true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.
OnScrollLineRight

The virtual handler of the HScroll (horizontal scroll) dependent control "ScrollLineRight" (horizontal scroll line right) internal event.

```cpp
virtual bool OnScrollLineRight()
```

Return Value

- `true` - event processed, otherwise - `false`.

Note

The base class method does nothing and always returns `true`. 
ReBound

Sets new parameters of the control using CRect class coordinates.

```cpp
void ReBound(const &CRect rect) // CRect class
```

Return Value

None.
**CListView**

CListView is a class of the ListView complex control (with dependent controls).

**Description**

CListView class encapsulates list-control functionality.

**Declaration**

```cpp
class CListView : public CWndClient
```

**Title**

```cpp
#include <Controls\ListView.mqh>
```

**Inheritance hierarchy**

- **CObject**
- **CWnd**
- **CWndContainer**
  - **CWndClient**
  - **CListView**

}
Create

Creates CListView control.

```cpp
virtual bool Create(  
    const long chart,   // chart ID  
    const string name,  // name  
    const int subwin,   // chart subwindow  
    const int x1,       // coordinate  
    const int y1,       // coordinate  
    const int x2,       // coordinate  
    const int y2        // coordinate
)
```

Parameters

- **chart**
  - [in] ID of the chart, at which the control is created.

- **name**
  - [in] Unique name of the control.

- **subwin**
  - [in] Subwindow, at which the control is created.

- **x1**
  - [in] X coordinate of the upper left corner.

- **y1**
  - [in] Y coordinate of the upper left corner.

- **x2**
  - [in] X coordinate of the lower right corner.

- **y2**
  - [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lparam,  // parameter
    const double& dparam, // parameter
    const string& sparam  // parameter
)
```

**Parameters**

- **id**
  
  [in] Event ID.

- **lparam**
  

- **dparam**
  

- **sparam**
  

**Return Value**

- `true` - event processed, otherwise - `false`. 

TotalView

Sets the number of items shown on the control.

```cpp
bool TotalView(
    const int value // number of items shown
)
```

Parameters

- `value` [in] The number of items shown on the control.

Return Value

- `true` - successful, otherwise - `false`.

Note

The number of shown items can be specified only at once.
AddItem

Adds an item to the control list.

```cpp
bool AddItem(
    const string item,  // text
    const long value    // value
)
```

Parameters

`item`

`value`

[in] Value.

Return Value

true - successful, otherwise - false.
Select

Selects current list element by index.

```cpp
bool Select(
    const int index    // index
)
```

Parameters

index

[in] Item index.

Return Value

true - successful, otherwise - false.
SelectByText

Selects the current list element by text.

```cpp
bool SelectByText(
    const string text  // text
)
```

Parameters

text
    [in] Element text.

Return Value

true - successful, otherwise - false.
SelectByValue

Selects the current list element by value.

```cpp
bool SelectByValue(
    const long value // value
);
```

**Parameters**

- **value**
  - [in] Value.

**Return Value**

- true - successful, otherwise - false.
**Value**

Gets the value of the current list element.

```c
long Value()
```

**Return Value**

The value of the current list element.
CreateRow

Creates a row of the CListView control.

```cpp
bool CreateRow(
    const int index  // index
)
```

**Parameters**

`index`

[in] Item index.

**Return Value**

- `true` - successful, otherwise - `false`.
OnResize

The virtual handler of the control "Resize" internal event.

```cpp
virtual bool OnResize()
```

Return Value

- true - event processed, otherwise - false.
OnVScrollShow

The virtual handler of the VScroll (vertical scroll) dependent control "VScrollShow" (vertical scroll bar show) internal event.

```cpp
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.
OnVScrollHide

The virtual handler of the VScroll (vertical scroll) dependent control "VScrollHide" (vertical scroll bar hide) internal event.

```cpp
virtual bool OnVScrollHide()
```

**Return Value**

- true - event processed, otherwise - false.
OnScrollLineDown

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineDown" (vertical scroll line down) internal event.

```cpp
virtual bool OnScrollLineDown()
```

Return Value

true - event processed, otherwise - false.
OnScrollLineUp

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineUp" (vertical scroll line up) internal event.

```
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.
OnItemClick

The virtual handler of “ItemClick” (mouse button click) internal event on a specified row of CListView control.

```cpp
virtual bool OnItemClick()
{
    const int index; // index
}
```

Return Value

true - event processed, otherwise - false.
Redraw

Redraws the control.

```cpp
bool Redraw()
```

Return Value

- true - successful, otherwise - false.
RowState

Changes the state of the specified row of the CListView control.

```cpp
bool RowState(
    const int index // index
    const bool select // state
);
```

Parameters

- **index**
  - [in] Row index.

- **select**
  - [in] Row state.

Return Value

- `true` - successful, otherwise `false`. 
CheckView

Checks the “visibility” of the specified row of the CListView control.

```cpp
bool CheckView()
```

Return Value

- true - selected row is visible, otherwise - false.
CComboBox

CComboBox is a class of the ComboBox complex control (with dependent controls).

Description

ComboBox consists of a list box, combined with a static control, intended for selection. The list-box portion of the control may be dropped down when a user selects the drop-down arrow next to the control.

Declaration

```cpp
class CComboBox : public CWndContainer
```

Title

```cpp
#include <Controls\ComboBox.mqh>
```

Inheritance hierarchy

- `CObject`
- `CWnd`
- `CWndContainer`
- `CComboBox`

    const double& dparam, // event parameter of the double type
    const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id, lparam, dparam, sparam);
}
Create

Creates CComboBox control.

```cpp
virtual bool Create(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
    const int x1, // coordinate
    const int y1, // coordinate
    const int x2, // coordinate
    const int y2 // coordinate
)
```

Parameters

**chart**
[in] ID of the chat, at which the control is created.

**name**
[in] Unique name of the control.

**subwin**
[in] Subwindow of the chart, at which the control is created.

**x1**
[in] X coordinate of the upper left corner.

**y1**
[in] Y coordinate of the upper left corner.

**x2**
[in] X coordinate of the lower right corner.

**y2**
[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id, // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

Parameters

- `id` [in] Event ID.

Return Value

true - event processed, otherwise - false.
**AddItem**

Adds an item to the control.

```cpp
bool AddItem(
    const string item,  // text
    const long value    // value
)
```

**Parameters**

- **item**
  - [in] Text.
- **value**=0
  - [in] Value.

**Return Value**

- true - successful, otherwise - false.
ListViewItems

Sets the number of list elements of the CComboBox control.

```cpp
void ListViewItems(
    const int value  // number of elements
);
```

Parameters

- `value`
  - [in] Number of the drop-down list elements.

Return Value

- true - successful, otherwise - false.
Select

Selects the current list element by index.

```cpp
bool Select(
    const int index    // index
)
```

Parameters

- `index`
  - [in] Item index.

Return Value

- true - successful, otherwise - false.
SelectByText

Selects the current list element by a specified text.

```cpp
bool SelectByText(
    const string text // text
)
```

Parameters

text
    [in] Text of the item.

Return Value

true - successful, otherwise - false.
SelectByValue

Selects the current list element by a specified value.

```cpp
bool SelectByValue(const long value) // value
```

Parameters

value

[in] Value.

Return Value

true - successful, otherwise - false.
Value

Gets the value of the current list element.

```cpp
long Value()
```

Return Value

The value of the current list element.
CreateEdit

Creates dependent control (edit) of the control.

```cpp
virtual bool CreateEdit()
```

Return Value

true - successful, otherwise - false.
CreateButton

Creates dependent control (button).

```cpp
virtual bool CreateButton()
```

Return Value

true - successful, otherwise - false.
CreateList

Creates dependent control (list view).

```
virtual bool CreateList()
```

Return Value

true - successful, otherwise - false.
**OnClickEdit**

The virtual handler of the control "ClickEdit" (mouse click on the edit) internal event.

```cpp
virtual bool OnClickEdit()
```

**Return Value**

true - event processed, otherwise - false.
**OnClickButton**

The virtual handler of the “ClickButton” (mouse click on the button) internal event.

```cpp
virtual bool OnClickButton()
```

**Return Value**

- true - event processed, otherwise - false.
**OnChangeList**

The virtual handler of the "ChangeList" (change of the list) internal event.

```cpp
virtual bool OnChangeList()
```

**Return Value**

- true - event processed, otherwise - false.
ListShow

Shows the drop-down list of the control.

```cpp
virtual bool ListShow()
```

Return Value

- true - successful, otherwise - false.
ListHide

Hides the drop-down list of the control.

```cpp
virtual bool ListHide()
```

Return Value

true - successful, otherwise - false.
**CCheckBox**

CCheckBox is class of the CheckBox complex control.

**Description**

CCheckBox control displays a check box that allows a user to select a true or false condition at a mouse click.

**Declaration**

```cpp
class CCheckBox : public CWndContainer
```

**Title**

```cpp
#include <Controls\CheckBox.mqh>
```

**Inheritance hierarchy**

- **CObject**
- **CWnd**
  - **CWndContainer**
  - **CCheckBox**

                 const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates `CCheckBox` control.

```cpp
virtual bool Create(
    const long chart,  // chart ID
    const string name,  // name
    const int subwin,  // chart subwindow
    const int x1,      // coordinate
    const int y1,      // coordinate
    const int x2,      // coordinate
    const int y2       // coordinate
)
```

Parameters

- `chart`  
  [in] ID of the chart, at which the control is created.

- `name`  
  [in] Unique name of the control.

- `subwin`  
  [in] Subwindow of the chart, at which the control is created.

- `x1`  
  [in] X coordinate of the upper left corner.

- `y1`  
  [in] Y coordinate of the upper left corner.

- `x2`  
  [in] X coordinate of the lower right corner.

- `y2`  
  [in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id, // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

**Parameters**

- **id**
  
  [in] Event ID.

- **lparam**
  

- **dparam**
  

- **sparam**
  

**Return Value**

- `true` - event processed, otherwise - `false`.
Text (Get method)

Gets text of the label associated with the control.

```csharp
string Text()
```

**Return Value**

Text of the label.

Text (Set method)

Sets text of the label associated with the control.

```csharp
bool Text(
    const string value // text
)
```

**Parameters**

- `value`
  - [in] New text of the label.

**Return Value**

- true - successful, otherwise - false.

**Note**

Label text is specified by setting `OBJPROP_TEXT` (text) of a chart object.
**Color (Get method)**

Gets color of the label associated with the control.

```
color Color() const
```

**Return Value**

Label color.

**Color (Set method)**

Sets color of the label associated with the control.

```
bool Color(
    const color value   // color
)
```

**Parameters**

- `value`
  

**Return Value**

- `true` - successful, otherwise - `false`.

**Note**

Label color is specified by setting `OBJPROP_COLOR` (color) of a chart object.
**Checked (Get method)**

Gets state of the control.

```cpp
bool Checked() const
```

**Return Value**

State of the control.

---

**Checked (Set method)**

Sets state of the control.

```cpp
bool Checked(
    const bool flag  // state
)
```

**Parameters**

*flag*

[in] New state.

**Return Value**

true - successful, otherwise - false.
Value (Get method)

Gets the value associated with the control.

```cpp
int Value() const
```

Return Value

The value associated with the control.

Value (Set method)

Sets the value associated with the control.

```cpp
void Value(
    const int value  // value
)
```

Parameters

- `value`
  - `[in]` New value.

Return Value

None.
CreateButton

Creates dependent control (button).

```cpp
virtual bool CreateButton()
```

Return Value

true - successful, otherwise - false.
CreateLabel

Creates dependent control (label).

```cpp
virtual bool CreateLabel()
```

Return Value

true - successful, otherwise - false.
**OnClickButton**

The virtual handler of the control "ClickButton" (mouse click on the button) internal event.

```cpp
virtual bool OnClickButton()
```

**Return Value**

true - event processed, otherwise - false.
**OnClickLabel**

The virtual handler of the control "ClickLabel" (mouse click on the label) internal event.

```cpp
virtual bool OnClickLabel()
```

**Return Value**

true - event processed, otherwise - false.
**CCheckGroup**

CCheckGroup is a class of the CheckGroup complex control (with dependent controls).

**Description**

CCheckGroup provides the possibility for creation of controls, which allow to display and edit flags.

**Declaration**

```cpp
class CCheckGroup : public CWndClient
```

**Title**

```cpp
#include <Controls\CheckGroup.mqh>
```

**Inheritance hierarchy**

- CObject
  - CWnd
    - CWndContainer
      - CWndClient
        - CCheckGroup

    const double dparam,  // event parameter of the double type
    const string sparam)  // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates new CCheckGroup control.

```cpp
virtual bool Create(
    const long chart,   // chart ID
    const string name,  // name
    const int subwin,   // chart subwindow
    const int x1,       // coordinate
    const int y1,       // coordinate
    const int x2,       // coordinate
    const int y2        // coordinate
)
```

Parameters

`chart`

[in] ID of the chart, at which the control is created.

`name`

[in] Unique name of the control.

`subwin`

[in] Subwindow of the chart, at which the control is created.

`x1`

[in] X coordinate of the upper left corner.

`y1`

[in] Y coordinate of the upper left corner.

`x2`

[in] X coordinate of the lower right corner.

`y2`

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

Parameters

id

[in] Event ID.

lparam

dparam

sparam

Return Value

true - event processed, otherwise - false.
AddItem

Adds an item (row) to the control.

```cpp
bool AddItem(
    const string item, // text
    const long value   // value
)
```

Parameters

- **item**
  - [in] Added control label text.

- **value=0**
  - [in] Value associated with the added control.

Return Value

- `true` - successful, otherwise `false`.
**Value**

Gets the value associated with the control.

```cpp
long Value()
```

**Return Value**

The value associated with the control.

**Note**

The value depends on state of all items of the CCheckGroup.
CreateButton

Creates new CCheckBox class instance at a specified index.

```cpp
bool CreateButton(
    int index    // index
);
```

**Parameters**

* index

  [in] Index of the new item in the CCheckGroup.

**Return Value**

true - successful, otherwise - false.
OnVScrollShow

The virtual handler of the dependent VScroll (vertical scroll) control “Show” internal event.

```
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.
OnVScrollHide

The virtual handler of the dependent VScroll (vertical scroll) control "Hide" internal event.

```cpp
virtual bool OnVScrollHide()
```

**Return Value**

- true - event processed, otherwise - false.
OnScrollLineDown

The virtual handler of the dependent VScroll (vertical scroll) control “ScrollLineDown” internal event.

```
virtual bool OnScrollLineDown()
```

Return Value

true - event processed, otherwise - false.
OnScrollLineUp

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineUp" internal event.

```cpp
virtual bool OnScrollLineUp()
```

Return Value

- true - event processed, otherwise - false.
OnChangelItem

The virtual handler of the control “ChangelItem” (item change) internal event.

```cpp
virtual bool OnChangelItem(
    const int index     // index
)
```

**Parameters**

- `index`  
  [in] Index of the changed item.

**Return Value**

- true - event processed, otherwise - false.
Redraw

Redraws the control.

```cpp
bool Redraw()
```

**Return Value**

- true - successful, otherwise - false.
RowState

Sets the state of the specified item.

```cpp
bool RowState(
    const int index,  // item index
    const bool select  // state
)
```

Parameters

- **index**
  
  [in] Item index to change.

- **select**
  
  [in] New state.

Return Value

true - successful, otherwise - false.
CRadioButton

CRadioButton is a class of RadioButton complex control.

Description

CRadioButton itself is not used, it used for creation of CRadioGroup items.

Declaration

```cpp
class CRadioButton : public CWndContainer
```

Title

```cpp
#include <Controls\RadioButton.mqh>
```

Inheritance hierarchy

```
CObject
  CWnd
    CWndContainer
      CRadioButton
```

Methods inherited from class CObject

Pre, Prev, Next, Next, Type, Compare

Methods inherited from class CWnd

Name, ControlsTotal, Control, Rect, Left, Left, Top, Top, Right, Right, Bottom, Bottom, Width, Width, Height, Height, Size, Size, Size, Contains, Contains, Alignment, Align, Id, IsEnabled, IsVisible, Visible, IsActive, Activate, Deactivate, StateFlags, StateFlags, StateFlags, StateFlagsSet, StateFlagsReset, PropFlags, PropFlags, PropFlagsSet, PropFlagsReset, MouseX, MouseX, MouseY, MouseY, MouseFlags, MouseFlags, MouseFocusKill, BringToTop

Methods inherited from class CWndContainer

Destroy, OnMouseEvent, ControlsTotal, Control, ControlFind, MouseFocusKill, Add, Add, Delete, Delete, Move, Move, Shift, Id, Enable, Disable, Show, Hide, Save, Load
Create

Creates new CRadioButton control.

```cpp
virtual bool Create(
    const long chart,     // chart ID
    const string name,    // name
    const int subwin,     // chart subwindow
    const int x1,         // coordinate
    const int y1,         // coordinate
    const int x2,         // coordinate
    const int y2          // coordinate
)
```

Parameters

- `chart` [in] ID of the chart, at which the control is created.
- `name` [in] Unique name of the control.
- `subwin` [in] Subwindow of the chart, at which the control is created.
- `x1` [in] X coordinate of the upper left corner.
- `y1` [in] Y coordinate of the upper left corner.
- `x2` [in] X coordinate of the lower right corner.
- `y2` [in] Y coordinate of the lower right corner.

Return Value

- `true` - successful, otherwise - `false`.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

**Parameters**

- `id`  
  [in] Event ID.

- `lparam`  

- `dparam`  

- `sparam`  

**Return Value**

- `true` - event processed, otherwise - `false`. 
**Text (Get method)**

Gets text of the label associated with the control.

```cpp
string Text()
```

**Return Value**

Text of the label.

**Text (Set method)**

Sets text of the label.

```cpp
bool Text(
    const string value // text
)
```

**Parameters**

`value`

[in] New text of the label.

**Return Value**

true - successful, otherwise - false.
**Color (Get method)**

Gets color of the label associated with the control.

```cpp
color Color() const
```

Return Value

Label color.

**Color (Set method)**

Sets color of the label associated with the control.

```cpp
bool Color(const color value // color
```

Parameters

value

Return Value

true - successful, otherwise - false.
State (Get method)

Gets the button state.

```cpp
bool State() const
```

Return Value

Button state.

State (Set method)

Sets the button state.

```cpp
bool State(
    const bool flag // flag
)
```

Parameters

`flag`

[in] New button state.

Return Value

true - successful, otherwise - false.
CreateButton

Creates button.

`virtual bool CreateButton()`

Return Value

- true - successful, otherwise - false.
**CreateLabel**

Creates label.

```cpp
virtual bool CreateLabel()
```

**Return Value**

true - successful, otherwise - false.
**OnClickButton**

The virtual handler of the control "ClickButton" (button click) internal event.

```cpp
virtual bool OnClickButton()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
OnClickLabel

The virtual handler of the control "ClickLabel" (click on the label) internal event.

```cpp
virtual bool OnClickLabel()
```

Return Value

true - event processed, otherwise - false.
**CRadioGroup**

CRadioGroup is a class of RadioGroup complex control (with dependent controls).

**Description**

CRadioGroup enables creation of a control allowing the display and editing the enumerable type field.

**Declaration**

```cpp
class CRadioGroup : public CWndClient
```

**Title**

```
#include <Controls\RadioGroup.mqh>
```

**Inheritance hierarchy**

- CObject
  - CWnd
    - CWndContainer
      - CWndClient
        - CRadioGroup
```

//+------------------------------------------------------------------+

void OnChartEvent(const int id,       // event ID
                   const long& lparam,  // event parameter of the long type
                   const double& dparam, // event parameter of the double type
                   const string& sparam) // event parameter of the string type
{
     ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
Create

Creates new CRadioGroup control.

```cpp
virtual bool Create(
    const long  chart,    // chart ID
    const string name,    // name
    const int  subwin,    // chart subwindow
    const int  x1,        // coordinate
    const int  y1,        // coordinate
    const int  x2,        // coordinate
    const int  y2         // coordinate
)
```

Parameters

`chart`

[in] ID of the chart, at which the control is created.

`name`

[in] Unique name of the control.

`subwin`

[in] Subwindow of the chart, at which the control is created.

`x1`

[in] X coordinate of the upper left corner.

`y1`

[in] Y coordinate of the upper left corner.

`x2`

[in] X coordinate of the lower right corner.

`y2`

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent
Chart event handler.

```cpp
global bool OnEvent(
    const int id,       // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam) // parameter
```

Parameters

- **id**
  - [in] Event ID.

- **lparam**

- **dparam**
  - [in] Event parameter of `double` type passed by reference.

- **sparam**
  - [in] Event parameter of `string` type passed by reference.

Return Value

- true - event processed, otherwise - false.
AddItem

Adds an item to the control.

```c++
bool AddItem(
    const string item, // text
    const long value=0  // value
)
```

Parameters

- `item` [in] Added control label text.
- `value=0` [in] Value associated with the added control.

Return Value

- `true` - successful, otherwise `false`. 
Value

Gets the value associated with the control.

```cpp
long Value()
```

Return Value

The value associated with the control.

Note

The value depends on state of all CRadioButton items of the CRadioGroup control.
**CreateButton**

Creates new CRadioButton class instance at a specified index.

```cpp
bool CreateButton(
    const int index // index
)
```

**Parameters**

- `index`  
  [in] Index of the new item in the CRadioGroup.

**Return Value**

- `true` - successful, otherwise - `false`. 
OnVScrollShow

The virtual handler of the dependent VScroll (vertical scroll) control "Show" internal event.

```cpp
virtual bool OnVScrollShow()
```

Return Value

- true - event processed, otherwise - false.
OnVScrollHide

The virtual handler of the dependent VScroll (vertical scroll) control “Hide” internal event.

```
virtual bool OnVScrollHide()
```

Return Value

true - event processed, otherwise - false.
OnScrollLineDown

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineDown" internal event.

```cpp
virtual bool OnScrollLineDown()
```

**Return Value**

- true - event processed, otherwise - false.
OnScrollLineUp

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineUp" internal event.

```cpp
virtual bool OnScrollLineUp()
```

Return Value

- `true` - event processed, otherwise - `false`.
OnChangelItem

The virtual handler of the control "ChangelItem" (item change) event.

```cpp
virtual bool OnChangelItem(
    const int index  // index
)
```

**Parameters**

`index`

[in] Index of the changed item.

**Return Value**

true - event processed, otherwise - false.
Redraw

Redraws the control.

```cpp
bool Redraw()
```

Return Value

true - successful, otherwise - false.
RowState

Changes the state of an item.

```cpp
bool RowState(
    const int index,  // index
    const bool select  // state
)
```

Parameters

index

[in] Item index to change.

select

[in] New state.

Return Value

true - successful, otherwise - false.

## Select

Selects the current item.

```c
void Select(
    const int index  // index
)
```

### Parameters

- `index`
  - `[in]` Item index to select.

### Return Value

None.
CSpinEdit

CSpinEdit is a class of SpinEdit complex control (with dependent controls).

Description

CSpinEdit class is intended for creation of a control, which allows editing a value of integer type with a specified step and within specified limitations.

Declaration

```cpp
class CSpinEdit : public CWndContainer
```

Title

```
#include <Controls\SpinEdit.mqh>
```

Inheritance hierarchy

```
CObject
   CWnd
      CWndContainer
         CSpinEdit
```

}
Create

Creates new CSpinEdit control.

```
virtual bool Create(
    const long chart,  // chart ID
    const string name,  // name
    const int subwin,   // chart subwindow
    const int x1,       // coordinate
    const int y1,       // coordinate
    const int x2,       // coordinate
    const int y2        // coordinate
)
```

Parameters

- `chart`
  
  [in] ID of the chart, at which the control is created.

- `name`
  
  [in] Unique name of the control.

- `subwin`
  
  [in] Subwindow of the chart, at which the control is created.

- `x1`
  
  [in] X coordinate of the upper left corner.

- `y1`
  
  [in] Y coordinate of the upper left corner.

- `x2`
  
  [in] X coordinate of the lower right corner.

- `y2`
  
  [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
**OnEvent**

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

**Parameters**

- **id**
  
  [in] Event ID.

- **lparam**
  

- **dparam**
  

- **sparam**
  

**Return Value**

- true - event processed, otherwise - false.
MinValue (Get method)

Gets the value of "MinValue" property (minimal value) of the control.

```cpp
int MinValue() const
```

Return Value

The value of "MinValue" property.

MinValue (Set method)

Sets the value of "MinValue" property (minimal value) of the control.

```cpp
void MinValue(
    const int value // value
)
```

Parameters

- `value`
  

Return Value

None.
MaxValue (Get method)

Gets the value of "MaxValue" property (maximal value) of the control.

```cpp
int MaxValue() const
```

Return Value

The value of "MaxValue" property.

MaxValue (Set method)

Sets the value of "MaxValue" property (maximal value) of the control.

```cpp
void MaxValue(
    const int value // value
)
```

Parameters

value

[in] New value of "MaxValue" property.

Return Value

None.
Value (Get method)

Gets the “Value” property (current value) of the control.

```c
int Value() const
```

Return Value

The “Value” property.

Value (Set method)

Sets the “Value” property (current value) of the control.

```c
void Value(
    const int value // value
)
```

Parameters

value

Return Value

None.
CreateEdit

Creates dependent control (CEdit).

```
virtual bool CreateEdit() 
```

Return Value

true - successful, otherwise - false.
CreateInc

Creates dependent control (increment button).

```cpp
virtual bool CreateInc()
```

Return Value

true - successful, otherwise - false.
CreateDec

Creates dependent control (decrement button).

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.
**OnClickInc**

The virtual handler of the control "ClickInc" (mouse click on the increment button) internal event.

```cpp
virtual bool OnClickInc()
```

**Return Value**

- true - event processed, otherwise - false.
OnClickDec

The virtual handler of the control "ClickDec" (mouse click on the decrement button) internal event.

```cpp
virtual bool OnClickDec()
```

**Return Value**

- `true` - event processed, otherwise - `false`. 
**OnChangeValue**

The virtual handler of the control "ChangeValue" (changing the current value) internal event.

```cpp
virtual bool OnChangeValue()
```

**Return Value**

- true - event processed, otherwise - false.
CDialog

CDialog is class of the Dialog complex control.

Description

CDialog class is intended to combine the controls with different functions in the group.

Declaration

```cpp
class CDialog : public CWndContainer
```

Title

```cpp
#include <Controls\Dialog.mqh>
```

Inheritance hierarchy

Create

Creates new CDialog control.

```cpp
virtual bool Create(
    const long chart,  // chart ID
    const string name,  // name
    const int subwin,  // chart subwindow
    const int x1,      // coordinate
    const int y1,      // coordinate
    const int x2,      // coordinate
    const int y2       // coordinate
)
```

Parameters

**chart**

[in] ID of the chart, at which the control is created.

**name**

[in] Unique name of the control.

**subwin**

[in] Subwindow of the chart, at which the control is created.

**x1**

[in] X coordinate of the upper left corner.

**y1**

[in] Y coordinate of the upper left corner.

**x2**

[in] X coordinate of the lower right corner.

**y2**

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id, // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

**Parameters**

- `id`  
  [in] Event ID.

- `lparam`  

- `dparam`  

- `sparam`  

**Return Value**

- `true` - event processed, otherwise - `false`. 
Caption (Get method)

Gets the "Caption" property of the CDialog control.

```cpp
string MinValue() const
```

Return Value

The "Caption" property.

Caption (Set method)

Sets the "Caption" property of the CDialog control.

```cpp
bool Caption(
    const string text  // text
)
```

Parameters

`text`

Return Value

true - successful, otherwise - false.
### Add

**Description**

Adds control to the client area by pointer.

**Syntax**

```cpp
bool Add(
    CWnd *control,   // pointer
)
```

**Parameters**

- `control`:
  - `[in]` Pointer to control.

**Return Value**

- `true` - successful, otherwise - `false`.

### Add

**Description**

Adds control to the client area by reference.

**Syntax**

```cpp
bool Add(
    CWnd &control,   // reference
)
```

**Parameters**

- `control`:
  - `[in]` Reference to control.

**Return Value**

- `true` - successful, otherwise - `false`. 
CreateWhiteBorder

Creates dependent control (white border).

```cpp
virtual bool CreateWhiteBorder()
```

Return Value

true - successful, otherwise - false.
CreateBackground

Creates dependent control (background).

```cpp
virtual bool CreateBackground()
```

Return Value

true - successful, otherwise - false.
CreateCaption

Creates dependent control (caption).

```cpp
virtual bool CreateCaption()
```

Return Value

true - successful, otherwise - false.
CreateButtonClose

Creates dependent control (close button)

virtual bool CreateButtonClose()

Return Value

ture - successful, otherwise - false.
CreateClientArea

Creates dependent control (client area).

virtual bool CreateClientArea()  

Return Value

true - successful, otherwise - false.
**OnClickCaption**

The virtual handler of the control "ClickCaption" internal event.

```cpp
virtual bool OnClickCaption()
```

**Return Value**

- true - successful, otherwise - false.
OnButtonClickClose

The virtual handler of the control "ButtonClickClose" internal event.

```cpp
virtual bool OnButtonClickClose()
```

Return Value

true - successful, otherwise - false.
ClientAreaVisible

Sets a flag indicating whether the client area is visible.

```cpp
bool ClientAreaVisible(
    const bool visible  // visibility flag
)
```

Parameters

`visible`

Return Value

true - successful, otherwise - false.
# ClientAreaLeft

**Gets X coordinate of the upper-left corner of the control client area.**

```c
int ClientAreaLeft()
```

**Return Value**

The X coordinate of the upper-left corner of the control client area.
ClientAreaTop

Gets Y coordinate of the upper-left corner of the control client area.

```cpp
int ClientAreaTop()
```

Return Value

The Y coordinate of the upper-left corner of the control client area.
ClientAreaRight

Gets X coordinate of the lower-right corner of the control client area.

```c
int  ClientAreaRight()
```

Return Value

The X coordinate of the lower-right corner of the control client area.
**ClientAreaBottom**

Gets Y coordinate of the lower-right corner of the control client area.

```c
int ClientAreaBottom()
```

**Return Value**

The Y coordinate of the lower-right corner of the control client area.
ClientAreaWidth

Gets the width of the control client area.

```c
int ClientAreaWidth()
```

Return Value

The width of the client area.
ClientAreaHeight

Gets the height of the control client area.

```plaintext
int ClientAreaHeight()
```

**Return Value**

The height of the control client area.
OnDialogDragStart

The virtual handler of the control "DialogDragStart" event.

```cpp
virtual bool OnDialogDragStart()
```

Return Value

- true - event processed, otherwise - false.

Note

The "DialogDragStart" event occurs at start of the drag of the control.
OnDialogDragProcess

The virtual handler of the control "DialogDragProcess" event.

```cpp
virtual bool OnDialogDragProcess()
```

Return Value

true - event processed, otherwise - false.

Note

The "DialogDragProcess" event occurs when the control is dragged.
OnDialogDragEnd

The virtual handler of the control "DialogDragEnd" event.

```cpp
virtual bool OnDialogDragEnd()
```

Return Value

- **true** - event processed, otherwise - **false**.

Note

The "DialogDragEnd" event occurs at the end of the drag of the control.
CAppDialog

CAppDialog is a class of Application Dialog complex control (with dependent controls).

Description

CAppDialog class is intended to combine the controls with different functions in the group inside the MQL5 program.

Declaration

```cpp
class CAppDialog : public CDialog
```

Title

```cpp
#include <Controls\Dialog.mqh>
```

Inheritance hierarchy

```
CObject
    CWnd
        CWndContainer
            CDialog
                CAppDialog
```

OnMouseEvent, ControlsTotal, Control, ControlFind, MouseFocusKill, Add, Add, Delete, Delete, Move, Move, Shift, Id, Enable, Disable, Show, Hide

Methods inherited from class CDialog

Caption, Caption, Add, Add
Create

Creates new CAppDialog control.

```cpp
virtual bool Create(  
    const long chart,   // chart ID  
    const string name,  // name  
    const int subwin,   // chart subwindow  
    const int x1,       // coordinate  
    const int y1,       // coordinate  
    const int x2,       // coordinate  
    const int y2        // coordinate
)
```

Parameters

- `chart`: [in] ID of the chart, at which the control is created.
- `name`: [in] Unique name of the control.
- `subwin`: [in] Subwindow of the chart, at which the control is created.
- `x1`: [in] X coordinate of the upper left corner.
- `y1`: [in] Y coordinate of the upper left corner.
- `x2`: [in] X coordinate of the lower right corner.
- `y2`: [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
Destroy

CAppDialog control deinitialization method.

```cpp
virtual void Destroy(
    const int reason=REASON_PROGRAM   // reason code
)
```

Parameters

- `reason`
  - [in] Deinitialization reason code. `REASON_PROGRAM` is set by default.

Return Value

None.
OnEvent

Chart event handler.

```cpp
virtual bool OnEvent(
    const int id,       // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam  // parameter
)
```

Parameters

- `id` [in] Event ID.

Return Value

- `true` - event processed, otherwise - `false`.
Run

Runs control.

```cpp
bool Run()
```

Return Value

- true - successful, otherwise - false.
ChartEvent

Virtual handler of the control events.

```cpp
virtual bool ChartEvent(
    const int id,    // ID
    const long& lparam, // parameter
    const double& dparam, // parameter
    const string& sparam // parameter
)
```

Parameters

- **id**
  - [in] Event ID.

- **lparam**

- **dparam**
  - [in] Event parameter of `double` type passed by reference.

- **sparam**
  - [in] Event parameter of `string` type passed by reference.

Return Value

- `true` - event processed, otherwise - `false`. 

Minimized

Sets the value of "Minimized" (window state) property of the control.

```cpp
bool Minimized(
    const bool flag // state
)
```

Parameters

- `flag`
  - [in] New state.

Return Value

- `true` - successful, otherwise - `false`.
IniFileSave

Saves the control state to file.

```c
void IniFileSave()
```

Return Value

true - successful, otherwise - false.
IniFileLoad

Loads the control state from file.

```cpp
void IniFileLoad()
```

Return Value

true - successful, otherwise - false.
IniFileName

Sets the file name for loading/saving the control state.

```cpp
virtual string IniFileName() const
```

Return Value

File name for loading/saving of the control state.

Note

The file name includes the name of the Expert Advisor/indicator and working symbol, on which MQL5 program is launched.
**IniFileExt**

Sets the file extension for loading/saving the control state.

```cpp
virtual string IniFileExt() const
```

**Return Value**

File extension used for loading/saving of the control state.
CreateCommon

Common initialization method.

```cpp
bool CreateCommon(
    const long chart, // chart ID
    const string name, // name
    const int subwin, // chart subwindow
);
```

**Parameters**

*chart*

[in] ID of the chart, at which the control is created.

*name*

[in] Unique name of the control.

*subwin*

[in] Subwindow of the chart, at which the control is created.

**Return Value**

true - successful, otherwise - false.
**CreateExpert**

Initialization method for working in Expert Advisors.

```cpp
bool CreateExpert(
    const int x1,   // coordinate
    const int y1,   // coordinate
    const int x2,   // coordinate
    const int y2   // coordinate
)
```

**Parameters**

- `x1`
  - [in] X coordinate of the upper left corner.

- `y1`
  - [in] Y coordinate of the upper left corner.

- `x2`
  - [in] X coordinate of the lower right corner.

- `y2`
  - [in] Y coordinate of the lower right corner.

**Return Value**

- true - successful, otherwise - false.
CreateIndicator

Initialization method for working in indicators.

```cpp
bool CreateIndicator(
    const int x1,  // coordinate
    const int y1,  // coordinate
    const int x2,  // coordinate
    const int y2   // coordinate
)
```

Parameters

- `x1` [in] X coordinate of the upper left corner.
- `y1` [in] Y coordinate of the upper left corner.
- `x2` [in] X coordinate of the lower right corner.
- `y2` [in] Y coordinate of the lower right corner.

Return Value

- true - successful, otherwise - false.
CreateButtonMinMax

Creates dependent controls (minimize/maximize buttons).

```cpp
virtual void CreateButtonMinMax()
```

Return Value

None.
OnClickButtonClose

The virtual handler of the control “ButtonClickClose” (mouse click on close button) internal event.

```
virtual void OnClickButtonClose()
```

Return Value

None.
OnClickButtonMinMax

The virtual handler of the control "ButtonClickMinMax" (mouse click on minimize/maximize button) internal event.

```cpp
virtual void OnClickButtonClose()
```

Return Value

None.
OnAnotherApplicationClose

The virtual handler of the control external events.

```cpp
virtual void OnAnotherApplicationClose()
```

Return Value

None.
Rebound

Sets new coordinates of the control using CRect class coordinates.

```cpp
bool Rebound(const &CRect rect) // CRect class
```

Return Value

true - successful, otherwise - false.
Minimize

Shows the control window in the minimized state.

```
virtual void Minimize()
```

Return Value

true - successful, otherwise - false.
Maximize

Shows the control window in the maximized (restored) state.

```cpp
virtual void Maximize()
```

Return Value

- true - successful, otherwise - false.
CreateInstanceId

Creates a unique prefix for the names of the control objects.

```cpp
string CreateInstanceId()
```

Return Value

*Prefix for the object names.*
**ProgramName**

Gets the name of the MQL5 program, at which the control is used.

```csharp
string ProgramName()
```

**Return Value**

Name of the MQL5 program.
SubwinOff

Gets the Y offset of the control subwindow.

```cpp
void SubwinOff()
```

Return Value

None.
Moving from MQL4 to MQL5

MQL5 is the evolution of its predecessor - the MQL4 programming language, in which numerous indicators, scripts, and Expert Advisors were written. Despite the fact that the new programming language is maximally compatible with the previous-generation language, there are still some differences between these languages. And when transferring programs these differences should be noted.

This section contains information intended to facilitate the adaptation of codes to the new MQL5 language for programmers who know MQL4.

First it should be noted:
- The new language does not contain functions start(), init() and deinit().
- No limit for the number of indicator buffers.
- DLLs are loaded immediately after loading an Expert Advisor (or any other mql5 program).
- Check of logical conditions is shortened.
- When limits of an array are exceeded, the current performance is terminated (critically - with the output of an errors).
- Precedence of operators like in C ++.
- The language offers the implicit type cast (even from string to a number).
- Local variables are not initialized automatically (except for strings).
- Common local arrays are automatically deleted.

Special Functions init, start and deinit

The MQL4 language contained only three predefined functions that could be used in the indicator, script or Expert Advisor (not taking into account the include files *.mqh and library files). In MQL5 there are no such functions, but there are their analogues. The table shows the approximate correspondence of functions.

<table>
<thead>
<tr>
<th>MQL4</th>
<th>MQL5</th>
</tr>
</thead>
<tbody>
<tr>
<td>init</td>
<td>OnInit</td>
</tr>
<tr>
<td>start</td>
<td>OnStart</td>
</tr>
<tr>
<td>deinit</td>
<td>OnDeinit</td>
</tr>
</tbody>
</table>

Functions OnInit and OnDeinit perform the same role as init and deinit in MQL4 - they are designed to locate the code, which must be performed during initialization and deinitialization of mql5 programs. You can either just rename these functions accordingly, or leave them as they are, but add calls of these functions in corresponding places.

Example:

```c
void OnInit()
{
    //--- Call function upon initialization
    init();
}
```
The start function is replaced by `OnStart` only in scripts. In Expert Advisors and indicators it should be renamed to `OnTick` and `OnCalculate`, respectively. The code that is to be executed during a `mq5` program operation should be located in these three functions:

<table>
<thead>
<tr>
<th><code>mq5</code>-program</th>
<th>main function</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>OnStart</td>
</tr>
<tr>
<td>indicator</td>
<td>OnCalculate</td>
</tr>
<tr>
<td>Expert Advisor</td>
<td>OnTick</td>
</tr>
</tbody>
</table>

If the indicator or script code does not contain the main function, or the function name differs from the required one, the call of this function is not performed. It means, if the source code of a script doesn’t contain OnStart, such a code will be compiled as an Expert Advisor.

If an indicator code doesn’t contain the OnCalculate function, the compilation of such an indicator is impossible.

**Predefined Variables**

In MQL5 there are no such predefined variables as Ask, Bid, Bars. Variables Point and Digits have a slightly different spelling:

<table>
<thead>
<tr>
<th>MQL4</th>
<th>MQL5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digits</td>
<td>_Digits</td>
</tr>
<tr>
<td>Point</td>
<td>_Point</td>
</tr>
<tr>
<td></td>
<td>_LastError</td>
</tr>
<tr>
<td></td>
<td>_Period</td>
</tr>
<tr>
<td></td>
<td>_Symbol</td>
</tr>
<tr>
<td></td>
<td>_StopFlag</td>
</tr>
<tr>
<td></td>
<td>_UninitReason</td>
</tr>
</tbody>
</table>

**Access to Timeseries**

In MQL5 there are no such predefined timeseries as Open[], High[], Low[], Close[], Volume[] and Time[]. The necessary depth of a timeseries can now be set using corresponding functions to access timeseries.
Expert Advisors

Expert Advisors in MQL5 do not require the obligatory presence of functions that handle the events of a new tick receipt - OnTick, as it was in MQL4 (the start function in MQL4 is executed when a new tick is received). In MQL5 Expert Advisors can contain pre-defined handler functions of several types of events:

- **OnTick** - receipt of a new tick;
- **OnTimer** - timer event;
- **OnTrade** - trade event;
- **OnChartEvent** - events of input from the keyboard and mouse, events of a graphic object moving, event of a text editing completion in the entry field of the LabelEdit object;
- **OnBookEvent** - event of Depth of Market status change.

Custom Indicators

In MQL4, the number of indicator buffers is limited and can't exceed 8. In MQL5 there are no such limitations, but it should be remembered that each indicator buffer requires allocation of a certain part of memory for its location in the terminal, so the new possibility should not be abused.

MQL4 offered only 6 types of custom indicator plotting; while MQL5 now offers 18 drawing styles. The names of drawing types haven't changed, but the ideology of the graphical representation of indicators has changed significantly.

The direction of indexing in indicator buffers also differs. By default, in MQL5 all the indicator buffers have the behavior of common arrays, i.e. 0 indexed element is the oldest one in the history, and as the index increases, we move from the oldest data to the most recent ones.

The only function for working with custom indicators that was preserved from MQL4 is `SetIndexBuffer`. But its call has changed; now you should specify type of data to be stored in an array, linked to the indicator buffer.

Properties of custom indicators also have changed and expanded. New functions for accessing timeseries have been added, so the total calculation algorithm must be reconsidered.

Graphical Objects

The number of graphical objects in MQL5 has been significantly increased. Besides, graphical objects can now be positioned in time with the accuracy of a second in a chart of any timeframe - now object anchor points are not rounded off to the bar opening time in the current price chart.

For the Arrow, Text and Label objects now you can specify binding methods, and for the Label, Button, Chart, Bitmap Label and Edit objects you can set chart corner to which an object is attached.
## List of MQL5 Functions

All MQL5 functions in alphabetical order.

<table>
<thead>
<tr>
<th>Function</th>
<th>Action</th>
<th>Section</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccountInfoDouble</td>
<td>Returns a value of double type of the corresponding account property</td>
<td>Account Information</td>
</tr>
<tr>
<td>AccountInfoInteger</td>
<td>Returns a value of integer type (bool, int or long) of the corresponding account property</td>
<td>Account Information</td>
</tr>
<tr>
<td>AccountInfoString</td>
<td>Returns a value string type corresponding account property</td>
<td>Account Information</td>
</tr>
<tr>
<td>acos</td>
<td>Returns the arc cosine of x in radians</td>
<td>Math Functions</td>
</tr>
<tr>
<td>Alert</td>
<td>Displays a message in a separate window</td>
<td>Common Functions</td>
</tr>
<tr>
<td>ArrayBsearch</td>
<td>Searches for a specified value in a multidimensional numeric array sorted ascending</td>
<td>Array Functions</td>
</tr>
<tr>
<td>ArrayCompare</td>
<td>Returns the result of comparing two arrays of simple types or custom structures without complex objects</td>
<td>Array Functions</td>
</tr>
<tr>
<td>ArrayCopy</td>
<td>Copies one array into another</td>
<td>Array Functions</td>
</tr>
<tr>
<td>ArrayFill</td>
<td>Fills an array with the specified value</td>
<td>Array Functions</td>
</tr>
<tr>
<td>ArrayFree</td>
<td>Frees up buffer of any dynamic array and sets the size of the zero dimension in 0.</td>
<td>Array Functions</td>
</tr>
<tr>

<td>CalendarEventByCountry</td>
<td>Get the array of descriptions of all events available in the calendar by a specified country code</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>CalendarEventByCurrency</td>
<td>Get the array of descriptions of all events available in the calendar by a specified currency</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>CalendarValueHistoryByEvent</td>
<td>Get the array of values for all events in a specified time range by an event ID</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>CalendarValueHistory</td>
<td>Get the array of values for all events in a specified time range with the ability to sort by country and/or currency</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>CalendarValueLastByEvent</td>
<td>Get the array of event values by its ID since the calendar database status with a specified change_id</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>CalendarValueLast</td>
<td>Get the array of values for all events with the ability to sort by country and/or currency since the calendar database status with a specified change_id</td>
<td>Economic Calendar</td>
</tr>
<tr>
<td>ceil</td>
<td>Returns integer numeric value closest from above</td>
<td>Math Functions</td>
</tr>
<tr>
<td>CharArrayToString</td>
<td>Converting symbol code (ansi) into one-symbol array</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>ChartApplyTemplate</td>
<td>Applies a specific template from a specified file to the chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartClose</td>
<td>Closes the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartFirst</td>
<td>Returns the ID of the first chart of the client terminal</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartGetDouble</td>
<td>Returns the double value property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartGetInteger</td>
<td>Returns the integer value property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartGetString</td>
<td>Returns the string value property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>ChartID</td>
<td>Returns the ID of the current chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartIndicatorAdd</td>
<td>Adds an indicator with the specified handle into a specified chart window</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartIndicatorDelete</td>
<td>Removes an indicator with a specified name from the specified chart window</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartIndicatorGet</td>
<td>Returns the handle of the indicator with the specified short name in the specified chart window</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartIndicatorName</td>
<td>Returns the short name of the indicator by the number in the indicators list on the specified chart window</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartIndicatorsTotal</td>
<td>Returns the number of all indicators applied to the specified chart window.</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartNavigate</td>
<td>Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartNext</td>
<td>Returns the chart ID of the chart next to the specified one</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartOpen</td>
<td>Opens a new chart with the specified symbol and period</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>CharToString</td>
<td>Converting a symbol code into a one-character string</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>ChartPeriod</td>
<td>Returns the period value of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartPriceOnDropped</td>
<td>Returns the price coordinate of the chart point, the Expert Advisor or script has been dropped to</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartRedraw</td>
<td>Calls a forced redrawing of a specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartSaveTemplate</td>
<td>Saves current chart settings in a template with a specified name</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>ChartScreenShot</td>
<td>Provides a screenshot of the chart of its current state in a</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td><strong>ChartSetDouble</strong></td>
<td>Sets the double value for a corresponding property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartSetInteger</strong></td>
<td>Sets the integer value (datetime, int, color, bool or char) for a corresponding property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartSetString</strong></td>
<td>Sets the string value for a corresponding property of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartSetSymbolPeriod</strong></td>
<td>Changes the symbol value and a period of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartSymbol</strong></td>
<td>Returns the symbol name of the specified chart</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartTimeOnDropped</strong></td>
<td>Returns the time coordinate of the chart point, the Expert Advisor or script has been dropped to</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartTimePriceToXY</strong></td>
<td>Converts the coordinates of a chart from the time/price representation to the X and Y coordinates</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartWindowFind</strong></td>
<td>Returns the number of a subwindow where an indicator is drawn</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartWindowOnDropped</strong></td>
<td>Returns the number (index) of the chart subwindow, the Expert Advisor or script has been dropped to</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartXOnDropped</strong></td>
<td>Returns the X coordinate of the chart point, the Expert Advisor or script has been dropped to</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartXYToTimePrice</strong></td>
<td>Converts the X and Y coordinates on a chart to the time and price values</td>
<td>Chart Operations</td>
</tr>
<tr>
<td><strong>ChartYOnDropped</strong></td>
<td>Returns the Y coordinate of the chart point, the Expert Advisor or script has been dropped to</td>
<td>Chart Operations</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>CheckPointer</td>
<td>Returns the type of the object pointer</td>
<td>Common Functions</td>
</tr>
<tr>
<td>CLBufferCreate</td>
<td>Creates an OpenCL buffer</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLBufferFree</td>
<td>Deletes an OpenCL buffer</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLBufferRead</td>
<td>Reads an OpenCL buffer into an array</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLBufferWrite</td>
<td>Writes an array into an OpenCL buffer</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLContextCreate</td>
<td>Creates an OpenCL context</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLContextFree</td>
<td>Removes an OpenCL context</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLEexecute</td>
<td>Runs an OpenCL program</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLGetDeviceInfo</td>
<td>Receives device property from OpenCL driver</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLGetInfoInteger</td>
<td>Returns the value of an integer property for an OpenCL object or device</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLHandleType</td>
<td>Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLKernelCreate</td>
<td>Creates an OpenCL start function</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLKernelFree</td>
<td>Removes an OpenCL start function</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLProgramCreate</td>
<td>Creates an OpenCL program from a source code</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLProgramFree</td>
<td>Removes an OpenCL program</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLSetKernelArg</td>
<td>Sets a parameter for the OpenCL function</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>CLSetKernelArgMem</td>
<td>Sets an OpenCL buffer as a parameter of the OpenCL function</td>
<td>Working with OpenCL</td>
</tr>
<tr>
<td>ColorToARGB</td>
<td>Converting color type to uint type to receive ARGB representation of the color.</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>ColorToString</td>
<td>Converting color value into string as &quot;R,G,B&quot;</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>Comment</td>
<td>Outputs a comment in the left top corner of the chart</td>
<td>Common Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>CopyBuffer</td>
<td>Gets data of a specified buffer from a specified indicator into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyClose</td>
<td>Gets history data on bar closing price for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyHigh</td>
<td>Gets history data on maximal bar price for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyLow</td>
<td>Gets history data on minimal bar price for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyOpen</td>
<td>Gets history data on bar opening price for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyRates</td>
<td>Gets history data of the Rates structure for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyRealVolume</td>
<td>Gets history data on trade volumes for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopySpread</td>
<td>Gets history data on spreads for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyTicks</td>
<td>Gets ticks accumulated by the terminal for the current working session into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyTickVolume</td>
<td>Gets history data on tick volumes for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>CopyTime</td>
<td>Gets history data on bar opening time for a specified symbol and period into an array</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>cos</td>
<td>Returns the cosine of a number</td>
<td>Math Functions</td>
</tr>
<tr>
<td>CryptDecode</td>
<td>Performs the inverse transformation of the data</td>
<td>Common Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>CryptEncode</td>
<td>Transforms the data from array with the specified method</td>
<td>Common Functions</td>
</tr>
<tr>
<td>CustomSymbolCreate</td>
<td>Create a custom symbol with the specified name in the specified group</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolDelete</td>
<td>Delete a custom symbol with the specified name</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetInteger</td>
<td>Set the integer type property value for a custom symbol</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetDouble</td>
<td>Set the real type property value for a custom symbol</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetString</td>
<td>Set the string type property value for a custom symbol</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetMarginRate</td>
<td>Set the margin rates depending on the order type and direction for a custom symbol</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetSessionQuote</td>
<td>Set the start and end time of the specified quotation session for the specified symbol and week day</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomSymbolSetSessionTrade</td>
<td>Set the start and end time of the specified trading session for the specified symbol and week day</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomRatesDelete</td>
<td>Delete all bars from the price history of the custom symbol in the specified time interval</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomRatesReplace</td>
<td>Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlRates type array</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomRatesUpdate</td>
<td>Add missing bars to the custom symbol history and replace existing data with the ones from the MqlRates type array</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomTicksAdd</td>
<td>Adds data from an array of the MqlTick type to the price</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>CustomTicksDelete</td>
<td>Delete all ticks from the price history of the custom symbol in the specified time interval</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomTicksReplace</td>
<td>Fully replace the price history of the custom symbol within the specified time interval with the data from the MqlTick type array</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>CustomBookAdd</td>
<td>Passes the status of the Depth of Market for a custom symbol</td>
<td>Custom Symbols</td>
</tr>
<tr>
<td>DebugBreak</td>
<td>Program breakpoint in debugging</td>
<td>Common Functions</td>
</tr>
<tr>
<td>Digits</td>
<td>Returns the number of decimal digits determining the accuracy of the price value of the current chart symbol</td>
<td>Checkup</td>
</tr>
<tr>
<td>DoubleToString</td>
<td>Converting a numeric value to a text line with a specified accuracy</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>EnumToString</td>
<td>Converting an enumeration value of any type to string</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>EventChartCustom</td>
<td>Generates a custom event for the specified chart</td>
<td>Working with Events</td>
</tr>
<tr>
<td>EventKillTimer</td>
<td>Stops the generation of events by the timer in the current chart</td>
<td>Working with Events</td>
</tr>
<tr>
<td>EventSetMillisecondTimer</td>
<td>Launches event generator of the high-resolution timer with a period less than 1 second for the current chart</td>
<td>Working with Events</td>
</tr>
<tr>
<td>EventSetTimer</td>
<td>Starts the timer event generator with the specified periodicity for the current chart</td>
<td>Working with Events</td>
</tr>
<tr>
<td>exp</td>
<td>Returns exponent of a number</td>
<td>Math Functions</td>
</tr>
<tr>
<td>ExpertRemove</td>
<td>Stops Expert Advisor and unloads it from the chart</td>
<td>Common Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>fabs</td>
<td>Returns absolute value (modulus) of the specified numeric value</td>
<td>Math Functions</td>
</tr>
<tr>
<td>FileClose</td>
<td>Closes a previously opened file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileCopy</td>
<td>Copies the original file from a local or shared folder to another file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileDelete</td>
<td>Deletes a specified file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileFindClose</td>
<td>Closes search handle</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileFindFirst</td>
<td>Starts the search of files in a directory in accordance with the specified filter</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileFindNext</td>
<td>Continues the search started by the FileFindFirst() function</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileFlush</td>
<td>Writes to a disk all data remaining in the input/output file buffer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileGetInteger</td>
<td>Gets an integer property of a file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileIsEnding</td>
<td>Defines the end of a file in the process of reading</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileIsExist</td>
<td>Checks the existence of a file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileIsLineEnding</td>
<td>Defines the end of a line in a text file in the process of reading</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileMove</td>
<td>Moves or renames a file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileOpen</td>
<td>Opens a file with a specified name and flag</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadArray</td>
<td>Reads arrays of any type except for string from the file of the BIN type</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadBool</td>
<td>Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string to a value of bool type</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadDatetime</td>
<td>Reads from the file of the CSV type a string of one of the formats: “YYYY.MM.DD</td>
<td>File Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>FileReadDouble</td>
<td>Reads a double value from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadFloat</td>
<td>Reads a float value from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadInteger</td>
<td>Reads int, short or char value from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadLong</td>
<td>Reads a long type value from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadNumber</td>
<td>Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string into a double value</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadString</td>
<td>Reads a string from the current position of a file pointer from a file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileReadStruct</td>
<td>Reads the contents from a binary file into a structure passed as a parameter, from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileSeek</td>
<td>Moves the position of the file pointer by a specified number of bytes relative to the specified position</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileSize</td>
<td>Returns the size of a corresponding open file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileTell</td>
<td>Returns the current position of the file pointer of a corresponding open file</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileWrite</td>
<td>Writes data to a file of CSV or TXT type</td>
<td>File Functions</td>
</tr>
<tr>
<td>FileWriteArray</td>
<td>Writes arrays of any type except for string into a file of BIN type</td>
<td>File Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td><strong>FileWriteDouble</strong></td>
<td>Writes value of the double type from the current position of a file pointer into a binary file</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FileWriteFloat</strong></td>
<td>Writes value of the float type from the current position of a file pointer into a binary file</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FileWriteInteger</strong></td>
<td>Writes value of the int type from the current position of a file pointer into a binary file</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FileWriteLong</strong></td>
<td>Writes value of the long type from the current position of a file pointer into a binary file</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FileWriteString</strong></td>
<td>Writes the value of a string parameter into a BIN or TXT file starting from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FileWriteStruct</strong></td>
<td>Writes the contents of a structure passed as a parameter into a binary file, starting from the current position of the file pointer</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>floor</strong></td>
<td>Returns integer numeric value closest from below</td>
<td>Math Functions</td>
</tr>
<tr>
<td><strong>fmax</strong></td>
<td>Returns the maximal value of the two numeric values</td>
<td>Math Functions</td>
</tr>
<tr>
<td><strong>fmin</strong></td>
<td>Returns the minimal value of the two numeric values</td>
<td>Math Functions</td>
</tr>
<tr>
<td><strong>fmod</strong></td>
<td>Returns the real remainder after the division of two numbers</td>
<td>Math Functions</td>
</tr>
<tr>
<td><strong>FolderClean</strong></td>
<td>Deletes all files in the specified folder</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FolderCreate</strong></td>
<td>Creates a folder in the Files directory</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FolderDelete</strong></td>
<td>Removes a selected directory. If the folder is not empty, then it can't be removed</td>
<td>File Functions</td>
</tr>
<tr>
<td><strong>FrameAdd</strong></td>
<td>Adds a frame with data</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td><strong>FrameFilter</strong></td>
<td>Sets the frame reading filter and moves the pointer to the</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>FrameFirst</td>
<td>Moves a pointer of frame reading to the beginning and resets the previously set filter</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>FrameInputs</td>
<td>Receives input parameters, on which the frame is formed</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>FrameNext</td>
<td>Reads a frame and moves the pointer to the next one</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>GetLastError</td>
<td>Returns the last error</td>
<td>Checkup</td>
</tr>
<tr>
<td>GetPointer</td>
<td>Returns the object pointer</td>
<td>Common Functions</td>
</tr>
<tr>
<td>GetTickCount</td>
<td>Returns the number of milliseconds that have elapsed since the system was started</td>
<td>Common Functions</td>
</tr>
<tr>
<td>GlobalVariableCheck</td>
<td>Checks the existence of a global variable with the specified name</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableDel</td>
<td>Deletes a global variable</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableGet</td>
<td>Returns the value of a global variable</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableName</td>
<td>Returns the name of a global variable by its ordinal number in the list of global variables</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariablesDeleteAll</td>
<td>Deletes global variables with the specified prefix in their names</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableSet</td>
<td>Sets the new value to a global variable</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableSetOnCondition</td>
<td>Sets the new value of the existing global variable by condition</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariablesFlush</td>
<td>Forcibly saves contents of all global variables to a disk</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariablesTotal</td>
<td>Returns the total number of global variables</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>GlobalVariableTemp</td>
<td>Sets the new value to a global variable, that exists only in the current session of the terminal</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>GlobalVariableTime</td>
<td>Returns time of the last accessing the global variable</td>
<td>Global Variables of the Terminal</td>
</tr>
<tr>
<td>HistoryDealGetDouble</td>
<td>Returns the requested property of a deal in the history (double)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryDealGetInteger</td>
<td>Returns the requested property of a deal in the history (datetime or int)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryDealGetString</td>
<td>Returns the requested property of a deal in the history (string)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryDealGetTicket</td>
<td>Returns a ticket of a corresponding deal in the history</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryDealSelect</td>
<td>Selects a deal in the history for further calling it through appropriate functions</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryDealsTotal</td>
<td>Returns the number of deals in the history</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrderGetDouble</td>
<td>Returns the requested property of an order in the history (double)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrderGetInteger</td>
<td>Returns the requested property of an order in the history (datetime or int)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrderGetString</td>
<td>Returns the requested property of an order in the history (string)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrderGetTicket</td>
<td>Return order ticket of a corresponding order in the history</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrderSelect</td>
<td>Selects an order in the history for further working with it</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistoryOrdersTotal</td>
<td>Returns the number of orders in the history</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistorySelect</td>
<td>Retrieves the history of transactions and orders for the specified period of the server time</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>HistorySelectByPosition</td>
<td>Requests the history of deals with a specified position identifier.</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>iAC</td>
<td>Accelerator Oscillator</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------</td>
<td>----------------------</td>

<tr>
<td>IndicatorCreate</td>
<td>Returns the handle to the specified technical indicator</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>IndicatorParameters</td>
<td>Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>IndicatorRelease</td>
<td>Removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else</td>
<td>Timeseries and Indicators Access</td>
</tr>
<tr>
<td>IndicatorSetDouble</td>
<td>Sets the value of an indicator property of the double type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td>IndicatorSetInteger</td>
<td>Sets the value of an indicator property of the int type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td>IndicatorSetString</td>
<td>Sets the value of an indicator property of the string type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td>IntegerToString</td>
<td>Converting int into a string of preset length</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>iOBV</td>
<td>On Balance Volume</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>iOsMA</td>
<td>Moving Average of Oscillator (MACD histogram)</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>iRSI</td>
<td>Relative Strength Index</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>iRVI</td>
<td>Relative Vigor Index</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>iSAR</td>
<td>Parabolic Stop And Reverse System</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>IsStopped</td>
<td>Returns true, if an mq5 program has been commanded to stop its operation</td>
<td>Checkup</td>
</tr>
<tr>
<td>iStdDev</td>
<td>Standard Deviation</td>
<td>Technical Indicators</td>
</tr>
<tr>
<td>iStochastic</td>
<td>Stochastic Oscillator</td>
<td>Technical Indicators</td>

### List of MQL5 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>log</strong></td>
<td>Returns natural logarithm</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>log10</strong></td>
<td>Returns the logarithm of a number by base 10</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MarketBookAdd</strong></td>
<td>Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes</td>
<td><strong>Market Info</strong></td>
</tr>
<tr>
<td><strong>MarketBookGet</strong></td>
<td>Returns a structure array containing records of the Depth of Market of a specified symbol</td>
<td><strong>Market Info</strong></td>
</tr>
<tr>
<td><strong>MarketBookRelease</strong></td>
<td>Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes</td>
<td><strong>Market Info</strong></td>
</tr>
<tr>
<td><strong>MathAbs</strong></td>
<td>Returns absolute value (modulus) of the specified numeric value</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathArccos</strong></td>
<td>Returns the arc cosine of x in radians</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathArcsin</strong></td>
<td>Returns the arc sine of x in radians</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathArctan</strong></td>
<td>Returns the arc tangent of x in radians</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathCeil</strong></td>
<td>Returns integer numeric value closest from above</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathCos</strong></td>
<td>Returns the cosine of a number</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathExp</strong></td>
<td>Returns exponent of a number</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathFloor</strong></td>
<td>Returns integer numeric value closest from below</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathIsValidNumber</strong></td>
<td>Checks the correctness of a real number</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathLog</strong></td>
<td>Returns natural logarithm</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathLog10</strong></td>
<td>Returns the logarithm of a number by base 10</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathMax</strong></td>
<td>Returns the maximal value of the two numeric values</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td><strong>MathMin</strong></td>
<td>Returns the minimal value of the two numeric values</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathMod</strong></td>
<td>Returns the real remainder after the division of two numbers</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathPow</strong></td>
<td>Raises the base to the specified power</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathRand</strong></td>
<td>Returns a pseudorandom value within the range of 0 to 32767</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathRound</strong></td>
<td>Rounds of a value to the nearest integer</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathSin</strong></td>
<td>Returns the sine of a number</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathSqrt</strong></td>
<td>Returns a square root</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathSrand</strong></td>
<td>Sets the starting point for generating a series of pseudorandom integers</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MathTan</strong></td>
<td>Returns the tangent of a number</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>MessageBox</strong></td>
<td>Creates, displays a message box and manages it</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>MQLInfoInteger</strong></td>
<td>Returns an integer value of a corresponding property of a running mql5 program</td>
<td><strong>Checkup</strong></td>
</tr>
<tr>
<td><strong>MQLInfoString</strong></td>
<td>Returns a string value of a corresponding property of a running mql5 program</td>
<td><strong>Checkup</strong></td>
</tr>
<tr>
<td><strong>MT5Initialize</strong></td>
<td>Establish a connection with the MetaTrader 5 terminal</td>
<td><strong>MetaTrader for Python</strong></td>
</tr>
<tr>
<td><strong>MT5Shutdown</strong></td>
<td>Close the previously established connection to the MetaTrader 5 terminal</td>
<td><strong>MetaTrader for Python</strong></td>
</tr>
<tr>
<td><strong>MT5TerminalInfo</strong></td>
<td>Get status and parameters of the connected MetaTrader 5 terminal</td>
<td><strong>MetaTrader for Python</strong></td>
</tr>
<tr>
<td><strong>MT5Version</strong></td>
<td>Return the MetaTrader 5 terminal version</td>
<td><strong>MetaTrader for Python</strong></td>
</tr>
<tr>
<td><strong>MT5WaitForTerminal</strong></td>
<td>Wait till the MetaTrader 5 terminal connects to the trade server</td>
<td><strong>MetaTrader for Python</strong></td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
<td>Library</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------</td>
</tr>
<tr>
<td>MT5CopyRatesFrom</td>
<td>Get bars from the MetaTrader 5 terminal starting from the specified date</td>
<td>MetaTrader for Python</td>
</tr>
<tr>
<td>MT5CopyRatesFromPos</td>
<td>Get bars from the MetaTrader 5 terminal starting from the specified index</td>
<td>MetaTrader for Python</td>
</tr>
<tr>
<td>MT5CopyRatesRange</td>
<td>Get bars in the specified date range from the MetaTrader 5 terminal</td>
<td>MetaTrader for Python</td>
</tr>
<tr>
<td>MT5CopyTicksFrom</td>
<td>Get ticks from the MetaTrader 5 terminal starting from the specified date</td>
<td>MetaTrader for Python</td>
</tr>
<tr>
<td>MT5CopyTicksRange</td>
<td>Get ticks for the specified date range from the MetaTrader 5 terminal</td>
<td>MetaTrader for Python</td>
</tr>
<tr>
<td>NormalizeDouble</td>
<td>Rounding of a floating point number to a specified accuracy</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>ObjectCreate</td>
<td>Creates an object of the specified type in a specified chart</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectDelete</td>
<td>Removes the object with the specified name from the specified chart</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectFind</td>
<td>Searches for an object with the specified ID by the name</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectGetDouble</td>
<td>Returns the double value of the corresponding object property</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectGetInteger</td>
<td>Returns the integer value of the corresponding object property</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectGetString</td>
<td>Returns the string value of the corresponding object property</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectGetTimeByValue</td>
<td>Returns the time value for the specified object price value</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectGetValueByTime</td>
<td>Returns the price value of an object for the specified time</td>
<td>Object Functions</td>
</tr>
<tr>
<td>ObjectMove</td>
<td>Changes the coordinates of the specified object anchor point</td>
<td>Object Functions</td>
</tr>
<tr>
<td><strong>ObjectName</strong></td>
<td>Returns the name of an object of the corresponding type in the specified chart (specified chart subwindow)</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>ObjectsDeleteAll</strong></td>
<td>Removes all objects of the specified type from the specified chart (from the specified chart subwindow)</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>ObjectSetDouble</strong></td>
<td>Sets the value of the corresponding object property</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>ObjectSetInteger</strong></td>
<td>Sets the value of the corresponding object property</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>ObjectSetString</strong></td>
<td>Sets the value of the corresponding object property</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>ObjectsTotal</strong></td>
<td>Returns the number of objects of the specified type in the specified chart (specified chart subwindow)</td>
<td><strong>Object Functions</strong></td>
</tr>
<tr>
<td><strong>OnStart</strong></td>
<td>The function is called when the Start event occurs to perform actions set in the script</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td><strong>OnInit</strong></td>
<td>The function is called in indicators and EAs when the Init event occurs to initialize a launched MQL5 program</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td><strong>OnDeinit</strong></td>
<td>The function is called in indicators and EAs when the Deinit event occurs to deinitialize a launched MQL5 program</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td><strong>OnTick</strong></td>
<td>The function is called in EAs when the NewTick event occurs to handle a new quote</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td><strong>OnCalculate</strong></td>
<td>The function is called in indicators when the Calculate event occurs to handle price data changes</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td><strong>OnTimer</strong></td>
<td>The function is called in indicators and EAs during the Timer periodic event generated by the terminal at fixed time intervals</td>
<td><strong>Event Handling</strong></td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td><strong>OnTrade</strong></td>
<td>The function is called in EAs during the <strong>Trade</strong> event generated at the end of a trading operation on a trade server</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnTradeTransaction</strong></td>
<td>The function is called in EAs when the <strong>TradeTransaction</strong> event occurs to process a trade request execution results</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnBookEvent</strong></td>
<td>The function is called in EAs when the <strong>BookEvent</strong> event occurs to process changes in the market depth</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnChartEvent</strong></td>
<td>The function is called in indicators and EAs when the <strong>ChartEvent</strong> event occurs to process chart changes made by a user or an MQL5 program</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnTester</strong></td>
<td>The function is called in EAs when the <strong>Tester</strong> event occurs to perform necessary actions after testing an EA on history data</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnTesterInit</strong></td>
<td>The function is called in EAs when the <strong>TesterInit</strong> event occurs to perform necessary actions before optimization in the strategy tester</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnTesterDeinit</strong></td>
<td>The function is called in EAs when the <strong>TesterDeinit</strong> event occurs after EA optimization in the strategy tester</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OnTesterPass</strong></td>
<td>The function is called in EAs when the <strong>TesterPass</strong> event occurs to handle an arrival of a new data frame during EA optimization in the strategy tester</td>
<td>Event Handling</td>
</tr>
<tr>
<td><strong>OrderCalcMargin</strong></td>
<td>Calculates the margin required for the specified order type, in the deposit currency</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><strong>OrderCalcProfit</strong></td>
<td>Calculates the profit based on the parameters passed, in the deposit currency</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>OrderCheck</td>
<td>Checks if there are enough funds to execute the required trade operation.</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderGetDouble</td>
<td>Returns the requested property of the order (double)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderGetInteger</td>
<td>Returns the requested property of the order (datetime or int)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderGetString</td>
<td>Returns the requested property of the order (string)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderGetTicket</td>
<td>Return the ticket of a corresponding order</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderSelect</td>
<td>Selects a order for further working with it</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderSend</td>
<td>Sends trade requests to a server</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrderSendAsync</td>
<td>Asynchronously sends trade requests without waiting for the trade response of the trade server</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>OrdersTotal</td>
<td>Returns the number of orders</td>
<td>Trade Functions</td>
</tr>
<tr>
<td>ParameterGetRange</td>
<td>Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>ParameterSetRange</td>
<td>Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values</td>
<td>Working with Optimization Results</td>
</tr>
<tr>
<td>Period</td>
<td>Returns the current chart timeframe</td>
<td>Checkup</td>
</tr>
<tr>
<td>PeriodSeconds</td>
<td>Returns the number of seconds in the period</td>
<td>Common Functions</td>
</tr>
<tr>
<td>PlaySound</td>
<td>Plays a sound file</td>
<td>Common Functions</td>
</tr>
<tr>
<td>PlotIndexGetInteger</td>
<td>Returns the value of an indicator line property of the integer type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td>PlotIndexSetDouble</td>
<td>Sets the value of an indicator line property of the type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>----------</td>
</tr>
<tr>
<td><code>double</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>PlotIndexSetInteger</code></td>
<td>Sets the value of an indicator line property of the <code>int</code> type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td><code>PlotIndexSetString</code></td>
<td>Sets the value of an indicator line property of the <code>string</code> type</td>
<td>Custom Indicators</td>
</tr>
<tr>
<td><code>Point</code></td>
<td>Returns the point size of the current symbol in the quote currency</td>
<td>Checkup</td>
</tr>
<tr>
<td><code>PositionGetDouble</code></td>
<td>Returns the requested property of an open position (double)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionGetInteger</code></td>
<td>Returns the requested property of an open position (datetime or int)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionGetString</code></td>
<td>Returns the requested property of an open position (string)</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionGetSymbol</code></td>
<td>Returns the symbol corresponding to the open position</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionGetTicket</code></td>
<td>Returns the ticket of the position with the specified index in the list of open positions</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionSelect</code></td>
<td>Chooses an open position for further working with it</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionSelectByTicket</code></td>
<td>Selects a position to work with by the ticket number specified in it</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>PositionsTotal</code></td>
<td>Returns the number of open positions</td>
<td>Trade Functions</td>
</tr>
<tr>
<td><code>pow</code></td>
<td>Raises the base to the specified power</td>
<td>Math Functions</td>
</tr>
<tr>
<td><code>Print</code></td>
<td>Displays a message in the log</td>
<td>Common Functions</td>
</tr>
<tr>
<td><code>PrintFormat</code></td>
<td>Formats and prints the sets of symbols and values in a log file in accordance with a preset format</td>
<td>Common Functions</td>
</tr>
<tr>
<td><code>rand</code></td>
<td>Returns a pseudorandom value within the range of 0 to 32767</td>
<td>Math Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td><strong>ResetLastError</strong></td>
<td>Sets the value of a predetermined variable _LastError to zero</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>ResourceCreate</strong></td>
<td>Creates an image resource based on a data set</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>ResourceFree</strong></td>
<td>Deletes dynamically created resource ( freeing the memory allocated for it)</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>ResourceReadImage</strong></td>
<td>Reads data from the graphical resource created by ResourceCreate() function or saved in EX5 file during compilation</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>ResourceSave</strong></td>
<td>Saves a resource into the specified file</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>round</strong></td>
<td>Rounds of a value to the nearest integer</td>
<td><strong>Math Functions</strong></td>
</tr>
<tr>
<td><strong>SendFTP</strong></td>
<td>Sends a file at the address specified in the settings window of the &quot;FTP&quot; tab</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>SendMail</strong></td>
<td>Sends an email at the address specified in the settings window of the &quot;Email&quot; tab</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>SendNotification</strong></td>
<td>Sends push notifications to mobile terminals, whose MetaQuotes ID are specified in the &quot;Notifications&quot; tab</td>
<td><strong>Common Functions</strong></td>
</tr>
<tr>
<td><strong>SeriesInfoInteger</strong></td>
<td>Returns information about the state of historical data</td>
<td><strong>Timeseries and Indicators Access</strong></td>
</tr>
<tr>
<td><strong>SetIndexBuffer</strong></td>
<td>Binds the specified indicator buffer with one-dimensional dynamic array of the double type</td>
<td><strong>Custom Indicators</strong></td>
</tr>
<tr>
<td><strong>ShortArrayToString</strong></td>
<td>Copying array part into a string</td>
<td><strong>Conversion Functions</strong></td>
</tr>
<tr>
<td><strong>ShortToString</strong></td>
<td>Converting symbol code (unicode) into one-symbol string</td>
<td><strong>Conversion Functions</strong></td>
</tr>
<tr>
<td><strong>SignalBaseGetDouble</strong></td>
<td>Returns the value of double type property for selected signal</td>
<td><strong>Trade Signals</strong></td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>SignalBaseGetInteger</td>
<td>Returns the value of integer type property for selected signal</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalBaseGetString</td>
<td>Returns the value of string type property for selected signal</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalBaseSelect</td>
<td>Selects a signal from signals, available in terminal for further working with it</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalBaseTotal</td>
<td>Returns the total amount of signals, available in terminal</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalInfoGetDouble</td>
<td>Returns the value of double type property of signal copy settings</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalInfoGetInteger</td>
<td>Returns the value of integer type property of signal copy settings</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalInfoGetString</td>
<td>Returns the value of string type property of signal copy settings</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalInfoSetDouble</td>
<td>Sets the value of double type property of signal copy settings</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalInfoSetInteger</td>
<td>Sets the value of integer type property of signal copy settings</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalSubscribe</td>
<td>Subscribes to the trading signal</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>SignalUnsubscribe</td>
<td>Cancels subscription</td>
<td>Trade Signals</td>
</tr>
<tr>
<td>sin</td>
<td>Returns the sine of a number</td>
<td>Math Functions</td>
</tr>
<tr>
<td>Sleep</td>
<td>Suspends execution of the current Expert Advisor or script within a specified interval</td>
<td>Common Functions</td>
</tr>
<tr>
<td>SocketCreate</td>
<td>Create a socket with specified flags and return its handle</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketClose</td>
<td>Close a socket</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketConnect</td>
<td>Connect to the server with timeout control</td>
<td>Network Functions</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>SocketIsConnected</td>
<td>Checks if the socket is currently connected</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketIsReadable</td>
<td>Get a number of bytes that can be read from a socket</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketIsWritable</td>
<td>Check whether data can be written to a socket at the current time</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTimeouts</td>
<td>Set timeouts for receiving and sending data for a socket</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketRead</td>
<td>Read data from a socket</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketSend</td>
<td>Write data to a socket</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTlsHandshake</td>
<td>Initiate secure TLS (SSL) connection to a specified host via TLS Handshake protocol</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTlsCertificate</td>
<td>Get data on the certificate used to secure network connection</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTlsRead</td>
<td>Read data from secure TLS connection</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTlsReadAvailable</td>
<td>Read all available data from secure TLS connection</td>
<td>Network Functions</td>
</tr>
<tr>
<td>SocketTlsSend</td>
<td>Send data via secure TLS connection</td>
<td>Network Functions</td>
</tr>
<tr>
<td>sqrt</td>
<td>Returns a square root</td>
<td>Math Functions</td>
</tr>
<tr>
<td>srand</td>
<td>Sets the starting point for generating a series of pseudorandom integers</td>
<td>Math Functions</td>
</tr>
<tr>
<td>StringAdd</td>
<td>Adds a string to the end of another string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringBufferLen</td>
<td>Returns the size of buffer allocated for the string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringCompare</td>
<td>Compares two strings and returns 1 if the first string is greater than the second; 0 - if the strings are equal; -1 (minus 1) - if the first string is less than the second one</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringConcatenate</td>
<td>Forms a string of parameters passed</td>
<td>String Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>StringFill</td>
<td>Fills out a specified string by selected symbols</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringFind</td>
<td>Search for a substring in a string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringFormat</td>
<td>Converting number into string according to preset format</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringGetCharacter</td>
<td>Returns the value of a number located in the specified string position</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringInit</td>
<td>Initializes string by specified symbols and provides the specified string length</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringLen</td>
<td>Returns the number of symbols in a string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringReplace</td>
<td>Replaces all the found substrings of a string by a set sequence of symbols</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringSetCharacter</td>
<td>Returns a copy of a string with a changed value of a symbol in a specified position</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringSplit</td>
<td>Gets substrings by a specified separator from the specified string, returns the number of substrings obtained</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringSubstr</td>
<td>Extracts a substring from a text string starting from a specified position</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringToCharArray</td>
<td>Symbol-wise copying a string converted from Unicode to ANSI, to a selected place of array of uchar type</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringToColor</td>
<td>Converting &quot;R,G,B&quot; string or string with color name into color type value</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringToDouble</td>
<td>Converting a string containing a symbol representation of number into number of double type</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringToInt</td>
<td>Converting a string containing a symbol representation of number into number of int type</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>StringToLower</td>
<td>Transforms all symbols of a selected string to lowercase</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringToShortArray</td>
<td>Symbol-wise copying a string to a selected part of array of ushort type</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringToTime</td>
<td>Converting a string containing time or date in &quot;yyyy.mm.dd [hh:mi]&quot; format into datetime type</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td>StringToUpper</td>
<td>Transforms all symbols of a selected string into capitals</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringTrimLeft</td>
<td>Cuts line feed characters, spaces and tabs in the left part of the string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StringTrimRight</td>
<td>Cuts line feed characters, spaces and tabs in the right part of the string</td>
<td>String Functions</td>
</tr>
<tr>
<td>StructToTime</td>
<td>Converts a variable of MqlDateTime structure type into a datetime value</td>
<td>Date and Time</td>
</tr>
<tr>
<td>Symbol</td>
<td>Returns the name of a symbol of the current chart</td>
<td>Checkup</td>
</tr>
<tr>
<td>SymbolInfoDouble</td>
<td>Returns the double value of the symbol for the corresponding property</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolInfoInteger</td>
<td>Returns a value of an integer type (long, datetime, int or bool) of a specified symbol for the corresponding property</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolInfoMarginRate</td>
<td>Returns the margin rates depending on the order type and direction</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolInfoSessionQuote</td>
<td>Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolInfoSessionTrade</td>
<td>Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.</td>
<td>Market Info</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>SymbolInfoString</td>
<td>Returns a value of the string type of a specified symbol for the corresponding property</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolInfoTick</td>
<td>Returns the current prices for the specified symbol in a variable of the MqlTick type</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolsSynchronized</td>
<td>Checks whether data of a selected symbol in the terminal are synchronized with data on the trade server</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolName</td>
<td>Returns the name of a specified symbol</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolSelect</td>
<td>Selects a symbol in the Market Watch window or removes a symbol from the window</td>
<td>Market Info</td>
</tr>
<tr>
<td>SymbolsTotal</td>
<td>Returns the number of available (selected in Market Watch or all) symbols</td>
<td>Market Info</td>
</tr>
<tr>
<td>tan</td>
<td>Returns the tangent of a number</td>
<td>Math Functions</td>
</tr>
<tr>
<td>TerminalClose</td>
<td>Commands the terminal to complete operation</td>
<td>Common Functions</td>
</tr>
<tr>
<td>TerminalInfoDouble</td>
<td>Returns a double value of a corresponding property of the mql5 program environment</td>
<td>Checkup</td>
</tr>
<tr>
<td>TerminalInfoInteger</td>
<td>Returns an integer value of a corresponding property of the mql5 program environment</td>
<td>Checkup</td>
</tr>
<tr>
<td>TerminalInfoString</td>
<td>Returns a string value of a corresponding property of the mql5 program environment</td>
<td>Checkup</td>
</tr>
<tr>
<td>TesterStatistics</td>
<td>It returns the value of a specified statistic calculated based on testing results</td>
<td>Common Functions</td>
</tr>
<tr>
<td>TextGetSize</td>
<td>Returns the string’s width and height at the current font settings</td>
<td>Object Functions</td>
</tr>
<tr>
<td>TextOut</td>
<td>Transfers the text to the custom array (buffer) designed for creation of a graphical resource</td>
<td>Object Functions</td>
</tr>
<tr>
<td><strong>Function</strong></td>
<td><strong>Description</strong></td>
<td><strong>Category</strong></td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td><strong>TextSetFont</strong></td>
<td>Sets the font for displaying the text using drawing methods (Arial 20 used by default)</td>
<td>Object Functions</td>
</tr>
<tr>
<td><strong>TimeCurrent</strong></td>
<td>Returns the last known server time (time of the last quote receipt) in the datetime format</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeDaylightSavings</strong></td>
<td>Returns the sign of Daylight Saving Time switch</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeGMT</strong></td>
<td>Returns GMT in datetime format with the Daylight Saving Time by local time of the computer, where the client terminal is running</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeGMTOffset</strong></td>
<td>Returns the current difference between GMT time and the local computer time in seconds, taking into account DST switch</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeLocal</strong></td>
<td>Returns the local computer time in datetime format</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeToString</strong></td>
<td>Converting a value containing time in seconds elapsed since 01.01.1970 into a string of &quot;yyyy.mm.dd hh:mm&quot; format</td>
<td>Conversion Functions</td>
</tr>
<tr>
<td><strong>TimeToStruct</strong></td>
<td>Converts a datetime value into a variable of MqlDateTime structure type</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>TimeTradeServer</strong></td>
<td>Returns the current calculation time of the trade server</td>
<td>Date and Time</td>
</tr>
<tr>
<td><strong>UninitializeReason</strong></td>
<td>Returns the code of the reason for deinitialization</td>
<td>Checkup</td>
</tr>
<tr>
<td><strong>WebRequest</strong></td>
<td>Sends HTTP request to the specified server</td>
<td>Common Functions</td>
</tr>
<tr>
<td><strong>ZeroMemory</strong></td>
<td>Resets a variable passed to it by reference. The variable can be of any type, except for classes and structures that have constructors.</td>
<td>Common Functions</td>
</tr>
</tbody>

### List of MQL5 Constants

All MQL5 constants in alphabetical order.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__DATE__</code></td>
<td>File compilation date without time (hours, minutes and seconds are equal to 0)</td>
<td>Print</td>
</tr>
<tr>
<td><code>__DATETIME__</code></td>
<td>File compilation date and time</td>
<td>Print</td>
</tr>
<tr>
<td><code>__FILE__</code></td>
<td>Name of the currently compiled file</td>
<td>Print</td>
</tr>
<tr>
<td><code>__FUNCSIG__</code></td>
<td>Signature of the function in whose body the macro is located. Logging of the full description of functions can be useful in the identification of overloaded functions</td>
<td>Print</td>
</tr>
<tr>
<td><code>__FUNCTION__</code></td>
<td>Name of the function, in whose body the macro is located</td>
<td>Print</td>
</tr>
<tr>
<td><code>__LINE__</code></td>
<td>Line number in the source code, in which the macro is located</td>
<td>Print</td>
</tr>
<tr>
<td><code>__MQLBUILD__</code>, <code>__MQL5BUILD__</code></td>
<td>Compiler build number</td>
<td>Print</td>
</tr>
<tr>
<td><code>__PATH__</code></td>
<td>An absolute path to the file that is currently being compiled</td>
<td>Print</td>
</tr>
<tr>
<td><code>ACCOUNT_ASSETS</code></td>
<td>The current assets of an account</td>
<td><code>AccountInfoDouble</code></td>
</tr>
<tr>
<td><code>ACCOUNT_BALANCE</code></td>
<td>Account balance in the deposit currency</td>
<td><code>AccountInfoDouble</code></td>
</tr>
<tr>
<td><code>ACCOUNT_COMMISSION_BLOKED</code></td>
<td>The current blocked commission amount on an account</td>
<td><code>AccountInfoDouble</code></td>
</tr>
<tr>
<td><code>ACCOUNT_COMPANY</code></td>
<td>Name of a company that serves the account</td>
<td><code>AccountInfoString</code></td>
</tr>
<tr>

<tr>
<td>ERR_WRONG_STRING_TIME</td>
<td>Wrong time in the string</td>
<td>GetLastError</td>
</tr>
<tr>
<td>ERR_zerosize_array</td>
<td>An array of zero length</td>
<td>GetLastError</td>
</tr>
<tr>
<td>FILE_ACCESS_DATE</td>
<td>Date of the last access to the file</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_ANSI</td>
<td>Strings of ANSI type (one byte symbols). Flag is used in FileOpen().</td>
<td>FileOpen</td>
</tr>
<tr>
<td>FILE_BIN</td>
<td>Binary read/write mode (without string to string conversion). Flag is used in FileOpen().</td>
<td>FileOpen</td>
</tr>
<tr>
<td>FILE_COMMON</td>
<td>The file path in the common folder of all client terminals \Terminal\Common\Files. Flag is used in FileOpen(), FileCopy(), FileMove() and in FileIsExist() functions.</td>
<td>FileOpen, FileCopy, FileMove, FileIsExist</td>
</tr>
<tr>
<td>FILE_CREATE_DATE</td>
<td>Date of creation</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_CSV</td>
<td>CSV file (all its elements are converted to strings of the appropriate type, Unicode or ANSI, and separated by separator). Flag is used in FileOpen().</td>
<td>FileOpen</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
<td>Function</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>FILE_END</td>
<td>Get the end of file sign</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_EXISTS</td>
<td>Check the existence</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_ANSI</td>
<td>The file is opened as ANSI (see FILE_ANSI)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_BINARY</td>
<td>The file is opened as a binary file (see FILE_BIN)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_COMMON</td>
<td>The file is opened in a shared folder of all terminals (see FILE_COMMON)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_CSV</td>
<td>The file is opened as CSV (see FILE_CSV)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_READABLE</td>
<td>The opened file is readable (see FILE_READ)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_TEXT</td>
<td>The file is opened as a text file (see FILE_TXT)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_IS_WRITABLE</td>
<td>The opened file is writable (see FILE_WRITE)</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_LINE_END</td>
<td>Get the end of line sign</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_MODIFY_DATE</td>
<td>Date of the last modification</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_POSITION</td>
<td>Position of a pointer in the file</td>
<td>FileGetInteger</td>
</tr>
<tr>
<td>FILE_READ</td>
<td>File is opened for reading. Flag is used in FileOpen(). When opening a file specification of FILE_WRITE and/or FILE_READ is required.</td>
<td>FileOpen</td>
</tr>
<tr>
<td>FILE_REWRITE</td>
<td>Possibility for the file rewrite using functions FileCopy() and FileMove(). The file should exist or should be opened for writing, otherwise the file will not be opened.</td>
<td>FileCopy, FileMove</td>
</tr>
<tr>
<td>FILE_SHARE_READ</td>
<td>Shared access for reading from several programs. Flag is used in FileOpen(), but it does not replace the necessity to indicate FILE_WRITE and/or the FILE_READ flag when opening a file.</td>
<td>FileOpen</td>
</tr>
<tr>
<td>FILE_SHARE_WRITE</td>
<td>Shared access for writing from several programs. Flag is used in FileOpen(), but it does not</td>
<td>FileOpen</td>
</tr>
<tr>
<td><strong>MQL5 Constants</strong></td>
<td>Description</td>
<td>Function</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------</td>
<td>----------</td>
</tr>
<tr>
<td><strong>FILE_SIZE</strong></td>
<td>File size in bytes</td>
<td><code>FileGetInteger</code></td>
</tr>
<tr>
<td><strong>FILE_TXT</strong></td>
<td>Simple text file (the same as csv file, but without taking into account the separators). Flag is used in <code>FileOpen()</code></td>
<td><code>FileOpen</code></td>
</tr>
<tr>
<td><strong>FILE_UNICODE</strong></td>
<td>Strings of UNICODE type (two byte symbols). Flag is used in <code>FileOpen()</code></td>
<td><code>FileOpen</code></td>
</tr>
<tr>
<td><strong>FILE_WRITE</strong></td>
<td>File is opened for writing. Flag is used in <code>FileOpen()</code>. When opening a file specification of <code>FILE_WRITE</code> and/or <code>FILE_READ</code> is required.</td>
<td><code>FileOpen</code></td>
</tr>
<tr>
<td><strong>FLT_DIG</strong></td>
<td>Number of significant decimal digits for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_EPSILON</strong></td>
<td>Minimal value, which satisfies the condition: 1.0+DBL_EPSILON != 1.0 (for float type)</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MANT_DIG</strong></td>
<td>Bits count in a mantissa for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MAX</strong></td>
<td>Maximal value, which can be represented by float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MAX_10_EXP</strong></td>
<td>Maximal decimal value of exponent degree for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MAX_EXP</strong></td>
<td>Maximal binary value of exponent degree for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MIN</strong></td>
<td>Minimal positive value, which can be represented by float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MIN_10_EXP</strong></td>
<td>Minimal decimal value of exponent degree for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>
<tr>
<td><strong>FLT_MIN_EXP</strong></td>
<td>Minimal binary value of exponent degree for float type</td>
<td><code>Numerical Type Constants</code></td>
</tr>

<tr>
<td>MQL_LICENSE_TYPE</td>
<td>Type of license of the EX5 module. The license refers to the EX5 module, from which a request is made using MQLInfoInteger(MQL_LICENSE_TYPE).</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_MEMORY_LIMIT</td>
<td>Maximum possible amount of dynamic memory for MQL5 program in MB</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
<td>Type</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>MQL_MEMORY_USED</td>
<td>The memory size used by MQL5 program in MB</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_OPTIMIZATION</td>
<td>The flag, that indicates the optimization process</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_PROFILER</td>
<td>The flag, that indicates the program operating in the code profiling mode</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_PROGRAM_NAME</td>
<td>Name of the mql5-program executed</td>
<td>MQLInfoString</td>
</tr>
<tr>
<td>MQL_PROGRAM_PATH</td>
<td>Path for the given executed program</td>
<td>MQLInfoString</td>
</tr>
<tr>
<td>MQL_PROGRAM_TYPE</td>
<td>Type of the mql5 program</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_SIGNALS_ALLOWED</td>
<td>The permission to modify the Signals for the given executed program</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_TESTER</td>
<td>The flag, that indicates the tester process</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_TRADE_ALLOWED</td>
<td>The permission to trade for the given executed program</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>MQL_VISUAL_MODE</td>
<td>The flag, that indicates the visual tester process</td>
<td>MQLInfoInteger</td>
</tr>
<tr>
<td>NULL</td>
<td>Zero for any types</td>
<td>Other Constants</td>
</tr>
<tr>
<td>OBJ_ALL_PERIODS</td>
<td>The object is drawn in all timeframes</td>
<td>ObjectSetInteger, ObjectGetInteger</td>
</tr>
<tr>
<td>OBJ_ARROW</td>
<td>Arrow</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_BUY</td>
<td>Buy Sign</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_CHECK</td>
<td>Check Sign</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_DOWN</td>
<td>Arrow Down</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_LEFT_PRICE</td>
<td>Left Price Label</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_RIGHT_PRICE</td>
<td>Right Price Label</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_SELL</td>
<td>Sell Sign</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_STOP</td>
<td>Stop Sign</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_THUMB_DOWN</td>
<td>Thumbs Down</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_THUMB_UP</td>
<td>Thumbs Up</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROW_UP</td>
<td>Arrow Up</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ARROWED_LINE</td>
<td>Arrowed Line</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_BITMAP</td>
<td>Bitmap</td>
<td>Object Types</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------</td>
<td>---------------</td>
</tr>
<tr>
<td>OBJ_BITMAP_LABEL</td>
<td>Bitmap Label</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_BUTTON</td>
<td>Button</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_CHANNEL</td>
<td>Equidistant Channel</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_CHART</td>
<td>Chart</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_CYCLES</td>
<td>Cycle Lines</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_EDIT</td>
<td>Edit</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ELLIOTWAVE3</td>
<td>Elliott Correction Wave</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ELLIOTWAVES</td>
<td>Elliott Motive Wave</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_ELLIPSE</td>
<td>Ellipse</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_EVENT</td>
<td>The &quot;Event&quot; object corresponding to an event in the economic calendar</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_EXPANSION</td>
<td>Fibonacci Expansion</td>
<td>Object Types</td>
</tr>
<tr>
<td>OBJ_FIBO</td>
<td>Fibonacci Retracement</td>
<td>Object Types</td>
</tr>

<td><code>SYMBOL_TRADE_TICK_VALUE</code></td>
<td>Value of <code>SYMBOL_TRADE_TICK_VALUE_PROFIT</code></td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_TRADE_TICK_VALUE_LOSS</code></td>
<td>Calculated tick price for a losing position</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_TRADE_TICK_VALUE_PROFIT</code></td>
<td>Calculated tick price for a profitable position</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUME</code></td>
<td>Volume of the last deal</td>
<td><code>SymbolInfoInteger</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUME_LIMIT</code></td>
<td>Maximum allowed aggregate volume of an open position and pending orders in one direction (buy or sell) for the symbol. For example, with the limitation of 5 lots, you can have an open buy position with the volume of 5 lots and place a pending order Sell Limit with the volume of 5 lots. But in this case you cannot place a Buy Limit pending order (since the total volume in one direction will exceed the limitation) or place Sell Limit with the volume more than 5 lots.</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUME_MAX</code></td>
<td>Maximal volume for a deal</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUME_MIN</code></td>
<td>Minimal volume for a deal</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUME_STEP</code></td>
<td>Minimal volume change step for deal execution</td>
<td><code>SymbolInfoDouble</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUMEHIGH</code></td>
<td>Maximal day volume</td>
<td><code>SymbolInfoInteger</code></td>
</tr>
<tr>
<td><code>SYMBOL_VOLUMELow</code></td>
<td>Minimal day volume</td>
<td><code>SymbolInfoInteger</code></td>
</tr>
<tr>
<td><code>TENKANSEN_LINE</code></td>
<td>Tenkan-sen line</td>
<td><code>Indicators Lines</code></td>

<td>TRADE_RETCODE_ERROR</td>
<td>Request processing error</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_FROZEN</td>
<td>Order or position frozen</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID</td>
<td>Invalid request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_EXPIRATION</td>
<td>Invalid order expiration date in the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_FILL L</td>
<td>Invalid order filling type</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_ORDER</td>
<td>Incorrect or prohibited order type</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_PRICE</td>
<td>Invalid price in the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_STOPS</td>
<td>Invalid stops in the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_INVALID_VOLUME</td>
<td>Invalid volume in the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_LIMIT_ORDERS</td>
<td>The number of pending orders has reached the limit</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_LIMIT_VOLUME</td>
<td>The volume of orders and positions for the symbol has reached the limit</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_LOCKED</td>
<td>Request locked for processing</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_MARKET_CLOSED</td>
<td>Market is closed</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_NO_CHANGE S</td>
<td>No changes in request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_NO_MONEY</td>
<td>There is not enough money to complete the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_ONLY_REAL</td>
<td>Operation is allowed only for live accounts</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_ORDER_CHANGED</td>
<td>Order state changed</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>Constant</td>
<td>Description</td>
<td>Class</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>TRADE_RETCODE_PLACED</td>
<td>Order placed</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_POSITION_CLOSED</td>
<td>Position with the specified POSITION_IDENTIFIER has already been closed</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_PRICE_CHANGED</td>
<td>Prices changed</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_PRICE_OFF</td>
<td>There are no quotes to process the request</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_REJECT</td>
<td>Request rejected</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_REQUOTE</td>
<td>Requote</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_SERVER_DISCONNECTED_AT</td>
<td>Autotrading disabled by server</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_TIMEOUT</td>
<td>Request canceled by timeout</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_TOO_MANY_REQUESTS</td>
<td>Too frequent requests</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_RETCODE_TRADE_DISABLED</td>
<td>Trade is disabled</td>
<td>MqlTradeResult</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_DEAL_ADD</td>
<td>Adding a deal to the history. The action is performed as a result of an order execution or performing operations with an account balance</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_DEAL_DELETE</td>
<td>Deleting a deal from the history. There may be cases when a previously executed deal is deleted from a server. For example, a deal has been deleted in an external trading system (exchange) where it was previously transferred by a broker.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_DEAL_UPDATE</td>
<td>Updating a deal in the history. There may be cases when a previously executed deal is changed on a server. For example, a deal has been changed in an external trading system (exchange) where it was previously transferred by a broker.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_HISTORY_ADD</td>
<td>Adding an order to the history as a result of execution or</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>Constant Name</td>
<td>Description</td>
<td>Class</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>-------</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_HISTOR Y_DELETE</td>
<td>Deleting an order from the orders history. This type is provided for enhancing functionality on a trade server side.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_HISTOR Y_UPDATE</td>
<td>Changing an order located in the orders history. This type is provided for enhancing functionality on a trade server side.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_ORDER _ADD</td>
<td>Adding a new open order.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_ORDER _DELETE</td>
<td>Removing an order from the list of the open ones. An order can be deleted from the open ones as a result of setting an appropriate request or execution (filling) and moving to the history.</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_ORDER _UPDATE</td>
<td>Updating an open order. The updates include not only evident changes from the client terminal or a trade server sides but also changes of an order state when setting it (for example, transition from ORDER_STATE_STARTED to ORDER_STATE_PLACED or from ORDER_STATE_PLACED to ORDER_STATE_PARTIAL, etc.).</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>TRADE_TRANSACTIONPOSITION</td>
<td>Changing a position not related to a deal execution. This type of transaction shows that a position has been changed on a trade server side. Position volume, open price, Stop Loss and Take Profit levels can be changed. Data on changes are submitted in MqlTradeTransaction structure via OnTradeTransaction handler. Position change (adding, changing or closing), as a result of a deal execution,</td>
<td>MqlTradeTransaction</td>
</tr>
<tr>
<td>Constant Name</td>
<td>Description</td>
<td>Required Class</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TRADE_TRANSACTION_REQUEST</td>
<td>Notification of the fact that a trade request has been processed by a server and processing result has been received. Only type field (trade transaction type) must be analyzed for such transactions in MqlTradeTransaction structure. The second and third parameters of OnTradeTransaction (request and result) must be analyzed for additional data.</td>
<td>MqlTradeTransaction</td>
